Enables stop watch trigger by FlexRay 1 interrupt when bit FLXAnFRSTPW1.ESWT is 1.

(4) FLXAnFRSTPW1.EINT0

Enable FlexRay 0 Interrupt Trigger Bit

Enables stop watch trigger by FlexRay 0 interrupt when bit FLXAnFRSTPW1.ESWT = 1.

(5) FLXAnFRSTPW1.EETP

External Trigger Pin Enable Bit

When bit FLXAnFRSTPW1.ESWT is set to 1, the FLXA0STPWT pin event is treated as a stop watch trigger.

(6) FLXAnFRSTPW1.SSWT

Software Stop Watch Trigger Bit

Bits FLXAnFRSTPW1.ESWT and FLXAnFRSTPW1.SSWT cannot be set to 1 simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

Writing 1 in this bit activates the stop watch. This bit is reset to 0 after the cycle count and slot count, and macrotick (MT) value are stored in the FlexRay stop watch register.

(7) FLXAnFRSTPW1.EDGE

Stop Watch Trigger Edge Select Bit

(8) FLXAnFRSTPW1.SWMS

Stop Watch Mode Select Bit

(9) FLXAnFRSTPW1.ESWT

Enable Stop Watch Trigger Bit

Bits FLXAnFRSTPW1.ESWT and FLXAnFRSTPW1.SSWT cannot be set to 1 simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

If enabled, any of an external trigger pin input event, a FlexRay 0 interrupt event, or a FlexRay 1 interrupt event activates the stop watch.

In single-shot mode, this bit is reset to 0 after the cycle count and slot count, and macrotick (MT) value are stored in the FlexRay stop watch register.

18.2.5.5 FLXAnFRSTPW2 — FlexRay Stop Watch Register 2

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0050_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	SSCVB[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SSCVA[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.25 FLXAnFRSTPW2 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is read.
26 to 16	SSCVB[10:0]	Stop Watch Captured Slot Counter Value Channel B
15 to 11	Reserved	When read, the value after reset is read.
10 to 0	SSCVA[10:0]	Stop Watch Captured Slot Counter Value Channel A

(1) FLXAnFRSTPW2.SSCVB

Stop Watch Captured Slot Counter Value Channel B

State of the slot counter for channel B when the stop watch event occurred.

(2) FLXAnFRSTPW2.SSCVA

Stop Watch Captured Slot Counter Value Channel A

State of the slot counter for channel A when the stop watch event occurred.

18.2.6 CC Control Registers

This section describes the registers provided by the CC (Communication Controller) to allow the Host to control the operation of the CC. The FlexRay protocol specification requires the Host to write application configuration data in CONFIG state only. Please consider that the configuration registers are not locked for writing in DEFAULT_CONFIG state.

The configuration data is reset when DEFAULT_CONFIG state is entered from reset. To change POC state from DEFAULT_CONFIG to CONFIG state the Host has to apply CHI command CONFIG. If the Host wants the CC to leave CONFIG state, the Host has to execute the lock release sequence as described in **Section 18.2.3.1, FLXAnFRLCK — FlexRay Lock Register**.

18.2.6.1 FLXAnFRSUCC1 — FlexRay SUC Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0080_H

Value after reset: 0C40 1080_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	CCHB	CCHA	MTSB	MTSA	HCSE	TSM	WUCS	PTA[4:0]

Table 18.26 FLXAnFRSUCC1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is read. When writing, write the value after reset.
27	CCHB	Connected to Channel B Bit Configures pChannels 0: Not connected to channel B 1: Node connected to channel B (value after reset)
26	CCHA	Connected to Channel A Bit Configures pChannels 0: Not connected to channel A 1: Node connected to channel A (value after reset)
25	MTSB	Select Channel B for MTS Transmission Bit 0: Channel B disabled for MTS transmission 1: Channel B selected for MTS transmission
24	MTSA	Select Channel A for MTS Transmission Bit 0: Channel A disabled for MTS transmission 1: Channel A selected for MTS transmission
23	HCSE	Halt due to Clock Sync Error Bit Configures pAllowHaltDueToClock 0: CC will enter / remain in NORMAL_PASSIVE 1: CC will enter HALT state
22	TSM	Transmission Slot Mode Bit Configures pSingleSlotEnabled 0: ALL Slot Mode 1: SINGLE Slot Mode (value after reset)

Table 18.26 FLXAnFRSUCC1 Register Contents (2/2)

Bit Position	Bit Name	Function
21	WUCS	Wakeup Channel Select Bit Configures pWakeupChannel 0: Send wakeup pattern on channel A 1: Send wakeup pattern on channel B
20 to 16	PTA[4:0]	Passive to Active Bit Configures pAllowPassiveToActive
15 to 11	CSA[4:0]	Cold Start Attempts Bit Configures gColdStartAttempts
10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	TXSY	Transmit Sync Frame in Key Slot Bit Configures pKeySlotUsedForSync 0: No sync frame transmission in key slot, node is neither sync nor coldstart node 1: Key slot used to transmit sync frame, node is sync node
8	TXST	Transmit Startup Frame in Key Slot Bit Configures pKeySlotUsedForStartup 0: No startup frame transmission in key slot, node is non-coldstarter 1: Key slot used to transmit startup frame, node is leading or following coldstarter
7	PBSY	POC Busy Flag 0: POC not busy, bit FLXAnFRSUCC1.CMD writeable 1: POC is busy, bit FLXAnFRSUCC1.CMD locked
6 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	CMD[3:0]	CHI Command Vector Bit 0000: command_not_accepted 0001: CONFIG 0010: READY 0011: WAKEUP 0100: RUN 0101: ALL_SLOTS 0110: HALT 0111: FREEZE 1000: SEND_MTS 1001: ALLOW_COLDSTART 1010: RESET_STATUS_INDICATORS 1011: MONITOR_MODE 1100: CLEAR_RAMs others: reserved

(1) FLXAnFRSUCC1.CCHB

Connected to Channel B Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Configures whether the node is connected to channel B (pChannels).

(2) FLXAnFRSUCC1.CCHA

Connected to Channel A Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Configures whether the node is connected to channel A (pChannels).

(3) FLXAnFRSUCC1.MTSB

Select Channel B for MTS Transmission Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

The FLXAnFRSUCC1.MTSB bit may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to FLXAnFRSUCC1 register is directly preceded by the unlock sequence for the Configuration Lock Key as described in **Section 18.2.3.1, FLXAnFRLCK — FlexRay Lock Register**. This may be combined with CHI command SEND_MTS. If both bits FLXAnFRSUCC1.MTSA and FLXAnFRSUCC1.MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing 1000_B to the FLXAnFRSUCC1.CMD[3:0] bits.

The bit selects channel B for MTS symbol transmission.

(4) FLXAnFRSUCC1.MTSA

Select Channel A for MTS Transmission Bit

The user can only write to these bits when FLXAnFRCCSV.POCS[5:0] bits are DEFAULT_CONFIG or CONFIG.

Bit FLXAnFRSUCC1.MTSA may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to FLXAnFRSUCC1 register is directly preceded by the unlock sequence for the Configuration Lock Key as described in **Section 18.2.3.1, FLXAnFRLCK — FlexRay Lock Register**. This may be combined with CHI command SEND_MTS. If both bits FLXAnFRSUCC1.MTSA and FLXAnFRSUCC1.MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing 1000_B to the FLXAnFRSUCC1.CMD[3:0] bits.

The bit selects channel A for MTS symbol transmission.

(5) FLXAnFRSUCC1.HCSE

Halt due to Clock Sync Error Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Controls the transition to HALT state due to a clock synchronization error (pAllowHaltDueToClock).

(6) FLXAnFRSUCC1.TSM

Transmission Slot Mode Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] is DEFAULT_CONFIG or CONFIG.

Selects the value after transmission slot mode reset (pSingleSlotEnabled).

In SINGLE slot mode the CC may only transmit in the preconfigured key slot. The key slot ID is configured in the header section of message buffer 0 respectively message buffers 0 and 1 depending on bit FLXAnFRMRC.SPLM.

In case FLXAnFRSUCC1.TSM = 1, message buffer 0 respectively message buffers 0,1 can be (re)configured in DEFAULT_CONFIG or CONFIG state only. In ALL slot mode the CC may transmit in all slots.

FLXAnFRSUCC1.TSM is a configuration bit which can only be set / reset by the Host.

The CC changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing 0101_B to bits FLXAnFRSUCC1.CMD[3:0] in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. The actual slot mode is monitored by bits FLXAnFRCCSV.SLM[1:0].

(7) FLXAnFRSUCC1.WUCS

Wakeup Channel Select Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

With this bit the Host selects the channel on which the CC sends the Wakeup pattern (pWakeupChannel).

(8) FLXAnFRSUCC1.PTA

Passive to Active Bit

The user can only write to these bits when the FLXAnFRCCSV.POCS[5:0] bits is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 31 even / odd cycle pairs.

Defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state (pAllowPassiveToActive).

If set to “00000_B” the CC is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

(9) FLXAnFRSUCC1.CSA

Cold Start Attempts Bit

The user can only write to these bits when the FLXAnFRCCSV.POCS[5:0] bits is DEFAULT_CONFIG or CONFIG.

Must be identical in all nodes of a cluster.

Valid values are 2 to 31.

Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node (gColdStartAttempts).

(10) FLXAnFRSUCC1.TXSY

Transmit Sync Frame in Key Slot Bit

The user can only write to these bits when the FLXAnFRCCSV.POCS[5:0] bits is DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit sync frames (pKeySlotUsedForSync).

CAUTION

The protocol requires that both bits FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY are set for coldstart nodes.

(11) FLXAnFRSUCC1.TXST

Transmit Startup Frame in Key Slot Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit startup frames (pKeySlotUsedForStartup).

CAUTION

The protocol requires that both bits FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY are set for coldstart nodes.

(12) FLXAnFRSUCC1.PBSY

POC Busy Flag

Signals that the POC is busy and cannot accept a command from the Host. Bits FLXAnFRSUCC1.CMD[5:0] are locked against write accesses.

Set to 1 after reset during initialization of internal RAM blocks.

(13) FLXAnFRSUCC1.CMD

CHI Command Vector Bit

The Host may write any CHI command at any time, but certain commands are enabled only in certain POC states. If a command is not enabled, it will not be executed, the CHI command vector FLXAnFRSUCC1.CMD[3:0] bits will be reset to 0000_B = command_not_accepted, and flag FLXAnFREIR.CNA will be set to 1.

In general the Host must check FLXAnFRSUCC1.PBSY before writing a new CHI command.

In case the previous CHI command has not yet completed, flag FLXAnFREIR.CCL is set to 1 together with FLXAnFREIR.CNA; the CHI command needs to be repeated.

Except for HALT state, a POC state change command applied while the CC is already in the requested POC state neither causes a state change nor will flag FLXAnFREIR.CNA be set.

Reading bits FLXAnFRSUCC1.CMD[3:0] show whether the last CHI command was accepted. The actual POC state is monitored by bits FLXAnFRCCSV.POCS[5:0].

- command_not_accepted

Bits FLXAnFRSUCC1.CMD[3:0] are reset to 0000_B due to one of the following conditions:

- Illegal command applied by the Host
- Host applied command to leave CONFIG state without preceding config lock key
- Host applied new command while execution of the previous Host command has not completed
- Host writes command_not_accepted

When bits FLXAnFRSUCC1.CMD[3:0] are reset to 0000_B, FLXAnFREIR.CNA is set to 1, and if enabled an interrupt is generated. Commands which are not accepted are not executed.

CONFIG command

Go to POC state CONFIG when called in POC states DEFAULT_CONFIG, or READY. When called in HALT state the CC transits to POC state DEFAULT_CONFIG. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to 0000_B = command_not_accepted.

READY command

Go to POC state READY when called in POC states CONFIG, NORMAL_ACTIVE, NORMAL_PASSIVE, STARTUP, or WAKEUP. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to “0000_B” = command_not_accepted.

WAKEUP command

Go to POC state WAKEUP when called in POC state READY. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to “0000_B” = command_not_accepted.

RUN command

Go to POC state STARTUP when called in POC state READY. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to “0000_B” = command_not_accepted.

ALL_SLOTS command

Leave SINGLE slot mode and go to ALL-SLOTS mode after successful startup / integration at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to “0000_B” = command_not_accepted.

HALT command

Set halt request FLXAnFRCCSV.HRQ to 1 and go to POC state HALT at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to “0000_B” = command_not_accepted.

FREEZE command

Set the freeze status indicator FLXAnFRCCSV.FSI flag to 1 and go to POC state HALT immediately. Can be called from any state.

SEND_MTS command

Send single MTS symbol during the next following symbol window on the channel configured by the FLXAnFRSUCC1.MTSA and FLXAnFRSUCC1.MTSB bits, when called in POC state NORMAL_ACTIVE after CC entered ALL slot mode (the FLXAnFRCCSV.SLM[1:0] bits = “11”). When called in any other state, or when called while a previously requested MTS has not yet been transmitted, bits FLXAnFRSUCC1.CMD[3:0] will be reset to “0000_B” = command_not_accepted.

ALLOW_COLDSTART command

The command resets the FLXAnFRCCSV.CSI flag to enable the node to become leading coldstarter. When called in states DEFAULT_CONFIG, CONFIG, or HALT, bits FLXAnFRSUCC1.CMD[3:0] will be reset to “0000_B” = command_not_accepted. To become leading coldstarter it is also required that both FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY bits are set.

RESET_STATUS_INDICATORS command

Resets status flags FLXAnFRCCSV.FSI, FLXAnFRCCSV.HRQ, FLXAnFRCCSV.CSNI, and FLXAnFRCCSV.CSAI to their values after reset. May be called in POC states READY and STARTUP. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to “0000_B” = command_not_accepted.

CLEAR_RAM command

Sets bit FLXAnFRMHDS.CRAME to 1 when called in DEFAULT_CONFIG or CONFIG state. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to “0000_B” = command_not_accepted.

Bit FLXAnFRMHDS.CRAME is also set to 1 when the CC leaves reset. By setting bit FLXAnFRMHDS.CRAME all internal RAM blocks are initialized to zero. During the initialization of the RAMs, bit RSUCC1.PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAM.

The initialization of the internal message RAM requires 2048 bus clock cycles. There should be no Host access to IBF or OBF during initialization of the internal RAM blocks after reset or after assertion of CHI command CLEAR_RAM.

Before asserting CHI command CLEAR_RAM, the Host should make sure that no transfer between Message RAM and IBF / OBF or the TBFRAMs is ongoing and that the data transfer handler has no effect (bits FLXAnFRITS.ITS and FLXAnFROTS.OTS are 0). This command also resets the Message Buffer Status registers FLXAnFRMHDS, FLXAnFRLDTS, FLXAnFRFSR, FLXAnFRMHDF, FLXAnFRTRQ1 to FLXAnFRTRQ4, FLXAnFRNDAT1 to FLXAnFRNDAT14, and FLXAnFRMBSC1 to FLXAnFRMBSC4.

CAUTIONS

1. All accepted commands with exception of CLEAR_RAM and SEND_MTS will cause a change of the POC state in the FlexRay domain after at most 8 cycles of the slower of the two clocks “bus clock” and “FlexRay sample clock”, assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time frame. Reading register FLXAnFRCCSV will show data that is additionally delayed by synchronization from the FlexRay domain to the bus clock domain. The maximum additional delay is 12 cycles of the slower of the two clocks 'bus clock' and “FlexRay sample clock”.
2. When transfer is stopped by a FREEZE or READY command and then restarted as a leading ColdStart node, the startup frame may not be transmitted in cycle 0. This depends on the internal state of the FlexRay module. Such cases arise when the startup frame is set in a slot 1 to slot 7. This does not occur in a ColdStart after the reset of the microcontroller. Even if the above situation arises, the ColdStart will succeed on the second trial. Repetition prolongs the overall ColdStart process, but the ColdStart will not be obstructed by the earlier situation. To avoid this effect, allocate startup and sync frames to static slot 8 or a slot with a higher number.

Table 18.27 below references the CHI commands from the *FlexRay Protocol Specification* (Section 2.1.1.1, Table 2.2) to the FlexRay CHI command vector FLXAnFRSUCC1.CMD[3:0] bits.

Table 18.27 Reference to CHI Host Command Summary from FlexRay Protocol Specification

CHI command	Where processed (POC States)	CHI Command Vector CMD
ALL_SLOTS	POC: normal active, POC: normal passive	ALL_SLOTS
ALLOW_COLDSTART	All except POC: default config, POC: config, POC: halt	ALLOW_COLDSTART
CONFIG	POC: default config, POC: ready	CONFIG
CONFIG_COMPLETE	POC: config	Unlock sequence & READY
DEFAULT_CONFIG	POC: halt	CONFIG
FREEZE	All	FREEZE
HALT	POC: normal active, POC: normal passive	HALT
READY	All except POC: default config, POC: config, POC: ready, POC: halt	READY
RUN	POC: ready	RUN
WAKEUP	POC: ready	WAKEUP

18.2.6.2 FLXAnFRSUC2 — FlexRay SUC Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0084_H

Value after reset: 0100 0504_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	LTN[3:0]			—	—	—	LT[20:16]					
Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Table 18.28 FLXAnFRSUC2 Register Contents

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is read. When writing, write the value after reset.
27 to 24	LTN[3:0]	Listen Timeout Noise Bit Configures (gListenNoise - 1)
23 to 21	Reserved	When read, the value after reset is read. When writing, write the value after reset.
20 to 0	LT[20:0]	Listen Timeout Bit Configures pdListenTimeout

(1) FLXAnFRSUC2.LTN

Listen Timeout Noise Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

The range for gListenNoise is 2 to 16.

FLXAnFRSUC2.LTN must be configured identical in all nodes of a cluster.

Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of pdListenTimeout.

CAUTION

The wakeup / startup noise timeout is calculated as follows:

$$\text{pdListenTimeout} \times \text{gListenNoise} = \text{FLXAnFRSUC2.LT} \times (\text{FLXAnFRSUC2.LTN} + 1)$$

(2) FLXAnFRSUC2.LT

Listen Timeout Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

The range for pdListenTimeout is 1284 to 1283846 μ T.

Configures wakeup / startup listen time out in μ T.

18.2.6.3 FLXAnFRSUCC3 — FlexRay SUC Configuration Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0088_H

Value after reset: 0000 0011_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 18.29 FLXAnFRSUCC3 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is read. When writing, write the value after reset.
7 to 4	WCF[3:0]	Maximum Without Clock Correction Fatal Bit (transition to HALT state) Configures gMaxWithoutClockCorrectionFatal
3 to 0	WCP[3:0]	Maximum Without Clock Correction Passive Bit (transition to NORMAL_PASSIVE state) Configures gMaxWithoutClockCorrectionPassive

(1) FLXAnFRSUCC3.WCF

Maximum Without Clock Correction Fatal Bit (transition to HALT state)

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

Must be identical in all nodes of a cluster.

Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE or NORMAL_PASSIVE to HALT state.

CAUTION

The transition to HALT state is prevented if the FLXAnFRSUCC1.HCSE bit is not set.

(2) FLXAnFRSUCC3.WCP

Maximum Without Clock Correction Passive Bit (transition to NORMAL_PASSIVE state)

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

Must be identical in all nodes of a cluster.

Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE to NORMAL_PASSIVE state.

18.2.6.4 FLXAnFRNEMC — FlexRay NEM Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 008C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 18.30 FLXAnFRNEMC Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	NML[3:0]	Network Management Vector Length Bit Configures gNetworkManagementVectorLength

(1) FLXAnFRNEMC.NML

Network Management Vector Length Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 12 bytes.

The configured length must be identical in all nodes of a cluster.

These bits configure the length of the NM vector.

18.2.6.5 FLXAnFRPRTC1 — FlexRay PRT Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0090_H

Value after reset: 084C 0633_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.31 FLXAnFRPRTC1 Register Contents

Bit Position	Bit Name	Function
31 to 26	RWP[5:0]	Repetitions of Tx Wakeup Pattern Bit Configures pWakeupPattern
25	Reserved	When read, the value after reset is read. When writing, write the value after reset.
24 to 16	RXW[8:0]	Wakeup Symbol Receive Window Length Bit Configures gdWakeupSymbolRxWindow
15, 14	BRP[1:0]	Baud Rate Prescaler Bit Configures gdSampleClockPeriod and pSamplesPerMicrotick 00 = 10 Mbps 01 = 5 Mbps 10 = 2.5 Mbps 11 = 2.5 Mbps
13, 12	SPP[1:0]	Strobe Point Position Bit Configures Strobe point position 00 = Sample 5 01 = Sample 4 10 = Sample 6 11 = Sample 5
11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10 to 4	CASM[6:0]	Collision Avoidance Symbol Max Bit Configures gdCASRxLowMax
3 to 0	TSST[3:0]	Transmission Start Sequence Transmitter Bit Configures gdTSSTransmitter

(1) FLXAnFRPRTC1.RWP

Repetitions of Tx Wakeup Pattern Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 63.

Configures the number of repetitions (sequences) of the Tx wakeup symbol.

(2) FLXAnFRPRTC1.RXW

Wakeup Symbol Receive Window Length Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] DEFAULT_CONFIG or CONFIG.

Valid values are 76 to 301 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the received wakeup pattern.

(3) FLXAnFRPRTC1.BRP

Baud Rate Prescaler Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

The Baud Rate Prescaler configures the baud rate on the FlexRay bus. The baud rates listed below are valid with a sample clock set to 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate.

00 = 10 MBit/s

$$\text{gdSampleClockPeriod} = 12.5 \text{ ns} = 1 \times \text{“sample clock”}$$

$$\text{pSamplesPerMicrotick} = 2 \text{ (1 } \mu\text{T} = 25 \text{ ns)}$$

01 = 5 MBit/s

$$\text{gdSampleClockPeriod} = 25 \text{ ns} = 2 \times \text{“sample clock”}$$

$$\text{pSamplesPerMicrotick} = 1 \text{ (1 } \mu\text{T} = 25 \text{ ns)}$$

10, 11 = 2.5 MBit/s

$$\text{gdSampleClockPeriod} = 50 \text{ ns} = 4 \times \text{“sample clock”}$$

$$\text{pSamplesPerMicrotick} = 1 \text{ (1 } \mu\text{T} = 50 \text{ ns)}$$

(4) FLXAnFRPRTC1.SPP

Strobe Point Position Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

These bits specify the sample-counter position at which the Checker Core strobes in response to received bits.

The strobed bit value is determined by sampling at the timing specified by bits FLXAnFRPRTC1.SPP[1:0].

CAUTION

The current revision 2.1 of the FlexRay protocol requires that the FLXAnFRPRTC1.SPP[1:0] bits are 00. The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.

(5) FLXAnFRPRTC1.CASM

Collision Avoidance Symbol Max Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

CASM6 is fixed to 1.

Valid values are 67 to 99 bit times.

Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS).

(6) FLXAnFRPRTC1.TSST

Transmission Start Sequence Transmitter Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are is DEFAULT_CONFIG or CONFIG.

Valid values are 3 to 15 bit times.

Must be identical in all nodes of a cluster.

Configures the duration of the Transmission Start Sequence (TSS) in terms of bit times (1 bit time = 4 μ T = 100ns @ 10Mbps).

18.2.6.6 FLXAnFRPRTC2 — FlexRay PRT Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0094_H

Value after reset: 0F2D 0A0E_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.32 FLXAnFRPRTC2 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is read. When writing, write the value after reset.
29 to 24	TXL[5:0]	Wakeup Symbol Transmit Low Bit Configures gdWakeupSymbolTxLow
23 to 16	TXI[7:0]	Wakeup Symbol Transmit Idle Bit Configures gdWakeupSymbolTxIdle
15, 14	Reserved	When read, the value after reset is read. When writing, write the value after reset.
13 to 8	RXL[5:0]	Wakeup Symbol Receive Low Bit Configures gdWakeupSymbolRxLow
7, 6	Reserved	When read, the value after reset is read. When writing, write the value after reset.
5 to 0	RXI[5:0]	Wakeup Symbol Rx Idle Bit Configures gdWakeupSymbolRxIdle

(1) FLXAnFRPRTC2.TXL

Wakeup Symbol Transmit Low Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 15 to 60 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the low phase of the wakeup symbol.

(2) FLXAnFRPRTC2.TXI

Wakeup Symbol Transmit Idle Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 45 to 180 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the idle phase of the wakeup symbol.

(3) FLXAnFRPRTC2.RXL

Wakeup Symbol Receive Low Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 10 to 55 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the low phase of the received wakeup symbol.

(4) FLXAnFRPRTC2.RXI

Wakeup Symbol Rx Idle Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 14 to 59 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the idle phase of the received wakeup symbol.

18.2.6.7 FLXAnFRMHDC — FlexRay MHD Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0098_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.33 FLXAnFRMHDC Register Contents

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset is read. When writing, write the value after reset.
28 to 16	SLT[12:0]	Start of Latest Transmit Bit Configures pLatestTx
15 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	SFDL[6:0]	Static Frame Data Length Bit Configures gPayloadLengthStatic

(1) FLXAnFRMHDC.SLT

Start of Latest Transmit Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7981 minislots.

Configures the maximum minislot value allowed before inhibiting frame transmission in the dynamic segment of the cycle. There is no transmission in dynamic segment if FLXAnFRMHDC.SLT is set to zero.

(2) FLXAnFRMHDC.SFDL

Static Frame Data Length Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 127.

The payload length must be identical in all nodes of a cluster.

Configures the cluster-wide payload length for all frames sent in the static segment in double bytes.

18.2.6.8 FLXAnFRGTUC1 — FlexRay GTU Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 00A0_H

Value after reset: 0000 0280_H

Table 18.34 FLXAnFRGTUC1 Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is read. When writing, write the value after reset.
19 to 0	UT[19:0]	Setting of Communication Cycle in Microticks Bit Configures pMicroPerCycle

(1) FLXAnFRGTUC1.UT

Setting of Communication Cycle in Microticks Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 640 to 640000 μ T.

Configures the duration of the communication cycle in microticks.

18.2.6.9 FLXAnFRGTUC2 — FlexRay GTU Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 00A4_H

Value after reset: 0002 000A_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.35 FLXAnFRGTUC2 Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is read. When writing, write the value after reset.
19 to 16	SNM[3:0]	Sync Node Max Bit
15, 14	Reserved	When read, the value after reset is read. When writing, write the value after reset.
13 to 0	MPC[13:0]	Setting of Communication Cycle in Macro tick Bit Configures gMacroPerCycle

(1) FLXAnFRGTUC2.SNM

Sync Node Max Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCSDEFAULT_CONFIG or CONFIG.

Valid values are 2 to 15.

Must be identical in all nodes of a cluster.

Maximum number of frames within a cluster with sync frame indicator bit SYN set to 1.

(2) FLXAnFRGTUC2.MPC

Setting of Communication Cycle in Macro tick Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS [5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 10 to 16000 MT.

The cycle length must be identical in all nodes of a cluster.

Configures the duration of one communication cycle in macro ticks.

18.2.6.10 FLXAnFRGTUC3 — FlexRay GTU Configuration Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 00A8_H

Value after reset: 0202 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.36 FLXAnFRGTUC3 Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is read. When writing, write the value after reset.
30 to 24	MIOB[6:0]	Macrotick Initial Offset Channel B Bit Configures pMacroInitialOffset[B]
23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22 to 16	MIOA[6:0]	Macrotick Initial Offset Channel A Bit Configures pMacroInitialOffset[A]
15 to 8	UIOB[7:0]	Microtick Initial Offset Channel B Bit Configures pMicroInitialOffset[B]
7 to 0	UIOA[7:0]	Microtick Initial Offset Channel A Bit Configures pMicroInitialOffset[A]

(1) FLXAnFRGTUC3.MIOB

Macrotick Initial Offset Channel B Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

Must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration.

(2) FLXAnFRGTUC3.MIOA

Macrotock Initial Offset Channel A Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

Must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotock boundary of the secondary time reference point based on the nominal macrotock duration.

(3) FLXAnFRGTUC3.UIOB

Microtock Initial Offset Channel B Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCSDEFAULT_CONFIG or CONFIG.

Valid values are 0 to 240 μ T.

Configures the number of microticks between the actual time reference point on channel B and the subsequent macrotock boundary of the secondary time reference point. The parameter depends on pDelayCompensation [B] and therefore has to be set for each channel independently.

(4) FLXAnFRGTUC3.UIOA

Microtock Initial Offset Channel A Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS [5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 240 μ T.

Configures the number of microticks between the actual time reference point on channel A and the subsequent macrotock boundary of the secondary time reference point. The parameter depends on pDelayCompensation [A] and therefore has to be set for each channel independently.

18.2.6.11 FLXAnFRGTUC4 — FlexRay GTU Configuration Register 4

For details about configuration of FLXAnFRGTUC4.NIT and FLXAnFRGTUC4.OCS see **Section 18.3.2.5, Configuration of NIT Start and Offset Correction Start.**

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 00AC_H

Value after reset: 0008 0007_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	OCS[13:0]													
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Table 18.37 FLXAnFRGTUC4 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is read. When writing, write the value after reset.
29 to 16	OCS[13:0]	Offset Correction Start Bit Configures (gOffsetCorrectionStart - 1)
15, 14	Reserved	When read, the value after reset is read. When writing, write the value after reset.
13 to 0	NIT[13:0]	Network Idle Time Start Bit Configures (gMacroPerCycle -gdNIT - 1)

(1) FLXAnFRGTUC4.OCS

Offset Correction Start Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 8 to 15998 MT.

For cluster consisting of E-Ray implementations only, it is sufficient to program
FLXAnFRGTUC4.OCS = FLXAnFRGTUC4.NIT + 1.

Must be identical in all nodes of a cluster.

Determines the start of the offset correction within the NIT phase, calculated from start of cycle.

(2) FLXAnFRGTUC4.NIT

Network Idle Time Start Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 7 to 15997 MT.

Must be identical in all nodes of a cluster.

Configures the starting point of the Network Idle Time NIT at the end of the communication cycle expressed in terms of macroticks from the beginning of the cycle. The start of NIT is recognized if $\text{Macrotick} = \text{gMacroPerCycle} - \text{gdNIT} - 1$ and the increment pulse of Macrotick is set.

18.2.6.12 FLXAnFRGTUC5 — FlexRay GTU Configuration Register 5

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 00B0_H

Value after reset: 0E00 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.38 FLXAnFRGTUC5 Register Contents

Bit Position	Bit Name	Function
31 to 24	DEC[7:0]	Decoding Correction Bit Configures pDecodingCorrection
23 to 21	Reserved	When read, the value after reset is read. When writing, write the value after reset.
20 to 16	CDD[4:0]	Cluster Drift Damping Bit Configures pClusterDriftDamping
15 to 8	DCB[7:0]	Delay Compensation Channel B Bit Configures pDelayCompensation[B]
7 to 0	DCA[7:0]	Delay Compensation Channel A Bit Configures pDelayCompensation[A]

(1) FLXAnFRGTUC5.DEC

Decoding Correction Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 14 to 143 μ T.

Configures the decoding correction value in microticks used to determine the primary time reference point.

(2) FLXAnFRGTUC5.CDD

Cluster Drift Damping Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 20 μ T.

Configures the cluster drift damping value in microticks used in clock synchronization to minimize accumulation of rounding errors.

(3) FLXAnFRGTUC5.DCB

Delay Compensation Channel B Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 μ T.

Used to compensate for reception delays on channel B. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05 μ s. In practice, the minimum of the propagation delays of all sync nodes should be applied.

(4) FLXAnFRGTUC5.DCA

Delay Compensation Channel A Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 μ T.

Used to compensate for reception delays on channel A. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05 μ s. In practice, the minimum of the propagation delays of all sync nodes should be applied.

18.2.6.13 FLXAnFRGTUC6 — FlexRay GTU Configuration Register 6

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 00B4_H

Value after reset: 0002 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.39 FLXAnFRGTUC6 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is read. When writing, write the value after reset.
26 to 16	MOD[10:0]	Maximum Oscillator Drift Bit Configures pdMaxDrift
15 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10 to 0	ASR[10:0]	Accepted Startup Range Bit Configures pdAcceptedStartupRange

(1) FLXAnFRGTUC6.MOD

Maximum Oscillator Drift Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 μ T.

Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in μ T.

(2) FLXAnFRGTUC6.ASR

Accepted Startup Range Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 1875 μ T.

Number of microticks constituting the expanded range of measured deviation for startup frames during integration.

18.2.6.14 FLXAnFRGTUC7 — FlexRay GTU Configuration Register 7

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 00B8_H

Value after reset: 0002 0004_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.40 FLXAnFRGTUC7 Register Contents

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is read. When writing, write the value after reset.
25 to 16	NSS[9:0]	Number of Static Slots Bit Configures gNumberOfStaticSlots
15 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9 to 0	SSL[9:0]	Static Slot Length Bit Configures gdStaticSlot

(1) FLXAnFRGTUC7.NSS

Number of Static Slots Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1023.

The number of static slots must be identical in all nodes of a cluster.

Configures the number of static slots in a cycle.

(2) FLXAnFRGTUC7.SSL

Static Slot Length Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 4 to 659 MT.

The static slot length must be identical in all nodes of a cluster.

Configures the length of a static slot in macroticks.

18.2.6.15 FLXAnFRGTUC8 — FlexRay GTU Configuration Register 8

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 00BC_H

Value after reset: 0000 0002_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.41 FLXAnFRGTUC8 Register Contents

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset is read. When writing, write the value after reset.
28 to 16	NMS[12:0]	Number of Minislots Bit Configures gNumberOfMinislots
15 to 6	Reserved	When read, the value after reset is read. When writing, write the value after reset.
5 to 0	MSL[5:0]	Minislot Length Bit Configures gdMinislot

(1) FLXAnFRGTUC8.NMS

Number of Minislots Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7986.

The number of minislots must be identical in all nodes of a cluster.

Configures the number of minislots within the dynamic segment of a cycle.

(2) FLXAnFRGTUC8.MSL

Minislot Length Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 63 MT.

The minislot length must be identical in all nodes of a cluster.

Configures the length of a minislot in macroticks.

18.2.6.16 FLXAnFRGTUC9 — FlexRay GTU Configuration Register 9

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 00C0_H

Value after reset: 0000 0101_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.42 FLXAnFRGTUC9 Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is read. When writing, write the value after reset.
17, 16	DSI[1:0]	Dynamic Slot Idle Phase Bit Configures gdDynamicSlotIdlePhase
15 to 13	Reserved	When read, the value after reset is read. When writing, write the value after reset.
12 to 8	MAPO[4:0]	Minislot Action Point Offset Bit Configures gdMinislotActionPointOffset
7, 6	Reserved	When read, the value after reset is read. When writing, write the value after reset.
5 to 0	APO[5:0]	Action Point Offset Bit Configures gdActionPointOffset

(1) FLXAnFRGTUC9.DSI

Dynamic Slot Idle Phase Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 2 Minislot.

Must be identical in all nodes of a cluster.

Configures the duration of the dynamic slot idle phase in the number of minislots. The duration has to be greater or equal than the idle detection time.

(2) FLXAnFRGTUC9.MAPO

Minislot Action Point Offset Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 31 MT.

Must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within the minislots of the dynamic segment.

(3) FLXAnFRGTUC9.APO

Action Point Offset Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 63 MT.

Must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within static slots and symbol window.

18.2.6.17 FLXAnFRGTUC10 — FlexRay GTU Configuration Register 10

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 00C4_H

Value after reset: 0002 0005_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.43 FLXAnFRGTUC10 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is read. When writing, write the value after reset.
26 to 16	MRC[10:0]	Maximum Rate Correction Bit Configures pRateCorrectionOut
15, 14	Reserved	When read, the value after reset is read. When writing, write the value after reset.
13 to 0	MOC[13:0]	Maximum Offset Correction Bit Configures pOffsetCorrectionOut

(1) FLXAnFRGTUC10.MRC

Maximum Rate Correction Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 μ T.

Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The CC checks only the internal rate correction value against the maximum rate correction value (absolute value).

(2) FLXAnFRGTUC10.MOC

Maximum Offset Correction Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 5 to 15266 μ T.

Holds the maximum permitted offset correction value (absolute value) to be applied by the internal clock synchronization algorithm (absolute value). The CC checks only the internal offset correction value against the maximum offset correction value.

18.2.6.18 FLXAnFRGTUC11 — FlexRay GTU Configuration Register 11

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 00C8_H

Value after reset: 0000 0000_H

Table 18.44 FLXAnFRGTUC11 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is read. When writing, write the value after reset.
26 to 24	ERC[2:0]	External Rate Correction Bit Configures pExternRateCorrection
23 to 19	Reserved	When read, the value after reset is read. When writing, write the value after reset.
18 to 16	EOC[2:0]	External Offset Correction Bit Configures pExternOffsetCorrection
15 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9, 8	ERCC[1:0]	External Rate Correction Control Bit Configures vExternRateControl 00: External rate correction is prohibited. 01: External rate correction is prohibited. 10: Subtract 11: Add
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	EOCC[1:0]	External Offset Correction Control Bit Configures vExternOffsetControl 00: External offset correction is prohibited. 01: External offset correction is prohibited. 10: Subtract 11: Add

(1) FLXAnFRGTUC11.ERC

External Rate Correction Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 μ T.

Holds the external rate correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated rate correction value. The value is applied during NIT.

(2) FLXAnFRGTUC11.EOC

External Offset Correction Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 μ T.

Holds the external offset correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated offset correction value. The value is applied during NIT.

(3) FLXAnFRGTUC11.ERCC

External Rate Correction Control Bit

Should be modified only outside NIT (Network Idle Time).

Writing the following values enables the external rate correction.

00 = External rate correction is prohibited.

01 = External rate correction is prohibited.

10 = Subtract

External rate correction value subtracted from calculated rate correction value

11 = Add

External rate correction value added to calculated rate correction value

(4) FLXAnFRGTUC11.EOCC

External Offset Correction Control Bit

Should be modified only outside NIT (Network Idle Time).

Writing the following values enables the external offset correction.

00 = External offset correction is prohibited.

01 = External offset correction is prohibited.

10 = Subtract

External offset correction value subtracted from calculated offset correction value

11 = Add

External offset correction value added to calculated offset correction value

18.2.7 CC Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the CC between two accesses (non-atomic read accesses).

18.2.7.1 FLXAnFRCCSV — FlexRay CC Status Vector Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0100_H

Value after reset: 0010 4000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	PSL[5:0]					RCA[4:0]				WSV[2:0]

Table 18.45 FLXAnFRCCSV Register Contents (1/2)

Bit	Symbol	Function
31, 30	Reserved	When read, the value after reset is read.
29 to 24	PSL[5:0]	POC Status Log Flag Status of FLXAnFRCCSV.POCS immediately before entering HALT state.
23 to 19	RCA[4:0]	Remaining Coldstart Attempts Flag Indicates vRemainingColdstartAttempts
18 to 16	WSV[2:0]	Wakeup Status Flag Indicates vPOC!WakeupStatus 000: UNDEFINED 001: RECEIVED_HEADER 010: RECEIVED_WUP 011: COLLISION_HEADER 100: COLLISION_WUP 101: COLLISION_UNKNOWN 110: TRANSMITTED 111: Reserved
15	Reserved	When read, the value after reset is read.
14	CSI	Cold Start Inhibit Flag Indicates vColdStartInhibit 0: Cold starting of node enabled 1: Cold starting of node disabled
13	CSAI	Coldstart Abort Indicator Flag
12	CSNI	Coldstart Noise Indicator Flag Indicates vPOC!ColdstartNoise
11, 10	Reserved	When read, the value after reset is read.
9, 8	SLM[1:0]	Slot Mode Flag Indicates vPOC!SlotMode 00: SINGLE 01: reserved 10: ALL_PENDING 11: ALL

Table 18.45 FLXAnFRCCSV Register Contents (2/2)

Bit	Symbol	Function
7	HRQ	Halt Request Flag Indicates vPOC!CHIHaltRequest
6	FSI	Freeze Status Indicator Flag Indicates vPOC!Freeze
5 to 0	POCS[5:0]	Protocol Operation Control Status Flag

(1) FLXAnFRCCSV.PSL

POC Status Log Flag

Set the value of bits FLXAnFRCCSV.POCS[5:0] immediately before entering HALT state.

Set to HALT when FREEZE command is applied during HALT state and FLXAnFRCCSV.FSI is not already set i.e. the HALT state was not reached by FREEZE command.

Reset to “000000_B” when leaving HALT state.

(2) FLXAnFRCCSV.RCA

Remaining Coldstart Attempts Flag

Indicates the number of remaining coldstart attempts (vRemainingColdstartAttempts).

The value after a reset during CONFIG and DEFAULT_CONFIG state is also bits FLXAnFRSUCC1.CSA[4:0].

The RUN command resets this counter to the maximum number of coldstart attempts as configured by the FLXAnFRSUCC1.CSA [4:0] bits.

(3) FLXAnFRCCSV.WSV

Wakeup Status Flag

Indicates the status of the current wakeup attempt (vPOC!WakeupStatus).

Reset to 0 when entering Wakeup state, by CHI command RESET_STATUS_INDICATORS, or by transition from DEFAULT_CONFIG to CONFIG state

000_B = UNDEFINED

Wakeup not yet executed by the CC.

001_B = RECEIVED_HEADER

Set when the CC finishes wakeup due to the reception of a frame header without coding violation on either channel in WAKEUP_LISTEN state.

010_B = RECEIVED_WUP

Set when the CC finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in WAKEUP_LISTEN state.

011_B = COLLISION_HEADER

Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid header on either channel.

100_B = COLLISION_WUP

Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel.

101_B = COLLISION_UNKNOWN

Set when the CC stops wakeup by leaving WAKEUP_DETECT state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid frame header.

110_B = TRANSMITTED

Set when the CC has successfully completed the transmission of the wakeup pattern.

111_B = reserved

(4) FLXAnFRCCSV.CSI

Cold Start Inhibit Flag

Indicates that the node is disabled from cold starting (vColdStartInhibit).

The flag is set to 1 whenever the POC enters READY state due to CHI command READY.

The flag has to be reset under control of the Host by CHI command ALLOW_COLDSTART (bits FLXAnFRSUCC1.CMD[3:0] are 1001_B).

(5) FLXAnFRCCSV.CSAI

Coldstart Abort Indicator Flag

Indicates that a coldstart attempt was aborted.

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(6) FLXAnFRCCSV.CSNI

Coldstart Noise Indicator Flag

Indicates that the cold start procedure occurred under noisy conditions (vPOC!ColdstartNoise).

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(7) FLXAnFRCCSV.SLM

Slot Mode Flag

Indicates the actual slot mode of the POC (vPOC!SlotMode) in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE.

Default value is SINGLE. Changes to ALL, depending on FLXAnFRSUCC1.TSM.

In NORMAL_ACTIVE or NORMAL_PASSIVE state the CHI command ALL_SLOTS will change the slot mode from SINGLE over ALL_PENDING to ALL.

Set FLXAnFRSUCC1.TSM to SINGLE except for NORMAL_ACTIVE or NORMAL_PASSIVE.

(8) FLXAnFRCCSV.HRQ

Halt Request Flag

Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle (vPOC!CHIHaltRequest).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(9) FLXAnFRCCSV.FSI

Freeze Status Indicator Flag

Indicates that the POC has entered the HALT state due to CHI command, FREEZE (bits FLXAnFRSUCC1.CMD[3:0] are 0111_B) or due to an error condition requiring an immediate POC halt (vPOC!Freeze).

Reset by transition from HALT to DEFAULT_CONFIG state.

(10) FLXAnFRCCSV.POCS

Protocol Operation Control Status Flag

Indicates the actual state of operation of the CC Protocol Operation Control

00 0000_B = DEFAULT_CONFIG state

00 0001_B = READY state

00 0010_B = NORMAL_ACTIVE state

00 0011_B = NORMAL_PASSIVE state

00 0100_B = HALT state

00 1111_B = CONFIG state

Indicates the actual state of operation of the POC in the wakeup path

01 0000_B = WAKEUP_STANDBY state

01 0001_B = WAKEUP_LISTEN state

01 0010_B = WAKEUP_SEND state

01 0011_B = WAKEUP_DETECT state

Indicates the actual state of operation of the POC in the startup path

10 0000_B = STARTUP_PREPARE state

10 0001_B = COLDSTART_LISTEN state

10 0010_B = COLDSTART_COLLISION_RESOLUTION state

10 0011_B = COLDSTART_CONSISTENCY_CHECK state

10 0100_B = COLDSTART_GAP state

10 0101_B = COLDSTART_JOIN State

10 0110_B = INTEGRATION_COLDSTART_CHECK state

10 0111_B = INTEGRATION_LISTEN state

10 1000_B = INTEGRATION_CONSISTENCY_CHECK state

10 1001_B = INITIALIZE_SCHEDULE state

10 1010_B = ABORT_STARTUP state

10 1011_B = STARTUP_SUCCESS state

others = reserved

18.2.7.2 FLXAnFRCCEV — FlexRay CC Error Vector Register

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0104_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.46 FLXAnFRCCEV Register Contents

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is read.
12 to 8	PTAC[4:0]	Passive to Active Count Flag Indicates vAllowPassiveToActive
7, 6	ERRM[1:0]	Error Mode Flag Indicates vPOC!ErrorMode 00: ACTIVE 01: PASSIVE 10: COMM_HALT 11: reserved
5, 4	Reserved	When read, the value after reset is read.
3 to 0	CCFC[3:0]	Clock Correction Failed Counter Indicates vClockCorrectionFailed

(1) FLXAnFRCCEV.PTAC

Passive to Active Count Flag

Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from NORMAL_PASSIVE state to NORMAL_ACTIVE state. The transition takes place when this bit equals to the value of bits FLXAnFRSUCC1.PTA[4:0] –1.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(2) FLXAnFRCCEV.ERRM

Error Mode Flag

Indicates the actual error mode of the POC (vPOC!ErrorMode).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(3) FLXAnFRCCEV.CCFC

Clock Correction Failed Counter

Indicates the clock correction failed counter of the POC (vClockCorrectionFailed).

The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active.

The Clock Correction Failed Counter is reset to 0 at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active.

