

General Description

The 83052I-01 is a 2-bit, 2:1, Single-ended Multiplexer and a member of the family of High Performance Clock Solutions from IDT. The 83052I-01 has two selectable single-ended clock inputs and two single-ended clock outputs. The output has a V_{DDO} pin which may be set at 3.3V, 2.5V, or 1.8V, making the device ideal for use in voltage translation applications. An output enable pin places the output in a high impedance state which may be useful for testing or debug. Possible applications include systems with up to two transceivers which need to be independently set for different rates. For example, a board may have two transceivers, each of which need to be independently configured for 1 Gigabit Ethernet or 1 Gigabit Fibre Channel rates. Another possible application may require the ports to be independently set for FEC (Forward Error Correction) or non-FEC rates. The device operates up to 250MHz and is packaged in a 16 TSSOP.

Features

- 2-bit, 2:1 single-ended multiplexer
- Nominal output impedance: 15Ω ($V_{DDO} = 3.3V$)
- Maximum output frequency: 250MHz
- Propagation delay: 3ns (maximum), $V_{DD} = V_{DDO} = 3.3V$
- Input skew: 85ps (maximum), $V_{DD} = V_{DDO} = 3.3V$
- Part-to-part skew: 500ps (maximum), $V_{DD} = V_{DDO} = 3.3V$
- Output skew: 65ps (maximum), $V_{DD} = V_{DDO} = 3.3V$
- Additive phase jitter, RMS (12KHz - 20MHz): 0.15ps (typical)
- Operating supply modes:
 V_{DD}/V_{DDO}
 3.3V/3.3V
 3.3V/2.5V
 3.3V/1.8V
 2.5V/2.5V
 2.5V/1.8V
- -40°C to 85°C ambient operating temperature
- Available in lead-free (RoHS 6) package

Additive Phase Jitter

The spectral purity in a band at a specific offset from the fundamental compared to the power of the fundamental is called the **dBc Phase Noise**. This value is normally expressed using a Phase noise plot and is most often the specified plot in many applications. Phase noise is defined as the ratio of the noise power present in a 1Hz band at a specified offset from the fundamental frequency to the power value of the fundamental. This ratio is expressed in decibels (dBm) or a ratio of the power in the 1Hz band

to the power in the fundamental. When the required offset is specified, the phase noise is called a **dBc** value, which simply means dBm at a specified offset from the fundamental. By investigating jitter in the frequency domain, we get a better understanding of its effects on the desired application over the entire time record of the signal. It is mathematically possible to calculate an expected bit error rate given a phase noise plot.

As with most timing specifications, phase noise measurements has issues relating to the limitations of the equipment. Often the noise floor of the equipment is higher than the noise floor of the device. This is illustrated above. The device meets the noise floor

of what is shown, but can actually be lower. The phase noise is dependent on the input source and measurement equipment.

Recommendations for Unused Input and Output Pins

Inputs:

LVC MOS Control Pins

All control pins have internal pull-ups or pull-downs; additional resistance is not required but can be added for additional protection. A 1k Ω resistor can be used.

CLK Inputs

For applications not requiring the use of a clock input, it can be left floating. Though not required, but for additional protection, a 1k Ω resistor can be tied from the CLK input to ground.

Outputs:

LVC MOS Outputs

All unused LVC MOS output can be left floating. There should be no trace attached.
