

Figure 1.1. The physical photo of ATH10KL2C

Figure 1.2. The physical photo of ATH10KL2CT70S

MAIN FEATURES

- **C** Glass Encapsulated for Long Term Stability & Reliability
- \triangleright High Resistance Accuracy: 1%
- \triangle Maximum Temp. Range: -40° C to 270 $^{\circ}$ C
- **Packaged in Extra Small Ring Lug**
- 100 % Lead (Pb)-free and RoHS Compliant

APPLICATION AREAS

Temperature sensing for laser diodes, optical components, etc.

DESCRIPTIONS

The ATH10KL2C is a thermistor assembly with a glass encapsulated thermistor packaged in an extra compact ring lug. The ATH10KL2C series thermistor consists of three versions, ATH10KL2C, ATH10KL2CT70 and ATH10KL2CT70S. The ATH10KL2C has bear leads coated with copper, the ATH10KL2CT70S has the leads covered by high temperature plastic tubing and sealed by epoxy, while the ATH10KL2CT70 is the non-sealed version. Comparing with conventional assemblies containing epoxy encapsulated thermistors, ATH10KL2C series thermistor presents higher long term stability, higher reliability and wider temperature range. In addition, it has a small size and short response time.

The ATH10KL2C series thermistor can be used to measure the temperatures of laser diodes, optical components, etc., with high accuracy and long term stability.

There are some differences among ATH10KL2**A**, ATH10KL2**B** and ATH10KL2**C**. First, the ring sizes of them are different. Second, the thermistor head in ATH10KL2**A** is the same as ATH10KR8, while the heads in ATH10KL2**B** and ATH10KL2**C** are the same as ATH10K1R25. Last, the resistance temperature characteristics in ATH10KL2**B** and ATH10KL2**C** are the same, different from ATH10KL2**A**.

APPLICATIONS

Use #2 imperial or M2.5 metric screw to mount the thermistor assembly onto a smooth metal surface of the object for which the temperature needs to be measured.

The thermistor lead wires are made of plain copper; make sure that they do not touch each other, or any other electrically conductive objects.

For high precision applications, use a cover which is made of thermal isolation material to cover the thermistor area, see Figure 3. In this way, the air flow will not affect the temperature sensing accuracy.

Figure 3. Using an Insulation Cover to Improve Accuracy

CAUTIONS

- 1. Do not apply a large DC voltage across the thermistor in the temperature sensing circuit. The thermistor selfheating temperature is about 1° C/mW. By injecting a $10\mu A$ current into the thermistor, it consumes $1mW$ and the self-heating temperature is about 1° C if the thermistor is placed in still air. Therefore, the sensing current needs to be much lower than $10\mu A$ when the thermistor is placed in the air for high accuracy applications. Injecting short current pulses into the thermistor is one of the ways to reduce the average current level on the thermistor in order to minimize the self-heating effect.
- 2. Handle the thermistor with care, do not use metal tools to hold the thermistor body with excessive force, otherwise, the glass body may crack, affecting its accuracy and stability.

Thermistor Resistance

Beta Value (β)

A simple approximation for the relationship between the resistance and temperature for ATH10KL2C is to use an exponential approximation. This approximation is based on simple curve fitting to experimental data and uses two points on a curve to determine the value of β. The equation relating resistance to temperature using $β$ is:

$$
R = Ae^{\frac{\beta}{T}};
$$

Where:

- $R =$ thermistor resistance at temp T,
- $A = constant of equation,$
- $β = beta$, the material constant,
- $T =$ thermistor temperature in $K(Kelvin)$,

To calculate β for any given temperature range, the following formula applies:

ln(*RT*¹ /*RT*²)/(1/*T*11/*T*2) ;

Where β is measured in K, R_{T1} is the resistance at T1, while R_{t2} is the resistance at T2.

 β can be used to compare the relative steepness of ATH10KL2C curves. However, the value of $β$ will vary depending on the temperatures used for calculating the value. For example, to calculate β for the temperature range of 25˚C to 50° C:

 $T1 = (25 + 273.15)$ °K = 298.15°K, $T2 = (50 + 273.15)$ °K = 323.15°K, $R_{T1} = 10K\Omega$, $R_{T2} = 3.6085 KΩ;$

This value of β would be referenced as β 25°C/50°C, and calculated as:

 β 25[°]C/50[°]C = ln(10/3.6085) / (1/298.15 – 1/323.15) = 3950K;

By using the same formula, β25˚C/85˚C, will be:

 β 25°C/85°C = ln(10/1.0786) / (1/298.15 – 1/358.15) = 3990K.

When using the β value to compare 2 thermistors, make sure that the β values are calculated based on the same 2 temperature points.

Temperature Coefficient of Resistance (α)

Another way to characterize the R-T curve of the ATH10KL2C is to use the slope of the resistance versus temperature (R/T) curve at one temperature. By definition, the resistance slope vs. temperature is given by:

(1/*R*)(*dR*/*dT*) ;

Where T is the temperature in $°C$ or K , R is the resistance at temperature T.

Figure 4. Resistance vs. Temperature for ATH10KL2C

As shown in Figure 4, the steepest position of the ATH10KL2C curve is at colder temperatures.

The temperature coefficient is one method that can be used for comparing the relative steepness of the curves. It is highly recommended to compare the temperature coefficient at the same temperature because α varies widely over the operating temperature range.

Resistance Ratio (Slope)

The resistance ratio, or slope, for thermistors is defined as the ratio of the resistance at one temperature to the resistance at a higher temperature. As with resistance ratios, this method will vary depending on the temperatures used for calculating the value. This method can also be used to compare the relative steepness of two curves. There is no industry standard for the two temperatures that are used to calculate the ratio, we can select two common temperatures from the table below, for example, 25˚C and 50˚C, then the result of this calculation: $R@25^{\circ}C / R@50^{\circ}C$, will be:

 $R@25^{\circ}C / R@50^{\circ}C = 10/3.6085 = 2.771;$

And this calculation: $R@25^{\circ}C/R@85^{\circ}C$, will be:

 $R@25^{\circ}C / R@85^{\circ}C = 10/1.0786 = 9.271.$

Steinhart-Hart Thermistor Equation

The Steinhart**-**Hart Equation is an empirically derived polynomial formula which does best in describing the relationship between the resistance and the temperature of ATH10KL2C, which is much more accurate than β mathod. To solve for temperature when resistance is known, yields the following equation:

Where:

 $T =$ temperature in K (Kelvin),

a, b and c are equation constants,

R = resistance in Ω at temp T;

To solve for resistance when the temperature is known, the form of the equation is:

$$
R = \left[\left(\frac{x}{2}\left(\frac{x^2}{4}+\frac{y^3}{27}\right)^{\frac{1}{2}}\right)\left(\frac{x}{2}\left(\frac{x^2}{4}+\frac{y^3}{27}\right)^{\frac{1}{2}}\right)\right];
$$

Where:

$$
x=\frac{a-1/T}{c}\,,\,y=\frac{b}{c}\,.
$$

The a, b and c constants can be calculated for either a thermistor material or for individual values of the thermistors within a material type. To solve for the constants, three sets of data must be used. Normally, for a temperature range, the low end, middle end and high end values are used to calculate the constants, resulting in the best fit for the equation over the range. Using the Steinhart-Hart equation allows for accuracy as good as ±0.001˚C over a 100˚C temperature span.