The Clock Correction Failed Counter stops at 15.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

18.2.7.3 FLXAnFRSCV — FlexRay Slot Counter Value Register

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0110_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	SCCB[10:0]

Table 18.47 FLXAnFRSCV Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is read.
26 to 16	SCCB[10:0]	Slot Counter Channel B Indicates vSlotCounter[B]
15 to 11	Reserved	When read, the value after reset is read.
10 to 0	SCCA[10:0]	Slot Counter Channel A Indicates vSlotCounter[A]

(1) FLXAnFRSCV.SCCB

Slot Counter Channel B

Current slot counter value on channel B (vSlotCounter[B]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRSCV.SCCA

Slot Counter Channel A

Current slot counter value on channel A (vSlotCounter[A]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

18.2.7.4 FLXAnFRMTCCV — FlexRay Macrotick and Cycle Counter Value Register

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0114_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	CCV[5:0]

Table 18.48 FLXAnFRMTCCV Register Contents

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, the value after reset is read.
21 to 16	CCV[5:0]	Cycle Counter Value Indicates vCycleCounter
15, 14	Reserved	When read, the value after reset is read.
13 to 0	MTV[13:0]	Macrotick Value Indicates vMacrotick

(1) FLXAnFRMTCCV.CCV

Cycle Counter Value

Current cycle counter value (vCycleCounter). The value is incremented by the CC at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRMTCCV.MTV

Macrotick Value

Current macrotick value (vMacrotick). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

18.2.7.5 FLXAnFRRCV — FlexRay Rate Correction Value Register

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0118_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 18.49 FLXAnFRRCV Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset is read.
11 to 0	RCV[11:0]	Rate Correction Value Flag Indicates vRateCorrection

(1) FLXAnFRRCV.RCV

Rate Correction Value Flag

Indicates internal rate correction value (vRateCorrection/ two's complement) before limitation. If the value of this bit exceeds the limits defined by bits FLXAnFRGTUC10.MRC[10:0], flag FLXAnFRSFS.RCLR is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

CAUTION

The external rate correction value is added to the limited rate correction value.

18.2.7.6 FLXAnFROCV — FlexRay Offset Correction Value Register

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 011C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	OCV[18:16]

Table 18.50 FLXAnFROCV Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is read.
18 to 0	OCV[18:0]	Offset Correction Value Flag Indicates vOffsetCorrection

(1) FLXAnFROCV.OCV

Offset Correction Value Flag

Indicates offset correction value (vOffsetCorrection/ two's complement) before limitation. If the value of this bit exceeds the limits defined by bits FLXAnFRGTUC10.MOC[10:0], flag FLXAnFRSFS.OCLR is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

CAUTION

The external offset correction value is added to the limited offset correction value.

18.2.7.7 FLXAnFRSFS — FlexRay Sync Frame Status Register

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0120_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	RCLR	MRCS	OCLR	MOCS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VSBO[3:0]				VSBE[3:0]				VSAO[3:0]				VSAE[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.51 FLXAnFRSFS Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is read.
19	RCLR	Rate Correction Limit Reached Flag 0: Rate correction below limit 1: Rate correction limit reached
18	MRCS	Missing Rate Correction Signal Flag 0: Rate correction signal valid 1: Missing rate correction signal
17	OCLR	Offset Correction Limit Reached Flag 0: Offset correction below limit 1: Offset correction limit reached
16	MOCS	Missing Offset Correction Signal Flag 0: Offset correction signal valid 1: Missing offset correction signal
15 to 12	VSBO[3:0]	Valid Sync Frames Channel B, odd communication cycle
11 to 8	VSBE[3:0]	Valid Sync Frames Channel B, even communication cycle
7 to 4	VSAO[3:0]	Valid Sync Frames Channel A, odd communication cycle
3 to 0	VSAE[3:0]	Valid Sync Frames Channel A, even communication cycle

(1) FLXAnFRSFS.RCLR

Rate Correction Limit Reached Flag

The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit as defined by bits FLXAnFRGTUC10.MRC[10:0]. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(2) FLXAnFRSFS.MRCS

Missing Rate Correction Signal Flag

The Missing Rate Correction flag signals to the Host, that no rate correction calculation can be performed because no pairs of even / odd sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(3) FLXAnFRSFS.OCLR

Offset Correction Limit Reached Flag

The Offset Correction Limit Reached flag signals to the Host, that the offset correction value has exceeded its limit as defined by bits FLXAnFRGTUC10.MOC[10:0]. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(4) FLXAnFRSFS.MOCS

Missing Offset Correction Signal Flag

The Missing Offset Correction flag signals to the Host, that no offset correction calculation can be performed because no sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(5) FLXAnFRSFS.VSBO

Valid Sync Frames Channel B, odd communication cycle

These bits are only valid when bit FLXAnFRSUCC1.CCHB is 1.

Holds the number of valid sync frames received on channel B in the odd communication cycle. If transmission of sync frames is enabled by bit FLXAnFRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(6) FLXAnFRSFS.VSBE

Valid Sync Frames Channel B, even communication cycle

These bits are only valid when bit FLXAnFRSUCC1.CCHB is 1.

Holds the number of valid sync frames received on channel B in the even communication cycle. If transmission of sync frames is enabled by bit FLXAnFRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(7) FLXAnFRSFS.VSAO

Valid Sync Frames Channel A, odd communication cycle

These bits are only valid when bit FLXAnFRSUCC1.CCHA is 1.

Holds the number of valid sync frames received on channel A in the odd communication cycle. If transmission of sync frames is enabled by bit FLXAnFRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(8) FLXAnFRSFS.VSAE

Valid Sync Frames Channel A, even communication cycle

These bits are only valid when bit FLXAnFRSUCC1.CCHA is 1.

Holds the number of valid sync frames received on channel A in the even communication cycle. If transmission of sync frames is enabled by bit FLXAnFRSUCC1.TXSY, the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

18.2.7.8 FLXAnFRSWNIT — FlexRay Symbol Window and NIT Status Register

Symbol window related status information is updated by the CC at the end of the symbol window for each channel. NIT related status information is updated by the CC at the end of the NIT for each channel.

During startup the status data is not updated.

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0124_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 18.52 FLXAnFRSWNIT Register Contents (1/2)

Bit	Symbol	Function
31 to 12	Reserved	When read, the value after reset is read.
11	SBNB	Slot Boundary Violation during NIT Channel B Flag 0: No slot boundary violation detected 1: Slot boundary violation during NIT detected on channel B
10	SENB	Syntax Error during NIT Channel B Flag 0: No syntax error detected 1: Syntax error during NIT detected on channel B
9	SBNA	Slot Boundary Violation during NIT Channel A Flag 0: No slot boundary violation detected 1: Slot boundary violation during NIT detected on channel A
8	SENA	Syntax Error during NIT Channel A Flag 0: No syntax error detected 1: Syntax error during NIT detected on channel A
7	MTSB	MTS Received on Channel B Flag 0: No MTS symbol received on channel B 1: MTS symbol received on channel B
6	MTSA	MTS Received on Channel A Flag 0: No MTS symbol received on channel A 1: MTS symbol received on channel A
5	TCSB	Transmission Conflict in Symbol Window Channel B Flag 0: No transmission conflict detected 1: Transmission conflict in symbol window detected on channel B
4	SBSB	Slot Boundary Violation in Symbol Window Channel B Flag 0: No slot boundary violation detected 1: Slot boundary violation during symbol window detected on channel B
3	SESB	Syntax Error in Symbol Window Channel B Flag 0: No syntax error detected 1: Syntax error during symbol window detected on channel B

Table 18.52 FLXAnFRSWNIT Register Contents (2/2)

Bit	Symbol	Function
2	TCSA	Transmission Conflict in Symbol Window Channel A Flag 0: No transmission conflict detected 1: Transmission conflict in symbol window detected on channel A
1	SBSA	Slot Boundary Violation in Symbol Window Channel A Flag 0: No slot boundary violation detected 1: Slot boundary violation during symbol window detected on channel A
0	SESA	Syntax Error in Symbol Window Channel A Flag 0: No syntax error detected 1: Syntax error during symbol window detected on channel A

(1) FLXAnFRSWNIT.SBNB

Indicates a Slot Boundary Violation during NIT Channel B Flag (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRSWNIT.SENB

Indicates a Syntax Error during NIT Channel B Flag (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXAnFRSWNIT.SBNA

Indicates a Slot Boundary Violation during NIT Channel A Flag (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(4) FLXAnFRSWNIT.SENA

Indicates a Syntax Error during NIT Channel A Flag (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

(5) FLXAnFRSWNIT.MTSB

Indicates a MTS Received on Channel B Flag (vSS!ValidMTSB).

Media Access Test symbol received on channel B during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to 1, also bit FLXAnFRSIR.MTSB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) FLXAnFRSWNIT.MTSA

Indicates a MTS Received on Channel A Flag (vSS!ValidMTSA).

Media Access Test symbol received on channel A during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to 1, also bit FLXAnFRSIR.MTSA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) FLXAnFRSWNIT.TCSB

Indicates a Transmission Conflict in Symbol Window Channel B Flag (vSS!TxConflictB).

Reset when leaving CONFIG state or when entering STARTUP state.

(8) FLXAnFRSWNIT.SBSB

Indicates a Slot Boundary Violation in Symbol Window Channel B Flag (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(9) FLXAnFRSWNIT.SESB

Indicates a Syntax Error in Symbol Window Channel B Flag (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(10) FLXAnFRSWNIT.TCSA

Indicates a Transmission Conflict in Symbol Window Channel A Flag (vSS!TxConflictA).

Reset when leaving CONFIG state or when entering STARTUP state.

(11) FLXAnFRSWNIT.SBSA

Indicates a Slot Boundary Violation in Symbol Window Channel A Flag (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(12) FLXAnFRSWNIT.SESA

Indicates a Syntax Error in Symbol Window Channel A Flag (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

18.2.7.9 FLXAnFRACS — FlexRay Aggregated Channel Status Register

The aggregated channel status provides the Host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception.

The aggregated channel status also includes status data from the symbol window and the network idle time.

The status data is updated (set) after each slot and aggregated until it is reset by the Host.

During startup the status data is not updated.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0128_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 18.53 FLXAnFRACS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is read. When writing, write the value after reset.
12	SBVB	Slot Boundary Violation on Channel B Flag 0: No slot boundary violation observed 1: Slot boundary violation(s) observed on channel B
11	CIB	Communication Indicator Channel B Flag 0: No valid frame(s) received in slots containing any additional communication 1: Valid frame(s) received on channel B in slots containing any additional communication
10	CEDB	Content Error Detected on Channel B Flag 0: No frame with content error received 1: Frame(s) with content error received on channel B
9	SEDB	Syntax Error Detected on Channel B Flag 0: No syntax error observed 1: Syntax error(s) observed on channel B
8	VFRB	Valid Frame Received on Channel B Flag 0: No valid frame received 1: Valid frame(s) received on channel B
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	SBVA	Slot Boundary Violation on Channel A Flag 0: No slot boundary violation observed 1: Slot boundary violation(s) observed on channel A

Table 18.53 FLXAnFRACS Register Contents (2/2)

Bit Position	Bit Name	Function
3	CIA	Communication Indicator Channel A Flag 0: No valid frame(s) received in slots containing any additional communication 1: Valid frame(s) received on channel A in slots containing any additional communication
2	CEDA	Content Error Detected on Channel A Flag 0: No frame with content error received 1: Frame(s) with content error received on channel A
1	SEDA	Syntax Error Detected on Channel A Flag 0: No syntax error observed 1: Syntax error(s) observed on channel A
0	VFRA	Valid Frame Received on Channel A Flag 0: No valid frame received 1: Valid frame(s) received on channel A

(1) FLXAnFRACS.SBVB

Slot Boundary Violation on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from 0 to 1, bit FLXAnFREIR.EDB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRACS.CIB

Communication Indicator Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel B in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had When any combination of either syntax error OR content error OR slot boundary violation.

When this flag changes from 0 to 1, bit FLXAnFREIR.EDB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

The FLXAnFRACS.CIB flag is also set when the slot boundary at the end of the slot is reached during the channel idle recognition phase while there is only a single frame in the slot.

(3) FLXAnFRACS.CEDB

Content Error Detected on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more frames with a content error were received on channel B in any static or dynamic slot during the observation period.

When this flag changes from 0 to 1, bit FLXAnFREIR.EDB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(4) FLXAnFRACS.SEDB

Syntax Error Detected on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel B.

When this flag changes from 0 to 1, bit FLXAnFREIR.EDB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(5) FLXAnFRACS.VFRB

Valid Frame Received on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel B in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) FLXAnFRACS.SBVA

Slot Boundary Violation on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

Slot boundary violations were observed on channel A at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from 0 to 1, bit FLXAnFREIR.EDA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) FLXAnFRACS.CIA

Communication Indicator Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel A in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.

When this flag changes from 0 to 1, the FLXAnFREIR.EDA bit is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

The FLXAnFRACS.CIB flag is also set when the slot boundary at the end of the slot is reached during the channel idle recognition phase while there is only a single frame in the slot.

(8) FLXAnFRACS.CEDA

Content Error Detected on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more frames with a content error were received on channel A in any static or dynamic slot during the observation period.

When this flag changes from 0 to 1, bit FLXAnFREIR.EDA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(9) FLXAnFRACS.SEDA

Syntax Error Detected on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel A.

When this flag changes from 0 to 1, bit FLXAnFREIR.EDA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(10) FLXAnFRACS.VFRA

Valid Frame Received on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel A in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

18.2.7.10 FLXAnFRESIDm — FlexRay Even Sync ID Register m (m = 1 to 15)

Registers FLXAnFRESID1 to FLXAnFRESID15 hold the frame IDs of the sync frames received in even communication cycles used for clock synchronisation up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register FLXAnFRESID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an even communication cycle, register FLXAnFRESID1 holds the respective sync frame ID as configured in message buffer 0 and flags FLXAnFRESID1.RXEA, FLXAnFRESID1.RXEB are set. The value is updated during the NIT of each even communication cycle.

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0130_H to <FLXAn_base> + 0168_H (<FLXAn_base> + 0130_H + (n-1) × 4)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.54 FLXAnFRESIDn (n=1 to 15) Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read.
15	RXEB	Received / Configured Even Sync ID on Channel B Flag 0: No sync frame received on channel B / node not configured to transmit sync frames 1: Sync frame received on channel B / node configured to transmit sync frames
14	RXEA	Received / Configured Even Sync ID on Channel A Flag 0: No sync frame received on channel A / node not configured to transmit sync frames 1: Sync frame received on channel A / node configured to transmit sync frames
13 to 10	Reserved	When read, the value after reset is read.
9 to 0	EID[9:0]	Even Sync ID Flag (vsSyncIDListA,B even)

(1) FLXAnFRESIDn.RXEB

Received / Configured Even Sync ID on Channel B Flag

Signals that a sync frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot = bits FLXAnFRESID1.EID[9:0].

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRESIDn.RXEA

Received / Configured Even Sync ID on Channel A Flag

Signals that a sync frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = bits FLXAnFRESID1.EID[9:0].

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXAnFRESIDn.EID

Even Sync ID Flag (vsSyncIDListA,B even)

Sync frame ID even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

18.2.7.11 FLXAnFROSIDm — FlexRay Odd Sync ID Register m (m = 1 to 15)

Registers FLXAnFROSID1 to FLXAnFROSID15 hold the frame IDs of the sync frames received in odd communication cycles used for clock synchronisation up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register FLXAnFROSID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an odd communication cycle, register FLXAnFROSID1 holds the respective sync frame ID as configured in message buffer 0 and flags FLXAnFROSID1.RXOA, FLXAnFROSID1.RXOB are set. The value is updated during the NIT of each odd communication cycle.

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0170_H to <FLXAn_base> + 01A8_H (<FLXAn_base> + 0170_H + (n-1) × 4)

Value after reset: 0000 0000_H

Table 18.55 FLXAnFROSIDn Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read.
15	RXOB	Received / Configured Odd Sync ID on Channel B Flag 0: No sync frame received on channel B / node not configured to transmit sync frames 1: Sync frame received on channel B / node configured to transmit sync frames
14	RXOA	Received / Configured Odd Sync ID on Channel A Flag 0: No sync frame received on channel A / node not configured to transmit sync frames 1: Sync frame received on channel A / node configured to transmit sync frames
13 to 10	Reserved	When read, the value after reset is read.
9 to 0	OID[9:0]	Odd Sync ID Flag (vsSyncIDListA,B odd)

(1) FLXAnFROSIDn.RXOB

Received / Configured Odd Sync ID on Channel B Flag

Signals that a sync frame corresponding to the stored odd sync ID was received on channel B or that the node is configured to be a sync node with key slot = bits FLXAnFROSID1.OID[9:0].

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFROSIDn.RXOA

Received / Configured Odd Sync ID on Channel A Flag

Signals that a sync frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = bits FLXAnFROSID1.OID[9:0].

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXAnFROSIDn.OID

Odd Sync ID Flag (vsSyncIDListA,B odd)

Sync frame ID odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

18.2.7.12 FLXAnFRNMV_m — FlexRay Network Management Vector Register m (m = 1 to 3)

The three network management registers hold the accrued NM vector (see **Section 18.3.7, Network Management**).

The CC updates the NM vector at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state.

FLXAnFRNMV_m-bytes exceeding the configured NM vector length are not valid.

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 01B0_H to <FLXAn_base> + 01B8_H (<FLXAn_base> + 01B0_H + (m-1) × 4)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NM[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	NM[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.56 FLXAnFRNMV_n Register Contents

Bit Position	Bit Name	Function
31 to 0	NM[31:0]	NM Vector

(1) FLXAnFRNMV_m.NM

NM Vector

The three network management vector registers hold the accrued NM vector (configurable 0 to 12 bytes). The NM vector to be held is generated by bit-wise logic OR for each NM vector received on each channel (valid static frames with PPI = 1) (see **Section 18.3.7, Network Management**).

FLXAnFRNMV_m-bytes exceeding the configured NM vector length are not valid.

The Register Contents are updated at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state.

These bits are cleared when leaving CONFIG state or when entering STARTUP state.

18.2.8 Message Buffer Control Registers

18.2.8.1 FLXAnFRMRC — FlexRay Message RAM Configuration Register

The Message RAM Configuration register defines the number of message buffers assigned to the static segment, dynamic segment, and FIFO.

The Message RAM can be divided into up three different areas; Static Buffer area, Static and Dynamic Buffer area, FIFO area. If present, the Static Buffer area is starting at Message Buffer 0.

The start of the Static and Dynamic Buffer area is configured by bits FLXAnFRMRC.FDB[7:0]. Bits FLXAnFRMRC.FDB[7:0] define the end of the Static Buffer area. If no Static Buffer area is present, the Static and Dynamic Buffer area starts at Message Buffer 0.

The start of the FIFO area is configured by bits FLXAnFRMRC.FFB[7:0]. Bits FLXAnFRMRC.FFB[7:0] define the end of the previous area, which can be either the Static Buffer area or the Static and Dynamic Buffer area. If no Static Buffer area and no Static and Dynamic Buffer area is present, the FIFO area starts at Message Buffer 0.

With bits FLXAnFRMRC.LCB[7:0], the end of the last configured area is configured which can be the Static Buffer area, the Static and Dynamic Buffer area or the FIFO area.

Figure 18.2 shows an example configuration of the Message RAM where all there area are configured.

Figure 18.2 Message RAM Organization

CAUTIONS

1. In case the node is configured as sync node (bit FLXAnFRSUCC1.TXSY = 1) or for single slot mode operation (bit FLXAnFRSUCC1.TSM = 1), message buffer 0 resp. 1 is reserved for sync frames or single slot frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation message buffer 0 resp. 1 is treated like all other message buffers.
2. The maximum number of header sections is 128. This means a maximum of 128 message buffers can be configured. The maximum length of a data section is 254 bytes. The length of the data section may be configured differently for each message buffer. For details see Section 18.3.13, Message RAM.
3. In case two or more message buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the “Static Buffers” or at the beginning of the “Static + Dynamic Buffers” section.

4. The FlexRay protocol specification requires that each node has to send a frame in its key slot. Therefore at least message buffer 0 is reserved for transmission in the key slot. Due to this requirement a maximum number of 127 message buffers can be assigned to the FIFO. Nevertheless, a non protocol conform configuration without a transmission slot in the static segment would still be operational.
5. The payload length configured and the length of the data section need to be configured identical for all message buffers belonging to the FIFO via the FLXAnFRWRHS2.PLC[6:0] and FLXAnFRWRHS3.DP[6:0] bits. When the CC is not in DEFAULT_CONFIG or CONFIG state reconfiguration of message buffers belonging to the FIFO is locked.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0300_H

Value after reset: 0180 0000_H

Table 18.57 FLXAnFRMRC Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is read. When writing, write the value after reset.
26	SPLM	Sync Frame Payload Multiplex Bit 0: Only message buffer 0 locked against reconfiguration 1: Both message buffers 0 and 1 are locked against reconfiguration
25, 24	SEC[1:0]	Secure Buffers Bit 00: all buffers unlocked 01: static buffers locked, FIFO locked, limited transmission 10: all buffers locked 11: all buffers locked, limited transmission
23 to 16	LCB[7:0]	Last Configured Buffer Bit 0 to 127: Number of message buffers is FLXAnFRMRF.LCB + 1 128: No message buffer assigned to the FIFO
15 to 8	FFB[7:0]	First Buffer of FIFO Bit 0: All message buffers assigned to the FIFO 1 to 127: Message buffers from FLXAnFRMRC.FFB to FLXAnFRMRC.LCB assigned to the FIFO 128: No message buffer configured
7 to 0	FDB[7:0]	First Dynamic Buffer Bit 0: No group of message buffers exclusively for the static segment configured 1 to 127: Message buffers 0 to FLXAnFRMRC.FDB - 1 reserved for static segment 128: No dynamic message buffers configured

(1) FLXAnFRMRC.SPLM

Sync Frame Payload Multiplex Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

This bit is only evaluated if the node is configured as sync node (bit FLXAnFRSUCC1.TXSY = 1) or for single slot mode operation (bit FLXAnFRSUCC1.TSM = 1).

When this bit is set to 1 message buffers 0 and 1 are dedicated for sync frame transmission with different payload data on channel A and B.

When this bit is set to 0, sync frames are transmitted from message buffer 0 with the same payload data on all channels configured. Note that the channel filter configuration for message buffer 0 resp. message buffer 1 has to be chosen according to this bit setting.

(2) FLXAnFRMRC.SEC

Secure Buffers Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Not evaluated when the CC is in DEFAULT_CONFIG or CONFIG state.

For temporary unlocking, see **Section 18.3.13.4, Host Handling of Access Errors**.

00_B = all buffers unlocked

Reconfiguration of message buffers enabled with numbers < FLXAnFRMRC.FFB enabled

Exception: In nodes configured for sync frame transmission or for single slot mode operation message buffer 0 (and if bit FLXAnFRMRC.SPLM = 1, also message buffer 1) is always locked

01_B = static buffers locked, FIFO locked, limited transmission

Reconfiguration of message buffers with numbers < FLXAnFRMRC.FDB and with numbers ≥ FLXAnFRMRC.FFB locked and transmission of message buffers for static segment with numbers ≥ FLXAnFRMRC.FDB disabled

10_B = all buffers locked

Reconfiguration of all message buffers locked

11_B = all buffers locked, limited transmission

Reconfiguration of all message buffers locked and transmission of message buffers for static segment with numbers ≥ FLXAnFRMRC.FDB disabled

(3) FLXAnFRMRC.LCB

Last Configured Buffer Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (bits FLXAnFRMRC.FDB[7:0] < 128), the user should configure FLXAnFRMRC.LCB ≥ FLXAnFRMRC.FDB.

When a FIFO area is configured (bits FLXAnFRMRC.FFB[7:0] < 128), the user should configure bits FLXAnFRMRC.LCB[7:0] ≥ bits FLXAnFRMRC.FFB[7:0].

(4) FLXAnFRMRC.FFB

First Buffer of FIFO Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (bits FLXAnFRMRC.FDB[7:0] < 128), the user should configure bits FLXAnFRMRC.FFB[7:0] > bits FLXAnFRMRC.FDB[7:0].

(5) FLXAnFRMRC.FDB

First Dynamic Buffer Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

18.2.8.2 FLXAnFRFRF — FlexRay FIFO Rejection Filter Register

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, frame ID, and cycle count of the incoming frames are compared. Together with the FIFO Rejection Filter Mask this register determines whether a message is rejected by the FIFO.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0304_H

Value after reset: 0180 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.58 FLXAnFRFRF Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is read. When writing, write the value after reset.
24	RNF	Reject Null Frames Bit 0: Null frames are stored in the FIFO 1: Reject all null frames
23	RSS	Reject in Static Segment Bit 0: FIFO also used for static segment 1: Reject messages in static segment
22 to 16	CYF[6:0]	Cycle Counter Filter Bit
15 to 13	Reserved	When read, the value after reset is read. When writing, write the value after reset.
12 to 2	FID[10:0]	Frame ID Filter Bit 0 to 2047: Frame ID filter values
1, 0	CH[1:0]	Channel Filter Bit 00: receive on both channels 01: receive only on channel B 10: receive only on channel A 11: no reception

(1) FLXAnFRFRF.RNF

Reject Null Frames Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

If this bit is set to 1, received null frames are not stored in the FIFO.

(2) FLXAnFRFRF.RSS

Reject in Static Segment Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

If this bit is set to 1, the FIFO is used only for the dynamic segment.

(3) FLXAnFRFRF.CYF

Cycle Counter Filter Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by FLXAnFRFRF.CYF, all frames are rejected. For details about the configuration of the cycle counter filter see **Section 18.3.8.2, Cycle Counter Filtering**.

(4) FLXAnFRFRF.FID

Frame ID Filter Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Determines the frame ID to be rejected by the FIFO. With the additional configuration of register FLXAnFRFRFM, the corresponding frame ID filter bits are ignored, which results in further rejected frame IDs. When bits FLXAnFRFRFM.MFID[10:0] are zero, a frame ID filter value of zero means that no frame ID is rejected.

(5) FLXAnFRFRF.CH

Channel Filter Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

If reception on both channels is configured, also in static segment always both frames (from channel A and B) are stored in the FIFO, even if they are identical.

18.2.8.3 FLXAnFRFRFM — FlexRay FIFO Rejection Filter Mask Register

The FlexRay FIFO Rejection Filter Mask specifies which of the corresponding frame ID filter bits are relevant for rejection filtering. If a bit is set to 1, it indicates that the corresponding bit in the FLXAnFRFRF register will not be considered for rejection filtering.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0308_H

Value after reset: 0000 0000_H

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is read. When writing, write the value after reset.
12 to 2	MFID[10:0]	Mask Frame ID Filter Bit 0: Corresponding frame ID filter bit is used for rejection filtering 1: Ignore corresponding frame ID filter bit.
1, 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

(1) FLXAnFRFRFM.MFID

Mask Frame ID Filter Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

18.2.8.4 FLXAnFRFCL — FlexRay FIFO Critical Level Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 030C_H

Value after reset: 0000 0080_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 to 0	CL[7:0]	Critical Level Bit Critical Level

(1) FLXAnFRFCL.CL

Critical Level Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

When the receive FIFO fill level (bits FLXAnFRCCSV.POCS[5:0]) FLXAnFRFSR.RFFL is equal or greater than the critical level configured by bits FLXAnFRFCL.CL[7:0], the receive FIFO critical level flag FLXAnFRFSR.RFCL is set to 1.

If FLXAnFRFCL.CL is programmed to values > 128, bit FLXAnFRFSR.RFCL is never set to 1.

18.2.9 Message Buffer Status Registers

18.2.9.1 FLXAnFRMHDS — FlexRay Message Handler Status Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0310_H

Value after reset: 0000 0080_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	MBU[6:0]						—	MBT[6:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	FMB[6:0]						CRAM	MFMB	FMBD	ATBF2	ATBF1	AMR	—	—	
Value after reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R

Table 18.61 FLXAnFRMHDS Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is read. When writing, write the value after reset.
30 to 24	MBU[6:0]	Message Buffer Updated Flag
23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22 to 16	MBT[6:0]	Message Buffer Transmitted Flag
15	Reserved	When read, the value after reset is read. When writing, write the value after reset.
14 to 8	FMB[6:0]	Faulty Message Buffer Number Flag
7	CRAM	Clear all internal RAM's Flag 0: No execution of the CHI command CLEAR_RAMs 1: Execution of the CHI command CLEAR_RAMs ongoing
6	MFMB	Multiple Faulty Message Buffer Detection Flag 0 = No additional faulty message buffer. 1 = Additional faulty message buffer was detected while the FMBD flag is set to 1.
5	FMBD	Faulty Message Buffer Detection Flag 0 = No faulty message buffer. 1 = Message buffer referenced by bit FLXAnFRMHDS.FMB holds faulty data with a parity error.
4	ATBF2	TBFRAM B Access Error Flag 0 = No access error 1 = Access error occurred when reading the RAM B.
3	ATBF1	TBFRAM A Access Error Flag 0 = No access error. 1 = Access error occurred when reading the RAM A.
2	AMR	Message RAM Access Error Flag 0 = No access error 1 = Access error occurred when reading the Message RAM.
1, 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

(1) FLXAnFRMHDS.MBU

Message Buffer Updated Flag

Number of message buffer that was updated last by the CC. For this message buffer the respective ND and / or MBC flag in the FLXAnFRNDAT1 to FLXAnFRNDAT4 registers and the FLXAnFRMBSC1 to FLXAnFRMBSC4 registers are also set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(2) FLXAnFRMHDS.MBT

Message Buffer Transmitted Flag

Number of last successfully transmitted message buffer.

If the message buffer is configured for single-shot mode, the respective TXR flag in the FLXAnFRTXRQ1 to FLXAnFRTXRQ4 registers was reset to 0.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(3) FLXAnFRMHDS.FMB

Faulty Message Buffer Number Flag

This flag indicates that an access error occurred when reading from the message buffer referenced by FLXAnFRMHDS.FMB.

The value of this flag is only valid when one of flags FLXAnFRMHDS.AMR, FLXAnFRMHDS.ATBF1, FLXAnFRMHDS.ATBF2, and FLXAnFRMHDS.FMBD is set to 1.

This flag is not updated while the FLXAnFRMHDS.FMBD flag is 1.

This flag is cleared by the CHI command CLEAR_RAMs.

(4) FLXAnFRMHDS.CRAMP

Internal RAM Clear Flag

This flag indicates that the CHI command CLEAR_RAMs is ongoing (all bits of the message RAM, input buffer, output buffer and TBF are written to 0).

This flag is set by the CHI command CLEAR_RAMs.

(5) FLXAnFRMHDS.MFMB

Multiple Faulty Message Buffer Detection Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This bit indicates that an additional faulty message buffer was detected while the FLXAnFRMHDS.FMBD flag is set.

This bit is cleared by the CHI command CLEAR_RAMs.

(6) FLXAnFRMHDS.FMBD

Faulty Message Buffer Detection Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This bit indicates that the message buffer referenced by FLXAnFRMHDS.FMB holds faulty data due to an access error.

This bit is cleared by the CHI command CLEAR_RAMs.

(7) FLXAnFRMHD.ATBF2

TBFRAM B Access Error Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This flag indicates that an access error occurred when reading the TBFRAM B.

CAUTION

When this flag changes from 0 to 1, the FLXAnFREIR.AERR bit is set to 1. This flag can be reset by the CHI command CLEAR_RAMs.

(8) FLXAnFRMHD.ATBF1

TBFRAM A Access Error Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This flag indicates that an access error occurred when reading the TBFRAM A.

CAUTION

When this flag changes from 0 to 1, the FLXAnFREIR.AERR bit is set to 1. This flag can be reset by the CHI command CLEAR_RAMs.

(9) FLXAnFRMHDS.AMR

Message RAM Access Error Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This flag indicates that an access error occurred when reading the Message RAM.

CAUTION

When this flag changes from 0 to 1, the FLXAnFREIR.AERR bit is set to 1. This flag can be reset by the CHI command CLEAR_RAMs.

18.2.9.2 FLXAnFRLDTS — FlexRay Last Dynamic Transmit Slot Register

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0314_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	LDTB[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	LDTA[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.62 FLXAnFRLDTS Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is read.
26 to 16	LDTB[10:0]	Last Dynamic Transmission Channel B Flag
15 to 11	Reserved	When read, the value after reset is read.
10 to 0	LDTA[10:0]	Last Dynamic Transmission Channel A Flag

(1) FLXAnFRLDTS.LDTB

Last Dynamic Transmission Channel B Flag

Stores the value of vSlotCounter[B] at the time of the last frame transmission on channel B in the dynamic segment of this node.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs of channel B.

(2) FLXAnFRLDTS.LDTA

Last Dynamic Transmission Channel A Flag

Stores the value of vSlotCounter[A] at the time of the last frame transmission on channel A in the dynamic segment of this node.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs of channel A.

18.2.9.3 FLXAnFRFSR — FlexRay FIFO Status Register

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0318_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFFL[7:0]							—	—	—	—	—	RFO	RFCL	RFNE	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.63 FLXAnFRFSR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read.
15 to 8	RFFL[7:0]	Receive FIFO Fill Level Flag
7 to 3	Reserved	When read, the value after reset is read.
2	RFO	Receive FIFO Overrun Flag 0: No receive FIFO overrun detected 1: A receive FIFO overrun has been detected
1	RFCL	Receive FIFO Critical Level Flag 0: Receive FIFO below critical level 1: Receive FIFO critical level reached
0	RFNE	Receive FIFO Not Empty Flag 0: Receive FIFO is empty 1: Receive FIFO is not empty

(1) FLXAnFRFSR.RFFL

Receive FIFO Fill Level Flag

Indicates the number of FIFO buffers filled with new data not yet read by the Host. Maximum value is 128.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(2) FLXAnFRFSR.RFO

Receive FIFO Overrun Flag

The flag is set to 1 by the CC when a receive FIFO overrun is detected.

When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, the FLXAnFREIR.RFO flag is set to 1.

The flag is cleared by the next FIFO read access issued by the Host.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(3) FLXAnFRFSR.RFCL

Receive FIFO Critical Level Flag

This flag is set to 1 when the value of the receive FIFO fill level FLXAnFRFSR.RFFL[7:0] is equal or greater than the critical level as configured by FLXAnFRFCL.CL.

When this bit changes from 0 to 1 bit FLXAnFRSIR.RFCL is set to 1, and if enabled, an interrupt is generated.

The flag is cleared by the CC as soon as the value of the FLXAnFRFSR.RFFL[7:0] bits drops below the value set in the FLXAnFRFCL.CL bit.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(4) FLXAnFRFSR.RFNE

Receive FIFO Not Empty Flag

This flag is set to 1 by the CC when a received valid frame (data or null frame depending on rejection mask) was stored in the FIFO. In addition, the FLXAnFRSIR.RFNE bit is set to 1.

The bit is reset to 0 after the Host has read all messages from the FIFO.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

18.2.9.4 FLXAnFRMHDF — FlexRay Message Handler Constraints Flags Register

Some constraints exist for the Message Handler regarding bus clock frequency, Message RAM configuration, and FlexRay bus traffic. To simplify software development, constraints violations are reported by setting flags in the FLXAnFRMHDF.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 031C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	WAHP	TNSB	TNSA	TBFB	TBFA	FNFB	FNFA	SNUB	SNUA
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.64 FLXAnFRMHDF Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is read. When writing, write the value after reset.
8	WAHP	Write Attempt to Header Partition Flag 0: No write attempt to header partition 1: Write attempt to header partition
7	TNSB	Transmission Not Started Channel B Flag 0: No transmission not started on channel B 1: Transmission not started on channel B
6	TNSA	Transmission Not Started Channel A Flag 0: No transmission not started on channel A 1: Transmission not started on channel A
5	TBFB	TBFB Access Failure B Flag 0: No TBFB access failure 1: TBFB access failure
4	TBFA	Temporary buffer Access Failure A Flag 0: No TBFA access failure 1: TBFA access failure
3	FNFB	Find Sequence Not Finished Channel B Flag 0: No find sequence not finished for channel B 1: Find sequence not finished for channel B
2	FNFA	Find Sequence Not Finished Channel A Flag 0: No find sequence not finished for channel A 1: Find sequence not finished for channel A
1	SNUB	Status Not Updated Channel B Flag 0: No overload condition occurred when updating MBS (FLXAnFRMBS) for channel B 1: Message buffer status (FLXAnFRMBS) for channel B not updated
0	SNUA	Status Not Updated Channel A Flag 0: No overload condition occurred when updating MBS (FLXAnFRMBS) for channel A 1: Message buffer status (FLXAnFRMBS) for channel A not updated

(1) FLXAnFRMHDF.WAHP

Write Attempt to Header Partition Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

Outside DEFAULT_CONFIG and CONFIG state this flag is set to 1 by the CC when the message handler tries to write message data into the header partition of the Message RAM due to faulty configuration of a message buffer. The write attempt is not executed, to protect the header partition from unintended write accesses.

When this flag changes from 0 to 1, the FLXAnFREIR.MHF flag is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(2) FLXAnFRMHDF.TNSB

Transmission Not Started Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot.

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(3) FLXAnFRMHDF.TNSA

Transmission Not Started Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot.

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(4) FLXAnFRMHDF.TBFB

TBFB Access Failure Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when a read or write access to TBFB requested by PRT (Protocol controller) B could not complete within the available time.

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(5) FLXAnFRMHDF.TBFA

TBFA Access Failure Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when a read or write access to TBFA requested by PRT A could not complete within the available time.

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(6) FLXAnFRMHDF.FNFB

Find sequence Not Finished flag, channel B

Writing 0 has no effect on the bit's value.

Writing a 1 to the bit clears it.

This flag is set to 1 by the CC when the message handler, due to being overloaded, was not able to finish a find sequence (scan of message RAM for a matching message buffer).

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is also set to 1.

The value is reset on leaving the CONFIG state or entering the STARTUP state.

The value is also reset by the CLEAR_RAMs CHI command.

(7) FLXAnFRMHDF.FNFA

Find sequence Not Finished flag, channel A

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching message buffer).

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(8) FLXAnFRMHDF.SNUB

Status Not Updated Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler, due to overload condition, was not able to update a message buffer's status (FLXAnFRMBS).

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(9) FLXAnFRMHDF.SNUA

Status Not Updated Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler, due to overload condition, was not able to update a message buffer's status (FLXAnFRMBS).

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

18.2.9.5 FLXAnFRTXRQm — FlexRay Transmission Request m (m = 1 to 4)

The four registers reflect the state of the TXR flags of all configured message buffers. The flags are evaluated for transmit buffers only. If the number of configured message buffers is less than 128, the remaining TXR flags have no meaning.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0320_H to <FLXAn_base> + 032C_H (<FLXAn_base> + 0320_H + (m-1) × 4)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TXRp[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TXRp[15:0]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.65 FLXAnFRTXRQm Register Contents

Bit Position	Bit Name	Function
31 to 0	TXRp[31:0]	Transmission Request Flag p

(1) FLXAnFRTXRQm.TXRp (p = (m - 1) × 32 to (m × 32 - 1))

Transmission Request Flag p

If the flag is set to 1, the respective message buffer is ready for transmission respectively transmission of this message buffer is in progress.

In single-shot mode the flags are reset to 0 after transmission has completed.

This bit is cleared by the CHI command CLEAR_RAMs.

18.2.9.6 FLXAnFRNDATm — FlexRay New Data Register m (m = 1 to 4)

The four registers reflect the state of the ND flags of all configured message buffers. ND flags belonging to transmit buffers have no meaning. If the number of configured message buffers is less than 128, the remaining ND flags have no meaning.

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0330_H to <FLXAn_base> + 033C_H (<FLXAn_base> + 0330_H + (m-1) × 4)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NDp[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NDp[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.66 FLXAnFRNDATm Register Contents

Bit Position	Bit Name	Function
31 to 0	NDp[31:0]	New Data Flag p

(1) FLXAnFRNDATm.NDp (p = (m - 1) × 32 to (m × 32 - 1))

New Data Flag p

The flags are set to 1 when a valid received data frame matches the message buffer's filter configuration, independent of the payload length received or the payload length configured for that message buffer.

The flags are not set to 1 after reception of null frames except for message buffers belonging to the receive FIFO.

An ND flag is reset to 0 when the header section of the corresponding message buffer is reconfigured or when the data section has been transferred to the Output Buffer.

Reset when leaving CONFIG state or when entering STARTUP state.

This bit is cleared by the CHI command CLEAR_RAMs.

18.2.9.7 FLXAnFRMBSCm — FlexRay Message Buffer Status Changed Register m (m = 1 to 4)

The four registers reflect the state of the MBC flags of all configured message buffers. If the number of configured message buffers is less than 128, the remaining MBC flags have no meaning.

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0340_H to <FLXAn_base> + 034C_H (<FLXAn_base> + 0340_H + (m-1) × 4)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MBCp[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MBCp[15:0]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.67 FLXAnFRMBSCm Register Contents

Bit Position	Bit Name	Function
31 to 0	MBCp[31:0]	Message Buffer Status Changed Flag p

(1) FLXAnFRMBSCm.MBCp (p = (m - 1) × 32 to (m × 32 - 1))

Message Buffer Status Changed Flag p

Indicates whether the Message Handler has changed one of the status flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB in the header section (see **Section 18.2.11.5, FLXAnFRMBS — FlexRay Message Buffer Status Register** and **Section 18.3.13.1, Header Partition**) of the respective message buffer.

An MBC flag is reset to 0 when the header section of the corresponding message buffer is reconfigured or when it has been transferred to the Output Buffer.

Reset when leaving CONFIG state or when entering STARTUP state.

This bit is cleared by the CHI command CLEAR_RAMs.

18.2.10 Input Buffer

Double buffer structure consisting of Input Buffer Host and Input Buffer Shadow. While the Host can write to Input Buffer Host, the transfer to the Message RAM is done from Input Buffer Shadow. The Input Buffer holds the header and data sections to be transferred to the selected message buffer in the Message RAM. It is used to configure the message buffers in the Message RAM and to update the data sections of transmit buffers.

When updating the header section of a message buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in **Section 18.2.11.5, FLXAnFRMBS — FlexRay Message Buffer Status Register** is automatically reset to zero.

The header sections of message buffers belonging to the receive FIFO can only be (re)configured when the CC is in DEFAULT_CONFIG or CONFIG state. For those message buffers only the payload length configured and the data pointer need to be configured via bits FLXAnFRWRHS2.PLC[6:0] and bits FLXAnFRWRHS3.DP[10:0]. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

The data transfer between Input Buffer (IBF) and Message RAM is described in detail in **Section 18.3.12.2, Host access to Message RAM**.

These registers cannot be written when the input data transfer function shown in **Section 18.3.16.1, Input Data Transfer** is used and the FLXAnFRITS.ITS bit is 1.

18.2.10.1 FLXAnFRWRDSm — FlexRay Write Data Section Register m (m = 1 to 64)

This register holds the data words to be transferred to the data section of the specified message buffer. The number of data words written to the Message RAM is defined by the payload length configured in bits FLXAnFRWRHS2.PLC[6:0].

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0400_H to <FLXAn_base> + 04FC_H(<FLXAn_base> + 0400_H + (m-1) × 4)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MD[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MD[15:0]

Table 18.68 FLXAnFRWRDSm Register Contents

Bit Position	Bit Name	Function
31 to 0	MD[31:0]	Message Data Bit

(1) FLXAnFRWRDSm.MD

Message Data Bit

Reset by the CHI command CLEAR_RAMs.

CAUTIONS

1. In case the FLXAnFRWRHS2.PLC[6:0] bits specifies an odd payload length, the remaining message data bytes are unused.
2. When writing to the FLXAnFRWRDSm register, all bytes have to be written by one 32-bit access, two consecutive 16-bit accesses, or four consecutive 8-bit accesses before the transfer from the Input Buffer to the Message RAM is started. If not all bytes of a 32-bit word have been written by the Host (8/16-bit access only), the FLXAnFRWRDSm register holds partly undefined data.

18.2.10.2 FLXAnFRWRHS1 — FlexRay Write Header Section Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0500_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	MBI	TXM	PPIT	CFG	CH[1:0]		—	CYC[6:0]

Table 18.69 FLXAnFRWRHS1 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is read. When writing, write the value after reset.
29	MBI	Message Buffer Interrupt Bit 0: The corresponding message buffer interrupt is disabled 1: The corresponding message buffer interrupt is enabled
28	TXM	Transmission Mode Setting Bit 0: Continuous mode 1: Single-shot mode
27	PPIT	Payload Preamble Indicator Transmit Bit 0: Payload Preamble Indicator is set to 0 1: Payload Preamble Indicator is set to 1
26	CFG	Message Buffer Direction Configuration Bit 0: The corresponding buffer is configured as Receive Buffer 1: The corresponding buffer is configured as Transmit Buffer
25,24	CH[1:0]	Channel Filter Control Bit
23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22 to 16	CYC[6:0]	Cycle Code Bit
15 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10 to 0	FID[10:0]	Frame ID Bit

(1) FLXAnFRWRHS1.MBI

Message Buffer Interrupt Enable Bit

This bit enables the message buffer interrupt.

After a dedicated receive buffer has been updated by the Message Handler, bit FLXAnFRSIR.RXI and /or bit FLXAnFRSIR.MBSI are set to 1. After a transmission has completed bit FLXAnFRSIR.TXI is set to 1.

(2) FLXAnFRWRHS1.TXM

Transmission Mode Setting Bit

This bit selects transmit mode of the corresponding message buffer. For transmit mode, see **Section 18.3.9.3, Transmit Buffers**.

(3) FLXAnFRWRHS1.PPIT

Payload Preamble Indicator Transmit Bit

This bit is used to control the state of the Payload Preamble Indicator in transmit frames in transmit frames of the corresponding message buffer.

If the bit is set to 1 in a static message buffer, the respective message buffer holds network management information.

If the bit is set to 1 in a dynamic message buffer the first two bytes of the payload segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay frames is not supported by the FlexRay module, but can be done by the Host.

(4) FLXAnFRWRHS1.CFG

Message Buffer Direction Configuration Bit

This bit is used to configure the corresponding buffer as transmit buffer or as receive buffer. For message buffers belonging to the receive FIFO the bit is not evaluated.

When an unused 32-bit or larger area is not allocated to the head of the data partition, set the data section of the message buffer that is allocated immediately after the header partition (of the last buffer) as a transmit buffer by setting this bit to 1.

(5) FLXAnFRWRHS1.CH

Channel Filter Control Bit

The 2-bit channel filtering field associated with each buffer serves as a filter for receive buffers, and as a control field for transmit buffers.

CH[1:0]	Transmit Buffer transmit frame on	Receive Buffer store frame received from
00	No transmission	Ignore frame
01	Channel A	Channel A
10	Channel B	Channel B
11	Both channels (static segment only)	Channel A or B (store first semantically valid frame; static segment only)

CAUTION

If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no frames are transmitted resp. received frames are ignored (same function as CH = "00_B")

(6) FLXAnFRWRHS1.CYC

Cycle Code Bit

The 7-bit cycle code determines the cycle set used for cycle counter filtering.

For details about the configuration of the cycle code **Section 18.3.8.2, Cycle Counter Filtering**.

(7) FLXAnFRWRHS1.FID

Frame ID Bit

Frame ID of the selected message buffer. The frame ID defines the slot number for transmission / reception of the respective message.

Message buffers with frame ID = 0 are considered as not valid.

18.2.10.3 FLXAnFRWRHS2 — FlexRay Write Header Section Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0504_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	PLC[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CRC[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.70 FLXAnFRWRHS2 Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22 to 16	PLC[6:0]	Payload Length Configured Bit
15 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10 to 0	CRC[10:0]	Header CRC Bit (vRF!Header!HeaderCRC) Receive Buffer: Configuration not required Transmit Buffer: Header CRC is configured

(1) FLXAnFRWRHS2.PLC

Payload Length Configured Bit

Length of data section (number of 2-byte words) as configured by the Host.

During static segment the static frame payload length as configured by bits

FLXAnFRMHDC.SFDL[6:0] defines the payload length for all static frames. If the payload length configured by bits FLXAnFRWRHS2.PLC[6:0] is shorter than this value padding bytes are inserted to ensure that frames have proper physical length. The padding pattern is “0000_H” (see **Section 18.3.9.3, Transmit Buffers**).

(2) FLXAnFRWRHS2.CRC

Header CRC Bit (vRF!Header!HeaderCRC)

Setting of the receive buffer is not required.

Transmitting of the message buffer needs the header CRC calculation and setting.

For calculation of the header CRC the payload length of the frame send on the bus has to be considered. In static segment the payload length of all frames is configured by bits FLXAnFRMHDC.SFDL[6:0].

18.2.10.4 FLXAnFRWRHS3 — FlexRay Write Header Section Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0508_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.71 FLXAnFRWRHS3 Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10 to 0	DP[10:0]	Data Pointer Bit

(1) FLXAnFRWRHS3.DP

Data Pointer Bit

Configures the pointer to the first 32-bit word of the data section of the addressed message buffer in the Message RAM.

18.2.10.5 FLXAnFRIBCM — FlexRay Input Buffer Command Mask Register

Configures how the message buffer in the Message RAM selected by register FLXAnFRIBCR is updated. When IBF Host and IBF Shadow are swapped, also mask bits FLXAnFRIBCM.LHSH, FLXAnFRIBCM.LDSH, and FLXAnFRIBCM.STXRH are swapped with bits FLXAnFRIBCM.LHSS, FLXAnFRIBCM.LDSS, and FLXAnFRIBCM.STXRS.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0510_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	STXRS	LDSS	LHSS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	STXRH	LDSH	LHSH
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 18.72 FLXAnFRIBCM Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is read. When writing, write the value after reset.
18	STXRS	Set Transmission Request Shadow Flag 0: Reset TXR flag 1: Set TXR flag, transmit buffer released for transmission (operation ongoing or finished)
17	LDSS	Load Data Section Shadow Flag 0: Data section is not updated 1: Data section selected for transfer from Input Buffer to the Message RAM (transfer ongoing or finished)
16	LHSS	Load Header Section Shadow Flag 0: Header section is not updated 1: Header section selected for transfer from Input Buffer to the Message RAM (transfer ongoing or finished)
15 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	STXRH	Set Transmission Request Host Bit 0: Reset TXR flag 1: Set TXR flag, transmit buffer released for transmission
1	LDSH	Load Data Section Host Bit 0: Data section is not updated 1: Data section selected for transfer from Input Buffer to the Message RAM
0	LHSH	Load Header Section Host Bit 0: Header section is not updated 1: Header section selected for transfer from Input Buffer to the Message RAM

(1) FLXAnFRIBCM.STXRS

Set Transmission Request Shadow Flag

(2) FLXAnFRIBCM.LDSS

Load Data Section Shadow Flag

(3) FLXAnFRIBCM.LHSS

Load Header Section Shadow Flag

(4) FLXAnFRIBCM.STXRH

Set Transmission Request Host Bit

If this bit is set to 1, the TXR flag for the selected message buffer is set in the FLXAnFRTXRQ1 to FLXAnFRTXRQ4 registers to release the message buffer for transmission. In single-shot mode the flag is cleared by the CC after transmission has completed.

TXR is evaluated for transmit buffers only.

(5) FLXAnFRIBCM.LDSH

Set Load Data Section Host Bit

(6) FLXAnFRIBCM.LHSH

Set Load Header Section Host Bit

18.2.10.6 FLXAnFRIBCR — FlexRay Input Buffer Command Request Register

When the Host writes the number of the target message buffer in the Message RAM to bits FLXAnFRIBCR.IBRH[6:0], IBF Host and IBF Shadow are swapped. In addition the message buffer numbers stored under bits FLXAnFRIBCR.IBRH[6:0] and bits FLXAnFRIBCR.IBRS[6:0] are also swapped (see **Section 18.3.12.2 (1), Data Transfer from Input Buffer to Message RAM**).

With this write operation bit FLXAnFRIBCR.IBSYS is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the message buffer in the Message RAM selected by bits FLXAnFRIBCR.IBRS[6:0].

While the Message Handler transfers the data from IBF Shadow to the target message buffer in the Message RAM, the Host may write the next message into the IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, bit FLXAnFRIBCR.IBSYS is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target message buffer number to bits FLXAnFRIBCR.IBRH[6:0].

If a write access to bits FLXAnFRIBCR.IBRH[6:0] occurs while bit FLXAnFRIBCR.IBSYS is 1, bit FLXAnFRIBCR.IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, bit FLXAnFRIBCR.IBSYH is reset to 0. Bit FLXAnFRIBCR.IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the message buffer numbers stored under bits FLXAnFRIBCR.IBRH[6:0] and bits FLXAnFRIBCR.IBRS[6:0] are also swapped.

Any write access to an Input Buffer register while both bit FLXAnFRIBCR.IBSYS and bit FLXAnFRIBCR.IBSYH are set to 1 will cause the error flag FLXAnFREIR.IIBA to be set to 1.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0514_H

Value after reset: 00000000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IBSYS	—	—	—	—	—	—	—	—	IBRS[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IBSYH	—	—	—	—	—	—	—	—	IBRH[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.73 FLXAnFRIBCR Register Contents (1/2)

Bit Position	Bit Name	Function
31	IBSYS	Input Buffer Busy Shadow Flag 0: Transfer between IBF Shadow and Message RAM completed 1: Transfer between IBF Shadow and Message RAM in progress
30 to 23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22 to 16	IBRS[6:0]	Input Buffer Request Shadow Flag
15	IBSYH	Input Buffer Busy Host Flag 0: No request pending 1: Request while transfer between IBF Shadow and Message RAM in progress

Table 18.73 FLXAnFRIBCR Register Contents (2/2)

Bit Position	Bit Name	Function
14 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	IBRH[6:0]	Input Buffer Request Host Bit

(1) FLXAnFRIBCR.IBSYS

Input Buffer Busy Shadow Flag

Set to 1 after writing bits FLXAnFRIBCR.IBRH[6:0].

This bit indicates transmitting between the IBF Shadow and the Message RAM is ongoing.

When the transfer between IBF Shadow and the Message RAM has completed, FLXAnFRIBCR.IBSYS is set back to 0.

(2) FLXAnFRIBCR.IBRS

Input Buffer Request Shadow Flag

Number of the target message buffer actually updated / lately updated.

(3) FLXAnFRIBCR.IBSYH

Input Buffer Busy Host Flag

Set to 1 by writing bits FLXAnFRIBCR.IBRH[6:0] while bit FLXAnFRIBCR.IBSYS is still 1.

This bit indicates transmitting between the IBF Shadow and the Message RAM is ongoing.

After the ongoing transfer between IBF Shadow and the Message RAM has completed, the FLXAnFRIBCR.IBSYH is set back to 0.

(4) FLXAnFRIBCR.IBRH

Input Buffer Request Host Bit

Selects the target message buffer in the Message RAM for data transfer from Input Buffer.

18.2.11 Output Buffer

Double buffer structure consisting of Output Buffer Host and Output Buffer Shadow. Used to read out message buffers from the Message RAM. While the Host can read from Output Buffer Host, the Message Handler transfers the selected message buffer from Message RAM to Output Buffer Shadow. The data transfer between Message RAM and Output Buffer (OBF) is described in **Section 18.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

These registers cannot be written when the output data transfer function shown in **Section 18.3.16.2, Output Data Transfer**, in Output Data Transfer is used and the FLXAnFROTS.OTS bit is 1.

18.2.11.1 FLXAnFRRDDSm — FlexRay Read Data Section Register m (m = 1 to 64)

Holds the data words read from the data section of the addressed message buffer. This register holds the data words to be transferred to the data section of the specified message buffer. The number of data words (DWN) read from the Message RAM is defined by the payload length configured in bits FLXAnFRRDHS2.PLC[6:0].

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0600_H to <FLXAn_base> + 06FC_H (<FLXAn_base> + 0600_H + (m-1) × 4)

Value after reset: 0000 0000_H

Table 18.74 FLXAnFRRDDSm Register Contents

Bit Position	Bit Name	Function
31 to 0	MD[31:0]	Message Data

(1) FLXAnFRRDDSm.MD

Message Data Flag

Cleared by the CHI command CLEAR_RAMs.

CAUTION

In case the FLXAnFRWRHS2.PLC[6:0] bits specifies an odd payload length, the remaining message data bytes are unused.

18.2.11.2 FLXAnFRRDHS1 — FlexRay Read Header Section Register 1

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0700_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.75 FLXAnFRRDHS1 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is read.
29	MBI	Message Buffer Interrupt Flag
28	TXM	Transmission Mode Flag
27	PPIT	Payload Preamble Indicator Transmit Flag
26	CFG	Message Buffer Direction Configuration Flag
25, 24	CH[1:0]	Channel Filter Control Flag
23	Reserved	When read, the value after reset is read.
22 to 16	CYC[6:0]	Cycle Code
15 to 11	Reserved	When read, the value after reset is read.
10 to 0	FID[10:0]	Frame ID

(1) FLXAnFRRDHS1.MBI

Message Buffer Interrupt Flag

Values as configured by the Host via bit FLXAnFRWRHS1.MBI.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(2) FLXAnFRRDHS1.TXM

Transmission Mode Flag

Values as configured by the Host via bit FLXAnFRWRHS1.TXM.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(3) FLXAnFRRDHS1.PPIT

Payload Preamble Indicator Transmit Flag

Values as configured by the Host via bit FLXAnFRWRHS1.PPIT.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(4) FLXAnFRRDHS1.CFG

Message Buffer Direction Configuration Flag

Values as configured by the Host via bit FLXAnFRWRHS1.CFG.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(5) FLXAnFRRDHS1.CH

Channel Filter Control Flag

Values as configured by the Host via bit FLXAnFRWRHS1.CH.

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are set to 0.

(6) FLXAnFRRDHS1.CYC

Cycle Code

Values as configured by the Host via bit FLXAnFRWRHS1.CYC.

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are set to 0.

(7) FLXAnFRRDHS1.FID

Frame ID

Values as configured by the Host via bit FLXAnFRWRHS1.FID.

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are holding the received frame ID.

18.2.11.3 FLXAnFRRDHS2 — FlexRay Read Header Section Register 2

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0704_H

Value after reset: 0000 0000_H

CAUTION

For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area, the FLXAnFRWRHS2 register is updated from data frames only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CRC[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.76 FLXAnFRRDHS2 Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is read.
30 to 24	PLR[6:0]	Payload Length Received Flag (vRF!Header!Length)
23	Reserved	When read, the value after reset is read.
22 to 16	PLC[6:0]	Payload Length Configuration Flag
15 to 11	Reserved	When read, the value after reset is read.
10 to 0	CRC[10:0]	Header CRC Flag (vRF!Header!HeaderCRC)

(1) FLXAnFRRDHS2.PLR

Payload Length Received Flag (vRF!Header!Length)

Payload length (vRF!Header!Length) value updated from received data frames (exception: if message buffer belongs to the receive FIFO FLXAnFRRDHS2.PLR is also updated from received null frames).

(2) FLXAnFRRDHS2.PLC

Payload Length Configuration Flag

Length of data section (number of 2-byte words) as configured by the Host.

(3) FLXAnFRRDHS2.CRC

Header CRC Flag (vRF!Header!HeaderCRC)

Receive Buffer: Header CRC (vRF!Header!HeaderCRC) updated from received data frames

Transmit Buffer: Header CRC configured by the Host

(4) Data storage

When a message is stored into a message buffer the following behavior with respect to payload length received and payload length configured is implemented:

Bits $FLXAnFRRDHS2.PLR[6:0] > Bits\ FLXAnFRRDHS2.PLC[6:0]$:

The payload data stored in the message buffer is truncated to the payload length configured if bits $FLXAnFRRDHS2.PLC[6:0]$ even or else truncated to bits $FLXAnFRRDHS2.PLC[6:0] + 1$.

Bits $FLXAnFRRDHS2.PLR[6:0] \leq Bits\ FLXAnFRRDHS2.PLC[6:0]$:

The received payload data is stored into the message buffers data section. The remaining data bytes of the data section as configured by bits $FLXAnFRRDHS2.PLC[6:0]$ are filled with undefined data.

Bits $FLXAnFRRDHS2.PLR[6:0] = zero$:

The message buffer's data section is filled with undefined data

Bits $FLXAnFRRDHS2.PLC[6:0] = zero$:

Message buffer has no data section configured. No data is stored into the message buffer's data section.

CAUTIONS

1. The Message RAM is organized in 4-byte words. When received data is stored into a message buffer's data section, the number of 2-byte data words written into the message buffer is the $FLXAnFRRDHS2.PLC[6:0]$ bits rounded to the next even value.
2. The $FLXAnFRRDHS2.PLC[6:0]$ bits should be configured identical for all message buffers belonging to the receive FIFO. Header 2 is updated from data frames only. For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area, the $FLXAnFRWRHS2$ register is updated from data frames only.

18.2.11.4 FLXAnFRRDHS3 — FlexRay Read Header Section Register 3

CAUTION

For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area, the FLXAnFRWRHS3 register is updated from data frames only.

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0708_H

Table 18.77 FLXAnFRRDHS3 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is read.
29	RES	Reserved Bit Indicator Flag (vRF!Header!Reserved)
28	PPI	Payload Preamble Indicator (vRF!Header!PPIIndicator)
27	NFI	Null Frame Indicator Flag (vRF!Header!NFIIndicator) 0: Up to now no data frame has been stored into the respective message buffer 1: At least one data frame has been stored into the respective message buffer
26	SYN	Sync Frame Indicator Flag (vRF!Header!SyFIndicator) 0: The received frame is not a sync frame 1: The received frame is a sync frame
25	SFI	Startup Frame Indicator Flag (vRF!Header!SuFIndicator) 0: The received frame is not a startup frame 1: The received frame is a startup frame
24	RCI	Received on Channel Indicator Flag (vSS!Channel) 0: Frame received on channel B 1: Frame received on channel A
23, 22	Reserved	When read, the value after reset is read.
21 to 16	RCC[5:0]	Receive Cycle Counter (vRF!Header!CycleCount)
15 to 11	Reserved	When read, the value after reset is read.
10 to 0	DP[10:0]	Data Pointer Flag

(1) FLXAnFRRDHS3.RES

Reserved Bit Flag (vRF!Header!Reserved)

Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.

(2) FLXAnFRRDHS3.PPI

Payload Preamble Indicator Flag (vRF!Header!PPIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.

0 = The payload segment of the received frame does not contain a network management vector nor a message ID

1 = Static segment: Network management vector in the first part of the payload
Dynamic segment: Message ID in the first part of the payload

(3) FLXAnFRRDHS3.NFI

Null Frame Indicator Flag (vRF!Header!NFIndicator)

Is set to 1 after storage of the first received data frame.

(4) FLXAnFRRDHS3.SYN

Sync Frame Indicator Flag (vRF!Header!SyFIndicator)

A sync frame is marked by the sync frame indicator.

(5) FLXAnFRRDHS3.SFI

Startup Frame Indicator Flag (vRF!Header!SuFIndicator)

A startup frame is marked by the startup frame indicator.

(6) FLXAnFRRDHS3.RCI

Received on Channel Indicator Flag (vSS!Channel)

Indicates the channel from which the received data frame was taken to update the respective receive buffer.

(7) FLXAnFRRDHS3.RCC

Receive Cycle Counter (vRF!Header!CycleCount)

Cycle counter value updated from received data frame.

(8) FLXAnFRRDHS3.DP

Data Pointer Flag

Pointer to the first 32-bit word of the data section of the addressed message buffer in the Message RAM.

The bit value is the same as that set in bit FLXAnFRWRHS3.DP

18.2.11.5 FLXAnFRMBS — FlexRay Message Buffer Status Register

The message buffer status is updated by the CC with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the message buffer.

The flags are updated only when the CC is in NORMAL_ACTIVE or NORMAL_PASSIVE state.

If only one channel (A or B) is assigned to a message buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a message buffer, the channel-specific status flags of both channels are updated.

The message buffer status is updated only when the slot counter reached the configured frame ID and when the cycle counter filter matched. When the Host updates a message buffer via Input Buffer, all FLXAnFRMBS flags are reset to zero independent of which FLXAnFRIBCM bits are set or not.

For details about receive / transmit filtering see **Section 18.3.8, Filtering and Masking**, **Section 18.3.9, Transmit Process** and **Section 18.3.10, Receive Process**.

Whenever the Message Handler changes one of the flags FLXAnFRMBS.VFRA, FLXAnFRMBS.VFRB, FLXAnFRMBS.SEOA, FLXAnFRMBS.SEOB, FLXAnFRMBS.CEOA, FLXAnFRMBS.CEOB, FLXAnFRMBS.SVOA, FLXAnFRMBS.SVOB, FLXAnFRMBS.TCIA, FLXAnFRMBS.TCIB, FLXAnFRMBS.ESA, FLXAnFRMBS.ESB, FLXAnFRMBS.MLST, FLXAnFRMBS.FTA, FLXAnFRMBS.FTB the respective message buffer's MBC flag in registers FLXAnFRMBSC1 to FLXAnFRMBSC4 is set.

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 070C_H

Value after reset: 0000 0000_H

28	PPIS	Payload Preamble Indicator Status Flag (vRF!Header!PPIndicator) 0: PPI indicator set to 0 1: PPI indicator set to 1
27	NFIS	Null Frame Indicator Status Flag (vRF!Header!NFIndicator) 0: Received frame is a null frame 1: Received frame is not a null frame
26	SYNS	Sync Frame Indicator Status Flag (vRF!Header!SyFIndicator) 0: No sync frame received 1: The received frame is a sync frame

Table 18.78 FLXAnFRMBS Register Contents (2/2)

Bit Position	Bit Name	Function
25	SFIS	Startup Frame Indicator Status Flag (vRF!Header!SuIndicator) 0: No startup frame received 1: The received frame is a startup frame
24	RCIS	Received on Channel Indicator Status Flag (vSS!Channel) 0: Frame received on channel B 1: Frame received on channel A
23, 22	Reserved	When read, the value after reset is read.
21 to 16	CCS[5:0]	Cycle Count Status Flag
15	FTB	Frame Transmitted on Channel B Flag 0: No data frame transmitted on channel B 1: Data frame transmitted on channel B
14	FTA	Frame Transmitted on Channel A Flag 0: No data frame transmitted on channel A 1: Data frame transmitted on channel A
13	Reserved	When read, the value after reset is read.
12	MLST	Message Lost Flag 0: No message lost 1: Unprocessed message was overwritten
11	ESB	Empty Slot Channel B Flag 0: Bus activity detected in the assigned slot on channel B 1: No bus activity detected in the assigned slot on channel B
10	ESA	Empty Slot Channel A Flag 0: Bus activity detected in the assigned slot on channel A 1: No bus activity detected in the assigned slot on channel A
9	TCIB	Transmission Conflict Indication Channel B Flag (vSS!TxConflictB) 0: No transmission conflict occurred on channel B 1: Transmission conflict occurred on channel B
8	TCIA	Transmission Conflict Indication Channel A Flag (vSS!TxConflictA) 0: No transmission conflict occurred on channel A 1: Transmission conflict occurred on channel A
7	SVOB	Slot Boundary Violation Observed on Channel B Flag (vSS!BViolationB) 0: No slot boundary violation observed on channel B 1: Slot boundary violation observed on channel B
6	SVOA	Slot Boundary Violation Observed on Channel A Flag (vSS!BViolationA) 0: No slot boundary violation observed on channel A 1: Slot boundary violation observed on channel A
5	CEOB	Content Error Observed on Channel B Flag (vSS!ContentErrorB) 0: No content error observed on channel B 1: Content error observed on channel B
4	CEOA	Content Error Observed on Channel A Flag (vSS!ContentErrorA) 0: No content error observed on channel A 1: Content error observed on channel A
3	SEOB	Syntax Error Observed on Channel B Flag (vSS!SyntaxErrorB) 0: No syntax error observed on channel B 1: Syntax error observed on channel B
2	SEOA	Syntax Error Observed on Channel A Flag (vSS!SyntaxErrorA) 0: No syntax error observed on channel A 1: Syntax error observed on channel A
1	VFRB	Valid Frame Received on Channel B (vSS!ValidFrameB) 0: No valid frame received on channel B 1: Valid frame received on channel B
0	VFRA	Valid Frame Received on Channel A Flag (vSS!ValidFrameA) 0: No valid frame received on channel A 1: Valid frame received on channel A

(1) FLXAnFRMBS.RESS

Reserved Bit Status Flag (vRF!Header!Reserved)

Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(2) FLXAnFRMBS.PPIS

Payload Preamble Indicator Status Flag (vRF!Header!PPIIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

0 = PPI indicator set to 0

The payload segment of the received frame does not contain a network management vector or a message ID

1 = PPI indicator set to 1

Static segment: Network management vector at the beginning of the payload

Dynamic segment: Message ID at the beginning of the payload

(3) FLXAnFRMBS.NFIS

Null Frame Indicator Status Flag (vRF!Header!NFIndicator)

If set to 0 the payload segment of the received frame contains no usable data.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(4) FLXAnFRMBS.SYNS

Sync Frame Indicator Status Flag (vRF!Header!SyFIndicator)

A sync frame is marked by the sync frame indicator.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(5) FLXAnFRMBS.SFIS

Startup Frame Indicator Status Flag (vRF!Header!SuFIndicator)

The startup frame indicator specifies a startup frame.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(6) FLXAnFRMBS.RCIS

Received on Channel Indicator Status Flag (vSS!Channel)

Indicates the channel on which the frame was received.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(7) FLXAnFRMBS.CCS

Cycle Count Status Flag

Actual cycle count when status was updated.

(8) FLXAnFRMBS.FTB

Frame Transmitted on Channel B Flag

Indicates that this node has transmitted a data frame in the configured slot on channel B.

CAUTION

The FlexRay protocol specification requires that this bit can only be reset by the Host. Therefore, the Cycle Count Status FLXAnFRMBS.CCS bit for this bit is only valid for the cycle where the bit is set to 1.

(9) FLXAnFRMBS.FTA

Frame Transmitted on Channel A Flag

Indicates that this node has transmitted a data frame in the configured slot on channel A.

CAUTION

The FlexRay protocol specification requires that this bit can only be reset by the Host. Therefore the Cycle Count Status FLXAnFRMBS.CCS bit for this bit is only valid for the cycle where this bit is set to 1.

(10) FLXAnFRMBS.MLST

Message Lost Flag

The flag is set in case the Host did not read the message before the message buffer was updated from a received data frame.

Not affected by reception of null frames except for message buffers belonging to the receive FIFO. Bits FLXAnFRNDATm.NDp is reset to 0 by a Host write to the message buffer via IBF or when a new message is stored into the message buffer after the message buffers ND flag was reset to 0 by reading out the message buffer via OBF.

(11) FLXAnFRMBS.ESB

Empty Slot Channel B Flag

In an empty slot, there is no activity on the bus. This means that any frame transmission is not detected. This state can be checked in static and dynamic slots.

(12) FLXAnFRMBS.ESA

Empty Slot Channel A Flag

In an empty slot, there is no activity on the bus. This means that any frame transmission is not detected. This state can be checked in static and dynamic slots.

(13) FLXAnFRMBS.TCIB

Transmission Conflict Indication Channel B Flag (vSS!TxConflictB)

A transmission conflict indication is set to 1 if a transmission conflict has occurred on channel B.

(14) FLXAnFRMBS.TCIA

Transmission Conflict Indication Channel A Flag (vSS!TxConflictA)

A transmission conflict indication is set if a transmission conflict has occurred on channel A.

(15) FLXAnFRMBS.SVOB

Slot Boundary Violation Observed on Channel B Flag (vSS!BViolationB)

A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B.

(16) FLXAnFRMBS.SVOA

Slot Boundary Violation Observed on Channel A Flag (vSS!BViolationA)

A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A.

(17) FLXAnFRMBS.CEOB

Content Error Observed on Channel B Flag (vSS!ContentErrorB)

A content error was observed in the assigned slot on channel B.

(18) FLXAnFRMBS.CEOA

Content Error Observed on Channel A Flag (vSS!ContentErrorA)

A content error was observed in the assigned slot on channel A.

(19) FLXAnFRMBS.SEOB

Syntax Error Observed on Channel B Flag (vSS!SyntaxErrorB)

A syntax error was observed in the assigned slot on channel B.

(20) FLXAnFRMBS.SEOA

Syntax Error Observed on Channel A Flag (vSS!SyntaxErrorA)

A syntax error was observed in the assigned slot on channel A.

(21) FLXAnFRMBS.VFRB

Valid Frame Received on Channel B Flag (vSS!ValidFrameB)

A valid frame indication is set if a valid frame was received on channel B.

(22) FLXAnFRMBS.VFRA

Valid Frame Received on Channel A Flag (vSS!ValidFrameA)

A valid frame indication is set if a valid frame was received on channel A.

18.2.11.6 FLXAnFROBCM — FlexRay Output Buffer Command Mask Register

Configures how the Output Buffer is updated from the message buffer in the Message RAM selected by bits FLXAnFROBCR.OBRS[6:0].

Mask bits FLXAnFROBCM.RDSS and FLXAnFROBCM.RHSS are copied to the register internal storage when a Message RAM transfer is requested by bit FLXAnFROBCR.REQ.

When OBF Host and OBF Shadow are swapped, mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the register internal storage to keep them attached to the respective Output Buffer transfer.

The data transfer between Output Buffer and Message RAM is described in detail in **Section 18.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

CAUTION

After the transfer of the header section from the Message RAM to OBF Shadow has completed, the message buffer status changed flag MBC of the selected message buffer in the FLXAnFRMBSC1 to FLXAnFRMBSC4 registers is cleared. After the transfer of the data section from the Message RAM to OBF Shadow has completed, the new data flag ND of the selected message buffer in the FLXAnFRNDAT1 to FLXAnFRNDAT4 registers is cleared.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0710_H

Value after reset: 0000 0000_H

Table 18.79 FLXAnFROBCM Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is read. When writing, write the value after reset.
17	RDSH	Read Data Section Host Flag 0: Data section is not read 1: Data section selected for transfer from Message RAM to Output Buffer
16	RHSH	Read Header Section Host Flag 0: Header section is not read 1: Header section selected for transfer from Message RAM to Output Buffer
15 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	RDSS	Read Data Section Shadow Bit 0: Data section is not read 1: Data section selected for transfer from Message RAM to Output Buffer
0	RHSS	Read Header Section Shadow Bit 0: Header section is not read 1: Header section selected for transfer from Message RAM to Output Buffer

(1) FLXAnFROBCM.RDSH

Read Data Section Host Flag

(2) FLXAnFROBCM.RHSH

Read Header Section Host Flag

(3) FLXAnFROBCM.RDSS

Read Data Section Shadow Bit

(4) FLXAnFROBCM.RHSS

Read Header Section Shadow Bit

18.2.11.7 FLXAnFROBCR — FlexRay Output Buffer Command Request Register

After setting bit FLXAnFROBCR.REQ to 1 while FLXAnFROBCR.OBSYS is 0, FLXAnFROBCR.OBSYS is automatically set to 1, bits FLXAnFROBCR.OBRS[6:0] is copied to the register internal storage, mask bits FLXAnFROBCM.RDSS and FLXAnFROBCM.RHSS are copied to register FLXAnFROBCM internal storage, and the transfer of the message buffer selected by bits FLXAnFROBCR.OBRS[6:0] from the Message RAM to OBF Shadow is started. When the transfer between the Message RAM and OBF Shadow has completed, this is signaled by setting FLXAnFROBCM.OBSYS back to 0.

By setting bit FLXAnFROBCR.VIEW to 1 while FLXAnFROBCR.OBSYS is 0, OBF Host and OBF Shadow are swapped. Additionally mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the register FLXAnFROBCM internal storage to keep them attached to the respective Output Buffer transfer. bits FLXAnFROBCR.OBRH[6:0] signals the number of the message buffer currently accessible by the Host.

If bits FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW are set to 1 with the same write access while FLXAnFROBCR.OBSYS is 0, FLXAnFROBCR.OBSYS is automatically set to 1 and OBF Shadow and OBF Host are swapped. Additionally mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the registers internal storage to keep them attached to the respective Output Buffer transfer. Afterwards FLXAnFROBCR.OBRS is copied to the register internal storage, and the transfer of the selected message buffer from the Message RAM to OBF Shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF Host. When the current transfer between Message RAM and OBF Shadow has completed, this is signaled by setting FLXAnFROBCR.OBSYS back to 0.

Any write access to bits FLXAnFROBCR[15:8] while FLXAnFROBCR.OBSYS is set to 1 will cause bit FLXAnFREIR.IOBA to be set to 1. In this case, this write access has no effect and the Output Buffer will not be changed.

The data transfer between Output Buffer and Message RAM is described in detail in **Section 18.3.12.2 (2), Data Transfer from Message RAM to Output Buffer.**

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0714_H

Table 18.80 FLXAnFROBCR Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22 to 16	OBRH[6:0]	Output Buffer Request Host Flag
15	OBSYS	Output Buffer Busy Shadow Flag 0: No transfer in progress 1: Transfer between Message RAM and OBF Shadow in progress
14 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	REQ	Request Message RAM Transfer Bit 0: No request 1: Transfer to OBF Shadow requested
8	VIEW	View Shadow Buffer Bit 0: No action 1: Swap OBF Shadow and OBF Host
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	OBRs[6:0]	Output Buffer Request Shadow Bit

(1) FLXAnFROBCR.OBRH

Output Buffer Request Host Flag

Number of message buffer currently accessible by the Host via the FLXAnFRRDHS1 to FLXAnFRRDHS3, FLXAnFRMBS, and FLXAnFRRDDS1 to FLXAnFRRDDS64 registers.

By writing bit FLXAnFROBCR.VIEW to 1 OBF Shadow and OBF Host are swapped and the transferred message buffer is accessible by the Host.

(2) FLXAnFROBCR.OBSYS

Output Buffer Busy Shadow Flag

Set to 1 after setting bit FLXAnFROBCR.REQ. When the transfer between the Message RAM and OBF Shadow has completed, FLXAnFROBCR.OBSYS is set back to 0.

(3) FLXAnFROBCR.REQ

Request Message RAM Transfer Bit

Only writeable while bit FLXAnFROBCR.OBSYS = 0.

Requests transfer of message buffer addressed by bits FLXAnFROBCR.OBRs[6:0] from Message RAM to OBF Shadow.

(4) FLXAnFROBCR.VIEW

View Shadow Buffer Bit

Only writeable while bit FLXAnFROBCR.OBSYS = 0.

Toggles between OBF Shadow and OBF Host.

(5) FLXAnFROBCR.OBRS

Output Buffer Request Shadow Bit

Only writeable while bit FLXAnFROBCR.OBSYS = 0.

Number of source message buffer to be transferred from the Message RAM to OBF Shadow.

If the number of the first message buffer of the receive FIFO is written to this register the Message Handler transfers the message buffer addressed by the GET Index (GIDX, see **Section 18.3.11, FIFO Function**) to OBF Shadow.

18.2.12 Data Transfer Control Register

18.2.12.1 FLXAnFRITC — FlexRay Input Transfer Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0800_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	ITM[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	IQEIE	IQFIE	—	—	—	—	—	—	IQHR	ITE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Table 18.81 FLXAnFRITC Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22 to 16	ITM[6:0]	Input queue Table Max Bit These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue.
15 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	IQEIE	Input Queue Empty Interrupt Enable Bit 0: Disabled 1: Enabled
8	IQFIE	Input Queue Full Interrupt Enable Bit 0: Disabled 1: Enabled
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	IQHR	Input Queue Halt Request Bit 0: Input queue run request 1: Input queue halt request
0	ITE	Input Transfer Enable Bit 0: Operation Disable request 1: Operation Enable request

(1) FLXAnFRITC.ITM

Input queue Table Max Bit

The user can only write to this bit when bit FLXAnFRITC.ITE is 0.

These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue.

Valid values are 00_H (1 queue entry) to 7F_H (128 queue entries).

Note that each entry requires two long words in the input pointer table.

(2) FLXAnFRITC.IQEIE

Input Queue Empty Interrupt Enable Bit

This bit controls the input queue empty interrupt.

0: Disabled

No interrupt will be generated and the input queue empty interrupt line will be released.

1: Enabled

Input queue empty interrupt will be generated when bit FLXAnFRITS.IQEIS is 1.

(3) FLXAnFRITC.IQFIE

Input Queue Full Interrupt Enable Bit

This bit controls the input queue full interrupt.

0: Disabled

No interrupt will be generated and the input queue full interrupt line will be released.

1: Enabled

Input queue full interrupt will be generated when bit FLXAnFRITS.IQFIS is 1.

(4) FLXAnFRITC.IQHR

Input Queue Halt Request Bit

The IQHR bit should not be set to 1 when FLXAnFRITS.ITS is 0.

This bit requests a halt of the input queue.

The status of the halt request is shown in the FLXAnFRITS.IQH register.

Refer to **Section 18.3.16.1 (5), Halting the input queue** about usage of this bit.

0: Input queue run request

The input queue resumes their operation.

1: Input queue halt request

The input queue gets halted. An active input transfer will be completed but no further transfer request will start.

(5) FLXAnFRITC.ITE

Input Transfer Enable Bit

The user should only set this bit to 1 when bit FLXAnFRIBCR.IBSYS is 0.

The user should only set this bit to 0 when bit FLXAnFRITC.IQHR is 0. Otherwise committed input transfers get lost.

This bit controls the operation mode of the input transfer queue.

The operation status of the input transfer queue function is shown in bit FLXAnFRITS.ITS.

Refer to **Section 18.3.16.1 (1), Activation and deactivation** about usage of this bit.

0: Operation Disable request

The input transfer queue is disabled when it becomes empty.

1: Operation Enable request

The input transfer queue is enabled. Input data structures are transferred to the FlexRay internal message RAM.

18.2.12.2 FLXAnFROTC — FlexRay Output Transfer Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0804_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	FTM[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	FWIE	OWIE	FIE	OIE	—	—	—	—	—	—	OTCS	OTE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Table 18.82 FLXAnFROTC Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is read. When writing, write the value after reset.
20 to 16	FTM[4:0]	FIFO Table Max Bit Configures the number of FIFO entries the output transfer handler is capable to maintain in the Local RAM/Global RAM.
15 to 12	Reserved	When read, the value after reset is read. When writing, write the value after reset.
11	FWIE	FIFO transfer Warning Interrupt Enable Bit 0: Disabled 1: Enabled
10	OWIE	Output transfer Warning Interrupt Enable Bit 0: Disabled 1: Enabled
9	FIE	FIFO transfer Interrupt Enable Bit 0: Disabled 1: Enabled
8	OIE	Output transfer Interrupt Enable Bit 0: Disabled 1: Enabled
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	OTCS	Output Transfer Condition Select Bit 0: New data only mode 1: New data and status changed mode
0	OTE	Output Transfer Enable Bit 0: Operation Disable request 1: Operation Enable request

(1) FLXAnFROTC.FTM

FIFO Table Max Bit

The user can only write to these bits when bit FLXAnFROTS.OTS is 0.

Configures the number of FIFO entries the output transfer handler is capable to maintain in the Local RAM/Global RAM.

Valid values are 00_H (1 FIFO entry) to 1F_H (32 FIFO entries).

(2) FLXAnFROTC.FWIE

FIFO transfer Warning Interrupt Enable Bit

This bit controls the FIFO transfer warning interrupt.

0: Disabled

No interrupt will be generated and the FIFO transfer warning interrupt line will be released.

1: Enabled

FIFO transfer warning interrupt will be generated when bit FLXAnFROTS.FWIS is 1.

(3) FLXAnFROTC.OWIE

Output transfer Warning Interrupt Enable Bit

This bit controls the output transfer warning interrupt.

0: Disabled

No interrupt will be generated and the output transfer warning interrupt line will be released.

1: Enabled

Output transfer warning interrupt will be generated when bit FLXAnFROTS.OWIS is 1.

(4) FLXAnFROTC.FIE

FIFO transfer Interrupt Enable Bit

This bit controls the FIFO transfer interrupt.

0: Disabled

No interrupt will be generated and the FIFO transfer interrupt line will be released.

1: Enabled

FIFO transfer interrupt will be generated when bit FLXAnFROTS.FIS is 1.

(5) FLXAnFROTC.OIE

Output transfer Interrupt Enable Bit

This bit controls the output transfer interrupt.

0: Disabled

No interrupt will be generated and the output transfer interrupt line will be released.

1: Enabled

Output transfer interrupt will be generated when bit FLXAnFROTS.OTIS is 1.

(6) FLXAnFROTC.OTCS

Output Transfer Condition Select Bit

The user can only write to this bit when bit FLXAnFROTS.OTS is 0.

This bit controls the output transfer condition.

0: New data only mode

Bits FLXAnFRNDATm.NDp are used to detect a transfer condition for dedicated receive buffer.

1: New data and status changed mode

Bits FLXAnFRNDATm.NDp and FLXAnFRMBSCm. are used to detect a transfer condition for dedicated transmit and receive buffer.

(7) FLXAnFROTC.OTE

Output Transfer Enable Bit

The user should only set this bit to 1 when bit FLXAnFROBCR.OBSYS is 0.

This bit controls the operation mode of the output transfer function.

The operation status of the output buffer transfer function is shown in FLXAnFROTS.OTS.

Refer to **18.3.16.2, (1) Activation and deactivation** about usage of this bit.

0: Operation Disable request

The output buffer transfer gets disabled.

An active message buffer transfer will be completed but no further transfer will start.

1: Operation Enable request

The output buffer transfer gets enabled. Message buffers are transferred from the FlexRay internal message RAM to output data structures.

The user should not change the E-Ray message RAM configuration by writing to the FLXAnFRMRC register.

18.2.12.3 FLXAnFRIBA — FlexRay Input Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0808_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ITA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ITA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 18.83 FLXAnFRIBA Register Contents

Bit Position	Bit Name	Function
31 to 0	ITA[31:0]	Input Table Base Address Bit These bits configure the base address of the input pointer table.

(1) FLXAnFRIBA.ITA

Input Table Base Address Bit

The user can only write to this bit when FLXAnFRITS.ITS is 0.

The address should be 32 bit aligned, thus the bits FLXAnFRIBA.ITA[1:0] are always 0.

These bits configure the base address of the input pointer table.

The table is used for the input transfer queue transferring message buffers from the Local RAM/Global RAM into the FlexRay internal message RAM.

The size of the input queue is configured in bits FLXAnFRITC.ITM[6:0].

Note that each entry requires two long words in the input pointer table.

18.2.12.4 FLXAnFRFBA — FlexRay FIFO Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 080C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FTA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FTA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 18.84 FLXAnFRFBA Register Contents

Bit Position	Bit Name	Function
31 to 0	FTA[31:0]	FIFO pointer Table Base Address Bit These bits configure the base address of the FIFO pointer table.

(1) FLXAnFRFBA.FTA

FIFO pointer Table Base Address Bit

The user can only write to this bit when FLXAnFROTS.OTS is 0.

The address should be 32 bit aligned, thus the bits FLXAnFRFBA.FTA[1:0] are always 0.

These bits configure the base address of the FIFO pointer table.

The table is used for message buffers transferred from the FlexRay internal FIFO to the Local RAM/ Global RAM.

The size of the FIFO is configured in bits FLXAnFROTC.FTM[4:0].

18.2.12.5 FLXAnFROBA — FlexRay Output Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0810_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OTA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OTA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 18.85 FLXAnFROBA Register Contents

Bit Position	Bit Name	Function
31 to 0	OTA[31:0]	Output pointer Table Base Address Bit These bits configure the base address of the output pointer table.

(1) FLXAnFROBA.OTA

Output pointer Table Base Address Bit

The user can only write to this bit when FLXAnFROTS.OTS is 0.

The address should be 32 bit aligned, thus the bits FLXAnFROBA.OTA[1:0] are always 0.

These bits configure the base address of the output pointer table.

The table is used for message buffers transferred from the FlexRay internal message RAM to the Local RAM/Global RAM.

The size of the table depends on the utilization of the FlexRay internal message RAM and can have up to 128 entries.

18.2.12.6 FLXAnFRIQC — FlexRay Input Queue Control Register

Access: This register can only be written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0814_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	IMBnr[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W

Table 18.86 FLXAnFRIQC Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When writing, write the value after reset.
6 to 0	IMBnr[6:0]	Input Message Buffer Number Bit Message buffer number added to the input queue

(1) FLXAnFRIQC.IMBnr

Input Message Buffer Number Bit

The user can only write to this bit when FLXAnFRITS.IQFP is 0.

The user should not write to this register when FLXAnFRITS.ITS is 0 or when FLXAnFRITC.ITE is 0.

These bits are read as 0.

This value specifies the message buffer added to the input queue.

The number has to be identical to FLXAnFRWRHS4.IMBnr[6:0] (see **Section 18.3.16.1 (3), Input pointer table**) of the input pointer table.

The address to the input data structure has to be provided in the input pointer table at the put index (bit FLXAnFRITS.IPIDX[6:0]) before writing to this register.

Writing to this register increments the input put index (bit FLXAnFRITS.IPIDX[6:0]).

18.2.12.7 FLXAnFRUIR — FlexRay User Input Transfer Request Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0818_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	UIDX[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.87 FLXAnFRUIR Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is read. When writing, write the value after reset.
7 to 0	UIDX[7:0]	User requested Input inDeX Bit Input pointer table index requested for input transfer

(1) FLXAnFRUIR.UIDX

User requested Input inDeX Bit

The user can only write to this bit when bit FLXAnFRITS.UIRP is 0.

The user should not write to this register when bit FLXAnFRITS.ITS is 0.

The user should not write to this register when bit FLXAnFRITS.UIRP is 1.

The user should not write to this register when bit FLXAnFRITS.IQH is 1.

The user should only write bits FLXAnFRITC.ITM[6:0] +1 to this register.

This value specifies the input pointer table index for the requested input transfer.

The address to the input data structure has to be provided in the input pointer table at the index FLXAnFRUIR.UIDX[7:0] before writing to this register.

When writing to this register, the requested input data structure will be transferred from input data structure position to the FlexRay internal message RAM.

In opposite to queued input transfers the related FLXAnFRDA.DA flag is not influenced by the user input transfer.

18.2.12.8 FLXAnFRUOR — FlexRay User Output Transfer Request Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 081C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	URDS	—	—	UMBNR[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.88 FLXAnFRUOR Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	URDS	User request Read Data Section Bit 0: Data section is not transferred 1: Data section is transferred
8, 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	UMBNR[6:0]	User requested output Message Buffer Number Bit Message buffer number requested for output transfer

(1) FLXAnFRUOR.URDS

User request Read Data Section Bit

The user can only write to this bit when bit FLXAnFROTS.UORP is 0.

The user should not write to this register when bit FLXAnFROTS.OTS is 0.

The user should not write to this register when bit FLXAnFROTS.UORP is 1.

0: Data section is not transferred

The data section of the message buffer selected by the bits FLXAnFRUOR.UMBNR[6:0] is not requested

1: Data section is transferred

The data section of the message buffer selected by the bits FLXAnFRUOR.UMBNR[6:0] is requested

(2) FLXAnFRUOR.UMBNR

User requested output Message Buffer Number Bit

The user can only write to this bit when bit FLXAnFROTS.UORP is 0.

The user should not write to this register when bit FLXAnFROTS.OTS is 0.

The user should not write to this register when bit FLXAnFROTS.UORP is 1.

The user should restrict this bit to dedicated receive and transmit buffers when the FlexRay module is not in the CONFIG state.

When writing to this register, the contents of the message buffer will be transferred to a given area. The destination will be the area specified by the value in the output pointer table.

The data to be transferred can be specified by setting the URDS bit whether to transfer the header section only or to include the data section.

18.2.12.9 FLXAnFRAHBC — FlexRay H-Bus Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0840_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	HPROT[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 18.89 FLXAnFRAHBC Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	HPROT[3:0]	Protection Control Bit

(1) FLXAnFRAHBC.HPROT

Protection Control Bit

The user should only write to this register only when bit FLXAnFRITS.ITS is 0 and bit FLXAnFROTS.OTS is 0.

This register configures the value assigned to the H-Bus protection control signal.

18.2.13 Data Transfer Status Register

18.2.13.1 FLXAnFRITS — FlexRay Input Transfer Status Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0820_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	IGIDX[6:0]						—	IPIDX[6:0]

Table 18.90 FLXAnFRITS Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is read. When writing, write the value after reset.
30 to 24	IGIDX[6:0]	Input queue Get InDeX Bit Represents the get index of the input pointer table
23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22 to 16	IPIDX[6:0]	Input queue Put InDeX Bit Represents the put index of the input pointer table
15 to 13	Reserved	When read, the value after reset is read. When writing, write the value after reset.
12	IQFP	Input Queue Full condition Pending Bit 0: Entries in the input queue are available 1: All entries in the input queue are occupied
11, 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	IQEIS	Input Queue Empty Interrupt Status Bit 0: No input queue empty condition detected 1: Input queue empty condition detected
8	IQFIS	Input Queue Full Interrupt Status Bit 0: No input queue full condition detected 1: Input queue full condition detected
7 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	UIRP	User Input transfer Request Pending Bit 0: No user input transfer request pending 1: User input transfer request pending
1	IQH	Input Queue Halted Bit 0: Input queue not halted 1: Input queue halted
0	ITS	Input Transfer Status Bit 0: Disabled 1: Enabled

(1) FLXAnFRITS.IGIDX

Input queue Get InDeX Bit

These bits are only valid when bit FLXAnFRITS.IQH is 1

These bits represent the input pointer index the input queue handler will transfer next.

Valid values are 00_H to FLXAnFRITC.ITM.

The get index is incremented when the input data structure has been transferred from the Local RAM/ Global RAM and the related FLXAnFRDA.DA flag is cleared.

The index is set to 00_H when bit FLXAnFRITS.ITS changes from 0 to 1.

(2) FLXAnFRITS.IPIDX

Input queue Put InDeX Bit

These bits represent the index where the next input data structure pointer in the input pointer table should be stored.

Valid values are 00_H to FLXAnFRITC.ITM.

After reaching the maximum value the put index continues from 00_H.

The index is incremented when writing to bits FLXAnFRIQC.IMBNR[6:0].

The index is set to 00_H when bit FLXAnFRITS.ITS changes from 0 to 1.

(3) FLXAnFRITS.IQFP

Input Queue Full condition Pending Bit

This bit represents that the input queue is full.

There should be no further input transfer requests, by writing to bits FLXAnFRIQC.IMBNR[6:0], as long as this bit is 1.

[Clearing condition]

- This bit is cleared when there is one free entry in the input queue.

[Setting condition]

- This bit is set when all entries in the input queue are occupied.

(4) FLXAnFRITS.IQEIS

Input Queue Empty Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFRITC.IQEIE, the input queue empty interrupt is generated when this bit is 1.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRITS.IQEIS.
- This bit is cleared when bit FLXAnFRITS.ITS changes from 0 to 1.

[Setting condition]

- This bit is set when all pending input transfers have been processed and consequently the input queue becomes empty.

(5) FLXAnFRITS.IQFIS

Input Queue Full Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFRITC.IQFIE the input queue full interrupt is generated when FLXAnFRITS.IQFIS is 1.

This flag is intended as interrupt status flag. It does not represent the current input queue status; for this status refer to bit FLXAnFRITS.IQFP.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRITS.IQFIS.
- This bit is cleared when bit FLXAnFRITS.ITS changes from 0 to 1.

[Setting condition]

- This bit is set when all entries in the input queue are occupied.

(6) FLXAnFRITS.UIRP

User Input transfer Request Pending Bit

This bit represents that a user input transfer is still pending.

There should be no further write access to bits FLXAnFRUIR.UIDX[7:0] when this bit is 1.

[Clearing condition]

- This bit is cleared when the user input transfer request is processed by the input transfer handler.

[Setting condition]

- This bit is set when writing to bits FLXAnFRUIR.UIDX[7:0].

(7) FLXAnFRITS.IQH

Input Queue Halted Bit

This bit represents the status of the input queue.

There should be no further write access to bits FLXAnFRUIR.UIDX[7:0] when this bit is 1.

[Clearing condition]

- This bit is cleared when bit FLXAnFRITC.IQHR is set to 0.

[Setting condition]

- This bit is set immediately when bit FLXAnFRITC.IQHR is set to 1 and there is no ongoing input transfer.
- This bit is set only after an ongoing input transfer has been completed and bit FLXAnFRITC.IQHR is set to 1.

(8) FLXAnFRITS.ITS

Input Transfer Status Bit

This bit represents the status of the input queue handler.

While this bit is 1, there should be no read or write access to the address area $\langle \text{FLXAn_base} \rangle + 0400_{\text{H}}$ to $\langle \text{FLXAn_base} \rangle + 05FF_{\text{H}}$ and there should be no CLEAR_RAM command applied to bits FLXAnFRSUCC1.CMD[3:0].

The input transfer queue indexes and related status flags are set to 0 when bit FLXAnFRITS.ITS changes from 0 to 1.

[Clearing condition]

- This bit is cleared immediately when bit FLXAnFRITC.ITE is set to 0 and there are no pending input transfers
- This bit is cleared after all pending requests have been processed and bit FLXAnFRITC.ITE is 0.

[Setting condition]

- This bit is set when bit FLXAnFRITC.ITE is set to 1.

18.2.13.2 FLXAnFROTS — FlexRay Output Transfer Status Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0824_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	FFL[5:0]					—	—	—	FGIDX[4:0]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R/W	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Table 18.91 FLXAnFROTS Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is read. When writing, write the value after reset.
29 to 24	FFL[5:0]	FIFO Fill Level Bit Represent the number of unprocessed output FIFO structures
23 to 21	Reserved	When read, the value after reset is read. When writing, write the value after reset.
20 to 16	FGIDX[4:0]	FIFO Get InDeX Bit Represent the get index in the FIFO pointer table
15	FWP	FIFO transfer Warning condition Pending Bit 0: No FIFO transfer warning condition pending 1: FIFO transfer warning condition pending
14	OWP	Output transfer Warning condition Pending 0: No output transfer warning condition pending 1: Output transfer warning condition pending
13	FDA	FIFO Data Available Bit 0: No available FIFO structures 1: FIFO structures available at current FLXAnFROTS.FGIDX index
12	Reserved	When read, the value after reset is read. When writing, write the value after reset.
11	FWIS	FIFO transfer Warning Interrupt Status Bit 0: No FIFO transfer warning condition detected 1: FIFO transfer warning condition detected
10	OWIS	Output transfer Warning Interrupt Status Bit 0: No output transfer warning condition detected 1: Output transfer warning condition detected
9	FIS	FIFO transfer Interrupt Status Bit 0: No FIFO structure updated in Local RAM/Global RAM 1: FIFO structure updated in Local RAM/Global RAM
8	OTIS	Output transfer Interrupt Status Bit 0: No output structure updated in Local RAM/Global RAM 1: Output structure updated in Local RAM/Global RAM
7 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	UORP	User Output transfer Request Pending Bit 0: No user output transfer request pending 1: User output transfer request pending

Table 18.91 FLXAnFROTS Register Contents (2/2)

Bit Position	Bit Name	Function
1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	OTS	Output Transfer Status Bit 0: Disabled 1: Enabled

(1) FLXAnFROTS.FFL

FIFO Fill Level Bit

These bits represent the number of available output FIFO structures in the Local RAM/Global RAM.

Valid values are 00_{H} to $\text{FLXAnFROTC.FTM}+1$.

The value 00_{H} represents that the FIFO is empty.

The value $\text{FLXAnFROTC.FTM}+1$ represents that the FIFO is full and no further FIFO transfers will be done.

The FIFO fill level is incremented when a FIFO data structure has been transferred from the FlexRay internal FIFO into the Local RAM/Global RAM.

The FIFO fill level is decremented when the user releases a FIFO data structure in the Local RAM/Global RAM by writing 1 to bit FLXAnFROTS.FDA .

The FIFO fill level is set to 00_{H} when bit FLXAnFROTS.OTS changes from 0 to 1.

(2) FLXAnFROTS.FGIDX

FIFO Get InDeX Bit

These bits represent the index where the current output data structure pointer in the FIFO pointer table is available for reading.

Valid values are 00_{H} to FLXAnFROTC.FTM .

After reaching the maximum value the get index continues from 00_{H} .

The index is incremented when a FIFO data structure is released by writing 1 to bit FLXAnFROTS.FDA .

The index is set to 00_{H} when bit FLXAnFROTS.OTS changes from 0 to 1.

(3) FLXAnFROTS.FWP

FIFO transfer Warning condition Pending Bit

This bit represents the FIFO transfer warning condition.

[Clearing condition]

- This bit is cleared when there are free output data structures ($\text{FLXAnFROTS.FFL} \leq \text{FLXAnFROTC.FTM}$).

This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when the output transfer handler detects a transfer condition for FIFO message buffers but there are no free output data structures ($\text{FLXAnFROTS.FFL} = \text{FLXAnFROTC.FTM}+1$).

(4) FLXAnFROTS.OWP

Output transfer Warning condition Pending Bit

This bit represents the output transfer warning condition.

[Clearing condition]

- This bit is cleared, when all output structure pointers that have a pending output handler transfer condition detected, are released (for dedicated transmit and receive message buffers or a user output transfer request).
- This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when the output transfer handler detects a transfer condition (for dedicated transmit and receive message buffers or a user output transfer request) but the related output structure pointer was not yet released by the application (data available flag is still set to 1).
- This bit is set when the output transfer handler detects a transfer condition for dedicated transmit and receive message buffers but there is a pending input transfer for the same message buffer (data available flag is set to 1 due to the input transfer request).

(5) FLXAnFROTS.FDA

FIFO Data Available Bit

Writing 0 has no effect on the bit value.

When this bit is 1, the next valid output data structure is available.

The related data structure pointer is in the FIFO pointer table at FLXAnFROTS.FGIDX.

Writing 1 to FLXAnFROTS.FDA

- increments FLXAnFROTS.FGIDX[4:0] and
- decrements the FIFO fill level (FLXAnFROTS.FFL)

If there are still unprocessed data structures FLXAnFROTS.FDA remains 1.

[Clearing condition]

- This bit is cleared when writing 1 to FLXAnFROTS.FDA and the FIFO fill level becomes 00_H.
- This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when there is at least one FIFO data structure available in the Local RAM/Global RAM.

(6) FLXAnFROTS.FWIS

FIFO transfer Warning Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFROTC.FWIE, the FIFO transfer warning interrupt is generated when this bit is 1.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFROTS.FWIS.
- This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when the output transfer handler detects a transfer condition for FIFO message buffers but there are no free output data structures (FLXAnFROTS.FFL = FLXAnFROTC.FTM+1).

(7) FLXAnFROTS.OWIS

Output transfer Warning Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFROTC.OWIE, the FIFO transfer warning interrupt is generated when this bit is 1.

[Clearing condition]

- This bit is cleared when writing a 1 to this bit.
- This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when the output transfer handler detects a transfer condition (for dedicated transmit and receive message buffers or a user output transfer request) but the related output structure pointer was not yet released by the application (data available flag is still set to 1).
- This bit is set when the output transfer handler detects a transfer condition for dedicated transmit and receive message buffers but there is a pending input transfer for the same message buffer (data available flag is set to 1 due to the input transfer request).

(8) FLXAnFROTS.FIS

FIFO transfer Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFROTC.FIE, the FIFO transfer interrupt is generated when this bit is 1.

[Clearing condition]

- This bit is cleared when writing a 1 to this bit.
- This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when a FIFO data structure is updated by the transfer handler or bits FLXAnFROTS.FFL[5:0] changes from 00_H to 01_H.

(9) FLXAnFROTS.OTIS

Output transfer Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFROTC.OIE, the output transfer interrupt is generated when this bit is 1.

[Clearing condition]

- This bit is cleared when writing a 1 to bit FLXAnFROTS.OTIS.
- This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when an output data structure is updated by the transfer handler (from a dedicated transmit or receive message buffer or by a user output transfer request).

(10) FLXAnFROTS.UORP

User Output transfer Request Pending Bit

This bit represents that a user output transfer is still pending.

There should be no further write access to bits FLXAnFRUOR.UMBNR[6:0] when this bit is 1.

[Clearing condition]

- This bit is cleared when the user output transfer request is processed by the output transfer handler.
- This bit is cleared when the bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when writing to bit FLXAnFRUOR.UMBNR.

(11) FLXAnFROTS.OTS

Output Transfer Status Bit

This bit represents the status of the output transfer handler.

While this bit is 1, there should be no read or write access to the address area $\langle \text{FLXAn_base} \rangle + 0600_{\text{H}}$ to $\langle \text{FLXAn_base} \rangle + 07FF_{\text{H}}$ and there should be no CLEAR_RAM command applied to bits FLXAnFRSUCC1.CMD[3:0].

While this bit is 1, the user should not change the E-Ray message RAM configuration by writing to the FLXAnFRMRC register.

The output handler transfer indexes and related status flags are set to 0 when this bit changes from 0 to 1.

[Clearing condition]

- This bit is cleared immediately when bit FLXAnFROTC.OTE is set to 0 and there are no ongoing output transfers.
- This bit is cleared after an ongoing transfer has been completed and bit FLXAnFROTC.OTE is 0.

[Setting condition]

- This bit is set when bit FLXAnFROTC.OTE is set to 1.

18.2.13.3 FLXAnFRAES — FlexRay Access Error Status Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0828_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MAE	FAE	OAE	IAE	EIDX[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Table 18.92 FLXAnFRAES Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset is read. When writing, write the value after reset.
11	MAE	Multiple Access Errors Bit 0: No multiple access errors occurred 1: Multiple access errors occurred
10	FAE	FIFO transfer Access Error Bit 0: No access error occurred during FIFO transfer 1: Access error occurred during FIFO transfer
9	OAE	Output transfer Access Error Bit 0: No access error occurred during output transfer 1: Access error occurred during output transfer
8	IAE	Input transfer Access Error Bit 0: No access error occurred during input transfer 1: Access error occurred during input transfer
7 to 0	EIDX[7:0]	Error InDeX Bit Data structure pointer index number

(1) FLXAnFRAES.MAE

Multiple Access Errors Bit

Writing 0 has no effect on the bit value.

This bit represents that there were multiple access errors during a data transfer.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRAES.MAE.

[Setting condition]

- This bit is set when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE and FLXAnFRAES.IAE is set and one of the conditions below is met:
 - an access to an protected address occurred during a FIFO data transfer or
 - an access to an protected address occurred during an output data transfer or
 - an access to an protected address occurred during an input data transfer

(2) FLXAnFRAES.FAE

FIFO transfer Access Error Bit

Writing 0 has no effect on the bit value.

This bit represent that there was an access error during a FIFO data transfer.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRAES.FAE.

[Setting condition]

- This bit is set when a Local RAM/Global RAM access error was detected during a FIFO transfer and bits FLXAnFRAES.OAE, FLXAnFRAES.IAE and FLXAnFRAES.MAE are 0.

(3) FLXAnFRAES.OAE

Output transfer Access Error Bit

Writing 0 has no effect on the bit value.

This bit represent that there was an access error during a output data transfer.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRAES.OAE.

[Setting condition]

- This bit is set when a Local RAM/Global RAM access error was detected during an output transfer and bits FLXAnFRAES.FAE, FLXAnFRAES.IAE and FLXAnFRAES.MAE are 0.

(4) FLXAnFRAES.IAE

Input transfer Access Error Bit

Writing 0 has no effect on the bit value.

This bit represent that there was an access error during an input data transfer.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRAES.IAE.

[Setting condition]

- This bit is set when a Local RAM/Global RAM access error was detected during an output transfer and bits FLXAnFRAES.OAE, FLXAnFRAES.FAE and FLXAnFRAES.MAE are 0.

(5) FLXAnFRAES.EIDX

Error InDeX Bit

This value is only valid when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE and FLXAnFRAES.IAE is 1.

When bit FLXAnFRAES.FAE is 1, FLXAnFRAES.EIDX holds the used FIFO put index when the access error has occurred.

When bit FLXAnFRAES.OAE is 1, FLXAnFRAES.EIDX holds the input pointer table get index used when an access error occurred during an input transfer or when the user request an input transfer.

When bit FLXAnFRAES.IAE is 1, FLXAnFRAES.EIDX holds the used input pointer table get index when the access error has occurred.

These bits are updated when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE and FLXAnFRAES.IAE is changing from 0 to 1.

18.2.13.4 FLXAnFRAEA — FlexRay Access Error Address Register

Access: This register can only be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 082C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	AEA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AEA[15:0]

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.93 FLXAnFRAEA Register Contents

Bit Position	Bit Name	Function
31 to 0	AEA[31:0]	Access Error Address Bit Address in the Local RAM/Global RAM when an access error has occurred

(1) FLXAnFRAEA.AEA

Access Error Address Bit

This value is only valid when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE and FLXAnFRAES.IAE is 1.

These bits represent the address of the access error indicated in the FLXAnFRAES register.

These bits are updated when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE and FLXAnFRAES.IAE is changing from 0 to 1.

18.2.13.5 FLXAnFRDAm — FlexRay message Data Available Register m (m = 0 to 3)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0830_H to <FLXAn_base> + 083C_H (<FLXAn_base> + 0830_H + m × 4)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DAP[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.94 FLXAnFRDAm Register Contents

Bit Position	Bit Name	Function
31 to 0	DAP[31:0]	Data Available Bit p 0: No data available for destination 1: Data available for destination

(1) FLXAnFRDAm.DAp (p = m × 32 to ((m + 1) × 32) – 1)

Data Available Bit p

The user should not write a 1 to bits that are 0.

To maintain the status of input transfers, the user should not clear bits related to input transfers.

This register is used for input and output transfers.

Each flag corresponds to a FlexRay message buffer.

[Clearing condition]

- Input transfer:
This bit is cleared when the input data structure has been transferred from the Local RAM/Global RAM. The data structure and the data structure pointer can be changed when the related flag is 0.
- Output transfer:
This bit is cleared when writing a 1 to it.

[Setting condition]

- Input transfer:
This bit is set when the corresponding message buffer number has been written to bits FLXAnFRIQC.IMBNR[6:0].
As long as this bit is 1, the input data structure and the data structure pointer corresponding to this input transfer request should not be changed.
- Output transfer:
This bit is set when the output data structure corresponding to this message buffer has been updated.

As long as this bit is 1, the data structure is stable; no further update of the data structure will be done by the output handler. While this bit is 1, the application is allowed to change the output data structure pointer in the output pointer table for this message buffer number.

18.3 Functional Description

This chapter describes the FlexRay implementation together with the related FlexRay protocol features. More information about the FlexRay protocol itself can be found in the FlexRay protocol specification.

18.3.1 FlexRay Module Operation Control

18.3.1.1 FlexRay Module Enable

After a reset or after the FlexRay module has been disabled (following **Section 18.3.1.2, FlexRay Module Disable**) the FlexRay module is in the reset state (bit FLXAnFROS.OS is 0) and the clocks of the FlexRay core module are disabled.

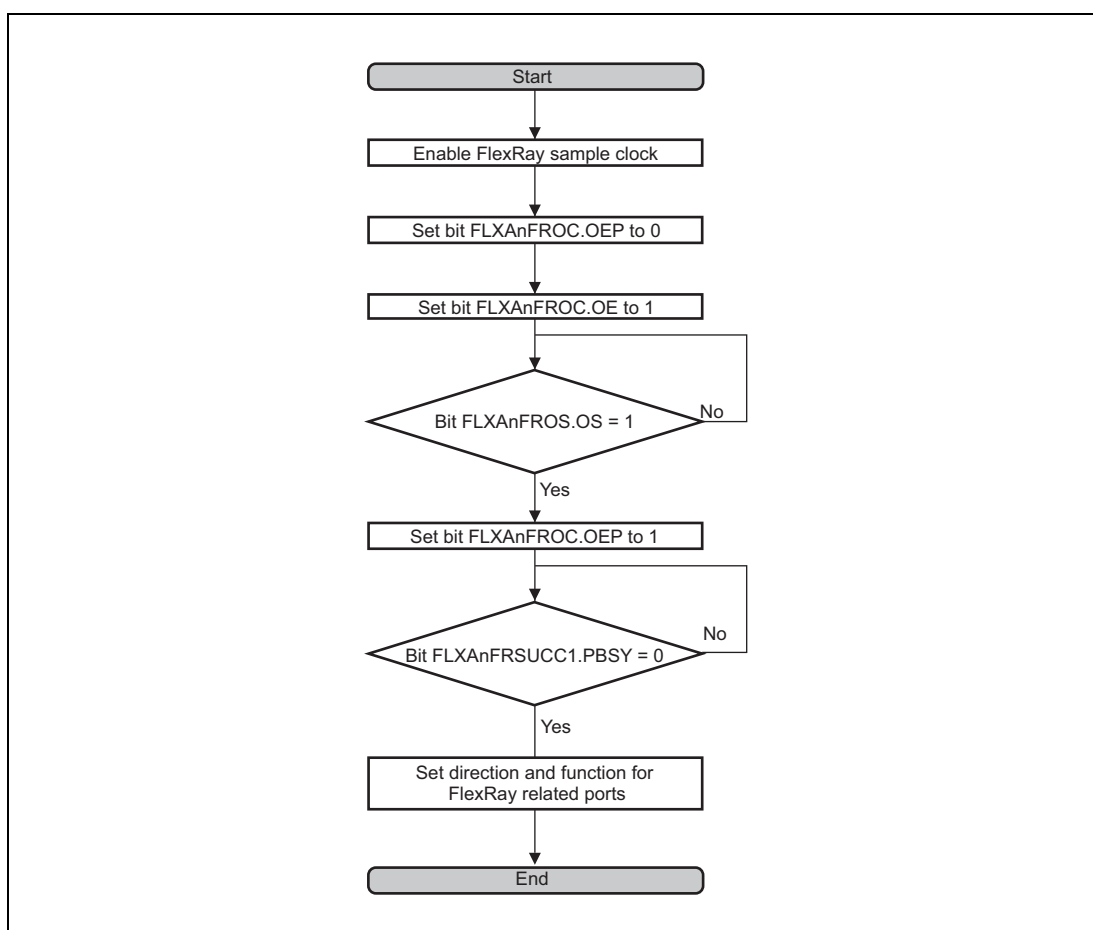

Figure 18.3 FlexRay Enable Processing Flow

18.3.1.2 FlexRay Module Disable

The FlexRay module can be disabled at any time. However, it is recommended to disable the FlexRay module using bit FLXAnFROC.OE only when the FlexRay module is in HALT, CONFIG or DEFAULT_CONFIG state. Resetting the FlexRay module in any other state will terminate any ongoing FlexRay communication.

If the data transfer function is used, it is also required to disable this function before disabling the FlexRay module (see **Section 18.3.16.1, Input Data Transfer (1), Activation and deactivation** for suspending input transfer function and **Section 18.3.16.2, Output Data Transfer (1), Activation and deactivation** for suspending output transfer).

The following flow should be executed to disable the FlexRay module.

Figure 18.4 FlexRay Disable Processing Flow

18.3.2 Communication Cycle

Communication on FlexRay networks is based on frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to setup the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

A FlexRay communication cycle consists of the following elements:

- Static Segment
- Dynamic Segment (optional)
- Symbol Window (optional)
- Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized macrotick.

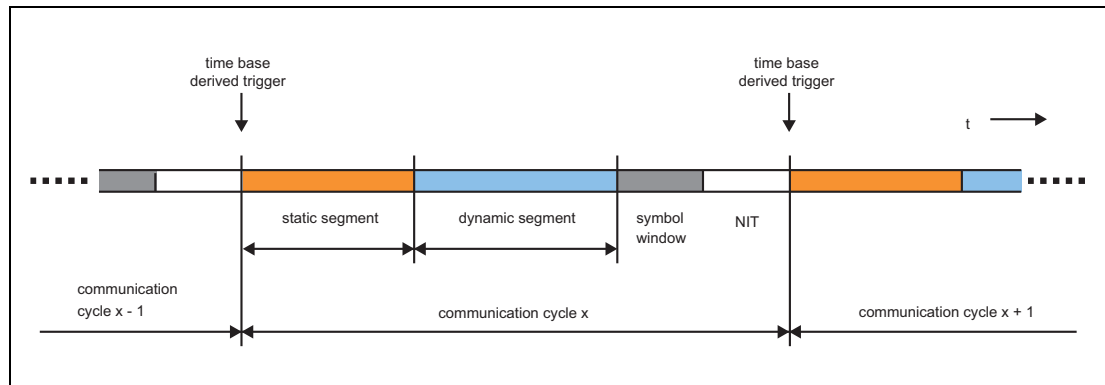

Figure 18.5 Structure of Communication Cycle

18.3.2.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of frame transmission at action point of the respective static slot
- Payload length same for all frames on both channels

Parameters:

Number of Static Slots (FLXAnFRGTUC7.NSS[9:0])

Static Slot Length (FLXAnFRGTUC7.SSL[9:0])

Payload Length Static (FLXAnFRMHDC.SFDL[6:0])

Action Point Offset (FLXAnFRGTUC9.APO[5:0])

18.3.2.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters:

Number of Minislots (FRGTUC8.NMS[12:0])

Minislot Length (FRGTUC8.MSL[5:0])

Minislot Action Point Offset (FRGTUC9.MAPO[4:0])

Start of Latest Transmit (last minislot) (FRMHDC.SLT[12:0])

18.3.2.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are sent in NORMAL_ACTIVE state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Parameters:

Symbol Window Action Point Offset (FRGTUC9.APO[4:0]) (same as for static slots)

Network Idle Time Start (FRGTUC4.NIT[13:0])

18.3.2.4 Network Idle Time (NIT)

During network idle time the CC has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple macroticks after offset correction start
- Perform cluster cycle related tasks

Parameters:

Network Idle Time Start (FLXAnFRGTUC4.NIT[13:0])

Offset Correction Start (FLXAnFRGTUC4.OCS[13:0])

18.3.2.5 Configuration of NIT Start and Offset Correction Start

Figure 18.6 Configuration of NIT Start and Offset Correction Start

The number of macroticks per cycle $gMacroPerCycle$ is assumed to be m . It is configured by programming $FLXAnFRGTUC2.MPC[13:0] = m$.

The static / dynamic segment starts with macrotick 0 and ends with macrotick n :

$$n = \text{static segment length} + \text{dynamic segment offset} + \text{dynamic segment length} - 1MT$$

$$= gNumberOfStaticSlots \times gdStaticSlot + \text{dynamic segment offset} + gNumberOfMinislots \times gdMinislot - 1 MT$$

The static segment length is configured by $FLXAnFRGTUC7.SSL[9:0]$ and $FLXAnFRGTUC7.NSS[9:0]$.

The dynamic segment length is configured by $FLXAnFRGTUC8.MSL[5:0]$ and $FLXAnFRGTUC8.NMS[12:0]$.

The dynamic segment offset is:

If $gdActionPointOffset \leq gdMinislotActionPointOffset$:

$$\text{dynamic segment offset} = 0 MT$$

Else if $gdActionPointOffset > gdMinislotActionPointOffset$:

$$\text{dynamic segment offset} = gdActionPointOffset - gdMinislotActionPointOffset$$

The NIT starts with macrotick $k+1$ and ends with the last macrotick of cycle $m-1$. It has to be configured by setting $FLXAnFRGTUC4.NIT[13:0] = k$.

For the FlexRay module the offset correction start is required to be $FLXAnFRGTUC4.OCS[13:0] \geq FLXAnFRGTUC4.NIT[13:0] + 1 = k + 1$.

The length of symbol window results from the number of macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by the number of macroticks $(k - n)$.

18.3.3 Communication Modes

The FlexRay Protocol Specification defines the Time-Triggered Distributed (TT-D) mode.

18.3.3.1 Time-triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- Pure static: Minimum 2 static slots + symbol window (optional)
- Mixed static/dynamic: Minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes needs to be configured for distributed time-triggered operation.

Two fault-free coldstart nodes are necessary for the cluster startup. Each startup frame must be a sync frame, therefore all coldstart nodes are sync nodes.

18.3.4 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received sync frames from other nodes.

18.3.4.1 Global Time

Activities in a FlexRay node, individual nodes independently operate. Operations including communication, are based on the concept of a global time. It is the clock synchronization mechanism that differentiates the FlexRay cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (macrotick counter).

Cluster specific:

- Macrotick (MT) = basic unit of time measurement in a FlexRay network, a macrotick consists of an integer number of microticks (μT)
- Cycle length = duration of a communication cycle in units of macroticks (MT)

18.3.4.2 Local Time

Internally, nodes time their behavior with microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a microtick (μT).

Node specific:

- Oscillator clock \rightarrow prescaler \rightarrow microtick (μT)
- μT = basic unit of time measurement in a CC, clock correction is done in units of μT s
- Cycle counter + macrotick counter = nodes local view of the global time

18.3.4.3 Synchronization Process

Clock synchronization is performed by means of sync frames. Only preconfigured nodes (sync nodes) are allowed to send sync frames. In a two-channel cluster a sync node has to send its sync frame on both channels.

For synchronization in FlexRay the following constraints have to be considered:

- Max. one sync frame per node in one communication cycle
- Max. 15 sync frames per cluster in one communication cycle
- Every node has to use a preconfigured number of sync frames (FLXAnFRGTUC2.SNM[3:0]) for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of sync frames received during the static segment is measured. In a two channel cluster the sync node has to be configured to send sync frames on both channels. The calculation of correction terms is done during NIT (offset: every cycle, rate: every odd cycle) by using an FTM algorithm. For details see *FlexRay protocol specification v2.1, chapter 8*.

(1) Offset (phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during NIT of every communication cycle
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values
- Correction value is a signed integer number of μ Ts
- Correction done in odd numbered cycles, distributed over the macroticks beginning at offset correction start up to cycle end (end of NIT) to shift nodes next start of cycle (MTs lengthened / shortened)

(2) Rate (frequency) Correction

- Pairs of deviation values measured and stored in even / odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during NIT of odd numbered cycles
- Cluster drift damping is performed using global damping value
- Checked against limit values
- Correction value is a signed integer number of μ Ts
- Distributed over macroticks comprising the next even / odd cycle pair (MTs lengthened / shortened)

(3) Sync Frame Transmission

Sync frame transmission is only possible from buffer 0 and 1. Message buffer 1 may be used for sync frame transmission in case that sync frames should have different payloads on the two channels. In this case bit FLXAnFRMRC.SPLM has to be programmed to 1.

Message buffers used for sync frame transmission have to be configured with the key slot ID and can be (re)configured in DEFAULT_CONFIG or CONFIG state only. For nodes transmitting sync frames, bit FLXAnFRSUCC1.TXSY must be set to 1.

(4) External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset / rate correction value is a signed integer
- External offset / rate correction value is added to calculated offset / rate correction value
- Aggregated offset / rate correction term (external + internal) is not checked against configured limits

18.3.5 Error Handling

The implemented error handling concept is intended to ensure that, in case of a lower layer protocol error in one single node, communication between non-affected nodes can be maintained. In some cases, higher layer program activity is required for the CC to resume normal operation. A change of the error handling state will set FLXAnFREIR.PEMC to 1 and may trigger an interrupt to the Host if enabled. The actual error mode is signaled by FLXAnFRCCCEV.ERRM[1:0].

Table 18.95 Error Modes of the POC (Degradation Model)

Error Mode	Activity
ACTIVE	Full operation, State: NORMAL_ACTIVE The CC is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers FLXAnFREIR and FLXAnFRSIR.
PASSIVE	Reduced operation, State: NORMAL_PASSIVE, CC self rescue allowed The CC stops transmitting frames and symbols, but received frames are still processed. Clock synchronization mechanisms are continued based on received frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers FLXAnFREIR and FLXAnFRSIR.
COMM_HALT	Operation halted, State: HALT, CC self rescue not allowed The CC stops frame and symbol processing, clock synchronization processing, and the macrotick generation. The host has still access to error and status information by reading the error and status interrupt flags from registers FLXAnFREIR and FLXAnFRSIR. The bus drivers are disabled.

18.3.5.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the “maximum without clock correction passive” limit defined by FLXAnFRSUCC3.WCP[3:0], the POC transits from NORMAL_ACTIVE to NORMAL_PASSIVE state. When it reaches the “maximum without clock correction fatal” limit defined by FLXAnFRSUCC3.WCF[3:0], it transits from NORMAL_ACTIVE or NORMAL_PASSIVE to HALT state.

The Clock Correction Failed Counter (FLXAnFRCCCEV.CCFC[3:0]) allows the Host to monitor the duration of the inability of a node to compute clock correction terms after the CC passed protocol startup phase. It will be incremented by one at the end of any odd communication cycle during which either the missing offset correction FLXAnFRSFS.MOCS or the missing rate correction FLXAnFRSFS.MRCS flag is set to 1.

The Clock Correction Failed Counter is reset to zero at the end of an odd communication cycle if neither the missing offset correction FLXAnFRSFS.MOCS nor the missing rate correction FLXAnFRSFS.MRCS flag is set to 1.

The Clock Correction Failed Counter stops incrementing when the “maximum without clock correction fatal” value FLXAnFRSUCC3.WCF is reached (i.e. incrementing the counter at its maximum value will not cause it to wrap around back to zero). The Clock Correction Failed Counter is initialized to zero when the CC enters READY state or when NORMAL_ACTIVE state is entered.

CAUTION

The transition to HALT state is prevented if the FLXAnFRSUCC1.HCSE bit is not set to 1.

18.3.5.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from NORMAL_PASSIVE to NORMAL_ACTIVE state. FLXAnFRSUCC1.PTA[4:0] defines the number of consecutive valid even/odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state. If FLXAnFRSUCC1.PTA[4:0] is set to 0 the CC is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

18.3.5.3 HALT Command

In case the Host wants to stop FlexRay communication of the local node it can bring the CC into HALT state by asserting the HALT command. This can be done by writing 0110 to bits FLXAnFRSUCC1.CMD[3:0]. In order to shut down communication on an entire FlexRay network, a higher layer protocol is required to assure that all nodes apply the HALT command at the same time.

The POC state from which the transition to HALT state took place can be read from flags FLXAnFRCCSV.PSL[5:0].

When called in NORMAL_ACTIVE or NORMAL_PASSIVE state the POC transits to HALT state at the end of the current cycle. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to “0000” = command_not_accepted and bit FLXAnFREIR.CNA is set to 1. If enabled an interrupt to the Host is generated.

18.3.5.4 FREEZE Command

In case the Host detects a severe error condition it can bring the CC into HALT state by asserting the FREEZE command. This can be done by writing 0111 to bits FLXAnFRSUCC1.CMD[3:0]. The FREEZE command triggers the entry of the HALT state immediately regardless of the actual POC state.

The POC state from which the transition to HALT state took place can be read from flags FLXAnFRCCSV.PSL[5:0].

CAUTION

When transfer is stopped by a FREEZE or READY command and then restarted as a leading ColdStart node, the startup frame may not be transmitted in cycle 0. This depends on the internal state of the FlexRay module. Such cases arise when the startup frame is set in a slot 1 to slot 7. This does not occur in a ColdStart after the reset of the microcontroller. Even if the above situation arises, the ColdStart will succeed on the second trial. Repetition prolongs the overall ColdStart process, but the ColdStart will not be obstructed by the earlier situation. To avoid this effect, allocate startup and sync frames to static slot 8 or a slot with a higher number.

18.3.6 Communication Controller States

18.3.6.1 Communication Controller State Diagram

Figure 18.7 Overall State Diagram of FlexRay Communication Controller

State transitions are controlled by reset, rxda_extfxr, rxdb_extfxr, by the POC state machine, and by the CHI Command Vector FLXAnFRSUCC1.CMD[3:0].

The CC transits from all states to HALT state after application of the FREEZE command (FLXAnFRSUCC1.CMD[3:0] = “0111”).

Table 18.96 State Transitions of FlexRay Overall State Machine

T#	Condition	From	To
1	Reset	All States	DEFAULT_CONFIG
2	Command CONFIG: FLXAnFRSUCC1.CMD[3:0] = "0001"	DEFAULT_CONFIG	CONFIG
3	Unlock sequence followed by command READY: FLXAnFRSUCC1.CMD[3:0] = "0010"	CONFIG	READY
4	Command CONFIG: FLXAnFRSUCC1.CMD[3:0] = "0001"	READY	CONFIG
5	Command WAKEUP: FLXAnFRSUCC1.CMD[3:0] = "0011"	READY	WAKEUP
6	Complete transmission of wakeup pattern, received WUP or received frame header, wakeup collision or command READY: FLXAnFRSUCC1.CMD[3:0] = "0010"	WAKEUP	READY
7	Command RUN: FLXAnFRSUCC1.CMD[3:0] = "0100"	READY	STARTUP
8	Successful STARTUP	STARTUP	NORMAL_ACTIVE
9	Clock Correction Failed counter reached Maximum Without Clock Correction Passive limit configured by FLXAnFRSUCC3.WCP[3:0]	NORMAL_ACTIVE	NORMAL_PASSIVE
10	Number of valid correction terms reached the Passive to Active limit configured by FLXAnFRSUCC1.PTA[4:0]	NORMAL_PASSIVE	NORMAL_ACTIVE
11	Command READY: FLXAnFRSUCC1.CMD[3:0] = "0010"	STARTUP, NORMAL_ACTIVE, NORMAL_PASSIVE	READY
12	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by FLXAnFRSUCC3.WCF[3:0] when bit FLXAnFRSUCC1.HCSE set to 1 or command HALT, FLXAnFRSUCC1.CMD[3:0] = "0110"	NORMAL_ACTIVE	HALT
13	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by FLXAnFRSUCC3.WCF[3:0] when bit FLXAnFRSUCC1.HCSE set to 1, or command HALT: FLXAnFRSUCC1.CMD[3:0] = "0110"	NORMAL_PASSIVE	HALT
14	Command FREEZE: FLXAnFRSUCC1.CMD[3:0] = "0111"	All States	HALT
15	Command CONFIG: FLXAnFRSUCC1.CMD[3:0] = "0001"	HALT	DEFAULT_CONFIG

18.3.6.2 DEFAULT_CONFIG State

In DEFAULT_CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The CC enters this state

- When the reset is applied (the reset of the microcontroller or the software reset of the FlexRay module)
- When exiting from HALT state

To leave DEFAULT_CONFIG state, the Host has to write 0001 to bits FLXAnFRSUCC1.CMD[3:0]. The CC then transits to CONFIG state.

18.3.6.3 CONFIG State

In CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the CC configuration.

The CC enters this state

- When exiting from DEFAULT_CONFIG state
- When exiting from READY state

When the state has been entered via HALT and DEFAULT_CONFIG state, the Host can analyze status information and configuration. Before leaving CONFIG state, the Host has to assure that the configuration is fault-free.

To leave CONFIG state, the Host has to perform the unlock sequence as described in **Section 18.2.3.1, FLXAnFRLCK — FlexRay Lock Register**. Directly after unlocking the CONFIG state the Host has to write bits FLXAnFRSUCC1.CMD[3:0] to enter the next state.

CAUTION

Status bits FLXAnFRMHDS[14:0], registers FLXAnFRTXRQ1 to FLXAnFRTXRQ4, and status data stored in the Message RAM are not affected by the transition of the POC from CONFIG to READY state.

When the CC is in CONFIG state it is also possible to bring the CC into a power saving mode by halting the module clocks (bus clock and sample clock). To do this the Host has to assure that all Message RAM transfers have finished before turning off the clocks.

18.3.6.4 READY State

After unlocking CONFIG state and writing 0010_B to FLXAnFRSUCC1.CMD[3:0], the CC enters READY state. From this state the CC can transit to WAKEUP state and perform a cluster wakeup or to STARTUP state to perform a coldstart or to integrate into a running cluster.

The CC enters this state

- When exiting from CONFIG, WAKEUP, STARTUP, NORMAL_ACTIVE, or NORMAL_PASSIVE state by writing 0010_B to FLXAnFRSUCC1.CMD[3:0] (READY command).

The CC exits from this state

- To CONFIG state by writing 0001_B to FLXAnFRSUCC1.CMD[3:0] (CONFIG command)
- To WAKEUP state by writing 0011_B to FLXAnFRSUCC1.CMD[3:0] (WAKEUP command)
- To STARTUP state by writing 0100_B to FLXAnFRSUCC1.CMD[3:0] (RUN command)

Internal counters and the CC status flags are reset when the CC enters STARTUP state.

CAUTION

Status bits FLXAnFRMHDS[14:0], registers FLXAnFRTXRQ1 to FLXAnFRTXRQ4, and status data stored in the Message RAM are not affected by the transition of the POC from READY to STARTUP state.

18.3.6.5 WAKEUP State

The description below is intended to help configuring wakeup for the FlexRay IP-module. A detailed description of the wakeup procedure together with the respective SDL diagrams can be found in the FlexRay protocol specification v2.1, section 7.1.

The CC enters this state

- When exiting from READY state by writing 0011_B to bits FLXAnFRSUCC1.CMD[3:0] (WAKEUP command).

The CC exits from this state to READY state

- After complete non-aborted transmission of wakeup pattern (WUP)
- After WUP reception
- After detecting a WUP collision
- After reception of a frame header
- By writing 0010_B to bits FLXAnFRSUCC1.CMD[3:0] (READY command)

The cluster wakeup must precede the communication startup in order to ensure that all nodes in a cluster are awake. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an external wakeup source.

The Host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the CC and configures bus guardian (if available) and CC to perform the cluster wakeup. The CC provides to the Host the ability to transmit a special wakeup pattern on each of its available channels separately. The CC needs to recognize the wakeup pattern only during WAKEUP state.

Wakeup may be performed on only one channel at a time. The Host has to configure the wakeup channel while the CC is in CONFIG state by writing the FLXAnFRSUCC1.WUCS bit. The CC ensures that ongoing communication on this channel is not disturbed. The CC cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the CC returns to READY state and signals the change of the wakeup status to the Host by setting flag FLXAnFRSIR.WST. The wakeup status vector can be read from FLXAnFRCCSV.WSV[2:0]. If a valid wakeup pattern was received also either flag FLXAnFRSIR.WUPA or flag FLXAnFRSIR.WUPB is set to 1.

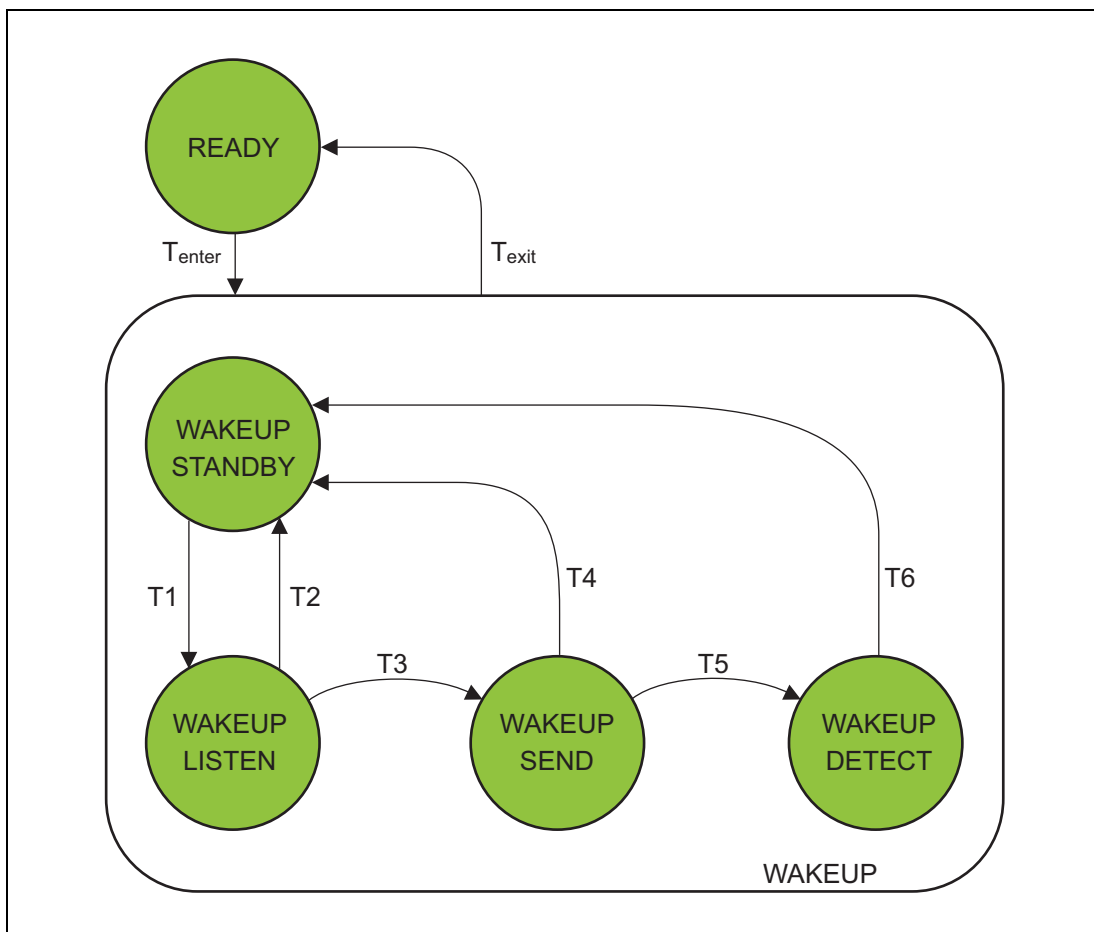

Figure 18.8 Structure of POC State WAKEUP

Table 18.97 State Transitions WAKEUP

T#	Condition	From	To
enter	Host commands change to WAKEUP state by writing 0011 to FLXAnFRSUCC1.CMD[3:0] (WAKEUP command)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to WAKEUP_LISTEN state	WAKEUP_STANDBY	WAKEUP_LISTEN
2	Received WUP on wakeup channel selected by bit FLXAnFRSUCC1.WUCS or frame header on either available channel	WAKEUP_LISTEN	WAKEUP_STANDBY
3	Timer event	WAKEUP_LISTEN	WAKEUP_SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_SEND	WAKEUP_STANDBY
5	Collision detected	WAKEUP_SEND	WAKEUP_DETECT
6	Wakeup timer expired or WUP detected on wakeup channel selected by bit FLXAnFRSUCC1.WUCS or frame header received on either available	WAKEUP_DETECT	WAKEUP_STANDBY
exit	Wakeup completed (after T2 or T4 or T6) or Host commands change to READY state by writing 0010 to FLXAnFRSUCC1.CMD[3:0] (READY command). This command also resets the wakeup FSM to WAKEUP_STANDBY state	WAKEUP	READY

The WAKEUP_LISTEN state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters Listen Timeout (bits FLXAnFRSUCC2.LT[20:0]) and Listen Timeout Noise (bits FLXAnFRSUCC2.LTN[3:0]). Listen Timeout enables a fast cluster wakeup in case of a noise free environment, while Listen Timeout Noise enables wakeup under more difficult conditions regarding noise interference.

In WAKEUP_SEND state the CC transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the Host has to bring the CC into STARTUP state by CHI command RUN.

In WAKEUP_DETECT state the CC attempts to identify the reason for the wakeup collision detected in WAKEUP_SEND state. The monitoring is bounded by the expiration of listen timeout as configured by bits FLXAnFRSUCC2.LT[20:0]. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a frame header indicating ongoing communication, causes the direct transition to READY state. Otherwise WAKEUP_DETECT is left after expiration of listen timeout; in this case the reason for wakeup collision is unknown.

The Host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay Protocol Specification recommends that two different CCs shall awake the two channels.

(1) Host activities

The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the Host. The wakeup pattern is detected by the remote BDs and signaled to their local Host.

Wakeup procedure controlled by Host (single-channel wakeup):

- Configure the CC in CONFIG state
 - Select wakeup channel by programming bit FLXAnFRSUCC1.WUCS
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command CC to enter READY state
- Command CC to start wakeup on the configured channel by writing 0011 to bits FLXAnFRSUCC1.CMD[3:0]
 - CC enters WAKEUP
 - CC returns to READY state and signals status of wakeup attempt to the Host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node:
 - In a dual channel cluster wait for WUP on the other channel
 - Set coldstart inhibit flag FLXAnFRCCSV.CSI by writing 1001_B to bits FLXAnFRSUCC1.CMD[3:0] (ALLOW_COLDSTART command)
- Command CC to enter startup by writing 0100_B to bits FLXAnFRSUCC1.CMD[3:0] (RUN command)

Wakeup procedure triggered by BD:

- Wakeup recognized by BD
- BD triggers power-up of Host (if required)
- BD signals wakeup event to Host
- Host configures its local CC
- If necessary, Host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands CC to enter STARTUP state by writing 0100 to bits FLXAnFRSUCC1.CMD[3:0] (RUN command)

(2) Wakeup pattern (WUP)

The wakeup pattern (WUP) is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by registers FLXAnFRPRTC1 and FLXAnFRPRTC2.

- Single channel wakeup, wakeup symbol may not be sent on both channels at the same time
- Wakeup symbol collision resilient for at least two sending nodes (two overlapping wakeup symbols always recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by bits FLXAnFRPRTC2.TXL[5:0]
- Wakeup symbol idle time used to listen for activity on the bus, configured by bits FLXAnFRPRTC2.TXI[7:0]
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by bits FLXAnFRPRTC1.RWP[5:0] (2 to 63 repetitions)
- Wakeup symbol receive window length configured by bits FLXAnFRPRTC1.RXW[8:0]
- Wakeup symbol receive low time configured by bits FLXAnFRPRTC2.RXL[5:0]
- Wakeup symbol receive idle time configured by bits FLXAnFRPRTC2.RXI[5:0]

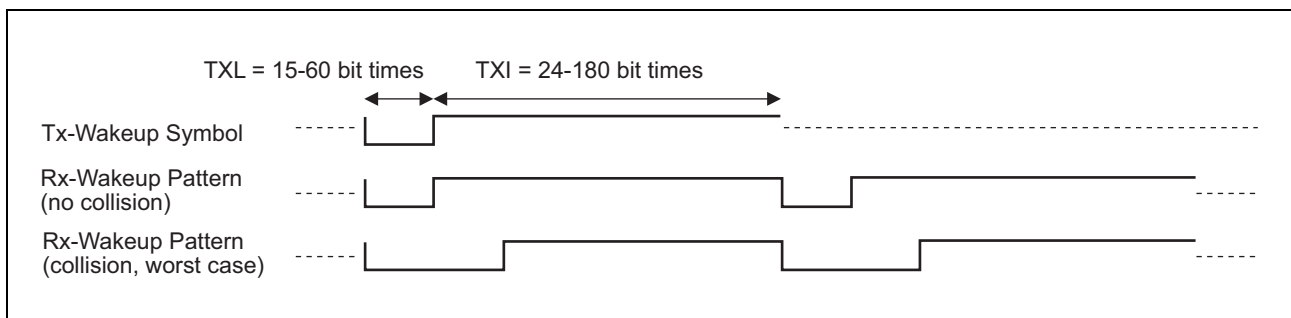

Figure 18.9 Timing of Wakeup Pattern

18.3.6.6 STARTUP State

The description below is intended to help configuring startup for the FlexRay module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the *FlexRay protocol specification v2.1, section 7.2*.

Any node entering STARTUP state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup frames. Startup frames are both sync frames and null frames during startup.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter NORMAL_ACTIVE state via (see **Figure 18.10**):

- Coldstart path initiating the schedule synchronization (LeadingColdstart node)
- Coldstart path joining other coldstart nodes (FollowingColdstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has bits FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY set to 1. Message buffer 0 holds the key slot ID which defines the slot number where the startup frame is sent. In the frame header of the startup frame the startup frame indicator bit is set to 1.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each startup frame must also be a sync frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by bits FLXAnFRSUCC1.CSA[4:0].

A non-coldstart node requires at least two startup frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration via the integration path as soon as they receive sync frames from which to derive the TDMA schedule information. During integration, the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

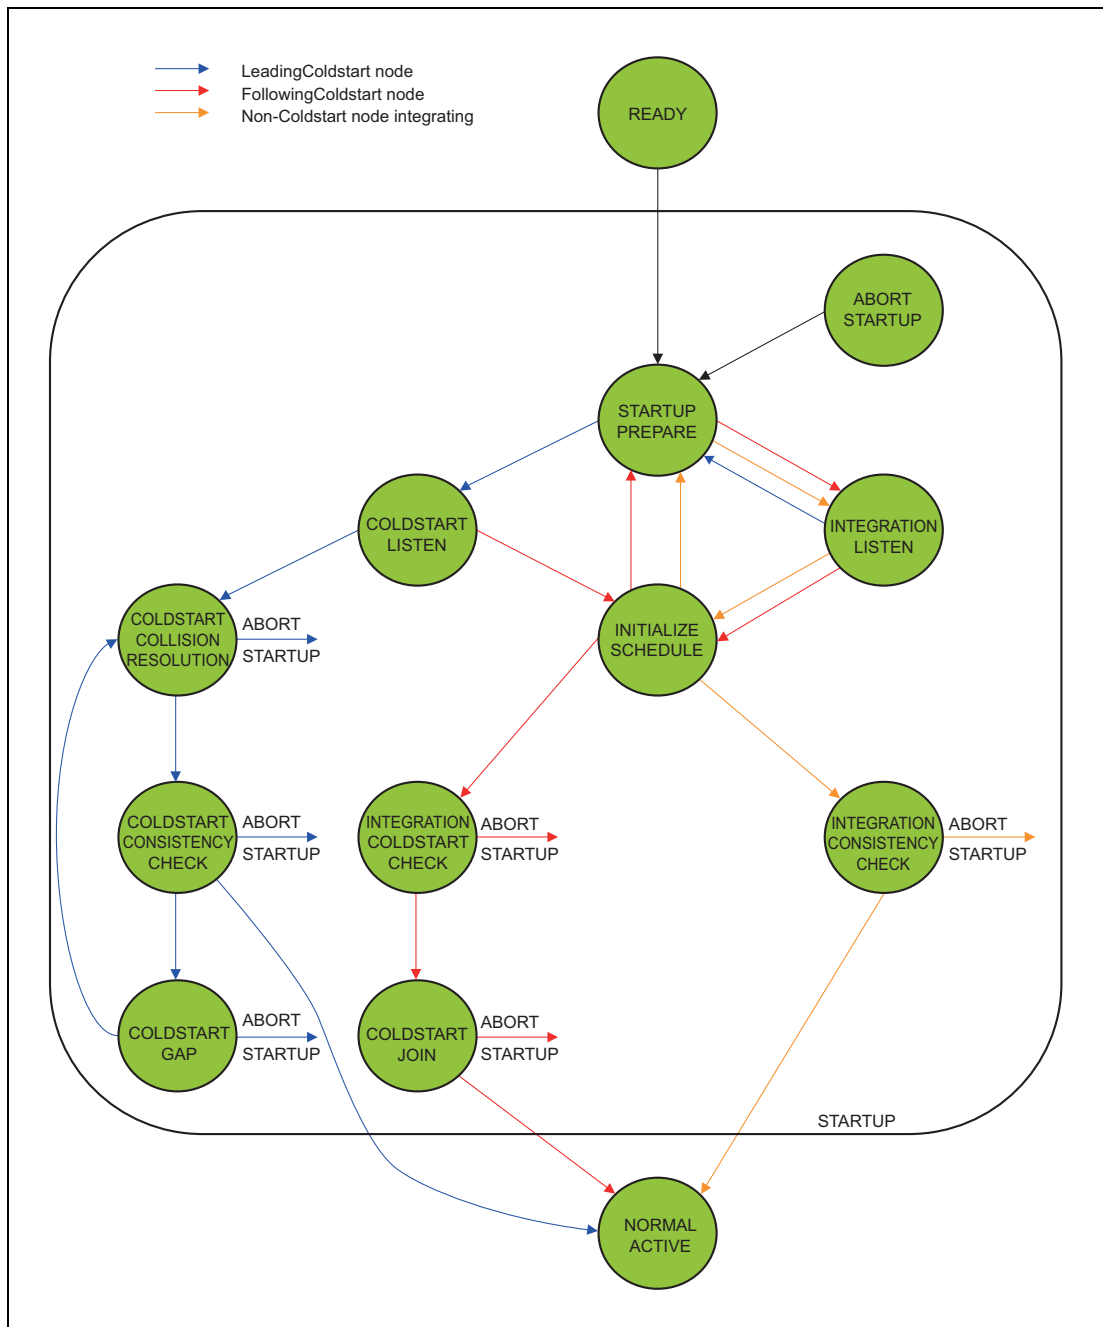

Figure 18.10 State Diagram Time-Triggered Startup

(1) Coldstart Inhibit Mode

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit FLXAnFRCCSV.CSI is set to 1, the node is not allowed to initialize the cluster communication, i.e. entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit FLXAnFRCCSV.CSI is set to 1 whenever the POC enters READY state. The bit has to be cleared under control of the Host by CHI command ALLOW_COLDSTART (bits FLXAnFRSUCC1.CMD[3:0] = “1001_B”)

(2) Startup Timeouts

The CC supplies two different μ T timers supporting two timeout values, startup timeout and startup noise timeout. The two timers are started when the CC enters the COLDSTART_LISTEN state. The expiration of either of these timers causes the node to leave the initial sensing phase (COLDSTART_LISTEN state) with the intention of starting up communication.

CAUTION

The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values FLXAnFRSUCC2.LT[20:0] and FLXAnFRSUCC2.LTN[3:0].

(a) Startup Timeout

The startup timeout limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others. The startup timer is configured by programming bits FLXAnFRSUCC2.LT[20:0] (see **Section 18.2.6.2, FLXAnFRSUCC2 — FlexRay SUC Configuration Register 2**).

The startup timeout is:

$$\text{pdListenTimeout} = \text{FLXAnFRSUCC2.LT}[20:0]$$

The startup timer is restarted upon:

- Entering the COLDSTART_LISTEN state
- Both channels reaching idle state while in COLDSTART_LISTEN state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the COLDSTART_LISTEN state
- When the COLDSTART_LISTEN state is left

Once the startup timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

(b) Startup Noise Timeout

At the same time the startup timer is started for the first time (transition from `STARTUP_PREPARE` state to `COLDSTART_LISTEN` state), the startup noise timer is started. This additional timeout is used to improve reliability of the startup procedure in the presence of noise. The startup noise timeout is configured by programming bits `FLXAnFRSUCC2.LTN[3:0]` (see **Section 18.2.6.2, FLXAnFRSUCC2 — FlexRay SUC Configuration Register 2**).

The startup noise timeout:

$$pdListenTimeout \times gListenNoise = FLXAnFRSUCC2.LT[20:0] \times (FLXAnFRSUCC2.LTN[3:0] + 1)$$

The startup noise timer is restarted upon:

- Entering the `COLDSTART_LISTEN` state
- Reception of correctly decoded headers or CAS symbols while the node is in `COLDSTART_LISTEN` state

The startup noise timer is stopped when the `COLDSTART_LISTEN` state is left.

Once the startup noise timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won't be restarted when random channel activity is sensed, this timeout defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

(3) Path of Leading Coldstart Node (initiating coldstart)

When a coldstart node enters `COLDSTART_LISTEN`, it listens to its attached channels.

If no communication is detected, the node enters the `COLDSTART_COLLISION_RESOLUTION` state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup frame. Since each coldstart node may perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a frame header during these four cycles, it re-enters the `COLDSTART_LISTEN` state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup frames.

After four cycles in `COLDSTART_COLLISION_RESOLUTION` state, the node that initiated the coldstart enters the `COLDSTART_CONSISTENCY_CHECK` state. It collects all startup frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid startup frame pair, the node leaves `COLDSTART_CONSISTENCY_CHECK` and enters `NORMAL_ACTIVE` state.

The number of coldstart attempts that a node is allowed to perform is configured by `FLXAnFRSUCC1.CSA[4:0]`. The number of remaining coldstarts attempts can be read from `FLXAnFRCCSV.RCA[4:0]`. The number of remaining coldstart attempts is reduced by one for each attempted coldstart. A node may enter the `COLDSTART_LISTEN` state only if this value is larger than one and it may enter the `COLDSTART_COLLISION_RESOLUTION` state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

(4) Path of Following Coldstart Node (responding to Leading Coldstart Node)

When a coldstart node enters the COLDSTART_LISTEN state, it tries to receive a valid pair of startup frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid startup frame has been received the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_COLDSTART_CHECK state is entered.

In INTEGRATION_COLDSTART_CHECK state it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all sync frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient frames from the same node it has integrated on, the COLDSTART_JOIN state is entered.

In COLDSTART_JOIN state following coldstart nodes begin to transmit their own startup frames and continue to do so in subsequent cycles. Thereby, the leading coldstart node and the nodes joining it can check if their schedules agree with each other. If the clock correction signals any error, the node aborts the integration attempt. If a node in this state sees at least one valid startup frame during all even cycles in this state and at least one valid startup frame pair during all double cycles in this state, the node leaves COLDSTART_JOIN state and enters NORMAL_ACTIVE state. Thereby it leaves STARTUP at least one cycle after the node that initiated the coldstart.

(5) Path of Non-coldstart Node

When a non-coldstart node enters the INTEGRATION_LISTEN state, it listens to its attached channels.

As soon as a valid startup frame has been received, the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_CONSISTENCY_CHECK state is entered.

In INTEGRATION_CONSISTENCY_CHECK state the node verifies that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) are sending startup frames that agree with the node's own schedule. Clock correction is activated, and if any errors are signaled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup frames or the startup frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid startup frame pairs or the startup frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup frames are received within an even cycle, or less than two valid startup frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid startup frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

18.3.6.7 NORMAL_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering STARTUP via coldstart path) and one additional node have entered the NORMAL_ACTIVE state, the startup phase for the cluster has finished. In the NORMAL_ACTIVE state, all configured messages are scheduled for transmission. This includes all data frames as well as the sync frames. Rate and offset measurement is started in all even cycles (even / odd cycle pairs required).

In NORMAL_ACTIVE state the CC supports regular communication functions

- The CC performs transmissions and reception on the FlexRay bus as configured
- Clock synchronization is running
- The Host interface is operational

The CC exits from that state to

- HALT state by writing 0110_B to bits FLXAnFRSUCC1.CMD[3:0] (HALT command, at the end of the current cycle)
- HALT state by writing 0111_B to bits FLXAnFRSUCC1.CMD[3:0] (FREEZE command, immediately)
- HALT state due to change of the error state from ACTIVE to COMM_HALT
- NORMAL_PASSIVE state due to change of the error state from ACTIVE to PASSIVE
- READY state by writing 0010_B to bits FLXAnFRSUCC1.CMD[3:0] (READY command)

18.3.6.8 NORMAL_PASSIVE State

NORMAL_PASSIVE state is entered from NORMAL_ACTIVE state when the error state changes from ACTIVE to PASSIVE.

In NORMAL_PASSIVE state, the node is able to receive all frames (node is fully synchronized and performs clock synchronization). Contrary to the NORMAL_ACTIVE state, the node does not actively participate in communication, i.e. neither symbols nor frames are transmitted.

In NORMAL_PASSIVE state

- The CC performs reception on the FlexRay bus
- The CC does not transmit any frames or symbols on the FlexRay bus
- Clock synchronization is running
- The Host interface is operational

The CC exits from this state to

- HALT state by writing 0110_B to bits FLXAnFRSUCC1.CMD[3:0] (HALT command, at the end of the current cycle)
- HALT state by writing 0111_B to bits FLXAnFRSUCC1.CMD[3:0] (FREEZE command, immediately)
- HALT state due to change of the error state from PASSIVE to COMM_HALT
- NORMAL_ACTIVE state due to change of the error state from PASSIVE to ACTIVE. The transition takes place when bits FLXAnFRCCEV.PTAC[4:0] equals bits FLXAnFRSUCC1.PTA[4:0] - 1
- To READY state by writing 0010_B to bits FLXAnFRSUCC1.CMD[3:0] (READY command)

18.3.6.9 HALT State

In this state all communication (reception and transmission) is stopped.

The CC enters this state

- By writing 0110_B to bits FLXAnFRSUCC1.CMD[3:0] (HALT command) while the CC is in NORMAL_ACTIVE or NORMAL_PASSIVE state
- By writing 0111_B to bits FLXAnFRSUCC1.CMD[3:0] (FREEZE command) from all states
- When exiting from NORMAL_ACTIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit and FLXAnFRSUCC1.HCSE is set to 1
- When exiting from NORMAL_PASSIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit and FLXAnFRSUCC1.HCSE is set to 1

The CC exits from this state to DEFAULT_CONFIG state

- By writing 0001_B to bits FLXAnFRSUCC1.CMD[3:0] (CONFIG command)

When the CC enters HALT state, all configuration and status data is maintained for analyzing purposes.

When the Host writes 0110_B to bits FLXAnFRSUCC1.CMD[3:0] (HALT command), the CC sets flag FLXAnFRCCSV.HRQ to 1 and enters HALT state at the next end of cycle.

When the Host writes 0111_B to bits FLXAnFRSUCC1.CMD[3:0] (FREEZE command), the CC enters HALT state immediately and sets flag FLXAnFRCCSV.FSI to 1.

The POC state from which the transition to HALT state took place can be read from FLXAnFRCCSV.PSL[5:0].

18.3.7 Network Management

The accrued Network Management (NM) vector can be read from registers FLXAnFRNMV1 to FLXAnFRNMV3. The CC performs a bit-wise OR operation over all NM vectors out of all received valid NM frames with the Payload Preamble Indicator (PPI) bit set. Only static frames may be configured to hold NM information. The CC updates the NM vector at the end of each cycle.

The length of the NM vector can be configured from 0 to 12 bytes by bits FLXAnFRNEMC.NML[3:0]. The NM vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay frames with the PPI bit set as 1, bit PPIT in the header section of the respective transmit buffer has to be set to 1 via bit FLXAnFRWRHS1.PPIT. In addition the Host has to write the NM information to the data section of the respective transmit buffer.

The evaluation of the NM vector has to be done by the application running on the Host.

CAUTIONS

1. In case a message buffer is configured for transmission / reception of network management frames, the payload length configured in header 2 of that message buffer should be equal or greater than the length of the NM vector configured by the FLXAnFRNEMC.NML[3:0] bits.
 2. When the CC transits to HALT state, the cycle count is not incremented and therefore the NM vector is not updated. In this case FLXAnFRNMV1 to FLXAnFRNMV3 holds the value from the cycle before.
-

18.3.8 Filtering and Masking

Filtering is done by comparison of the configuration of assigned message buffers against actual slot and cycle counter values and channel ID (channel A, B). A message buffer is only updated / transmitted if the required matches occur.

Filtering is done on:

- Slot Counter
- Cycle Counter
- Channel ID

The following filter combinations for acceptance / transmit filtering are allowed:

- Slot Counter + Channel ID
- Slot Counter + Cycle Counter + Channel ID

All configured filters must match in order to store a received message in a message buffer.

CAUTION

For the FIFO the acceptance filter is configured by the FIFO Rejection Filter (FLXAnFRFRF) and the FIFO Rejection Filter Mask (FLXAnFRFRFM).

A message will be transmitted in the time slot corresponding to the configured frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

18.3.8.1 Slot Counter Filtering

Every transmit and receive buffer contains a frame ID stored in the header section. This frame ID is compared against the actual slot counter value in order to assign receive and transmit buffers to the corresponding slot.

If two or more message buffers are configured with the same frame ID and channel ID, and if they have a matching cycle counter filter value for the same slot, then the message buffer with the lowest message buffer number is used.

18.3.8.2 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in header section 1 of each message buffer.

If message buffer 0 resp. 1 is configured to hold the startup / sync frame or the single slot frame by bits FLXAnFRSUCC1.TXST, FLXAnFRSUCC1.TXSY, and FLXAnFRSUCC1.TSM, cycle counter filtering for message buffer 0 resp. 1 shall be disabled.

CAUTION

Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay network is not allowed.

The set of cycle numbers belonging to a cycle set is determined as described in **Table 18.98**.

Table 18.98 Definition of cycle set

Cycle Code	Matching Cycle Counter Values
0b000000x	all Cycles
0b000001c	every second Cycle at (Cycle Count) mod2 = c
0b00001cc	every fourth Cycle at (Cycle Count) mod4 = cc
0b0001ccc	every eighth Cycle at (Cycle Count) mod8 = ccc
0b001cccc	every sixteenth Cycle at (Cycle Count) mod16 = cccc
0b01ccccc	every thirty-second Cycle at (Cycle Count) mod32 = ccccc
0b1cccccc	every sixty-fourth Cycle at (Cycle Count) mod64 = ccccc

Table 18.99 below gives some examples for valid cycle sets to be used for cycle counter filtering.

Table 18.99 Examples for valid cycle sets

Cycle Code	Matching Cycle Counter Values
0b0000011	1-3-5-7-.... -63
0b0000100	0-4-8-12-.... -60
0b0001110	6-14-22-30-.... -62
0b0011000	8-24-40-56
0b0100011	3-35
0b1001001	9

The received message is stored only if the cycle counter value of the cycle during which the message is received matches an element of the receive buffer's cycle set. Channel ID and frame ID must also be met.

The content of a transmit buffer is transmitted on the configured channel(s) when an element of the cycle set matches the current cycle counter value. Channel ID and frame ID must also be met.

18.3.8.3 Channel ID Filtering

There is a 2-bit channel filtering field (CH) located in the header section of each message buffer in the Message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see **Table 18.100**).

Table 18.100 Channel filtering configuration

CH[1:0]	Transmit Buffer transmit frame	Receive Buffer store valid receive frame
00	no transmission	ignore frame
01	on channel A	received on channel A
10	on channel B	received on channel B
11	on both channels (static segment only)	received on channel A or B (store first semantically valid frame, static segment only)

The contents of a transmit buffer is transmitted on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be set up for transmission on both channels (CH = “11_B”).

Valid received frames are stored if they are received on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a receive buffer may be setup for reception on both channels (CH = “11”).

CAUTION

If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no frames are transmitted resp. received frames are ignored (same function as CH = “00”).

18.3.8.4 FIFO Filtering

For FIFO filtering registers FLXAnFRFRF and FLXAnFRFRFM are used. The FIFO filter consists of channel filter bits FLXAnFRFRF.CH[1:0], frame ID filter bits FLXAnFRFRF.FID[10:0], and cycle counter filter bits FLXAnFRFRF.CYF[6:0]. Registers FLXAnFRFRF and FLXAnFRFRFM can be configured in DEFAULT_CONFIG or CONFIG state only. The filter configuration in the header section of message buffers belonging to the FIFO is ignored.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by FLXAnFRFRF.CYF, all frames are rejected.

A valid received frame is stored in the FIFO if channel ID, frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

18.3.9 Transmit Process

18.3.9.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the frame ID corresponding to the next sending slot is selected for transmission.

The data section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

18.3.9.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest frame ID) is selected next. In the dynamic segment different slot counter sequences on channel A and channel B are possible (concurrent sending of different frame IDs on both channels).

The data section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

The start of latest transmit configured by bits `FLXAnFRMHDC.SLT[12.0]` defines the maximum minislot value allowed before inhibiting new frame transmission in the dynamic segment of the current cycle.

18.3.9.3 Transmit Buffers

FlexRay message buffers can be configured as transmit buffers by programming bit `CFG` in the header section of the respective message buffer to 1 via `FLXAnFRWRHS1`.

There exist the following possibilities to assign a transmit buffer to the CC channels:

- Static segment: channel A or channel B,
channel A and channel B
- Dynamic segment: channel A or channel B

Message buffer 0 resp. 1 is dedicated to hold the startup frame, the sync frame, or the designated single slot frame as configured by `FLXAnFRSUCC1.TXST`, `FLXAnFRSUCC1.TXSY`, and `FLXAnFRSUCC1.TSM`. In this case, it can be reconfigured in `DEFAULT_CONFIG` or `CONFIG` state only. This ensures that any node transmits at most one startup / sync frame per communication cycle. Transmission of startup / sync frames from other message buffers is not possible.

All other message buffers configured for transmission in static or dynamic segment are reconfigurable during runtime depending on the configuration of bits `FLXAnFRMRC.SEC[1.0]` (see **Section 18.3.12.1, Reconfiguration of Message Buffers**). Due to the organization of the data partition in the Message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the header section of a message buffer may lead to erroneous configurations.

If a message buffer is reconfigured (header section updated) during runtime, it may happen that this message buffer is not send out in the respective communication cycle.

The CC does not have the capability to calculate the header CRC. The Host is supposed to provide the header CRCs for all transmit buffers. If network management is required, the Host has to set the `PPIT` bit in the header section of the respective message buffer to 1 and write the network management information to the data section of the message buffer (see **Section 18.3.7, Network Management**).

The payload length field configures the payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by

FLXAnFRMHDC.SFDL[6.0], the CC generates padding bytes to ensure that frames have proper physical length. The padding pattern is “0000_H”.

CAUTION

In case of an odd payload length (PLC = 1, 3, 5, so on) the application has to write zero to the last 16 bit of the message buffers data section to ensure that the padding pattern is 0000_H.

Each transmit buffer provides a transmission mode flag TXM that allows the Host to configure the transmission mode for the transmit buffer. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode.

In single-shot mode the CC resets the respective TXR flag to 0 after transmission has completed. Now the Host may update the transmit buffer.

In continuous mode, the CC does not reset the respective transmission request flag TXR to 0 after successful transmission. In this case a frame is sent out each time the filter criteria match. The TXR flag can be reset to 0 by the Host by writing the respective message buffer number to the FLXAnFRIBCR register while bit FLXAnFRIBCM.STXRH is set to 0.

If two or more transmit buffers meet the filter criteria simultaneously, the transmit buffer with the lowest message buffer number will be transmitted in the respective slot.

18.3.9.4 Frame Transmission

The following steps are required to prepare a message buffer for transmission:

- Configure the transmit buffer in the Message RAM via registers FLXAnFRWRHS1 to FLXAnFRWRHS3
- Write the data section of the transmit buffer via register FLXAnFRWRDSm
- Transfer the configuration and message data from Input Buffer to the Message RAM by writing the number of the target message buffer to register FLXAnFRIBCR
- If configured in register FLXAnFRIBCM, the transmission request flag TXR for the respective message buffer will be set as soon as the transfer has completed, and the message buffer is ready for transmission.
- Check whether the message buffer has been transmitted by checking the respective TXR bit (TXR = 0) in the FLXAnFRTRXQ1 to FLXAnFRTRXQ4 registers (single-shot mode only).

After transmission has completed, the respective TXR flag in the FLXAnFRTXRQ1 to FLXAnFRTXRQ4 registers is reset to 0 (single-shot mode), and, if bit MBI in the header section of the message buffer is set to 1, bit FLXAnFRSIR.TXI is set to 1. If enabled, an interrupt is generated.

18.3.9.5 Null Frame Transmission

If in static segment the Host does not set the transmission request flag to 1 before transmit time, the CC transmits a null frame with the null frame indication bit set to 0 and the payload data set to zero.

In the following cases the CC transmits a null frame:

- If the message buffer with the lowest message buffer number matching the filter criteria does not have its transmission request flag set (TXR = 0) to 1.
- No transmit buffer configured for the slot has a cycle counter filter that matches the current cycle. In this case, no message buffer status FLXAnFRMBS is updated.

Null frames are not transmitted in the dynamic segment.

18.3.10 Receive Process

18.3.10.1 Dedicated Receive Buffers

A portion of the FlexRay message buffers can be configured as dedicated receive buffers by programming bit CFG in the header section of the respective message buffer to 0 via FLXAnFRWRHS1.

The following possibilities exist to assign a receive buffer to the CC channels:

- Static segment: channel A or channel B,
channel A and channel B (the CC stores the first semantically valid frame)
- Dynamic segment: channel A or channel B

The CC transfers the payload data of valid received messages from the shift register of the FlexRay channel protocol controller (channel A or B) to the receive buffer with the matching filter configuration. A receive buffer stores all frame elements except the frame CRC.

All message buffers configured for reception in static or dynamic segment are reconfigurable during runtime depending on the configuration of bits FLXAnFRMRC.SEC[1.0] (see **Section 18.3.12.1, Reconfiguration of Message Buffers**). If a message buffer is reconfigured (header section updated) during runtime it may happen that in the respective communication cycle a received message is lost.

If two or more receive buffers meet the filter criteria simultaneously, the receive buffer with the lowest message buffer number is updated with the received message.

18.3.10.2 Frame Reception

The following steps are required to prepare a dedicated message buffer for reception:

- Configure the receive buffer in the Message RAM via registers FLXAnFRWRHS1 to FLXAnFRWRHS3
- Transfer the configuration from Input Buffer to the Message RAM by writing the number of the target message buffer to register FLXAnFRIBCR

Once these steps are performed, the message buffer functions as an active receive buffer and participates in the internal acceptance filtering process which takes place every time the CC receives a message. The first matching receive buffer is updated from the received message.

If a valid payload segment was stored in the data section of a message buffer, the respective ND flag in the FLXAnFRNDAT1 to FLXAnFRNDAT4 registers is set to 1, and, if bit MBI in the header section of that message buffer is set to 1, bit FLXAnFRSIR.RXI is set to 1. If enabled, an interrupt is generated.

In case that bit ND was already set to 1 when the Message Handler updates the message buffer, bit FLXAnFRMBS.MLST of the respective message buffer is set to 1 and the unprocessed message data is lost.

If no frame, a null frame, or a corrupted frame was received in a slot, the data section of the message buffer configured for this slot is not updated. In this case only the respective message buffer status FLXAnFRMBS is updated.

When the Message Handler changed the message buffer status FLXAnFRMBS in the header section of a message buffer, the respective MBC flag in the FLXAnFRMBSC1 to FLXAnFRMBSC4 registers is set to 1, and if bit MBI in the header section of that message buffer is set, bit FLXAnFRSIR.MBSI is set to 1. If enabled an interrupt is generated.

If the payload length of a received frame PLR is longer than the value programmed by PLC in the header section of the respective message buffer, the data field stored in the message buffer is truncated to that length.

To read a receive buffer from the Message RAM via the Output Buffer, proceed as described in **Section 18.3.12.2 (2), Data Transfer from Message RAM to Output Buffer.**

CAUTION

The ND and MBC flags are automatically cleared by the Message Handler when the payload data and the header of a received message have been transferred to the Output Buffer, respectively.

18.3.10.3 Null Frame Reception

The payload segment of a received null frame is not copied into the matching dedicated receive buffer. If a null frame has been received, only the message buffer status FLXAnFRMBS of the matching message buffer is updated from the received null frame. All bits in header 2 and 3 of the matching message buffer remain unchanged. They are updated from received data frames only.

When the Message Handler changed the message buffer status FLXAnFRMBS in the header section of a message buffer, the respective MBC flag in the FLXAnFRMBSC1 to FLXAnFRMBSC4 register is set to 1, and if bit MBI in the header section of that message buffer is set to 1, flag FLXAnFRSIR.MBSI is set to 1. If enabled, an interrupt is generated.

18.3.11 FIFO Function

18.3.11.1 Description

A portion of the message buffers can be configured as a cyclic First-In-First-Out (FIFO) buffer. The group of message buffers belonging to the FIFO is contiguous in the register map starting with the message buffer referenced by FLXAnFRMRC.FFB[7.0] and ending with the message buffer referenced by FLXAnFRMRC.LCB[7.0]. Up to 127 message buffers can be assigned to the FIFO.

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case frame ID, payload length, receive cycle count, and the message buffer status FLXAnFRMBS of the addressed FIFO message buffer are overwritten with frame ID, payload length, receive cycle count, and the status from the received frame. When Flag FLXAnFRSIR.RFNE is set to 1, it shows that the FIFO is not empty. When bit FLXAnFRSIR.RFCL is set to 1, it shows that the receive FIFO fill level (FLXAnFRFSR.RFFL[7.0]) is equal or greater than the critical level as configured by FLXAnFRFCL.CL. When bit FLXAnFREIR.RFO is set to 1, it shows that a FIFO overrun has been detected. If interrupts are enabled, interrupt requests are generated.

If null frames are not rejected by the FIFO rejection filter, the null frames will be treated like data frames when they are stored into the FIFO.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the message buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available message buffer. If the PIDX register is incremented past the highest numbered message buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) message buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next message buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a message buffer belonging to the FIFO to the Output Buffer. The PUT Index Register and the GET Index Register are not accessible by the Host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message overwrites the oldest message in the FIFO. This will set FIFO overrun flag FLXAnFREIR.RFO to 1.

A FIFO non empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag FLXAnFRSIR.RFNE is set to 1. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in **Figure 18.11** for a three message buffer FIFO.

The programmable FlexRay FIFO Rejection Filter (FLXAnFRFRF) defines a filter pattern for messages to be rejected. The FIFO filter consists of channel filter, frame ID filter, and cycle counter filter. If bit FLXAnFRFRF.RSS is set to 1, all messages received in the static segment are rejected by the FIFO. If bit FLXAnFRFRF.RNF is set to 1, received null frames are not stored in the FIFO.

The FlexRay FIFO Rejection Filter Mask (FLXAnFRFRFM) specifies which bits of the frame ID filter in the FIFO Rejection Filter register are marked 'don't care' for rejection filtering.

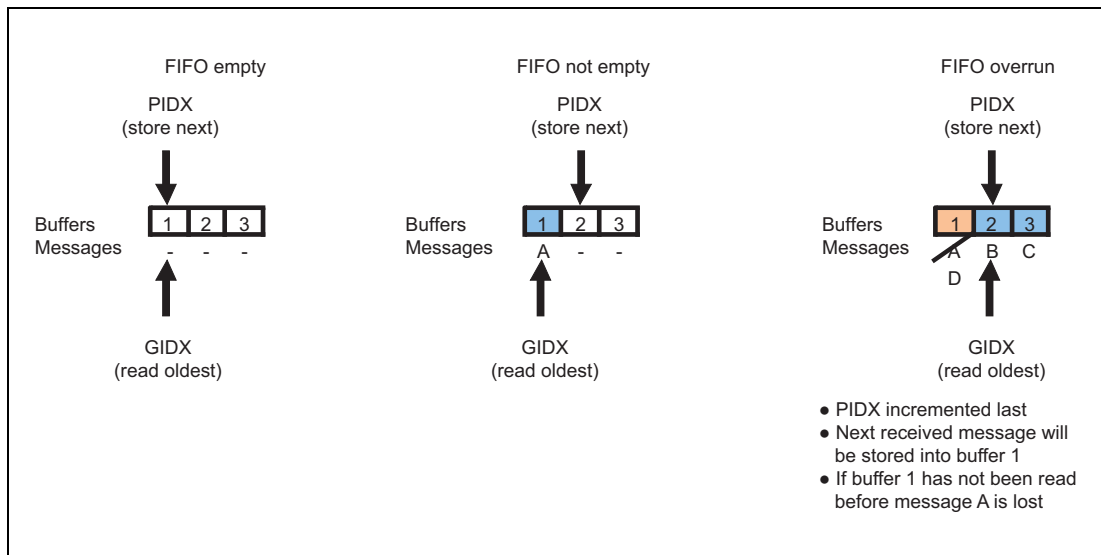

Figure 18.11 FIFO Status: Empty, Not Empty, Overrun

18.3.11.2 Configuration of the FIFO

(Re)configuration of message buffers belonging to the FIFO is only possible when the CC is in DEFAULT_CONFIG or CONFIG state. While the CC is in DEFAULT_CONFIG or CONFIG state, the FIFO function is not available.

For all message buffers belonging to the FIFO the payload length configured should be programmed to the same value via bits FLXAnFRWRHS2.PLC[6.0]. The data pointer to the first 32-bit word of the data section of the respective message buffer in the Message RAM has to be configured via bits FLXAnFRWRHS3.DP[10.0].

All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask. The values configured in the header sections of the message buffers belonging to the FIFO are, with exception of DP and PLC, irrelevant.

CAUTIONS

1. It is recommended to program the MBI bits of the message buffers belonging to the FIFO to 0 via FLXAnFRWRHS1.MBI to avoid generation of RX interrupts.
2. If the payload length of a received frame is longer than the value programmed by FLXAnFRWRHS2.PLC in the header section of the respective message buffer, the data field stored in a message buffer of the FIFO is truncated to that length.

18.3.11.3 Access to the FIFO

(1) When the output buffer is used:

For FIFO access outside DEFAULT_CONFIG and CONFIG state, the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first message buffer of the FIFO (referenced by FLXAnFRMRC.FFB[7.0]) to the register FLXAnFROBCR. The Message Handler then transfers the message buffer addressed by the GET Index Register (GIDX) to the Output Buffer. After this transfer the GET Index Register (GIDX) is incremented.

(2) When the data transfer function is used:

The message received in FIFO can be transferred to the Local RAM/Global RAM by using the output data transfer function. For the output data transfer function, see **Section 18.3.16.2, Output Data Transfer**, Output Data Transfer.

18.3.12 Message Handling

The Message Handler controls data transfers between the Input / Output Buffer and the Message RAM and between the Message RAM and the two TBFs.

Access to the message buffers stored in the Message RAM is done under control of the Message Handler state machine. This avoids conflicts between accesses of the two FlexRay channel protocol controllers and the Host to the Message RAM.

Frame IDs of message buffers assigned to the static segment have to be in the range from 1 to bits FLXAnFRGTUC7.NSS[9:0]. Frame IDs of message buffers assigned to the dynamic segment have to be in the range from bits FLXAnFRGTUC7.NSS[9:0] + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

Access of the Host to the message buffer contents using the input or output buffer function is described in this subsection. Access to the message buffer contents using the data transfer function is mentioned in **Section 18.3.16, Usage of Data Transfer**.

18.3.12.1 Reconfiguration of Message Buffers

In case that an application needs to operate with more than 128 different messages, static and dynamic message buffers may be reconfigured during FlexRay operation. This is done by updating the header section of the respective message buffer via Input Buffer registers FLXAnFRWRHS1 to FLXAnFRWRHS3.

Reconfiguration has to be enabled via control bit FLXAnFRMRC.SEC in the Message RAM Configuration register.

If a message buffer has not been transmitted / updated from a received frame before reconfiguration starts, the respective message is lost.

The point in time when a reconfigured message buffer is ready for transmission / reception according to the reconfigured frame ID depends on the actual state of the slot counter when the update of the header section has completed. Therefore it may happen that a reconfigured message buffer is not transmitted / updated from a received frame in the cycle where it was reconfigured.

The Message RAM is scanned according to **Table 18.101** below.

Table 18.101 Scan of Message RAM

Start of Scan in Slot	Scan for Slots
1	2 to 15, 1 (next cycle)
8	16 to 23, 1 (next cycle)
16	24 to 31, 1 (next cycle)
24	32 to 39, 1 (next cycle)
....

A Message RAM scan is terminated with the start of NIT regardless whether it has completed or not. The scan of the Message RAM for slots 2 to 15 starts at the beginning of slot 1 of the actual cycle. The scan of the Message RAM for slot 1 is done in the cycle before by checking in parallel to each scan of the Message RAM whether there is a message buffer configured for slot 1 of the next cycle.

The number of the first dynamic message buffer is configured by bits FLXAnFRMRC.FDB[7:0]. In case a Message RAM scan starts while the CC is in dynamic segment, the scan starts with the message buffer number configured by bit FLXAnFRMRC.FDB.

In case a message buffer should be reconfigured to be used in slot 1 of the next cycle, the following has to be considered:

- If the message buffer to be reconfigured for slot 1 is part of the “Static Buffers”, it will only be found if it is reconfigured before the last Message RAM scan in the static segment of the actual cycle evaluates this message buffer.
- If the message buffer to be reconfigured for slot 1 is part of the “Static + Dynamic Buffers”, it will be found if it is reconfigured before the last Message RAM scan in the actual cycle evaluates this message buffer.
- The start of NIT terminates the Message RAM scan. In case the Message RAM scan has not evaluated the reconfigured message buffer until this point in time, the message buffer will not be considered for the next cycle.

CAUTION

Reconfiguration of message buffers may lead to the loss of messages and therefore has to be used very carefully. In worst case (reconfiguration in consecutive cycles) it may happen that a message buffer is never transmitted / updated from a received frame.

18.3.12.2 Host access to Message RAM

The message transfer between Input Buffer and Message RAM as well as between Message RAM and Output Buffer is triggered by the Host by writing the number of the target / source message buffer to be accessed to FLXAnFRIBCR or FLXAnFROBCR register.

The FLXAnFRIBCM and FLXAnFROBCM registers can be used to write / read header and data section of the selected message buffer separately.

If bit FLXAnFRIBCM.STXR is set to 1, the transmission request flag TXR of the selected message buffer is automatically set to 1 after the message buffer has been updated. If bit FLXAnFRIBCM.STXR is reset to 0, the transmission request flag TXR of the selected message buffer is reset. This can be used to stop transmission from message buffers operated in continuous mode.

Input Buffer (IBF) and Output Buffer (OBF) are build up as a double buffer structure. One half of this double buffer structure is accessible by the Host (IBF Host / OBF Host), while the other half (IBF Shadow / OBF Shadow) is accessed by the Message Handler for data transfers between IBF / OBF and Message RAM.

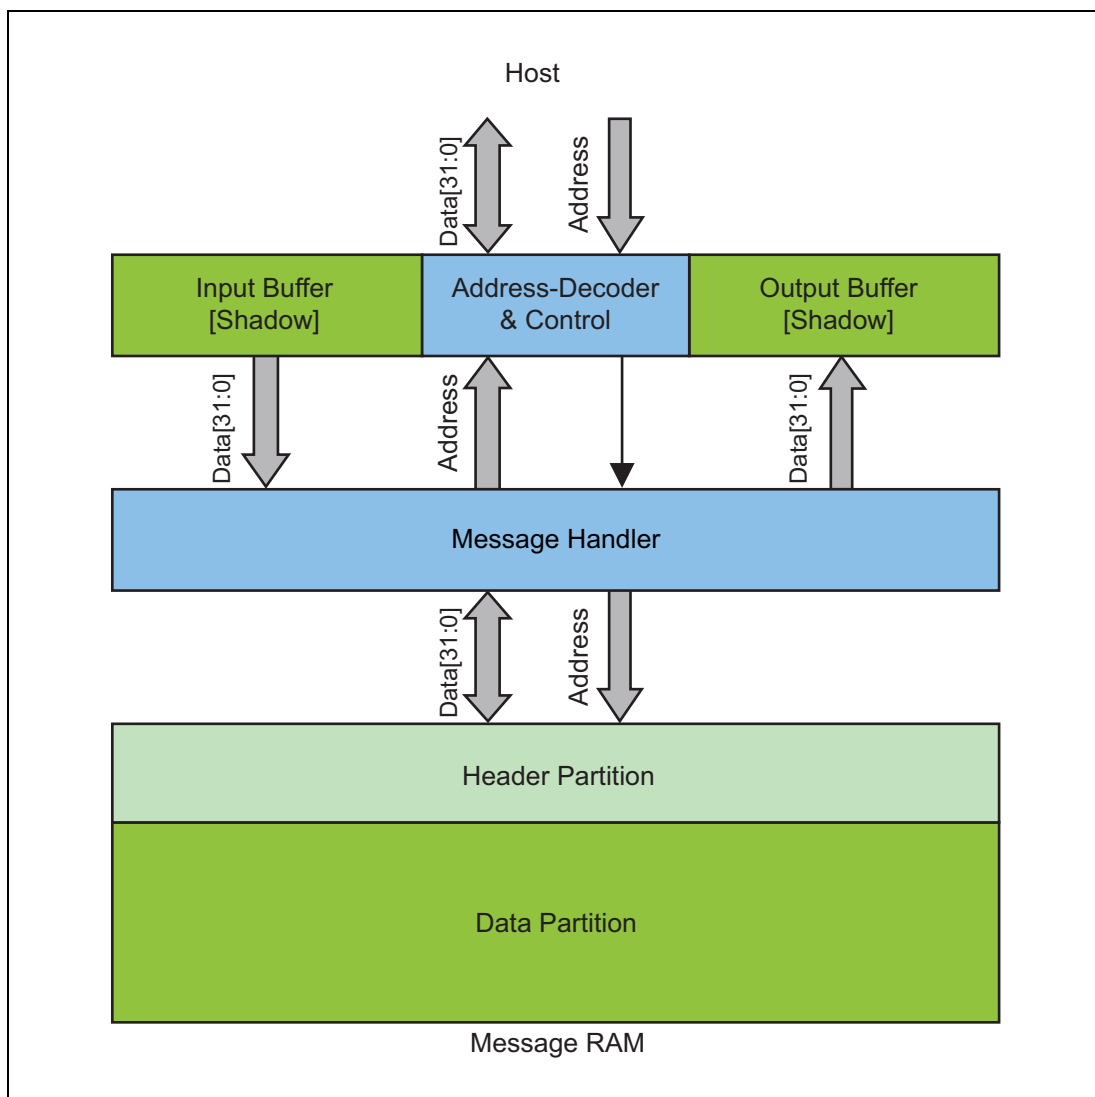

Figure 18.12 Host access to Message RAM

(1) Data Transfer from Input Buffer to Message RAM

To configure / update a message buffer in the Message RAM, the Host has to write the data to FLXAnFRWRDSm and the header to FLXAnFRWRHS1 to FLXAnFRWRHS3. The specific action is selected by configuring the FlexRay Input Buffer Command Mask FLXAnFRIBCM.

When the Host writes the number of the target message buffer in the Message RAM to bits FLXAnFRIBCR.IBRH[6:0], IBF Host and IBF Shadow are swapped (see **Figure 18.13**).

Figure 18.13 Double Buffer Structure Input Buffer

In addition the bits in the FLXAnFRIBCM and FLXAnFRIBCR registers are also swapped to keep them attached to the respective IBF section (see **Figure 18.14**).

Figure 18.14 Swapping of FLXAnFRIBCM and FLXAnFRIBCR bits

With this write operation bit FLXAnFRIBCR.IBSYS is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the message buffer in the Message RAM selected by bits FLXAnFRIBCR.IBRS[6:0].

While the Message Handler transfers the data from IBF Shadow to the target message buffer in the Message RAM, the Host may write the next message to IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, bit FLXAnFRIBCR.IBSYS is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target message buffer number to bits FLXAnFRIBCR.IBRH[6:0].

If a write access to bits FLXAnFRIBCR.IBRH[6:0] occurs while FLXAnFRIBCR.IBSYS is 1, FLXAnFRIBCR.IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, FLXAnFRIBCR.IBSYH is reset to 0, FLXAnFRIBCR.IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the message buffer numbers stored under bits FLXAnFRIBCR.IBRH[6:0] and FLXAnFRIBCR.IBRS[6:0] and the command mask flags are also swapped.

Example of a 8/16/32-bit Host access sequence:

Configure / update k-th message buffer via IBF

- Wait until FLXAnFRIBCR.IBSYH is reset
- Write data section to FLXAnFRWRDSm
- Write header section to FLXAnFRWRHS1 to FLXAnFRWRHS3
- Write Command Mask: write FLXAnFRIBCM.STXRH, FLXAnFRIBCM.LDSH, FLXAnFRIBCM.LHSH
- Demand data transfer to target message buffer: write FLXAnFRIBCR.IBRH[6:0]

Configure / update (k+1)th message buffer via IBF

- Wait until FLXAnFRIBCR.IBSYH is reset
- Write data section to FLXAnFRWRDSm
- Write header section to FLXAnFRWRHS1 to FLXAnFRWRHS3
- Write Command Mask: write FLXAnFRIBCM.STXRH, FLXAnFRIBCM.LDSH, FLXAnFRIBCM.LHSH
- Demand data transfer to target message buffer: set bits FLXAnFRIBCR.IBRH[6:0]

CAUTION

Any write access to IBF while bit FLXAnFRIBCR.IBSYH is 1 will set bit FLXAnFREIR.IIBA to 1. In this case the write access has no effect.

Table 18.102 Assignment of FLXAnFRIBCM Bits

Pos.	Access	Bit	Function
18	R	STXRS	Set Transmission Request Shadow ongoing or finished
17	R	LDSS	Load Data Section Shadow ongoing or finished
16	R	LHSS	Load Header Section Shadow ongoing or finished
2	R/W	STXRH	Set Transmission Request Host
1	R/W	LDSH	Load Data Section Host
0	R/W	LHSH	Load Header Section Host

Table 18.103 Assignment of FLXAnFRIBCR Bits

Pos.	Access	Bit	Function
31	R	IBSYS	IBF Busy Shadow, signals ongoing transfer from IBF Shadow to Message RAM
22 to 16	R	IBRS[6:0]	IBF Request Shadow, number of message buffer currently / lately updated
15	R	IBSYH	IBF Busy Host, transfer request pending for message buffer referenced by IBRH[6:0]
6 to 0	R/W	IBRH[6:0]	IBF Request Host, number of message buffer to be updated next

(2) Data Transfer from Message RAM to Output Buffer

To read a message buffer from the Message RAM, the Host has to write to register FLXAnFROBCR to trigger the data transfer as configured in FLXAnFROBCM. After the transfer has completed, the Host can read the transferred data from FLXAnFRRDDSm, FLXAnFRRDHS1 to FLXAnFRRDHS3, and FLXAnFRMBS.

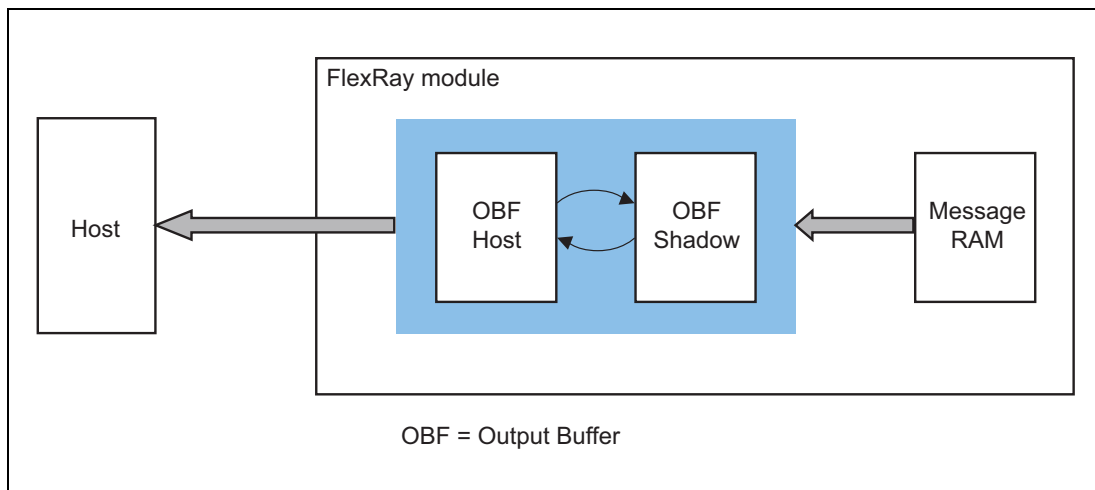

Figure 18.15 Double buffer structure Output Buffer

OBF Host and OBF Shadow as well as bits FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS, FLXAnFROBCM.RHSH, FLXAnFROBCM.RDSH and bits FLXAnFROBCR.OBRS[6:0], FLXAnFROBCR.OBRH[6:0] are swapped under control of bits FLXAnFROBCR.VIEW and FLXAnFROBCR.REQ.

Writing bit FLXAnFROBCR.REQ to 1 copies bits FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS and bits FLXAnFROBCR.OBRS[6:0] to an internal storage (see **Figure 18.16**).

After setting bit FLXAnFROBCR.REQ to 1, FLXAnFROBCR.OBSYS is set to 1, and the transfer of the message buffer selected by bits FLXAnFROBCR.OBRS[6:0] from the Message RAM to OBF Shadow is started. After the transfer between the Message RAM and OBF Shadow has completed, bit FLXAnFROBCR.OBSYS is set back to 0. Bits FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW can only be set to 1 while bit FLXAnFROBCR.OBSYS is 0.

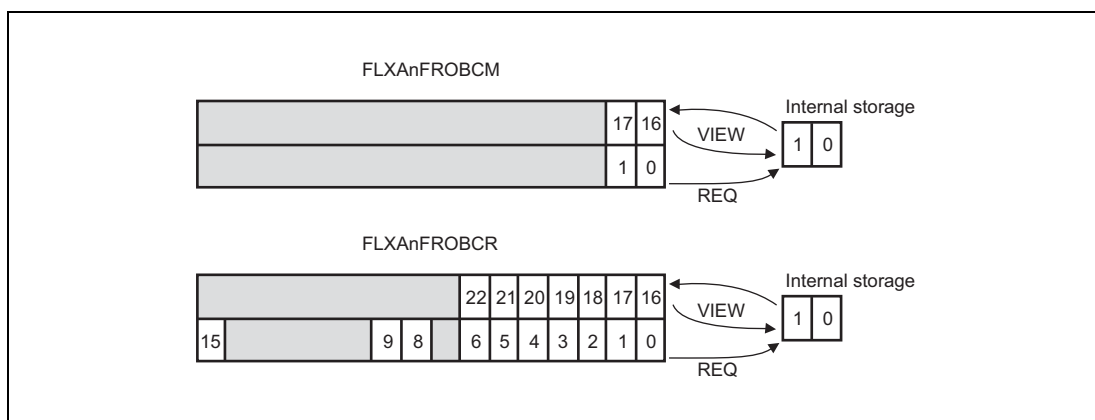

Figure 18.16 Swapping of FLXAnFROBCM and FLXAnFROBCR bits

OBF Host and OBF Shadow are switched by setting bit FLXAnFROBCR.VIEW to 1 while bit FLXAnFROBCR.OBSYS is 0 (see **Figure 18.15**).

In addition, bits FLXAnFROBCR.OBRH[6:0] and bits FLXAnFROBCM.RHSH and FLXAnFROBCM.RDSH are switched with the registers internal storage thus assuring that the message buffer number stored in bits FLXAnFROBCR.OBRH[6:0] and the mask configuration stored in FLXAnFROBCM.RHSH, FLXAnFROBCM.RDSH match the transferred data stored in OBF Host (see **Figure 18.16**).

Now the Host can read the transferred message buffer from OBF Host while the Message Handler may transfer the next message from the Message RAM to OBF Shadow.

If bits REQ and VIEW are set to 1 with the same write access while FLXAnFROBSYS is 0, FLXAnFROBSYS is automatically set to 1 and OBF Shadow and OBF Host are swapped. Additionally mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the registers internal storage to keep them attached to the respective Output Buffer transfer. Afterwards bits FLXAnFROBCR.OBRS[6:0] are copied to the register internal storage, mask bits FLXAnFROBCM.RDSS and FLXAnFROBCM.RHSS are copied to register FLXAnFROBCM internal storage, and the transfer of the selected message buffer from the Message RAM to OBF Shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF Host. When the current transfer between Message RAM and OBF Shadow has completed, this is signaled by setting FLXAnFROBCR.OBSYS back to 0.

Example of an 8/16/32-bit Host access to a single message buffer:

If a single message buffer has to be read out, two separate write accesses to FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW are necessary:

- Wait until FLXAnFROBCR.OBSYS is reset
- Write Output Buffer Command Mask FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS
- Request transfer of message buffer to OBF Shadow by writing FLXAnFROBCR.OBRS[6:0] and FLXAnFROBCR.REQ (in case of an 8-bit Host interface, FLXAnFROBCR.OBRS[6:0] have to be written before FLXAnFROBCR.REQ).
- Wait until FLXAnFROBCR.OBSYS is reset
- Toggle OBF Shadow and OBF Host by writing FLXAnFROBCR.VIEW = 1
- Read out transferred message buffer by reading FLXAnFRRDDSm, FLXAnFRRDHS1 to FLXAnFRRDHS3, and FLXAnFRMBS

Example of an 8/16/32-bit Host access sequence:

Request transfer of 1st message buffer to OBF Shadow

- Wait until FLXAnFROBCR.OBSYS is reset
- Write Output Buffer Command Mask FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS for 1st message buffer
- Request transfer of 1st message buffer to OBF Shadow by writing bits FLXAnFROBCR.OBRS[6:0] and FLXAnFROBCR.REQ (in case of accessing to the FLXAnFROBCR register in 8-bit units, bits FLXAnFROBCR.OBRS[6:0] have to be written before FLXAnFROBCR.REQ).

Toggle OBF Shadow and OBF Host to read out 1st transferred message buffer and request transfer of 2nd message buffer:

- Wait until FLXAnFROBCR.OBSYS is reset to 0
- Write Output Buffer Command Mask FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS for 2nd message buffer
- Toggle OBF Shadow and OBF Host and start transfer of 2nd message buffer to OBF Shadow simultaneously by writing FLXAnFROBCR.OBRS[6:0] of 2nd message buffer, bits FLXAnFROBCR.REQ, and FLXAnFROBCR.VIEW (in case of and 8-bit access to register FLXAnFROBCR, bits FLXAnFROBCR.OBRS[6:0] have to be written before bits FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW).
- Read out 1st transferred message buffer by reading FLXAnFRRDDSm, FLXAnFRRDHS1 to FLXAnFRRDHS3, and FLXAnFRMBS

Demand access to last requested message buffer without request of another message buffer:

- Wait until FLXAnFROBCR.OBSYS is reset to 0
- Demand access to last transferred message buffer by writing FLXAnFROBCR.VIEW
- Read out last transferred message buffer by reading FLXAnFRRDDSm, FLXAnFRRDHS1 to FLXAnFRRDHS3, and FLXAnFRMBS

Table 18.104 Assignment of FLXAnFROBCM bits

Pos.	Access	Bit	Function
17	R	RDSH	Data Section available for Host access
16	R	RHSH	Header Section available for Host access
1	R/W	RDSS	Read Data Section Shadow
0	R/W	RHSS	Read Header Section Shadow

Table 18.105 Assignment of FLXAnFROBCR bits

Pos.	Access	Bit	Function
22 to 16	R	OBRH[6:0]	OBF Request Host, number of message buffer available for Host access
15	R	OBSYS	OBF Busy Shadow, signals ongoing transfer from Message RAM to OBF Shadow
9	R/W	REQ	Request Transfer from Message RAM to OBF Shadow
8	R/W	VIEW	View OBF Shadow, swap OBF Shadow and OBF Host
6 to 0	R/W	OBRS[6:0]	OBF Request Shadow, number of message buffer for next request

18.3.12.3 FlexRay Protocol Controller Access to Message RAM

The two TBFs (A,B) are used to buffer the data for transfer between the two FlexRay Protocol Controllers and the Message RAM.

Each TBF is build up as a double buffer, able to store two complete FlexRay messages. There is always one buffer assigned to the corresponding Protocol Controller while the other one is accessible by the Message Handler.

If e.g. the Message Handler writes the next message to be sent to TBF Tx, the FlexRay Channel Protocol Controller can access TBF Rx to store the message it is actually receiving. During transmission of the message stored in TBF Tx, the Message Handler transfers the last received message stored in TBF Rx to the Message RAM (if it passes acceptance filtering) and updates the respective message buffer.

Data transfers between the TBFs and the shift registers of the FlexRay Channel Protocol Controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay messages.

Figure 18.17 Access to TBFs

18.3.13 Message RAM

To avoid conflicts between Host access to the Message RAM and FlexRay message reception / transmission, the Host cannot directly access the message buffers in the Message RAM. These accesses are handled via the Input and Output Buffers. The Message RAM is able to store up to 128 message buffers depending on the configured payload length.

The Message RAM is able to store up to 2048 32-bit words. To achieve the required flexibility with respect to different numbers of data bytes per FlexRay frame (0 to 254), the Message RAM has a structure as shown in **Figure 18.18**.

When a message buffer of the data section to be allocated immediately after to the header partition is set as a reception buffer (bit FLXAnFRWRHS1.CFG to 0) or reception FIFO buffer, set a 32-bit unused area (minimum) at the beginning of the data section. In this case, the data partition is allowed to start at Message RAM word number: $((\text{bits FLXAnFRMRC.LCB}[7:0] + 1) \times 4) + 1$.

When a message buffer of the data section to be allocated immediately after to the header partition is set as a transmit buffer (bit FLXAnFRWRHS1.CFG to 1), the data partition is allowed to start at Message RAM word number: $(\text{bits FLXAnFRMRC.LCB}[7:0] + 1) \times 4$.

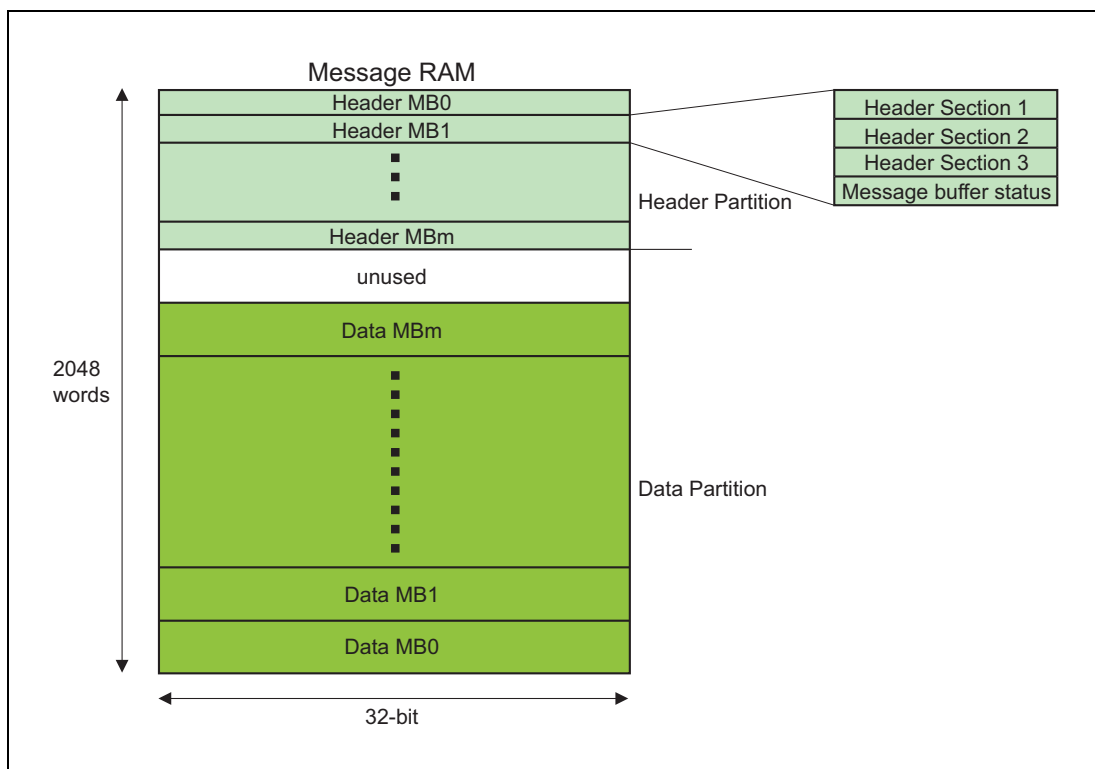

Figure 18.18 Configuration Example of Message Buffers in the Message RAM

Header Partition

Stores header sections of the configured message buffers:

- Supports a maximum of 128 message buffers
- Each message buffer has a header section of four 32 bit words
- Header 3 of each message buffer holds the 11-bit data pointer to the respective data section in the data partition

Data Partition

Flexible storage of data sections with different length. Some maximum values are:

- 30 message buffers with 254 byte data section each
- Or 56 message buffers with 128 byte data section each
- Or 128 message buffers with 48 byte data section each

CAUTION

header partition + data partition may not occupy more than 2048 32-bit words.

18.3.13.1 Header Partition

The elements used for configuration of a message buffer as well as the actual message buffer status are stored in the header partition of the Message RAM as listed in **Table 18.106** below. Configuration of the header sections of the message buffers is done via IBF (FLXAnFRWRHS1 to FLXAnFRWRHS3). Read access to the header sections is done via OBF (FLXAnFRRDHS1 to FLXAnFRRDHS3 + FLXAnFRMBS). The data pointer has to be calculated by the user to define the starting point of the data section for the respective message buffer in the data partition of the Message RAM. The data pointer should not be modified during runtime. For message buffers belonging to the receive FIFO (re)configuration is possible in DEFAULT_CONFIG or CONFIG state only.

The header section of each message buffer occupies four 32-bit words in the header partition of the Message RAM. The header of message buffer 0 starts with the first word in the Message RAM.

For transmit buffers the Header CRC has to be calculated by the Host.

Payload Length Received PLR, Receive Cycle Count RCC, Received on Channel Indicator RCI, Startup Frame Indicator SFI, Sync Frame Indicator SYN, Null Frame Indicator NFI, Payload Preamble Indicator PPI, and Reserved Bit RES are updated from received valid data frames only.

Table 18.106 Header Section of a Message Buffer in the Message RAM

18.3.13.2 Data Partition

The data partition of the Message RAM stores the data sections of the message buffers configured for reception / transmission as defined in the header partition. The number of data bytes for each message buffer can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay Protocol Controllers and the Message RAM as well as between the Host interface and the Message RAM, the physical width of the Message RAM is set to 4 bytes.

The data partition starts after the last word of the header partition. When configuring the message buffers in the Message RAM the user has to assure that the data pointers point to addresses within the data partition. **Table 18.107** below shows an example how the data sections of the configured message buffers can be stored in the data partition of the Message RAM.

The beginning and the end of a message buffer’s data section is determined by the data pointer and the payload length configured in the message buffer's header section, respectively. This enables a flexible usage of the available RAM space for storage of message buffers with different data length.

If the size of the data section is an odd number of 2-byte words, the remaining 16 bits in the last 32bit word are unused (see **Table 18.107** below).

Table 18.107 Example for Structure of the Data Partition in the Message RAM

18.3.13.3 Message Data Integrity Check

There is a data integrity checking mechanism implemented in the FlexRay core to assure the integrity of the data stored in the related RAM. Each RAM has a checksum generator / checker attached as shown in **Figure 18.19**.

When data is written to a RAM, the local checksum generator generates the checksum. The checksum is stored together with the respective data word. The checksum is checked each time a data word is read from a RAM.

If a checksum error is detected, the respective access error flag is set. The access error flags (bits AMR, ATBF1, and ATBF2) and the faulty message buffer indicators (bits FMBD, MFMB, and FMB) are located in the FlexRay Message Handler Status register (FLXAnFRMHDS). These single access error flags control the error interrupt flag (bit FLXAnFREIR.AERR).

Figure 18.19 shows the data paths between the Input Buffer, TBF and Message RAM.

Figure 18.19 Checksum Generation and Check

When an access error has been detected the following actions will be performed:

In all cases:

- The respective access error flag in FLXAnFRMHDS register is set
- The access error flag FLXAnFREIR.AERR is set and, if enabled, a module interrupt to the Host will be generated.

Additionally in specific cases:**(1) Access error during data transfer from Input Buffer 1, 2 to Message RAM when reading header section of respective message buffer from Message RAM:**

- FLXAnFRMHDS.AMR is set.
- FLXAnFRMHDS.FMBD bit is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.
- The data section of the respective message buffer is not updated.
- Transmit buffer: Transmission request for the respective message buffer is not set.

(2) Access error during scan of header sections in Message RAM:

- FLXAnFRMHDS.AMR is set.
- Bit FLXAnFRMHDS.FMBD is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.
- Ignore message buffer (message buffer is skipped).

(3) Access error during data transfer from Message RAM to TBFA and TBFB:

- FLXAnFRMHDS.AMR is set.
- Bit FLXAnFRMHDS.FMBD is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.
- Frame not transmitted, frames already in transmission are invalidated by setting the frame CRC to zero.

(4) Access error during data transfer from TBFA and TBFB to Message RAM when reading header section of respective message buffer from Message RAM:

- FLXAnFRMHDS.AMR is set.
- FLXAnFRMHDS.FMBD bit is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.
- The data section of the respective message buffer is not updated.

(5) Access error during data transfer from Message RAM to Output Buffer:

- The FLXAnFRMHDS.AMR bit is set to 1.
- FLXAnFRMHDS.FMBD bit is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.

(6) Access error during a data transfer from TBFA and TBFB to Protocol Controller 1, 2:

- FLXAnFRMHDS.ATBF1, 2 bit is set.
- Frames already in transmission are invalidated by setting the frame CRC to zero.

(7) Access error during data transfer from TBFA and TBFB to Message RAM when reading TBFA and TBFB:

- FLXAnFRMHDS.ATBF1, 2 bit is set.
- FLXAnFRMHDS.FMBD bit is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.

(8) Access error during data read of TBFA and TBFB:

When an access error occurs while the Message Handler read a frame with network management information (PPI = 1) from the TBFA and TBFB, the corresponding network management vector registers FLXAnFRNMV1 to 3 are not updated from this frame.

18.3.13.4 Host Handling of Access Errors

Access error caused by bit flips can be fixed by:

(1) Self-healing

Access errors located in the Data Section of Message RAM, TBFA or TBFB are overwritten with the next write access to the disturbed bit(s) caused by Host access or by FlexRay communication.

(2) CLEAR_RAM Command

The POC command CLEAR_RAM initializes the message RAM to zero, when called in the DEFAULT_CONFIG or CONFIG state.

(3) Temporary Unlocking of Header Section

An access error in the header section of a locked message buffer can be fixed by a transfer from the Input Buffer to the locked buffer Header Section. For this transfer, the write access to the FLXAnFRIBCR register (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state (see **Section 18.2.3.1, FLXAnFRLCK — FlexRay Lock Register**).

For that single transfer the respective message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by FLXAnFRMRC.SEC, and will be updated with new data.

18.3.14 Interrupts

In general, interrupts provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the CC, a frame is received or transmitted, a configured timer interrupt is activated, or a stop watch event occurred. This enables the Host to react very quickly on specific error conditions, status changes, or timer events. On the other hand too many interrupts can cause the Host to miss deadlines required for the application. Therefore the CC supports enable / disable controls for each individual interrupt source separately.

An interrupt may be triggered when

- An error was detected
- A status flag is set to 1
- A timer reaches a preconfigured value
- A message transfer from Input Buffer to Message RAM or from Message RAM to Output Buffer has completed
- A message transfer from the Local RAM/Global RAM to Message RAM or from Message RAM to Local RAM/Global RAM has completed
- A stop watch event occurred

Tracking status and generating interrupts when a status change or an error occurs are two independent tasks. Regardless of whether an interrupt is enabled or not, the corresponding status is tracked and indicated by the CC. The Host has access to the actual status and error information by reading registers FLXAnFREIR, FLXAnFRSIR, FLXAnFROS, FLXAnFROTS and FLXAnFRITS.

The general purpose interrupt lines to the Host, FlexRay Interrupt 0, and FlexRay Interrupt 1 are controlled by the interrupts enabled by the FLXAnFREIES and FLXAnFRSIES registers. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit FLXAnFRILE.EINT0 and FLXAnFRILE.EINT1.

The input data transfer interrupt lines to the Host, FlexRay input queue empty interrupt, FlexRay input queue full interrupt, are controlled by the enabled interrupts in FLXAnFRITS. In addition, each of the input data transfer interrupts can be enabled or disabled separately by setting the related bits in FLXAnFRITC.

The output data transfer interrupt lines to the Host, FlexRay FIFO transfer warning interrupt, FlexRay output transfer warning interrupt, FlexRay FIFO transfer interrupt, FlexRay output transfer interrupt, are controlled by the enabled interrupts in FLXAnFROTS. In addition each of the output data transfer interrupts can be enabled or disabled separately by setting the related bits in FLXAnFROTC.

The three timer interrupts lines to the Host are controlled by the enabled interrupts in FLXAnFROS. In addition each of the interrupt lines can be enabled or disabled separately by setting bit FLXAnFROC.T0IE, FLXAnFROC.T1IE and FLXAnFROC.T2IE.

When a transfer between IBF/OBF and the Message RAM has completed bit FLXAnFRSIR.TIBC or FLXAnFRSIR.TOBC is set to 1.

An stop watch event is generated by the stpwt_extfxr pin input.

18.3.16 Usage of Data Transfer

The data transfer function is for the transfer of FlexRay messages between the FlexRay module's internal message RAM and areas of user RAM such as Local RAM/Global RAM.

Data transfer from an area of user RAM to the internal message RAM (input) is started by software. Input transfer is used to set up a message buffer or to update data for transmission.

Data transfer from the internal message RAM to an area of user RAM (output) starts in response to the following events.

- Data are stored in the reception message buffer or the internal FIFO buffer of the FlexRay module.
- The state of a slot changes.
- The user issues a transfer request.

An area of the user RAM needs to be secured for the data to be transferred. The data are transferred in a defined structure.

Access to the input and output buffers by the CPU is prohibited while this function is in use.

18.3.16.1 Input Data Transfer

When the automatic input data transfer function is enabled, committed input data structures are transferred from the Local RAM/Global RAM to the FlexRay internal message RAM with minimum CPU support.

(1) Activation and deactivation

The input data transfer function should be activated before usage. The activation of the input transfer handler initializes the input queue put index (FLXAnFRITS.IPIDX[6:0]) and get index (FLXAnFRITS.IGIDX[6:0]) to zero. Also the interrupt status bits in the FLXAnFRITS register (IQEIS and IQFIS) are set to 0.

Figure 18.20 Input Transfer Enable Processing Flow

A deactivation request of the input transfer function can be made at any time. The input queue put index and the input queue status are maintained independently from the input transfer function state.

Before the transfer function gets disabled (bit FLXAnFRITS.ITS = 0), user requested input transfers and all committed input transfers will be completed.

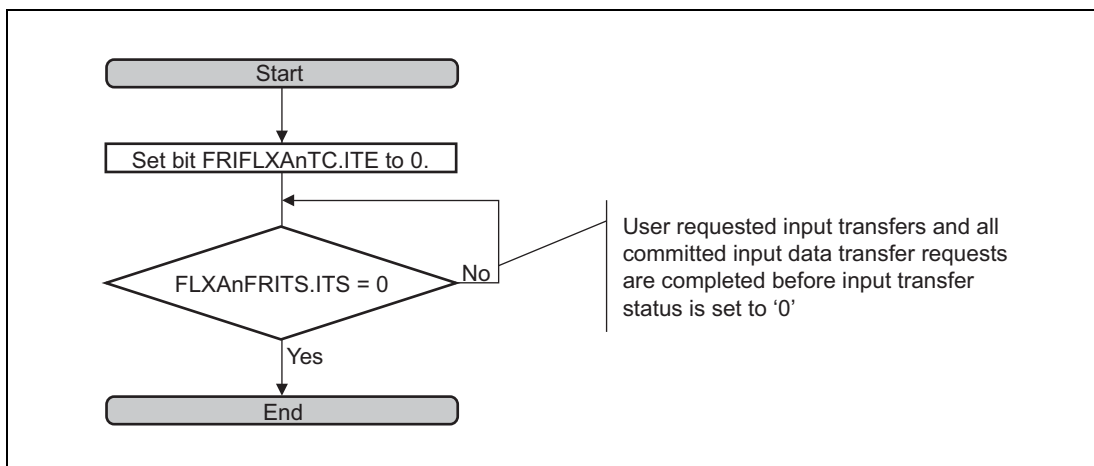

Figure 18.21 Input Transfer Disable Processing Flow

(2) Input data structure

The application has to reserve a location in the Local RAM/Global RAM to provide the content for message buffer configuration (input data structure).

The location of this input data structure needs to be defined by an input data structure pointer also located in the Local RAM/Global RAM.

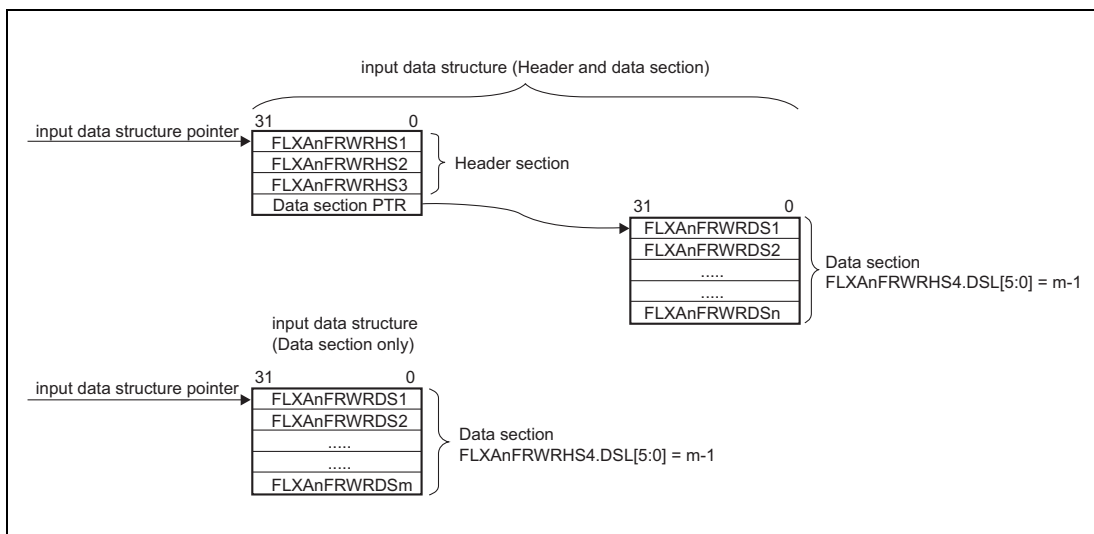

Figure 18.22 Input data structure

In general the input data structure consists of two sections, the header and the data section.

The header section consists of FLXAnFRWRHS1, FLXAnFRWRHS2, FLXAnFRWRHS3 and the data section pointer.

For bit alignment and bit function in the header section, see **Section 18.3.13.1, Header Partition**.

Depending on the settings in the control field (FLXAnFRWRHS4) located in the input pointer table, the data structure pointer is a reference to the address of FLXAnFRWRHS1 or FLXAnFRWRDS1. The data structure pointer has to be aligned to a 32 bit address.

If bit FLXAnFRWRHS4.LHS is set to 1, it is required to provide a valid header section. In this case FLXAnFRWRDS1 is the first element of the data structure.

If bit FLXAnFRWRHS4.LHS is set to 0, a header section is not required. In this case FLXAnFRWRDS1 is the first element of the data structure.

If bit FLXAnFRWRHS4.LDS is set to 1, it is required to provide a valid data section. The pointer to the data section is a reference to the address of the first payload long word (FLXAnFRWRDS1) and has to be aligned to a 32 bit address.

If bit FLXAnFRWRHS4.LDS is set to 0, a data section is not required. The data section pointer is not evaluated by the input handler.

The length of the data section and the size to be allocated in the Local RAM/Global RAM depends on the configuration of bits FLXAnFRWRHS4.DSL[5:0].

For the transfer into the FlexRay core internal message RAM the number of 16 bit words configured by bits FLXAnFRWRHS2.PLC[6:0] is used. The application has to ensure, that a proper number of data words is provided in the Local RAM/Global RAM. In case the buffer is configured by bits FLXAnFRWRHS2.PLC[6:0] to hold an odd payload length, the application has to write zero to the last 16 bit of the payload section to ensure that the padding data is all zero.

(3) Input pointer table

To transfer data from the input data structures located in the Local RAM/Global RAM to the FlexRay internal message RAM the related input data structure pointer and control field needs to be added to the input pointer table which is located in the Local RAM/Global RAM.

The location of the first element of this table is identified by the input pointer table base address (FLXAnFRIBA.ITA[31:0]). This base address has to be aligned to a 32 bit address.

The maximum number of input requests that can be queued is defined by the Input queue Table Max register (FLXAnFRITC.ITM[6:0]).

Each Input pointer table entry requires two long words. The required address range of the input pointer table for the queued transfer requests can be calculated by

$$\text{Input pointer table size (byte)} = (((\text{FLXAnFRITC.ITM}[6:0] + 1) \times 2) \times 4)$$

Equation 1

The input pointer entry for the user requested input transfer should be added after the end of the input pointer table.

The pointer table index related to this entry and hence the number to be written to FLXAnFRUIR.UIDX[7:0], is FLXAnFRITC.ITM[6:0] + 1. The address in the input pointer table related to the user requested input transfer (user input address) can be calculated by

$$\text{User input address} = \text{FLXAnFRIBA.ITA}[31:0] + \text{Input pointer table size}$$

Equation 2

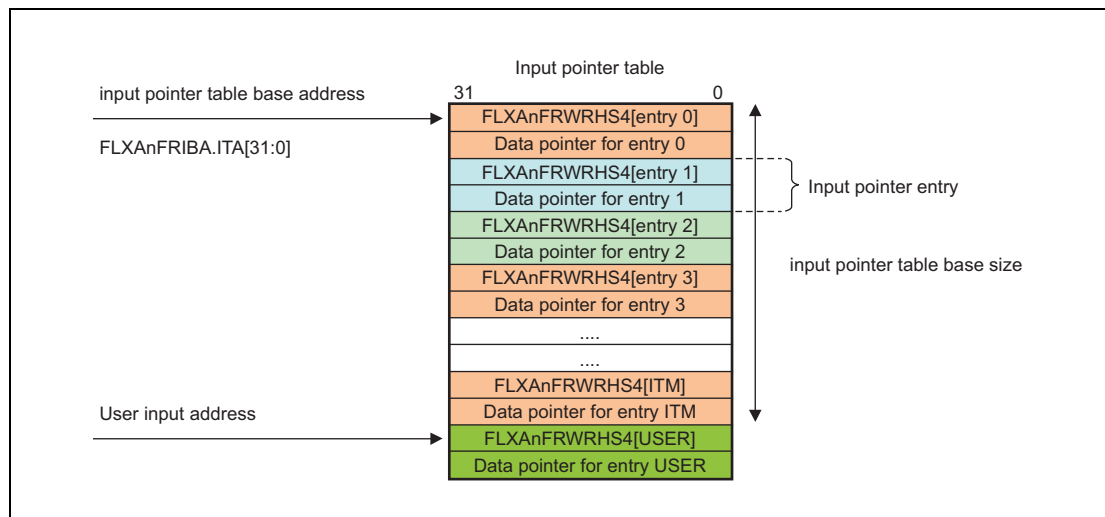

Figure 18.23 Input pointer table

The input pointer table holds the control field FLXAnFRWRHS4 and the pointers to the Local RAM/ Global RAM location where the message buffer content (header section and/or data section) is stored.

The application has to write FLXAnFRWRHS4 and the input data structure pointer at the addresses in the input pointer table related to the put index position before a transfer request is initiated.

FLXAnFRWRHS4:

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	DSL[5:0]					
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	INV	STR	LDS	LHS	—	IMBNR[6:0]						
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 18.109 FLXAnFRWRHS4 Register Contents

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, an undefined value is read. When writing, always write 0.
21 to 16	DSL[5:0]	Data Section Length Bit Specifies the length of the data section in terms of 32 bit values.
15 to 12	Reserved	When read, an undefined value is read. When writing, always write 0.
11	INV	Invalidate entry Bit 0: The data structure is valid and will be transferred to the FlexRay internal message RAM. 1: The data structure is invalid. FlexRay internal message RAM is not updated using this input pointer entry.
10	STR	Set transmission request Bit 0: The bit FLXAnFRTXRQm.TXRp for the message buffer selected by the bits IMBNR[6:0] is set to 0. No data from this message buffer is transmitted. 1: The bit FLXAnFRTXRQm.TXRp for the message buffer selected by the bits IMBNR[6:0] is set to 1 to release the message buffer for transmission. The application should not set the bit STR to 1 for receive buffers.
9	LDS	Load data section Bit 0: No update of data section. 1: Data section for the message buffer selected by the bits IMBNR[6:0] is updated.
8	LHS	Load header section Bit 0: No update of header section. 1: Header section for the message buffer selected by the bits IMBNR[6:0] is updated.
7	Reserved	When read, an undefined value is read. When writing, always write 0.
6 to 0	IMBNR[6:0]	Message buffer number to be updated Bit Selects the target message buffer number in the FlexRay internal message RAM for transfer

Note that the LHS bit should not be set for protected message buffers.

The bit LDS defines if the data section of the message buffer selected by the bits IMBNR[6:0] should be updated.

If LDS is set to 1 (DSL[5:0] + 1) 32 bit words of payload data are transferred from the Local RAM/Global RAM to the message buffer selected by the bits IMBNR[6:0].

If LDS is set to 0 no payload data is transferred from the Local RAM/Global RAM.

Note that the payload transferred is independent from the configured payload length (bits FLXAnFRWRHS2.PLC[6:0]).

The bit INV can be used to invalidate a committed data structure. This bit should be only used to cancel the transfer of committed data structures when the input queue is halted (see **Section 18.3.16.1 (5), Transfer function of dedicated message buffers**).

When this bit is set to 1 the message buffer number (IMBNR[6:0]) is not updated. When the bit is set to 0 the message buffer number (IMBNR[6:0]) is updated.

(4) Transfer function of input data structure

To use the input data structure transfer function the input transfer has to be activated (see **Section 18.3.16.1 (1), Activation and deactivation**). The activation process requires the setup of the input pointer table (see **Section 18.3.16.1 (3), Input pointer table**) in order to specify the source location (input data structures) for the data structures to be transferred. When the input transfer gets enabled the get index pointer is initialized to zero.

All FlexRay internal message buffers can be updated using the input transfer queue which is built in the input pointer table. The application has to write the pointer and control field (table entry) to the data structure to be transferred into the input pointer table. For that purpose the application has to maintain a put index for the input pointer table that indicates where the pointer has to be written to.

To commit this table entry to the input handler, the application has to write the target message buffer number to the input queue control register (bits FLXAnFRIQC.IMBNR[6:0]). Afterwards the application has to increment the application internal put index.

By writing to the input queue control register the data available bits (FLXAnFRDAm.DA[31:0]) are automatically set to 1. The input transfer handler also maintains the put index pointer in the status register (FLXAnFRITS.IPIDX[6:0]).

In case the input queue gets full (number of queued input transfer requests is equal to the input queue table size) FLXAnFRITS.IQFP and FLXAnFRITS.IQFIS are set to 1. The input queue full condition pending flag (FLXAnFRITS.IQFP) changes from 1 to 0 when there are entries in the input queue available, whereby the input queue full interrupt status flag (FLXAnFRITS.IQFIS) needs to be cleared by the application.

The application should not make any further write access to bits FLXAnFRIQC.IMBNR[6:0] as long as bit FLXAnFRITS.IQFP is 1.

In case the input queue gets empty (number of queued input transfer requests changes to zero) FLXAnFRITS.IQEIS is set to 1. The input queue empty interrupt status flag (FLXAnFRITS.IQEIS) needs to be cleared by the application.

The transfer of the input data structures to the FlexRay message RAM is controlled by a get index pointer which is handled inside the FlexRay module and flagged in bits FLXAnFRITS.IGIDX[6:0]. Note that the index is referring to the input entry and not the address offset in the input pointer table.

If the input queue is not empty, the transfer handler reads out the input pointer table entry of the transfer queue and starts the transfer of the input data structure from the address the input pointer is referring to. When all required data words are transferred to the FlexRay module, the data available flag for the transferred message buffer number is set to 0 and the get index in the transfer handler is incremented by one.

In case of an invalidated data structure (see **Section 18.3.16.1 (5), Halting the input queue**) no FlexRay internal message buffer is updated and the related data available flag is automatically set to 0. The change of the data available flag can be used to confirm the cancellation a transmit request.

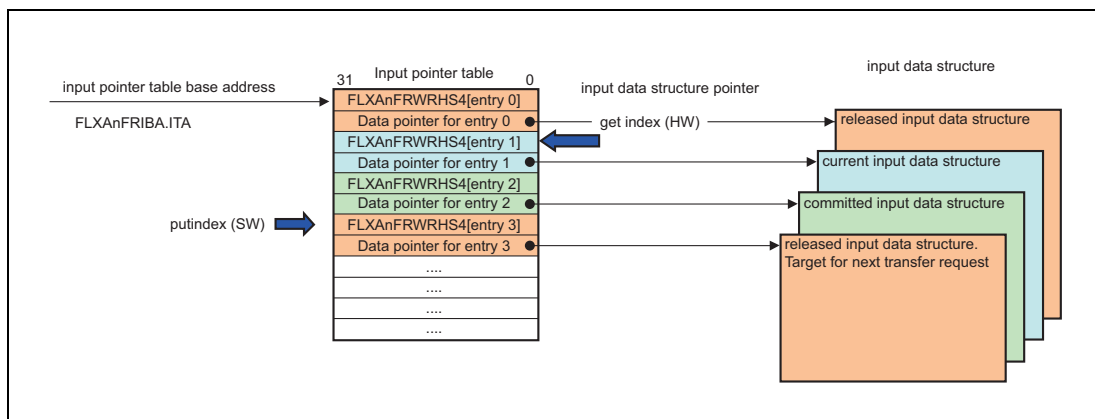

Figure 18.24 Input Pointer Table

Receive message buffers can be also configured using the input data transfer by setting up the required header sections and mark only the header section (`FLXAnFRWRHS4.LDS = 0`, `FLXAnFRWRHS4.LHS = 1`) to be updated in the FlexRay module.

(5) Halting the input queue

Committed data structures cannot be removed, but can be invalidated or updated when the input queue is halted.

To cancel data structures already committed to the input queue, the queue can be halted by writing a 1 to FLXAnFRITC.IQHR.

After the ongoing input transfer has been completed the queue is halted and FLXAnFRITS.IQH changes from 0 to 1.

To invalidate an entry of the input queue FLXAnFRWRHS4.INV has to be set to 1. All other bits in FWRHS4 should be unchanged.

The following processing flow shall be used to analyze whether a committed message has been already transferred to the FlexRay internal message RAM or not.

Figure 18.25 Input Table Analysis

In case the message buffer was already transferred to the FlexRay internal message RAM, the user input transfer request can be used to bypass the actual queue and update the required message buffer (see **Section 18.3.16.1 (6), Transfer function of user requested input transfers**).

(6) Transfer function of user requested input transfers

To use this function the input transfer has to be activated (see **Section 18.3.16.1 (1), Activation and deactivation**).

The application is capable, by using `FLXAnFRUIR.UIDX[7:0]`, to request a transfer of an input data structure. The user input transfer request is serviced first.

The application has to write the pointer and control field (table entry) to the data structure to be transferred into the input pointer table. The table entry for the user input transfer request should be added after the end of the input pointer table (see **Section 18.3.16.1 (3), Input pointer table**).

To commit this table entry to the input handler, the application has to write the index (`FLXAnFRITC.ITM[6:0] + 1`) to the user input transfer request register (`FLXAnFRUIR.UIDX[7:0]`).

By writing to the user input transfer request register, the user input transfer request pending flag (`FLXAnFRITS.UIRP`) is automatically set to 1.

As long this flag is 1 the application should not make any further user input transfer requests.

The user input transfer request pending flag (`FLXAnFRITS.UIRP`) changes from 1 to 0 when the requested input transfer is completed. As next the pending transfers are processed.

18.3.16.2 Output Data Transfer

When the output data transfer function is enabled, received messages (either in dedicated message buffers or in the FlexRay receive FIFO) are transferred to the Local RAM/Global RAM by the output data handler. The output data handler can also transfer the message buffer content to the Local RAM/Global RAM on application request. When enabled the output handler is also capable to initiate a transfer when the message buffer status has changed.

(1) Activation and deactivation

The output data transfer function should be activated before usage. The activation of the output transfer handler will initialize the FIFO put and get index pointer and FIFO fill level (FLXAnFROTS.FGIDX[4:0] and FLXAnFROTS.FFL[5:0]) to zero, set the bits FLXAnFROTS.FDA, FLXAnFROTS.OWP, FLXAnFROTS.FWP and FLXAnFROTS.UORP to 0. Also the interrupt status flags FLXAnFROTS.OTIS, FLXAnFROTS.FIS, FLXAnFROTS.OWIS and FLXAnFROTS.FWIS) are set to 0.

The activation has no influence to the data available flags (FLXAnFRDAm.DA[31:0]) which are related to the dedicated buffers; these flags have to be cleared by the application.

Figure 18.26 Output Transfer Enable Processing Flow

A deactivation request of the output data transfer function can be made at any time. An ongoing transfer will be completed and the completion of this transfer will be flagged. During this time FLXAnFROTS.OTS remains 1.

When FLXAnFROTS.OTS changes from 1 to 0, the output transfer function is deactivated. The data available status flags and the FIFO get index are still retained when the output transfer function is disabled.

Figure 18.27 Output Transfer Disable Processing Flow

(2) Output transfer data structure

The data in the Local RAM/Global RAM is stored in an output data structure. The location of the output data structures are determined by output data structure pointers also located in the Local RAM/Global RAM. The output data structure and indexing is visualized in **Figure 18.28**.

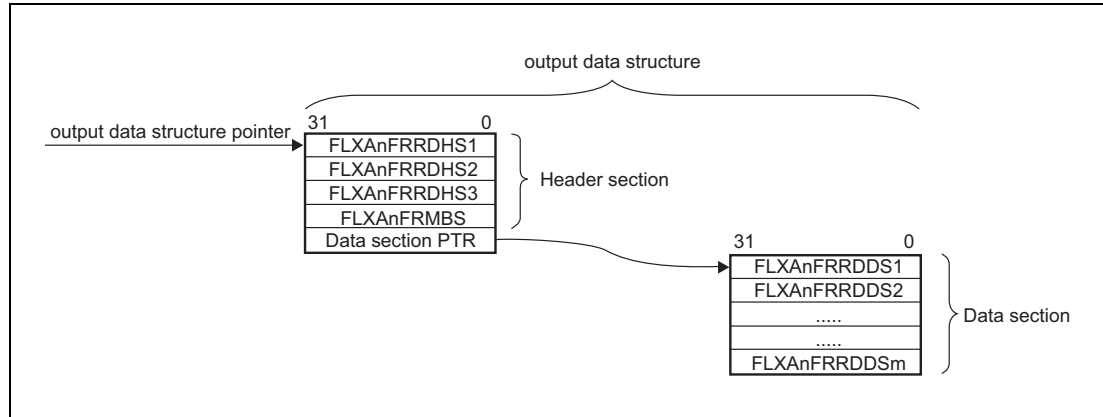

Figure 18.28 Output Data Structure

The output data structure consists of two sections, the header and data section. The header section consists of FLXAnFRRDHS1, FLXAnFRRDHS2, FLXAnFRRDHS3, FLXAnFRMBS and the data section pointer. FLXAnFRRDHS1 is the first element of the structure and has to be aligned to a 32 bit address. The data structure pointer is a reference to the address of FLXAnFRRDHS1. For information about the bit alignment and bit function within the header section refer to **Section 18.3.13.1, Header Partition**.

FLXAnFRRDDS1 is the first element of the data section. The data section pointer needs to be aligned with a 32-bit address corresponding to the FLXAnFRRDDS1 address.

The length of the data section as well as the total structure size to be allocated in the Local RAM/Global RAM depends on the configured payload length (bits FLXAnFRRDHS2.PLC[6:0]) of the related message buffer. In case the configured payload length is an odd number of words or the received payload length (bits FLXAnFRRDHS2.PLR[6:0]) is smaller than the configured payload length, the remaining data words in the Local RAM/Global RAM are unused and should not be used by the application.

The output data structure is identical for all three kinds of output transfers. In case only the header section is transferred the data section pointer is not evaluated by the output handler and the data section remains unchanged.

(3) Output pointer table

For the output data transfer function the application needs to setup an output pointer table in the Local RAM/Global RAM. The location of the first element of this table should be programmed into the output pointer table base address (bits FLXAnFROBA.OTA[6:0]). This base address has to be aligned to a 32 bit address.

The size of the output pointer table is defined by the maximum of: the last configured dedicated message buffer and the highest message buffer number which will be used for the user output transfer request.

The output pointer table holds pointers (output data structure pointers) to the Local RAM/Global RAM location where a memory space is reserved for the target message buffer content (header section and data section).

There is a fixed linear relationship between the address of the entries in the output pointer table and the number of the related message buffers (see **Figure 18.29**): the output pointer table starts with the entry for message buffer number 0 at the address configured in bits FLXAnFROBA.OTA[31:0] and continues in ascending order for each following message buffer number, by 32 bit aligned address (e.g. message buffer 1 at output pointer table address FLXAnFROBA.OTA[31:0] + 4, message buffer 2 at output pointer table address FLXAnFROBA.OTA[31:0] + 8, etc.) for all possible message buffers.

When a set of bit FLXAnFRNDATm.NDp is the only transfer condition (FLXAnFROTC.OTCS is set to 0), only message buffers configured as a dedicated receive buffer or that will be used for user output transfer requests need have valid pointer entries.

When a set of bit FLXAnFRNDATm.NDp or FLXAnFRMBSCm.MBCp is the transfer condition (FLXAnFROTC.OTCS is set to 1), all dedicated receive buffer and dedicated transmit buffers need to have valid pointer entries.

(4) FIFO output pointer table

The FlexRay module internal FIFO can be extended by a queued buffer structure in the Local RAM/Global RAM.

If the FlexRay module internal FIFO is used the application needs to setup the FIFO output pointer table. The location of the first element of this table is identified by the FIFO pointer table base address (bits FLXAnFRFBA.FTA[31:0]). This base address has to be aligned to a 32 bit address.

The size of the FIFO pointer table and hence the maximum number of messages that can be added to the queue, is defined by FIFO Table Max (bits FLXAnFROTC.FTM[4:0]).

The FIFO pointer table holds pointers (output data structure pointers) to the Local RAM/Global RAM location where a memory space is reserved the target message buffer content (header section and data section). For each table entry a data pointer shall be configured in this table.

(5) Transfer function of dedicated message buffers

To use this transfer function the output transfer has to be activated (see **Section 18.3.16.2 (1), Activation and deactivation**). The activation process requires to setup the output pointer table (see **Section 18.3.16.2 (3), Output pointer table**) in order to specify the destination location (output data structures) for the data to transfer. **Figure 18.29** shows how the output pointer table references the output data structures.

Figure 18.29 Output Data Structure and Indexing

With FLXAnFROTC.OTCS the output transfer condition can be selected between the 'New data only mode' and the 'New data and status changed mode'.

In the 'New data only mode' an output data transfer is initiated when a valid FlexRay data frame has been stored into a dedicated receive buffer which causes the related FLXAnFRNDATm.NDp flag to set. The FLXAnFRNDATm.NDp flag is automatically set to 0 during the transfer procedure. The header section is also transferred and hence the FLXAnFRMBSCm.MBCp flag is set to 0.

In the 'New data and status changed mode' an output data transfer is initiated as described in the 'New data only mode'. In addition an output data transfer is initiated when only the message buffer status has been changed which causes the related FLXAnFRMBSCm.MBCp flag to be set. In this case only the header section is transferred. The FLXAnFRMBSCm.MBCp flag is automatically set to 0 during the transfer procedure.

After transferring the message buffer data from the FlexRay internal message RAM to the output data structure the corresponding data available flag in the FLXAnFRDAm ($m = 0$ to 3) registers is set to 1. The update of the output data structure is also flagged by the setting of the output transfer interrupt status flag (FLXAnFROTS.OTIS).

As long as the data available flag remains 1 the corresponding output data structure will not be updated.

In the case

- the data available flag is 1 and a valid received message was stored or
- when FLXAnFROTC.OTCS is 1 and the message buffer status was updated,

the output transfer warning interrupt flag (FLXAnFROTS.OWIS) is set to 1 notifying the application that new data is available but the output data structure transfer cannot be processed. In addition FLXAnFROTS.OWP is set to 1 that continuously flags that status of the output transfer warning condition.

If a valid receive message in the FlexRay internal message RAM is overwritten by an additional receive message, the message lost flag (FLXAnFRMBS.MLST) is set to 1. This flag can be evaluated after the message buffer has been transferred into an output data structure.

Following sections are giving a guidance how output data structures can be handled.

(a) Data section copy method

One option is to copy the information from the output data structure to a different location of the Local RAM/Global RAM and then release the output data structure by clearing the related data available flag. The application should use the copied information for further processing.

(b) Data structure pointer method

A different option is to modify the output data structure pointer in the output pointer table and to release the output data structure by clearing the related data available flag. The changed output data pointer should refer to a free data structure. The application should use the old data structure for further processing.

(c) Data section pointer method

A third option is to modify the data section pointer in the output data structure and to release the output data structure by clearing the related data available flag. The changed data section pointer should refer to a free memory area. The application should use the old data section for further processing by forwarding the data section pointer.

(6) Transfer function of FIFO message buffers

To use this buffer transfer function the output transfer has to be activated (see **Section 18.3.16.2 (1), Activation and deactivation**). The activation process requires the setup of the FIFO pointer table (see **Section 18.3.16.2 (4), FIFO output pointer table**) in order to specify a location in the Local RAM/Global RAM reserved for the storage of the required output data structures.

A FIFO data transfer is initiated when a valid FlexRay data frame has been stored in the FlexRay internal FIFO.

After transfers from the internal FIFO to the output data structure, the FIFO interrupt status flag (FLXAnFROTS.FIS) and FIFO data available bit (FLXAnFROTS.FDA) are set to 1. The bit FLXAnFROTS.FIS can be used as an interrupt source. The bit FLXAnFROTS.FDA indicates that the FIFO is not empty.

The size of the output structure is up to the maximum number of entries in the FIFO table (as set by the FLXAnFROTC.FTM[4:0] bits).

The transfer to the extended FIFO buffer structure is controlled by index pointers. This put index is controlled by the FIFO transfer handler and is incremented after transferring a message to the output data structure.

The FIFO reception handler also maintains a get index which is indicated in FLXAnFROTS.FGIDX[4:0]. The value of this get index is known by the application by either reading the status or maintaining a software variable. The get index (the value after a reset is 00000_B) is incremented by one when the application releases the oldest entry of the FIFO queue by writing 1 to FLXAnFROTS.FDA. By comparing the put index and the get index the FIFO handler knows about the current fill level of the queued buffer structure.

The current FIFO fill level is flagged in FLXAnFROTS.FFL[5:0]. When FLXAnFROTS.FDA is 1, there is at least one entry in the FIFO queue.

In case the queued buffer structure in the Local RAM/Global RAM is full (FLXAnFROTS.FFL[5:0] = FLXAnFROTC.FTM[4:0] + 1), no further transfers are initialized, new messages remain in the FlexRay internal FIFO and the FIFO transfer warning interrupt status flag (FLXAnFROTS.FWIS) is set to 1.

In case the FlexRay internal FIFO structure becomes full, messages in the FlexRay internal FIFO structure may be overwritten. The related status flags and configuration registers of the FlexRay core module can be used to generate desired warning notifications.

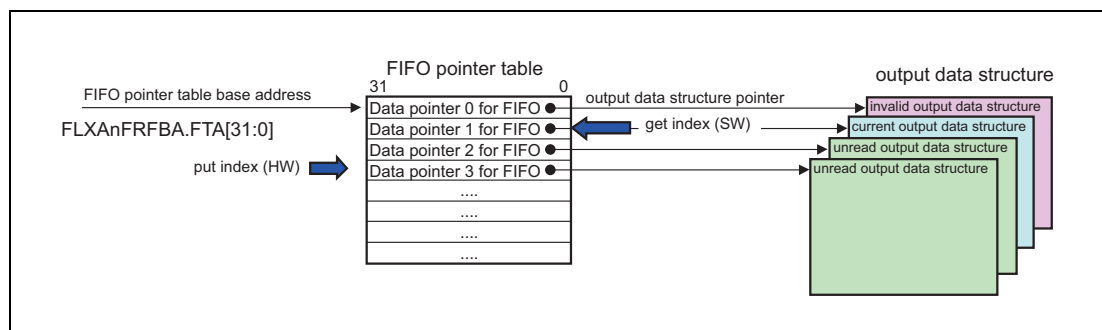

Figure 18.30 FIFO Pointer Table

(7) Transfer function of user output transfer requests

To use this transfer function the output transfer has to be activated (see **Section 18.3.16.2 (1), Activation and deactivation**). The activation process requires to setup the output pointer table (see **Section 18.3.16.2 (3), Output pointer table**) in order to specify the location in the Local RAM/ Global RAM reserved for the transfer of the data (output data structures).

The application is capable, by using FLXAnFRUOR.UMBNR[6:0], to request a transfer of dedicated message buffer to an output data structure. Except in CONFIG state, message buffers which are part of the FlexRay internal FIFO should not be requested.

The header section is always transferred to the output data structure. The transfer of the data section can be enabled by setting FLXAnFRUOR.URDS to 1. The selected message buffer content is stored in the output data structure location determined by the pointers in the output pointer table.

The data available status and transfer blocking by bits FLXAnFRDAm.DA[31:0] is also used for the user requested transfers. Therefore bits FLXAnFRDAm.DA[31:0] related to the requested buffer number (FLXAnFRUOR.UMBNR[6:0]) should be released before making the transfer request.

After writing to FLXAnFRUOR.UMBNR[6:0], the bit FLXAnFROTS.UORP is set to 1 to indicate that there is a pending user transfer request. When the transfer has been processed the bit FLXAnFROTS.UORP is set to 0, the bit FLXAnFROTS.OTIS is set to 1 and bits FLXAnFRDAm.DA[31:0] related to the requested buffer number (FLXAnFRUOR.UMBNR[6:0]) are set to 1.

User output transfer requests cannot be queued. The application should check the bit FLXAnFROTS.UORP before writing to FLXAnFRUOR.UMBNR[6:0].

User output transfer requests should not be made for message buffers which are pending in the input transfer queue.

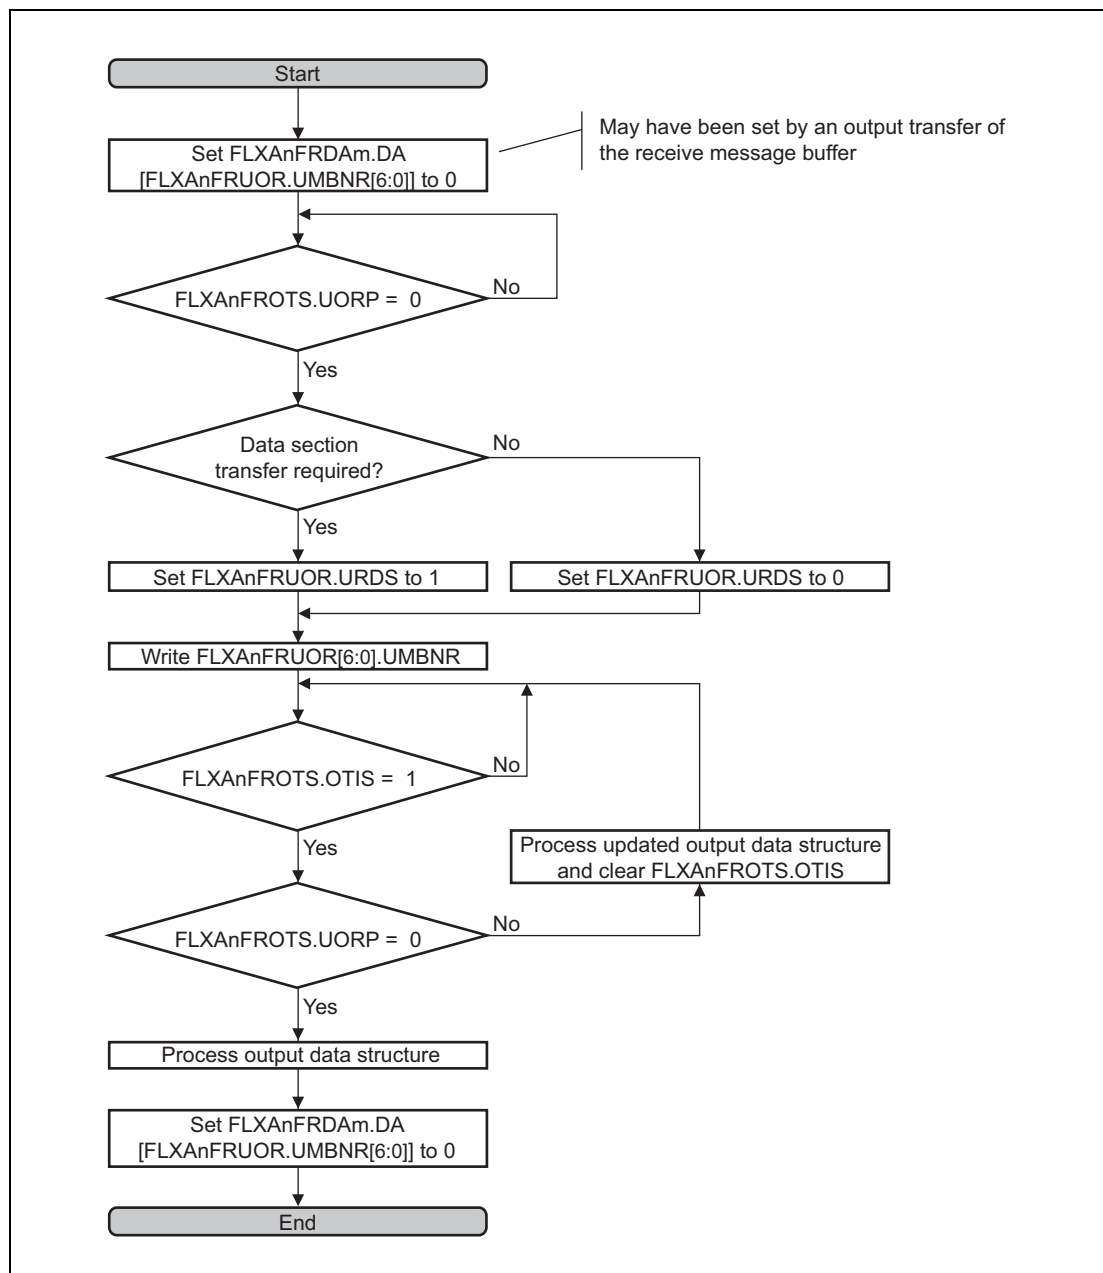

Figure 18.31 User Output Transfer Request Processing Flow

Note that it may be possible that the data structure addressed by a user request is being updated due to a receive message buffer update (which causes bits FLXAnFRDAm.DA[31:0] being set). This set FLXAnFRDAm.DA flags inhibits the user output transfer request. Therefore polling FLXAnFROTS.UORP is not a secure method to identify when the transfer of a requested message buffer has been completed. The bits FLXAnFROTS.OTIS or bits FLXAnFRDAm.DA[31:0] can be used instead. The exact flow depends on the software architecture.

18.3.16.3 Data Structure Transfer Scheduling

Cyclically the different types of transfer requests are checked. In order to guarantee a certain transfer time the different types of transfers have different priorities.

User requested input transfers have highest priority followed by the transfer of data structures committed into the active input transfer queue. No new output transfer will be started as long as there is a pending input transfer request.

The three output transfer request types are checked in a specific order:

(1) All dedicated message buffers in ascending order

When FLXAnFROTC.OTCS is set to 0, set flags FLXAnFRNDATm.NDp are causing a transfer of the message buffer to the output data structure if the destination area is free (bits FLXAnFRDAm.DA[31:0] are 0).

When FLXAnFROTC.OTCS is set to 1, set flags FLXAnFRNDATm.NDp or set flags in the FLXAnFRMBSCm.MBC[31:0] register are causing a transfer of the message buffer to the output data structure if the destination area is free (bits FLXAnFRDAm.DA[31:0] are 0).

(2) FlexRay internal FIFO

When the FlexRay internal FIFO is not empty and there is a free destination area, one FIFO message is transferred into the output data structure specified by the FIFO pointer table.

(3) User output request

If there is a pending user output transfer request, one message buffer is transferred into the corresponding output data structure.

The check sequence is suspended when an input transfer occurs.

18.3.16.4 Behavior in Case of Data Transfer Access Error

The memory areas accessed by the data transfer function may be protected by a memory protection unit (MPU). When the MPU flags an access to a protected address caused by an input or output transfer, an access error event is generated and the related bit in the FLXAnFRAES register is set.

The ongoing transfer is immediately terminated but succeeding transfers are processed and may generate further access errors. Any following access errors are only flagged in FLXAnFRAES.MAE. The other status flags are not updated.

(1) Access error during input transfer

When an access error occurs during an input transfer:

- The ongoing transfer is immediately terminated. The FlexRay internal message RAM will not be updated
- The address, the FlexRay module wanted to access to, is captured in the FLXAnFRAEA register
- FLXAnFRAES.IAE is set to 1
- The input pointer table index is flagged in FLXAnFRAES.EIDX[7:0]
- In case of an normal input transfer the to the transfer related bits FLXAnFRDAm.DA[31:0] is set to 0
- In case of a user input transfer request FLXAnFRITS.UIRP is set to 0

With the given status information the application is able to identify and correct the faulty data structure. In addition the application needs to clear the input access error flag (FLXAnFRAES.IAE).

(2) Access error during output transfer

When an access error occurs during an output transfer:

- The ongoing transfer is immediately terminated but the update of the data structure may have started.
- The address, the FlexRay module wanted to access to, is captured in the FLXAnFRAEA register
- FLXAnFRAES.OAE is set to 1
- The output pointer table index is flagged in FLXAnFRAES.EIDX[7:0]
- In case of an normal output transfer the to the transfer related bits FLXAnFRDAm.DA[31:0] remains 0 and no output transfer interrupt is generated
- In case of a user output transfer request FLXAnFROTS.UORP is set to 0

With the given status information the application is able to identify and correct the faulty data structure. The data structure in the Local RAM/Global RAM cannot be treated as valid.

In addition the application needs to clear the output access error flag (FLXAnFRAES.OAE).

The FlexRay module internal transfer of the message buffer is completed before the Local RAM/Global RAM access error is detected. The output transfer will not be re-initiated. To avoid loss of data, the application can perform a user output transfer request of this message buffer to a correct Local RAM/Global RAM location.

(3) Access error during FIFO transfer

When an access error occurs during an FIFO transfer:

- The ongoing transfer is immediately terminated
- The address, the FlexRay module wanted to access to, is captured in the FLXAnFRAEA register
- FLXAnFRAES.FAE is set to 1
- The FIFO pointer table index is flagged in FLXAnFRAES.EIDX[7:0]
- The FIFO index pointer are not changed and hence the FIFO status flags are unchanged

With the given status information the application is able to identify and correct the faulty data structure.

In addition the application needs to clear the FIFO access error flag (FLXAnFRAES.FAE).

The data in the Local RAM/Global RAM cannot be treated as valid and is not released to the application. The message cannot be recovered.

18.3.16.5 Behaviors in Case of RAM Read Errors

The FlexRay internal message RAM has an ECC checking mechanism. In case an uncorrectable RAM read error occurs, the application has to analyze the status in the FLXAnFRMHDS register and react as described in **Section 18.3.16.3, Data Structure Transfer Scheduling**. The input and output transfer handler reacts also on these errors detected in the message RAM when the error is related to an active transfer.

In addition, the TBFA and TBFB have an ECC checking mechanism as well. An uncorrectable RAM read errors does not impact the data transfer functionality but have to be handled as described in **Section 18.3.13.1 (4), Message Buffer Status FLXAnFRMBS (word 3)**.

In all cases, data causing a read error is never transferred to the Local RAM/Global RAM. If there is no recovery available in the application, the message is lost.

(1) Read error during transfer from TBF to MBF

This internal transfer is done for each valid FlexRay message received.

A read error can only occur when reading the header section in the FlexRay Message RAM (see read error flags in FLXAnFRMHDS). In this case, the message buffer needs to be re-configured.

For dedicated receive message buffers, the related flags FRNDATm.ND[31:0] will not get set. Consequently the affected message buffer will not be transferred to the output data structure.

For the FlexRay internal FIFO buffers, flags FRNDATm.ND[31:0] are not set but the FlexRay internal FIFO put index is incremented. Due to this, a transfer procedure from the FlexRay internal FIFO buffer to the output buffer is started. However, if the read error is still present in the header section, updating of the output data structure will not start (see **Section 18.3.16.5 (2), Read error during transfer from MBF to OBF**); thus the data in the Local RAM/Global RAM remains correct.

Note that the correction or any other reconfiguration of FIFO related to message buffers while there are pending FIFO transfers may result in incorrect data in the Local RAM/Global RAM. It is strongly recommended to deactivate the output data transfer before starting the reconfiguration and flush the FlexRay internal FIFO before reactivation of the output data transfer.

(2) Read error during transfer from MBF to OBF

This internal transfer is done for every output data transfer (dedicated reception, FIFO, user requested).

A read error can occur in the header and data section (see read error flags in FLXAnFRMHDS). In both cases the message gets lost. If the error is located in the header section, the message buffer needs to be re-configured. If the error is located in the data section, the error is corrected with the next data section update.

When a read error occurs during the transfer from the message RAM to the output buffer, the output data structure will not be updated and the data available will not be set to 1. The FIFO put index and the FIFO fill level are not changed also.

In case of user output transfer request, FLXAnFROTS.UORP is set to 0 even if there was no update of the output data structure.

(3) Read error during transfer from IBF to MBF

This internal transfer is done for every input data transfer.

A read error can occur only when there is no update of the header section requested (the bit LHS in FLXAnFRWRHS4 is set to 0) due to the reading of the header section from the message RAM (see read error flags in FLXAnFRMHDS). In this case, the message buffer needs to be re-configured.

When a read error occurs during the input data transfer, the actually transferred message in the input queue gets lost.

(4) Message RAM read errors

Read errors when reading the header section are flagged in the FLXAnFRMHDS register.

Depending on the buffer type and set buffer protection, a reconfiguration of the message buffer may not be possible.

The input transfer function cannot be used to reconfigure a locked message buffer using the method described in **Section 18.3.13.4 (3), Temporary Unlocking of Header Section**.

Before reconfiguring a locked buffer, the user should disable the input transfer function and the output transfer function.

Section 19 Single Edge Nibble Transmission (RSENT)

The Single Edge Nibble Transmission encoding scheme (SENT) is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D's and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal. RSENT is implemented 5 channels at 100 pin-product and 6 channels at 144 pin-product.

19.1 Features of RH850/P1M-E RSENT

19.1.1 Number of Channels

This product is provided with a RSENT with the following number of channels.

Table 19.1 Number of Channels

Product	RH850/P1M-E 100 pins	RH850/P1M-E 144 pins
Number of channels	5	6
Name	RSENT0, RSENT1, RSENT3, RSENT4, RSENT5	RSENT0, RSENT1, RSENT2, RSENT3, RSENT4, RSENT5

Table 19.2 Index

Index	Meaning
n	This section identifies each RSENT channel by "n" (n = 0 to 5).

19.1.2 Register Base Address

RSENT register base address are represented by an offset from the base address <RSENTn_base>.

The following table shows the base address <RSENTn_base> of each RSENT module.

Table 19.3 Register Base Address

RSENTn Channel	<RSENTn_base> Address
RSENT0	FFE0 5000 _H
RSENT1	FFE0 6000 _H
RSENT2	FFE0 7000 _H
RSENT3	FFE0 8000 _H
RSENT4	FFE0 9000 _H
RSENT5	FFE0 A000 _H

19.1.3 Clock Supply

The following clock input is supplied for the RSENT module.

Table 19.4 Clock Supply

Module	Clock	Supply Clock Name
RSENTn	pclk clkc	High-speed peripheral clock CLK_HSB

19.1.4 Interrupt Requests

The RSENT module can generate the following interrupt requests.

Table 19.5 Interrupt Requests

Unit Interrupt Name	Outline	Interrupt	DMA/DTS Trigger
RSENT0			
INTSENT0SI	SENT0 status interrupt	232	—
INTSENT0RI	SENT0 receive interrupt	233	119
RSENT1			
INTSENT1SI	SENT1 status interrupt	234	—
INTSENT1RI	SENT1 receive interrupt	235	120
RSENT2			
INTSENT2SI	SENT2 status interrupt	236	—
INTSENT2RI	SENT2 receive interrupt	237	121
RSENT3			
INTSENT3SI	SENT3 status interrupt	238	—
INTSENT3RI	SENT3 receive interrupt	239	122
RSENT4			
INTSENT4SI	SENT4 status interrupt	240	—
INTSENT4RI	SENT4 receive interrupt	241	123
RSENT5			
INTSENT5SI	SENT5 status interrupt	242	—
INTSENT5RI	SENT5 receive interrupt	243	124

19.1.5 Reset Sources

Please refer to **Section 8, Reset Controller**.

19.1.6 External Input/Output Signals

External input/output signals of RSENT are listed below.

Table 19.6 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
RSENT0			
sent_rx	I	RSENT data input	SENT0RX
sent_spc	O	RSENT SPC extension output	SENT0SPCO
RSENT1			
sent_rx	I	RSENT data input	SENT1RX
sent_spc	O	RSENT SPC extension output	SENT1SPCO
RSENT2			
sent_rx	I	RSENT data input	SENT2RX
sent_spc	O	RSENT SPC extension output	SENT2SPCO
RSENT3			
sent_rx	I	RSENT data input	SENT3RX
sent_spc	O	RSENT SPC extension output	SENT3SPCO
RSENT4			
sent_rx	I	RSENT data input	SENT4RX
sent_spc	O	RSENT SPC extension output	SENT4SPCO
RSENT5			
sent_rx	I	RSENT data input	SENT5RX
sent_spc	O	RSENT SPC extension output	SENT5SPCO

19.1.7 Combinations of Pins and Ports

Combinations of RSENT pins and ports are listed in the following table.

Table 19.7 Combinations of Pins and Ports

Function	Pin Name	Port Name	
		Group 1	Group 2
RSENT0	SENT0RX	P5_5	—
	SENT0SPCO	P0_8*1 / P5_5 / P5_6	—
RSENT1	SENT1RX	P5_8*1 / P5_10	—
	SENT1SPCO	P0_7*1 / P5_8*1 / P5_9 / P5_10	—
RSENT2	SENT2RX	P5_12*1	—
	SENT2SPCO	P0_6*1 / P5_12*1 / P5_13*1	—
RSENT3	SENT3RX	P5_14	P5_11*1
	SENT3SPCO	P0_0 / P0_5*1 / P5_14 / P5_15*1	P0_0 / P0_5*1 / P5_11*1 / P5_15*1
RSENT4	SENT4RX	P0_1	—
	SENT4SPCO	P0_1 / P0_4*1 / P3_11	—
RSENT5	SENT5RX	P0_2 / P2_10*1	—
	SENT5SPCO	P0_2 / P0_3*1	P2_10*1 / P2_11*1

Note 1. Available in devices with 144-pin.

19.2 Functions

Overview of Functions

The RSENT interface supports the following standard specification (SAE J2716 version JAN2010) functions:

- Triple speed expansion Tick Time: Clock cycle (1 μ s to 90 μ s)
- Variable data transmission rate
 - 24.7 kbps to 64.9 kbps: 3 clock rate 6 nibble data
 - 74.1 kbps to 194.7 kbps: 1 clock rate 6 nibble data
- Unidirectional communication: Between the sensor and MCU
- Bidirectional communication: Between the sensor and MCU (supported in SPC mode)
- Single edge data transmission: Coded by the temporal distance of two serially-detected rising edges on a data line
- Transmission frame with up to 6 data nibbles + status and communications nibbles
- Data transmission protected with CRC is available.
 - CRC data can be read with the RSENTnSRXD.SCRC bits.
- Calibration phrase in each data frame
- 1-wire interface (sent_rx and sent_spc share a single terminal.)
- Multiple sensors can connect to the RSENT channel that has the standard expansion function. Received data from sensors is detected by software or DMA.
- The timestamp function: Master or slave can be selected for the RSENT module.
- The RSENT circuit consists of the following functions:
 - Data receive part
 - Clock recovery
 - Register group

19.2.1 Block Diagram

The following figure shows a block diagram of the RSENT module.

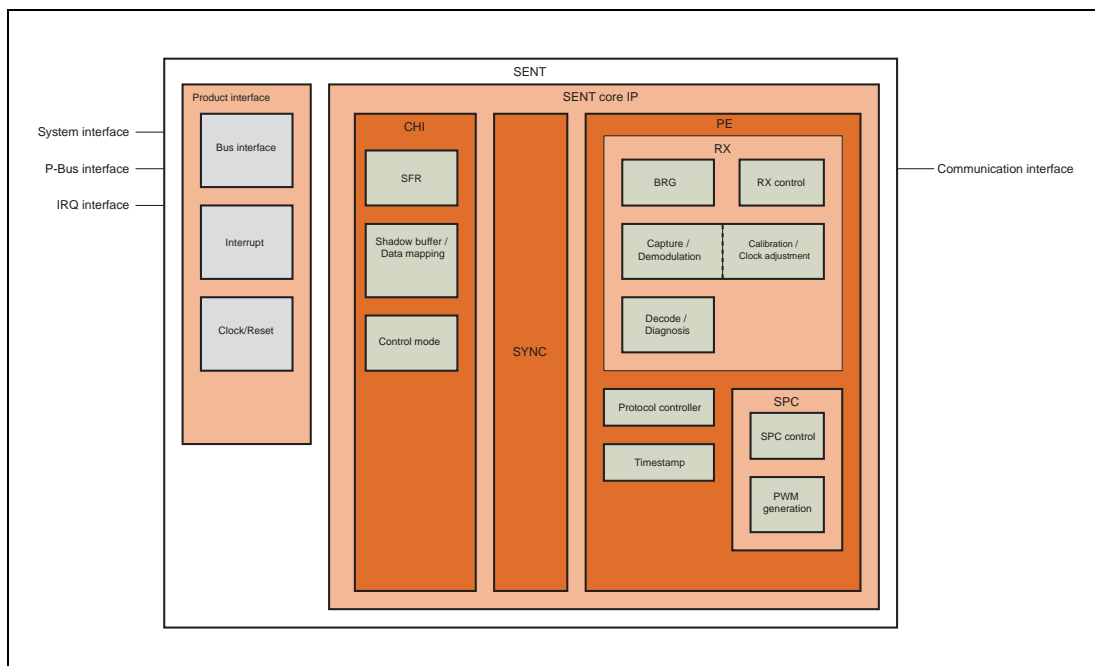

Figure 19.1 Block Diagram of RSENT

19.3 Registers

RSENTn is controlled and operated by the following registers.

For <RSENTn_base>, refer to **Section 19.1.2, Register Base Address**.

Table 19.8 Overview of RSENTn Registers

Register Name	Abbreviation	Address
RSENT timestamp register	RSENTnTSPC	<RSENTn_base> + 0000 _H
RSENT timestamp counter	RSENTnTSC	<RSENTn_base> + 0004 _H
RSENT communications configuration register	RSENTnCC	<RSENTn_base> + 0010 _H
RSENT baud rate prescaler register	RSENTnBRP	<RSENTn_base> + 0014 _H
RSENT interrupt/DMA enable register	RSENTnIDE	<RSENTn_base> + 0018 _H
RSENT mode control register	RSENTnMDC	<RSENTn_base> + 001C _H
RSENT SPC transmission register	RSENTnSPCT	<RSENTn_base> + 0020 _H
RSENT mode status register	RSENTnMST	<RSENTn_base> + 0024 _H
RSENT communication status register	RSENTnCS	<RSENTn_base> + 0028 _H
RSENT communication status clear register	RSENTnCSC	<RSENTn_base> + 002C _H
RSENT slow channel receive timestamp register	RSENTnSRTS	<RSENTn_base> + 0030 _H
RSENT slow channel receive data register	RSENTnSRXD	<RSENTn_base> + 0034 _H
RSENT calibration pulse length register	RSENTnCPL	<RSENTn_base> + 0038 _H
RSENT message length register	RSENTnML	<RSENTn_base> + 003C _H
RSENT fast channel receive timestamp register	RSENTnFRTS	<RSENTn_base> + 0040 _H
RSENT fast channel receive data register	RSENTnFRXD	<RSENTn_base> + 0044 _H
RSENT timestamp mode selection register	RSENTTSEL	<RSENT0_base> + A000 _H

19.3.1 RSENTnTSPC — RSENT Timestamp Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0000_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TMS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 19.9 RSENTnTSPC Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is read. When writing, write the value after reset.
16	TMS	Timestamp Mode Selection 0: Master mode 1: Slave mode
15	Reserved	When read, the value after reset is read. When writing, write the value after reset.
14 to 8	TTM[6:0]	Timestamp Tick Multiplier 000000 _B : 1 000001 _B : 2 000010 _B : 3 : 111111 _B : 128
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	TTPV[6:0]	Timestamp Tick Prescaler Value 000000 _B : 1 000001 _B : 2 000010 _B : 3 : 111111 _B : 128

RSENTnTSPC.TMS (Timestamp Mode Selection)

When this bit is set to 0, the timestamp counter operates in master mode.

Writing 0000 0000_H to RSENTnTSC by the module set as the master leads to clearing of the timestamps in that module and in the channels set as slaves.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

The RSENT operating in slave mode needs to have the same settings in the RSENT that is operated as a master and timestamp counter prescaler.

RSENTnTSPC.TTM (Timestamp Tick Multiplier)

These bits define the multiplication value of the 1- μ s time tick used for the timestamp counter.

For timestamp clock configuration, see **Section 19.5.1, Timestamp**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnTSPC.TTPV (Timestamp Tick Prescaler Value)

These bits define the prescaler value to generate a 1- μ s clock tick.

For timestamp clock configuration, see **Section 19.5.1, Timestamp**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

The CPU should configure this value in such a way that, based on the supplied communication clock, a 1- μ s clock tick is generated.

19.3.2 RSENTnTSC — RSENT Timestamp Counter

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0004_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TS[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 19.10 RSENTnTSC Register Contents

Bit Position	Bit Name	Function
31 to 0	TS[31:0]	Timestamp counter value

RSENTnTSC.TS (Timestamp)

These bits indicate the current timestamp counter value.

The CPU can only write desired values to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

When the timestamp counter is configured to operate in slave mode (RSENTnTSPC.TMS = 1), writing to this register has no effect when the RSENT module is in either of the OPERATION IDLE or OPERATION ACTIVE modes (the RSENTnMST.OMS bits are either 011_B or 101_B).

The timestamp counter is incremented on every timestamp counter tick (as configured in the RSENTnTSPC.TTPV and RSENTnTSPC.TTM bits) when the RSENT module is in either of the OPERATION IDLE or OPERATION ACTIVE modes (the RSENTnMST.OMS bits are either 011_B or 101_B).

When the timestamp counter is configured to operate in master mode (RSENTnTSPC.TMS = 0), the CPU writes 0000 0000_H to these bits and RSENTnTSC.TS is set to 0000 0000_H.

When the slave mode setting is made for the timestamp counter of channel n (RSENTnTSPC.TMS = 1), writing to the timestamp counter of the channel that is the master for channel n leads to the RSENTnTSC.TS bits being set to 0000 0000_H.

For timestamp mode selection, see **Section 19.5.1, Timestamp**.

19.3.3 RSENTnCC — RSENT Communications Configuration Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0010_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 19.11 RSENTnCC Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is read. When writing, write the value after reset.
12	SOPC	SPC Output Polarity Control 0: SPC pulse active high 1: SPC pulse active low
11	FCM	Frame Check Method 0: Check against next calibration pulse 1: Check against previous calibration pulse
10	SCCD	Slow Channel CRC Check 0: Slow channel CRC check enabled 1: Slow channel CRC check disabled
9	FCCD	Fast Channel CRC Check 0: Fast channel CRC check enabled 1: Fast channel CRC check disabled
8	—	When read, the value after reset is read. When writing, write the value after reset.
7, 6	SMF	Serial Message Format 00 _B : No serial message extraction 01 _B : Short serial message format 10 _B : Enhanced serial message format 11 _B : Setting prohibited
5	PPTC	Pause Pulse Type Configuration 0: Pause pulse for variable message length 1: Pause pulse for fixed message length
4	PPC	Pause Pulse Configuration 0: Pause pulse absent 1: Pause pulse present
3 to 1	NDN[2:0]	Number of Data Nibbles 000 _B : 1 data nibble 001 _B : 2 data nibbles 010 _B : 3 data nibbles 011 _B : 4 data nibbles 100 _B : 5 data nibbles 101 _B : 6 data nibbles Other than above: Setting prohibited

Table 19.11 RSENTnCC Register Contents (2/2)

Bit Position	Bit Name	Function
0	SPCE	SPC Mode Enable 0: SPC mode disabled 1: SPC mode enabled

RSENTnCC.SOPC (SPC Output Polarity Control)

When this bit is set to 0, the SPC pulse is sent as an active high signal. The default output value is low level.

When this bit is set to 1, the SPC pulse is sent as an active low signal. The default output value is high level.

For SPC operation, see also **Section 19.7, SPC Function**.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

NOTE

Any change to this bit from the default value becomes effective on the output value when entering the OPERATION_ACTIVE mode (MST.OMS is 101_B). When entering RESET mode (MST.OMS is 000_B), the output level is set to the default value (low level).

RSENTnCC.FCM (Frame Check Method)

When this bit is set to 0, the current calibration pulse is compared to the next received calibration pulse.

The buffer update mechanism is operating according to the preferred option as described in SAE J2716 2010.

When this bit is set to 1, the current calibration pulse is compared to the previously received calibration pulse.

The buffer update mechanism is operating according to the second option as described in SAE J2716 2010 which should be only used if extra latency to process the second calibration pulse cannot be tolerated.

For buffer update timings, see also **Section 19.6.2.3, Fast Channel Message Reception**.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.SCCD (Slow Channel CRC Check Disable)

When this bit is set to 1, the CRC check for the slow channel is disabled. In this case, messages are stored in the slow channel message reception buffer with the received CRC.

When this bit is set to 1, the RSENTnCS.SCS bit is not set.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.FCCD (Fast Channel CRC Check Disable)

When this bit is set to 1, the CRC check for the fast channel is disabled. In this case, messages are stored in the fast channel message reception buffer with the received CRC.

When this bit is set to 1, the RSENTnCS.FCS bit is not set.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.SMF (Serial Message Format)

These bits define the serial message format expected to be received for automatic extraction.

When these bits are set to 00_B, no serial message is extracted and the communications and status nibble are stored in the RSENTnSRXD register.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

The CPU shall set these bits to 00_B when RSENTnCC.SPCE is set to 1 and more than one sensor is connected to the RSENT module.

RSENTnCC.PPTC (Pause Pulse Type Configuration)

This bit defines the pause pulse type.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

The CPU should not set this bit to 1 when the RSENTnCC.PPC bit is set to 0.

RSENTnCC.PPC (Pause Pulse Configuration)

This bit defines the presence or absence of the pause pulse.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.NDN (Number of Data Nibbles)

These bits define the number of data nibbles included in an RSENT message.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.SPCE (SPC Mode Enable)

This bit enables the SPC mode.

For details about SPC mode operation, see also **Section 19.7, SPC Function**.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

19.3.4 RSENTnBRP — RSENT Baud Rate Prescaler Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0014_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	TTF[3:0]				—	TTI[6:0]

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is read. When writing, write the value after reset.
27 to 24	TTF[3:0]	Time Tick Decimal Fraction 0000 _B : 0.0 μs 0001 _B : 0.1 μs 0010 _B : 0.2 μs : 1000 _B : 0.8 μs 1001 _B : 0.9 μs Other than above: Setting prohibited
23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22 to 16	TTI[6:0]	Time Tick Integer 0000000 _B : 1 μs 0000001 _B : 2 μs 0000010 _B : 3 μs : 1011000 _B : 89 μs 1011001 _B : 90 μs Other than above: Setting prohibited
15	Reserved	When read, the value after reset is read. When writing, write the value after reset.
14 to 8	SCDV[6:0]	Sample Clock Division Value 0000000 _B : 1 0000001 _B : 2 0000010 _B : 3 : 1111110 _B : 127 1111111 _B : 128
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.

Table 19.12 RSENTnBRP Register Contents (2/2)

Bit Position	Bit Name	Function
4 to 0	SCMV[4:0]	Sample Clock Multiplication Value 00000 _B : 1 00001 _B : 2 00010 _B : 3 : 11110 _B : 31 11111 _B : 32

RSENTnBRP.TTF (Time Tick Decimal Fraction)

These bits define the decimal part of the tick length in 0.1- μ s granularity.

For tick length configuration, see **Section 19.5.2.2, RX and SPC Tick Settings**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnBRP.TTI (Time Tick Integer)

These bits define the integer part of the tick length.

For tick length configuration, see **Section 19.5.2.2, RX and SPC Tick Settings**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnBRP.SCDV (Sample Clock Division Value)

These bits define the division value for the sample clock generation logic.

For RSENTnBRP settings, see **Section 19.5.2.1, RX BRP Setting**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnBRP.SCMV (Sample Clock Multiplication Value)

These bits define the multiplication value for the sample clock generation logic.

For RSENTnBRP settings, see **Section 19.5.2.1, RX BRP Setting**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

19.3.5 RSENTnIDE — RSENT Interrupt/DMA Enable Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0018_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 19.13 RSENTnIDE Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10	SEIE	Slow Channel Encoding Error Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
9	SMIE	Slow Channel Message Lost Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
8	SCIE	Slow Channel CRC Error Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
7	NRIE	No Response Error Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
6	CVIE	Calibration Pulse Length Variation Error Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
5	CLIE	Calibration Pulse Length Error Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
4	FNIE	Fast Channel Nibble Count Error Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
3	FEIE	Fast Channel Nibble Encoding Error Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
2	FMIE	Fast Channel Message Lost Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
1	FCIE	Fast Channel CRC Error Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
0	FRIE	Fast Channel Receive Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled

RSENTnIDE.SEIE (Slow Channel Encoding Error Interrupt Enable)

This bit enables the generation of the slow channel encoding error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.SMIE (Slow Channel Message Lost Interrupt Enable)

This bit enables the generation of the slow channel message lost interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.SCIE (Slow Channel CRC Error Interrupt Enable)

This bit enables the generation of the slow channel CRC error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.NRIE (No Response Error Interrupt Enable)

This bit enables the generation of the no response error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

The CPU should not set this bit when the SPC mode is disabled (RSENTnCC.SPCE set to 0).

RSENTnIDE.CVIE (Calibration Pulse Length Variation Error Interrupt Enable)

This bit enables the generation of the calibration pulse length variation error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.CLIE (Calibration Pulse Length Error Interrupt Enable)

This bit enables the generation of the calibration pulse length error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FNIE (Fast Channel Nibble Count Error Interrupt Enable)

This bit enables the generation of the fast channel nibble count error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FEIE (Fast Channel Nibble Encoding Error Interrupt Enable)

This bit enables the generation of the fast channel nibble encoding error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FMIE (Fast Channel Message Lost Interrupt Enable)

This bit enables the generation of the fast channel message lost interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FCIE (Fast Channel CRC Error Interrupt Enable)

This bit enables the generation of the fast channel CRC error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FRIE (Fast Channel Receive Interrupt Enable)

This bit enables the generation of the fast channel receive interrupt.

The fast channel receive interrupt can be also used to notify a DMA request.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

19.3.6 RSENTnMDC — RSENT Mode Control Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 001C_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	OMC[2:0]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 19.14 RSENTnMDC Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2 to 0	OMC[2:0]	Operation Mode Control 000 _B : RESET 001 _B : CONFIGURATION 011 _B : OPERATION IDLE 101 _B : OPERATION ACTIVE Other than above: Setting prohibited

RSENTnMDC.OMC (Operation Mode Control)

These bits are used to control the operation mode of the RSENT module.

- 000_B: RESET

In RESET mode, the mode can only be changed to CONFIGURATION mode.

- 001_B: CONFIGURATION

In CONFIGURATION mode, the mode can only be changed to RESET mode or OPERATION ACTIVE mode.

- 011_B: OPERATION IDLE

In OPERATION IDLE mode, the mode can be changed to OPERATION ACTIVE mode, CONFIGURATION mode, or RESET mode.

- 101_B: OPERATION ACTIVE

In OPERATION ACTIVE mode, the mode can be changed to OPERATION IDLE mode, CONFIGURATION mode, or RESET mode. However, it is recommended to process to the OPERATION IDLE mode first.

For the recommended methods to change between operation modes, see **Section 19.6.1, Changing Operation Modes.**

- Other than above: Setting prohibited

The CPU should not write any other value than listed above into this register.

The CPU should follow the mode change flows as shown in section **Section 19.6.1, Changing Operation Modes**.

19.3.7 RSENTnSPCT — RSENT SPC Transmission Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0020_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	TLL[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 19.15 RSENTnSPCT Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	TLL[6:0]	Length of the Trigger Low Phase in Ticks 000000 _B : 1 tick 000001 _B : 2 ticks 000010 _B : 3 ticks : 111110 _B : 127 ticks 111111 _B : 128 ticks

RSENTnSPCT.TLL (Trigger Low Length)

These bits define the length of the SPC trigger pulse.

When the CPU writes to these bits, an SPC trigger pulse with the configured length is sent immediately independently of the current status of the RSENT module.

For details about SPC communication, see **Section 19.7, SPC Function**.

The CPU can only write to these bits if the RSENT module is in the OPERATION ACTIVE mode (the RSENTnMST.OMS bits are 101_B) and SPC communication is enabled (RSENTnCC.SPCE is 1).

It is important to note that two consecutive write access might not cause a no response error as the previous request might not have started yet.

After writing to this register, the CPU should wait for at least one SPC trigger tick before writing again to this register.

19.3.8 RSENTnMST — RSENT Mode Status Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0024_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 19.16 RSENTnMST Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is read.
2 to 0	OMS[2:0]	Operation Mode 000 _B : RESET 001 _B : CONFIGURATION 011 _B : OPERATION IDLE 101 _B : OPERATION ACTIVE Other than above: Reserved

RSENTnMST.OMS (Operation Mode Status)

These bits indicate the current operation mode.

These bits are read only.

These bits are updated after a mode change request is made in the RSENTnMDC.OMC register.

- 000_B: RESET mode

When in RESET mode, all registers are set to their reset values and write access to all registers except the RSENTnMDC register is disabled.

When in RESET mode, RSENT communication is disabled.

- 001_B: CONFIGURATION mode

When in CONFIGURATION mode, write access to the timestamp registers (RSENTnTSPC and RSENTnTSC register), configuration registers (RSENTnCC and RSENTnBRP register), RSENTnIDE register, and mode control register (RSENTnMDC.OMC) is enabled.

When in CONFIGURATION mode, RSENT communication is disabled.

When entering CONFIGURATION mode, all status registers and receive buffer registers are set to their reset values.

- 011_B: OPERATION IDLE mode

In OPERATION IDLE mode, no reception or SPC trigger transmission is possible.

When entering OPERATION IDLE mode, frames in the receive buffer can be analyzed as in OPERATION ACTIVE mode, but no new frames are received.

- 101_B: OPERATION ACTIVE mode

In OPERATION ACTIVE mode, reception and SPC trigger transmission are possible.

- Other than above: Reserved

19.3.9 RSENTnCS — RSENT Communication Status Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0028_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

3	FES	Fast Channel Nibble Encoding Error Interrupt Detection 0: Not detected 1: Detected
2	FMS	Fast Channel Message Lost Interrupt Detection 0: Not detected 1: Detected
1	FCS	Fast Channel CRC Error Interrupt Detection 0: Not detected 1: Detected
0	FRS	Fast Channel Receive Interrupt Detection 0: Not detected 1: Detected

RSENTnCS.SES (Slow Channel Encoding Error Status)

This bit represents the slow channel encoding error status.

This bit is read only.

In the short serial message format (RSENTnCC.SMF = 01_B), this bit is set when the sequence on serial start bit (status and communications nibble bit #3) is different from “1000 0000 0000 0000_B” (a single 1 and 15 0s).

In the enhanced serial message format (RSENTnCC.SMF = 10_B), this bit is set after receiving the serial message start frame (sequence on status and communications nibble bit 3 is 0111 1110_B), and if bit 13 or bit 18 are not received as ‘0’.

When this bit is set in the short serial message format the received communication and status nibble is used to assemble a serial message.

When this bit is set in the enhanced serial message format the RSENT module checks the presence of a new start sequence at the same time and uses the received communication and status nibble to assemble a serial message.

This bit is cleared when writing 1 to RSENTnCSC.SEC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.SMS (Slow Channel Message Lost Status)

This bit represents the slow channel message lost status.

This bit is read only.

This bit is set when there is an attempt to update the slow channel message reception buffer, but the previous message has not been read yet.

This bit is cleared when writing 1 to RSENTnCSC.SEC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.SCS (Slow Channel CRC Error Status)

This bit represents the slow channel CRC error status.

This bit is read only.

This bit is set when a CRC error is detected on the slow channel and the slow channel CRC detection is enabled (RSENTnCC.SCCD is set to 0).

This bit is cleared when writing 1 to RSENTnCSC.SCC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.NRS (No Response Error Status)

This bit represents the no response error status.

This bit is read only.

This bit is set when

- the CPU writes to the RSENTnSPCT.TLL bits and
- SPC mode enabled (RSENTnCC.SPCE set to 1) and
- no complete response was received from the sensor for the previous SPC trigger.

This bit is cleared when writing 1 to RSENTnCSC.NRC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.CVS (Calibration Pulse Length Variation Error Status)

This bit represents the calibration pulse length variation error status.

This bit is read only.

When RSENTnCC.PPTC is 0, then this bit is set when two successive calibration pulses differ by more than 1.5625%.

When RSENTnCC.PPTC is 1, this bit is never set. In this mode (pause pulse with fixed message length), the CPU needs to check the variation of the ratio of calibration pulse to message length by reading the RSENTnCPL and RSENTnML registers.

This bit is cleared when writing 1 to RSENTnCSC.CVC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.CLS (Calibration Pulse Length Error Status)

This bit represents the calibration pulse length error status.

This bit is read only.

This bit is set when the measured calibration pulse length is less than 42 clock ticks or more than 70 clock ticks (deviation of 25% from specification length (56 clock ticks)).

This bit is cleared when writing 1 to RSENTnCSC.CLC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FNS (Fast Channel Nibble Count Error Status)

This bit represents the fast channel nibble count error status.

This bit is read only.

This bit is set when there is an unexpected number of falling edges between two calibration pulses.

This bit is cleared when writing 1 to RSENTnCSC.FNC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FES (Fast Channel Nibble Encoding Error Status)

This bit represents the fast channel nibble encoding error status.

This bit is read only.

This bit is set when on the fast channel a measured nibble period is less than 12 clock ticks or more than 27 clock ticks.

This bit is cleared when writing 1 to RSENTnCSC.FEC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FMS (Fast Channel Message Lost Status)

This bit represents the fast channel message lost status.

This bit is read only.

This bit is set when the fast channel message reception buffer is updated, but the previous messages have not been read yet.

This bit is cleared when writing 1 to RSENTnCSC.FMC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FCS (Fast Channel CRC Error Status)

This bit represents the fast channel CRC error status.

This bit is read only.

This bit is set when a CRC error is detected on the fast channel and the fast channel CRC detection is enabled (RSENTnCC.FCCD is set to 0).

This bit is cleared when writing 1 to RSENTnCSC.FCC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FRS (Fast Channel Receive Status)

This bit represents the fast channel receive status.

This bit is read only.

This bit is set when the fast channel message reception buffer was updated.

This bit is cleared when the CPU reads the RSENTnFRXD.FND bit.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

19.3.10 RSENTnCSC — RSENT Communication Status Clear Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 002C_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

6	CVC	Calibration Pulse Length Variation Error Interrupt Clear 0: — 1: Clear
5	CLC	Calibration Pulse Length Error Interrupt Clear 0: — 1: Clear
4	FNC	Fast Channel Nibble Count Error Interrupt Clear 0: — 1: Clear
3	FEC	Fast Channel Nibble Encoding Error Interrupt Clear 0: — 1: Clear
2	FMC	Fast Channel Message Lost Interrupt Clear 0: — 1: Clear
1	FCC	Fast Channel CRC Error Interrupt Clear 0: — 1: Clear
0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

RSENTnCSC.SEC (Slow Channel Encoding Error Clear)

Writing 1 sets RSENTnCS.SES to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.SMC (Slow Channel Message Lost Clear)

Writing 1 sets RSENTnCS.SMS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.SCC (Slow Channel CRC Error Clear)

Writing 1 sets RSENTnCS.SCS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.NRC (No Response Error Clear)

Writing 1 sets RSENTnCS.NRS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.CVC (Calibration Pulse Length Variation Error Clear)

Writing 1 sets RSENTnCS.CVS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.CLC (Calibration Pulse Length Error Clear)

Writing 1 sets RSENTnCS.CLS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FNC (Fast Channel Nibble Count Error Clear)

Writing 1 sets RSENTnCS.FNS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FEC (Fast Channel Nibble Encoding Error Clear)

Writing 1 sets RSENTnCS.FES to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FMC (Fast Channel Message Lost Clear)

Writing 1 sets RSENTnCS.FMS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FCC (Fast Channel CRC Error Clear)

Writing 1 sets RSENTnCS.FCS to 0.

Writing 0 has no effect.

This bit is always read as 0.

19.3.11 RSENTnSRTS — RSENT Slow Channel Receive Timestamp Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0030_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	STS[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 19.19 RSENTnSRTS Register Contents

Bit Position	Bit Name	Function
31 to 0	STS	Slow Channel Receive Timestamp

RSENTnSRTS.STS (Slow Channel Receive Timestamp)

These bits are read only.

These bits are updated when the slow channel message reception buffer is updated with the timestamp counter value of the last frame provided to the slow channel message.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

19.3.12 RSENTnSRXD — RSENT Slow Channel Receive Data Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0034_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SND	—	SCRC[5:0]					—	—	—	SMGC	IDD[19:16]

Table 19.20 RSENTnSRXD Register Contents

Bit Position	Bit Name	Function
31	SND	Slow Channel New Data 0: Slow channel frame data is not updated since last read. 1: Slow channel frame data is updated since last read.
30	Reserved	When read, the value after reset is read.
29 to 24	SCRC[5:0]	Slow Channel CRC Data
23 to 21	Reserved	When read, the value after reset is read.
20	SMGC	Slow Channel Configuration Bit Data
19 to 0	IDD[19:0]	Slow Channel Data / ID Information

RSENTnSRXD.SND (Slow Channel New Data)

This bit indicates that the slow channel message reception buffer is holding data that has not been read.

This bit is read only.

This bit is set when the slow channel message reception buffer is updated.

This bit is cleared automatically whenever it is read.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnSRXD.SCRC (Slow Channel CRC)

These bits are representing the slow channel CRC data.

These bits are read only.

These bits are updated when the slow channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnSRXD.SMGC (Slow Channel Configuration Bit)

This bit represents the slow channel configuration bit data.

This bit is read only.

This bit is updated when the slow channel message reception buffer is updated.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnSRXD.IDD (ID/ Data)

These bits are representing the slow channel data and ID information.

The alignment within this register depends on the message format. For details, see **Section 19.6.2.5, Slow Channel Message Reception**.

These bits are read only.

These bits are updated when the slow channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

19.3.13 RSENTnCPL — RSENT Calibration Pulse Length Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0038_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPLV [16]
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CPLV[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 19.21 RSENTnCPL Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is read.
16 to 0	CPLV[16:0]	Calibration pulse length value of received message

RSENTnCPL.CPLV (Calibration Pulse Length Value)

These bits are used by the CPU to calculate the ratio of two consecutive calibration pulses or the calibration pulse to message length in pause pulse with fixed message length mode for message diagnostics.

These bits are read only.

Updating of the fast channel message reception buffer is storage of the value counted over the calibration pulse length (one tick time × the number of ticks between calibration pulses) based on the sample clock ($f_{\text{SAMPLE}} = 16 \text{ MHz}$).

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

19.3.14 RSENTnML — RSENT Message Length Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 003C_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	MLV[20:16]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MLV[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 19.22 RSENTnML Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is read.
20 to 0	MLV[20:0]	Message length of received message

RSENTnML.MLV (Message Length Value)

These bits are used by the CPU to calculate the ratio of the calibration pulse to message length in pause pulse with fixed message length mode for message diagnostics.

These bits are read only.

Updating of the fast channel message reception buffer is storage of the value counted over the message length (one tick time × the number of ticks taken to receive the overall message) based on the sample clock ($f_{\text{SAMPLE}} = 16 \text{ MHz}$).

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

19.3.15 RSENTnFRTS — RSENT Fast Channel Receive Timestamp Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0040_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FTS[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 19.23 RSENTnFRTS Register Contents

Bit Position	Bit Name	Function
31 to 0	FTS[31:0]	Fast Channel Receive Timestamp

RSENTnFRTS.FTS (Fast Channel Receive Timestamp)

These bits are read only.

These bits are updated when the fast channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

19.3.16 RSENTnFRXD — RSENT Fast Channel Receive Data Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0044_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SNDM	FND	FCCN[1:0]		FCRC[3:0]			ND[23:16]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	ND[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 19.24 RSENTnFRXD Register Contents

Bit Position	Bit Name	Function
31	SNDM	Slow Channel New Data Mirror 0: Slow channel frame data is not updated since last read. 1: Slow channel frame data is updated since last read.
30	FND	Fast Channel New Data 0: Fast channel frame data is not updated since last read. 1: Fast channel frame data is updated since last read.
29, 28	FCCN[1:0]	Fast Channel Status and Communications Nibble[1:0]
27 to 24	FCRC[3:0]	Fast Channel CRC Data
23 to 0	ND[23:0]	Fast Channel Nibble Data

RSENTnFRXD.SNDM (Slow Channel New Data Mirror)

This bit indicates that the slow channel message reception buffer is holding data that has not been read.

This bit is read only.

This bit is set when the slow channel message reception buffer is updated.

This bit is cleared automatically whenever the slow channel new data bit (RSENTnSRXD.SND) is read.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnFRXD.FND (Fast Channel New Data)

This bit indicates that the fast channel message reception buffer is holding data that has not been read.

This bit is read only.

This bit is set when the fast channel message reception buffer is updated.

This bit is cleared automatically whenever it is read.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnFRXD.FCCN (Fast Channel Status and Communications Nibble)

These bits are representing the fast channel status and communications nibble bits [1:0].

These bits are read only.

These bits are updated when the fast channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnFRXD.FCRC (Fast Channel CRC)

These bits are representing the fast channel CRC data.

These bits are read only.

These bits are updated when the fast channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

RSENTnFRXD.ND (Fast Channel Nibble Data)

These bits are representing the fast channel nibble data.

The alignment of the nibble data depends on nibble data count (RSENTnCC.NDN). For details, see **Section 19.6.2.3, Fast Channel Message Reception**.

These bits are read only.

These bits are updated when the fast channel message reception buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001_B (CONFIGURATION).

19.3.17 RSENTTSEL — RSENT Timestamp Mode Selection Register

This register controls the master channel of the RSENT timestamp.

Set this register when the RSENT module is stopped (RSENTnMST.OMS = 000_B).

Timestamp in each RSENT channel can be synchronized with other timestamp in other channel. A timestamp clear signal in each channel can clear other timestamp.

Access: This register can be read/written in 32-bit units.

Address: <RSENT0_base> +A000_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	MSEL	MSEL	MSEL	—	MSEL	MSEL	MSEL
										52	51	50		42	41	40
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 19.25 RSENTTSEL Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22 to 20	MSEL5[2:0]	RSENT5 Master Selection (when the RSENTnTSPC.TMS bit of RSENT5 = 1) 000 _B : No timestamp master 001 _B : RSENT0 is the timestamp master of RSENT5. 010 _B : RSENT1 is the timestamp master of RSENT5. 011 _B : RSENT2 is the timestamp master of RSENT5. 100 _B : RSENT3 is the timestamp master of RSENT5. 101 _B : RSENT4 is the timestamp master of RSENT5. 110 _B : No timestamp master Other than above: Setting prohibited
19	Reserved	When read, the value after reset is read. When writing, write the value after reset.
18 to 16	MSEL4[2:0]	RSENT4 Master Selection (when the RSENTnTSPC.TMS bit of RSENT4 = 1) 000 _B : No timestamp master 001 _B : RSENT0 is the timestamp master of RSENT4. 010 _B : RSENT1 is the timestamp master of RSENT4. 011 _B : RSENT2 is the timestamp master of RSENT4. 100 _B : RSENT3 is the timestamp master of RSENT4. 101 _B : No timestamp master 101 _B : RSENT5 is the timestamp master of RSENT4. Other than above: Setting prohibited
15	Reserved	When read, the value after reset is read. When writing, write the value after reset.

Table 19.25 RSENTTSEL Register Contents (2/2)

Bit Position	Bit Name	Function
14 to 12	MSSEL3[2:0]	RSENT3 Master Selection (when the RSENTnTSPC.TMS bit of RSENT3 = 1) 000 _B : No timestamp master 001 _B : RSENT0 is the timestamp master of RSENT3. 010 _B : RSENT1 is the timestamp master of RSENT3. 011 _B : RSENT2 is the timestamp master of RSENT3. 100 _B : No timestamp master 101 _B : RSENT4 is the timestamp master of RSENT3. 101 _B : RSENT5 is the timestamp master of RSENT3. Other than above: Setting prohibited
11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10 to 8	MSSEL2[2:0]	RSENT2 Master Selection (when the RSENTnTSPC.TMS bit of RSENT2 = 1) 000 _B : No timestamp master 001 _B : RSENT0 is the timestamp master of RSENT2. 010 _B : RSENT1 is the timestamp master of RSENT2. 011 _B : No timestamp master 100 _B : RSENT3 is the timestamp master of RSENT2. 101 _B : RSENT4 is the timestamp master of RSENT2. 110 _B : RSENT5 is the timestamp master of RSENT2. Other than above: Setting prohibited
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 4	MSSEL1[2:0]	RSENT1 Master Selection (when the RSENTnTSPC.TMS bit of RSENT1 = 1) 000 _B : No timestamp master 001 _B : RSENT0 is the timestamp master of RSENT1. 010 _B : No timestamp master 011 _B : RSENT2 is the timestamp master of RSENT1. 100 _B : RSENT3 is the timestamp master of RSENT1. 101 _B : RSENT4 is the timestamp master of RSENT1. 110 _B : RSENT5 is the timestamp master of RSENT1. Other than above: Setting prohibited
3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2 to 0	MSSEL0[2:0]	RSENT0 Master Selection (when the RSENTnTSPC.TMS bit of RSENT0 = 1) 000 _B : No timestamp master 001 _B : No timestamp master 010 _B : RSENT1 is the timestamp master of RSENT0. 011 _B : RSENT2 is the timestamp master of RSENT0. 100 _B : RSENT3 is the timestamp master of RSENT0. 101 _B : RSENT4 is the timestamp master of RSENT0. 110 _B : RSENT5 is the timestamp master of RSENT0. Other than above: Setting prohibited

19.4 Modes of Operation

The RSENT module can be in one of the following modes:

- RESET mode
- CONFIGURATION mode
- OPERATION IDLE mode
- OPERATION ACTIVE mode

CPU should follow the mode change flow as shown **Section 19.6.1, Changing Operation Modes**.

The current operation mode status can be seen in the RSENTnMST.OMS bits.

Figure 19.2 shows the possible transitions between the channel modes:

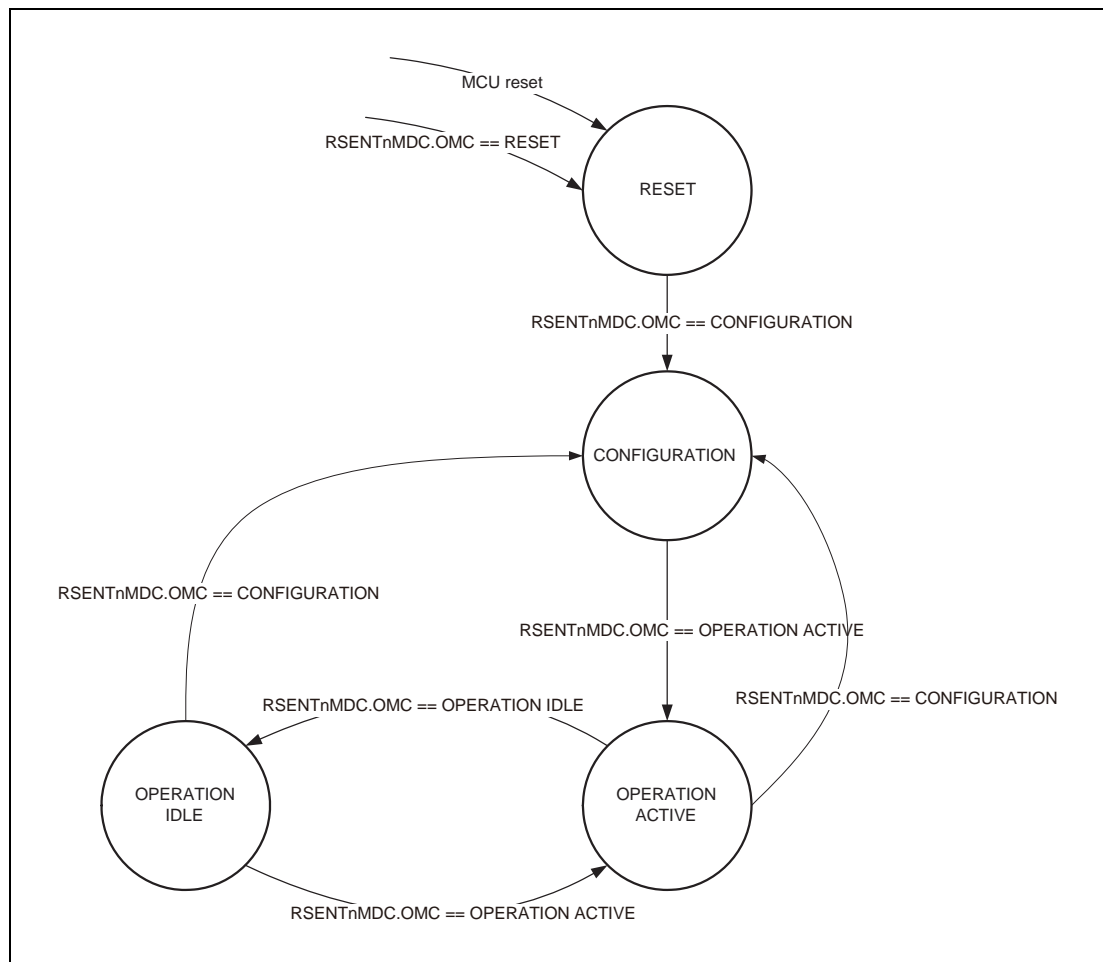

Figure 19.2 Transition between Operation Modes

19.4.1 RESET Mode

This mode is the initial mode that the RSENT module automatically enters after a reset is cleared. Its purpose is to provide a clean reset of the registers in the RSENT module.

The RESET mode is also entered after the RSENTnMDC.OMC bits have been set to 000_B. In this state, all, configuration, control (except RSENTnMDC.OMC bits and bits in the RSENTTSSEL register), and status registers are set to the value after their reset. Any on-going transmission or reception process is stopped immediately and the interface pins of the RSENT module are set to the value after their reset.

Read access to all registers is possible in this state. Write access is limited to the RSENTnMDC register and RSENTTSSEL registers.

19.4.2 CONFIGURATION Mode

The CONFIGURATION mode is entered after the RSENTnMDC.OMC bits have been set to 001_B.

The interface pins of the RSENT module are set to their default values.

Regarding the output polarity setting of RSENTnSPCO pin and the timing that becomes effective, please refer to the explanation of “RSENTnCC.SOPC (SPC Output Polarity Control)” in **Section 19.3.3, RSENTnCC — RSENT Communications Configuration Register**.

In this state, all status registers (RSENTnCS) and the receive buffer registers (RSENTnSRTS, RSENTnSRXD, RSENTnCPL, RSENTnML, RSENTnFRTS, and RSENTnFRXD) are set to the value after their reset.

Read access to all registers is possible in this state.

Write access is limited to both timestamp registers (RSENTnTSPC and RSENTnTSC) and configuration registers (RSENTnCC, RSENTnBRP, RSENTnIDE, RSENTnMDC, and RSENTnCSC).

19.4.3 OPERATION IDLE Mode

This mode is entered after the RSENTnMDC.OMC bits have been set to 011_B.

In OPERATION IDLE mode, no reception and transmission are done.

When entering OPERATION IDLE mode, frames in the receive buffer can be analyzed as in OPERATION ACTIVE mode, but no new frames are received.

Read access to all registers is possible in this state.

Write access is granted only to RSENTnTSC, RSENTnIDE, RSENTnMDC, and RSENTnCSC.

19.4.4 OPERATION ACTIVE Mode

This mode is entered after the RSENTnMDC.OMC bits have been set to 101_B.

In OPERATION ACTIVE mode, transmission and reception can take place.

Frame reception and status flagging starts after a valid calibration pulse (including the falling edge at the beginning) was detected.

Read access to all registers is possible in this state.

Write access is granted only to RSENTnTSC, RSENTnIDE, RSENTnMDC, RSENTnSPCT, and RSENTnCSC.

19.4.5 Register Behavior in Operation Modes

Table 19.26 shows the register behavior when the RSENT module transitions to the indicated operation modes. The table also gives an overview about the access restriction in each operation mode.

Table 19.26 Register Behavior in Operation Modes

Register Name	Symbol	MCU Reset	RESET		CONFIGURATION		OPERATION IDLE		OPERATION ACTIVE	
		Change	Change	R/W	Change	R/W	Change	R/W	Change	R/W
Timestamp prescaler configuration register	RSENTnTSPC	0000 0000 _H	0000 0000 _H	R	Unchanged	R/W	Unchanged	R	Unchanged	R
Timestamp counter register	RSENTnTSC	0000 0000 _H	0000 0000 _H	R	Unchanged	R/W	Unchanged	R/W _{*1}	Unchanged	R/W _{*1}
Communications configuration register	RSENTnCC	0000 0000 _H	0000 0000 _H	R	Unchanged	R/W	Unchanged	R	Unchanged	R
Baud rate prescaler register	RSENTnBRP	0000 0000 _H	0000 0000 _H	R	Unchanged	R/W	Unchanged	R	Unchanged	R
Interrupt/DMA enable register	RSENTnIDE	0000 0000 _H	0000 0000 _H	R	Unchanged	R/W	Unchanged	R/W	Unchanged	R/W
Mode control register	RSENTnMDC	0000 0000 _H	0000 0000 _H	R/W	Unchanged	R/W	Unchanged	R/W	Unchanged	R/W
SPC transmission register	RSENTnSPCT	0000 0000 _H	0000 0000 _H	R	Unchanged	R	Unchanged	R	Unchanged	R/W
Mode status register	RSENTnMST	0000 0000 _H	0000 0000 _H	R	0000 0001 _H	R	0000 0003 _H	R	0000 0005 _H	R
Communication status register	RSENTnCS	0000 0000 _H	0000 0000 _H	R	0000 0000 _H	R	Unchanged	R	Unchanged	R
Communication status clear register	RSENTnCSC	0000 0000 _H	0000 0000 _H	R	Unchanged	R/W	Unchanged	R/W	Unchanged	R/W
Slow channel receive timestamp register	RSENTnSRTS	0000 0000 _H	0000 0000 _H	R	0000 0000 _H	R	Unchanged	R	Unchanged	R
Slow channel receive data register	RSENTnSRXD	0000 0000 _H	0000 0000 _H	R	0000 0000 _H	R	Unchanged	R	Unchanged	R
Calibration pulse length register	RSENTnCPL	0000 0000 _H	0000 0000 _H	R	0000 0000 _H	R	Unchanged	R	Unchanged	R
Message length register	RSENTnML	0000 0000 _H	0000 0000 _H	R	0000 0000 _H	R	Unchanged	R	Unchanged	R
Fast channel receive timestamp register	RSENTnFRTS	0000 0000 _H	0000 0000 _H	R	0000 0000 _H	R	Unchanged	R	Unchanged	R
Fast channel receive data register	RSENTnFRXD	0000 0000 _H	0000 0000 _H	R	0000 0000 _H	R	Unchanged	R	Unchanged	R

Note 1. Means write restriction exists.

19.5 Clock Configuration

19.5.1 Timestamp

19.5.1.1 Timestamp Clock Configuration

RSENT incorporates the timestamp counter.

The user should configure the RSENTnTSPC.TTPV register according to the applied communication frequency. The resolution of the timestamp is 1 μ s. The input frequency is divided by the configured timestamp prescaler value RSENTnTSPC.TTPV.

Depending on the configured tick lengths, the resolution can be decreased by configuring the RSENTnTSPC.TTM bits. The already divided input frequency is divided further by the value of the TSPC.TTM bits.

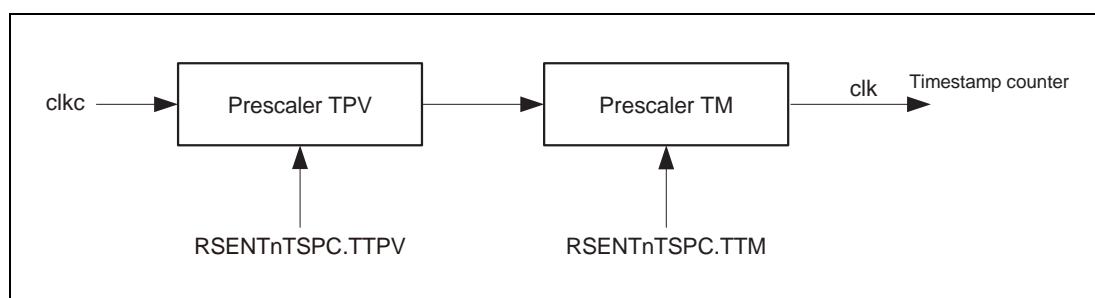

Figure 19.3 Timestamp Counter Clock Generation

19.5.1.2 Timestamp Counter Operation

The timestamp counter value can be initialized to any value by writing to the RSENTnTSC.TS bits only when the RSENT module is in CONFIGURATION mode.

When timestamp counters are configured to operate in master mode (RSENTnTSPC.TMS = 0), the CPU can reset the timestamp counter by writing 0000 0000_H to the RSENTnTSC.TS bits when the RSENT module is in OPERATION IDLE or OPERATION ACTIVE mode.

When timestamp counters are configured to operate in slave mode (RSENTnTSPC.TMS = 1), the timestamp counter is cleared when the CPU writes 0000 0000_H to the RSENTnTSC.TS bits of the channel set in the master when the RSENT module is in OPERATION IDLE or OPERATION ACTIVE mode. Make the same settings for the timestamp counter prescalers of channels operating in master mode and slave mode. When timestamp counter synchronization occurs, the internal timestamp counter prescalers are also synchronized.

The current timestamp counter value can be read from the RSENTnTSC.TS bits.

When the RSENT module is in OPERATION ACTIVE mode, each received message is stored with its related timestamp. Timestamp values are taken for fast channel and slow channel data.

The timestamp value is captured when the calibration pulse is detected.

The timestamp value for the fast channel is stored in the RSENTnFRTS.FTS bits.

The timestamp value for the slow channel is stored in the RSENTnSRTS.STS bits. The timestamp value for the slow channel is identical to the timestamp value of the last fast channel message contributing to the slow channel message.

In case timestamp counter synchronization is required, the following flow should be used.

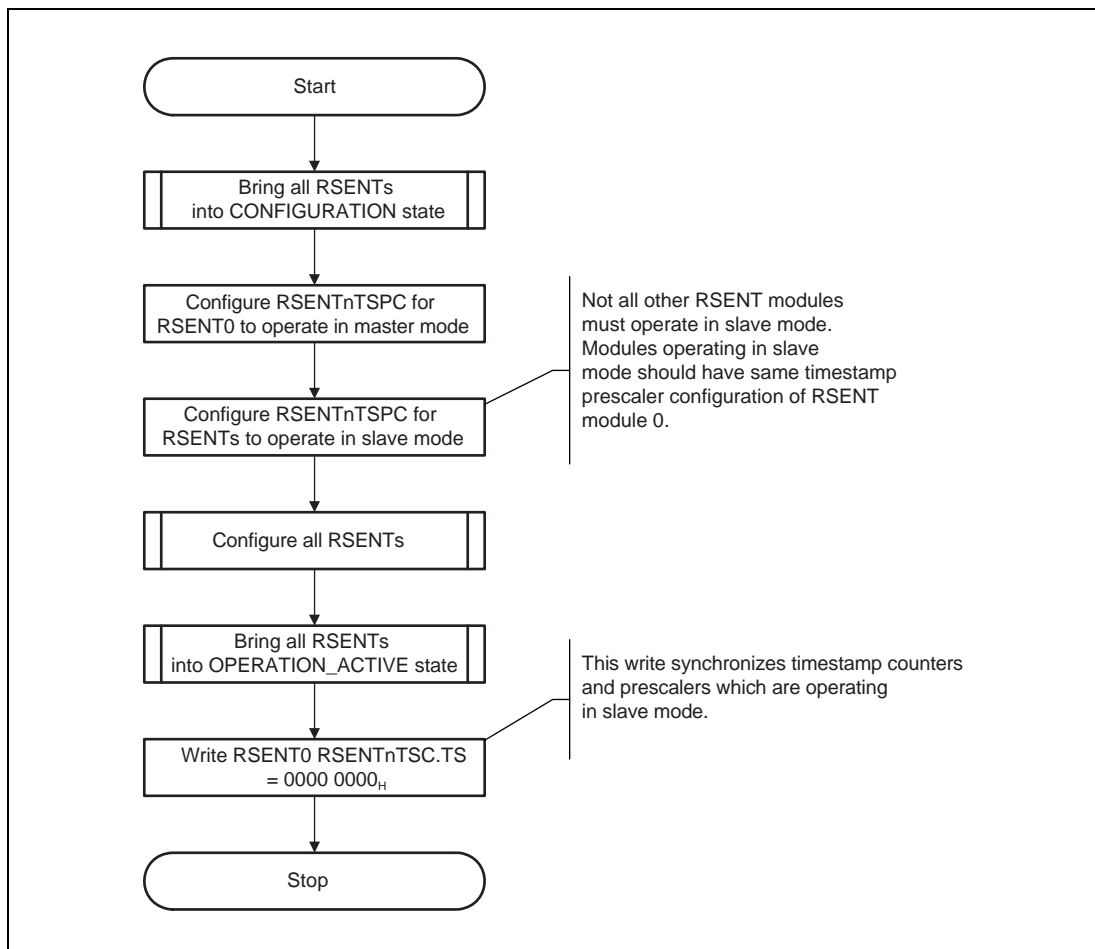

Figure 19.4 Timestamp Counter Synchronization

Synchronization of the timestamp can be done if the state of the master module has changed to OPERARION_ACTIVE or OPERARION_IDLE.

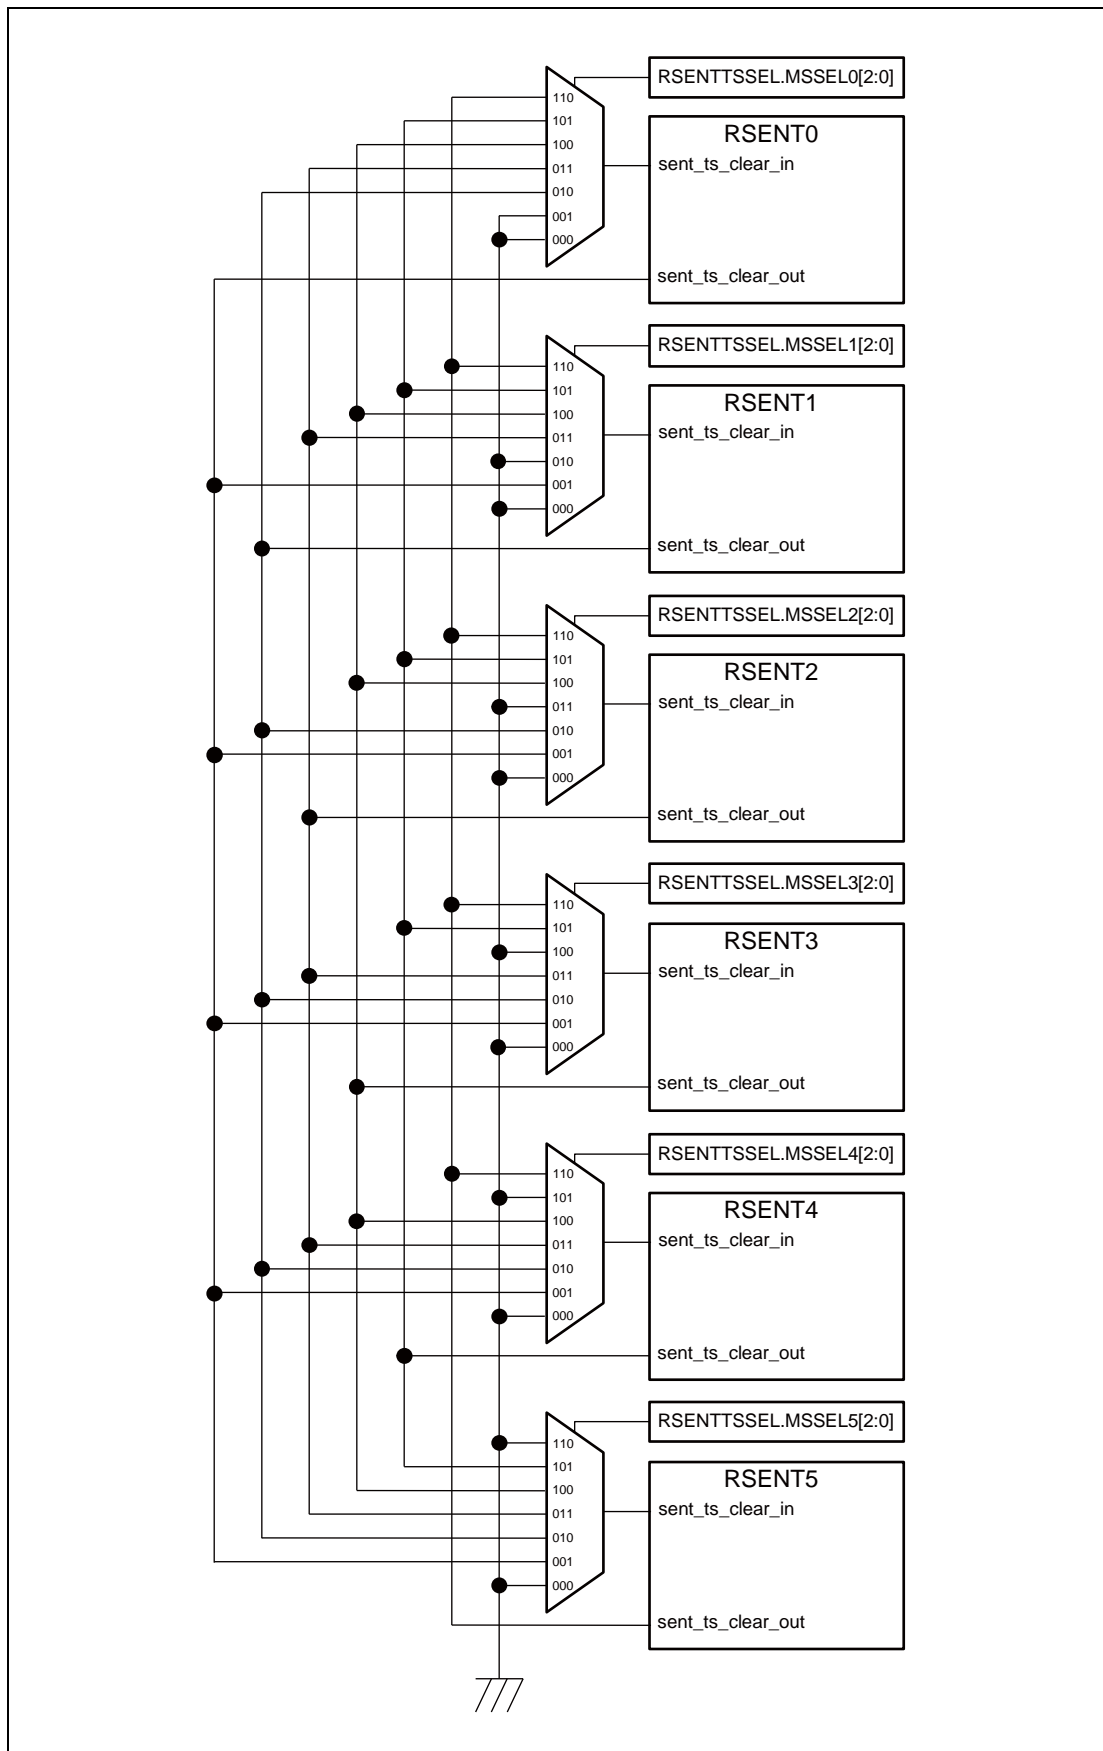

Figure 19.5 Timestamp Signal Connection among Channels

19.5.2 Communication Clock Configuration

19.5.2.1 RX BRP Setting

Use the formula below to obtain the settings for BRP.SCDV and BRP.SCMV in accord with $f_{\text{COMMUNICATION}}$ to be used (the frequency of the clk clock) so that the sample clock frequency is 16 MHz (for example, if the settings are for BRP.SCDV = 4/BRP.SCMV = 6, replace this with BRP.SCDV = 2/BRP.SCMV = 3). The input clock (clk clock) is frequency-divided according to the settings of BRP.SCDV and BRP.SCM to generate the sample clock.

Set $f_{\text{COMMUNICATION}}$ (the frequency of the clk clock) so that it falls within the range from 32 to 100 MHz (or at precisely 16 MHz). Use the formula below to obtain the values for BRP.SCDV and BRP.SCM such that the sample clock frequency becomes 16 MHz.

$$f_{\text{SAMPLE}} = 16 \text{ MHz} = f_{\text{COMMUNICATION}} \times \frac{\text{Sample Clock Multiplication Value}(\text{BRP.SCMV} + 1)}{\text{Sample Clock Division Value} (\text{BRP.SCDV} + 1)}$$

Where Sample Clock Multiplication Value = 1 (BRP.SCMV = 00000_B),

Sample Clock Division Value = 5 (BRP.SCDV = 0000100_B),

$f_{\text{COMMUNICATION}} = 80 \text{ MHz}$

$f_{\text{SAMPLE}} = 80 \times 1/5 = 16 \text{ MHz}$

19.5.2.2 RX and SPC Tick Settings

The used tick length in RX and SPC function can be configured with the RSENTnBRP.TTI and RSENTnBRP.TTF bits. Tick lengths from 1.0 μs to 90.0 μs with a resolution of 0.1 μs can be configured.

The RSENTnBRP.TTI holds the integer part of the tick length and the RSENTnBRP.TTF bits hold the fractional part of the tick length. The tick length is then calculated by:

$$T_{\text{TICK}} = T_{\text{BRP.TTI}} + T_{\text{BRP.TTF}}$$

Where BRP.TTI = 0000000_B, BRP.TTF = 0011_B

$T_{\text{TICK}} = 1 + 0.3 = 1.3 \mu\text{s}$

19.6 RSENT Operation

19.6.1 Changing Operation Modes

Once initialization has been completed in CONFIGURATION mode, operation can be enabled by entering OPERATION ACTIVE mode. This is done by setting the RSENTnMDC.OMC bits to OPERATION ACTIVE and waiting for the RSENTnMST.OMS to transition to OPERATION ACTIVE.

Once in OPERATION ACTIVE mode the RSENT module begins to receive messages or SPC communication can be started depending on the configuration.

Figure 19.6 shows the communication enabled flow assuming that the RSENT module is in RESET mode:

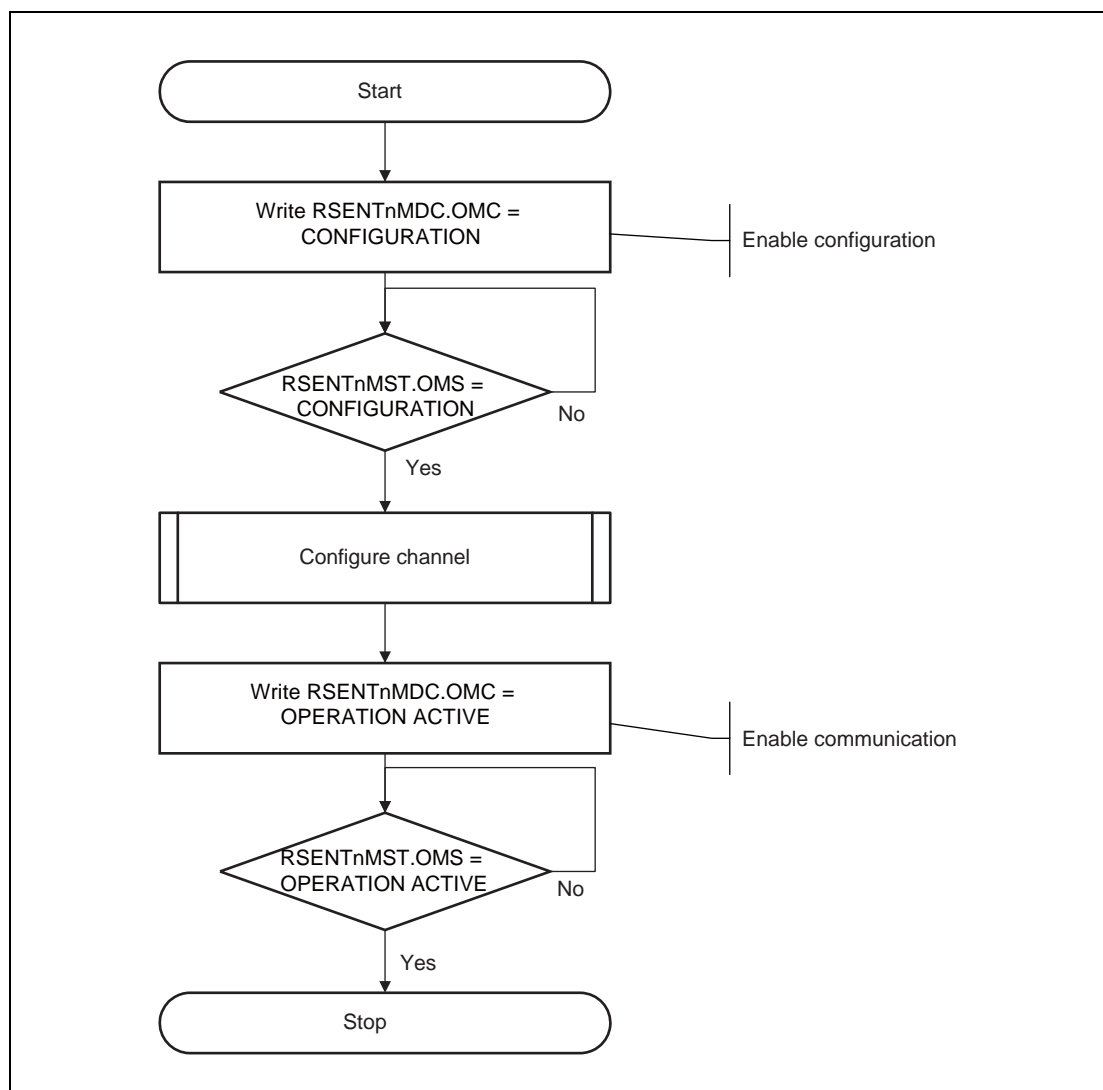

Figure 19.6 Communication Enable Flow

To leave OPERATION ACTIVE mode, communication should be disabled first by entering OPERATION IDLE mode. This is done by setting the RSENTnMDC.OMC bits to OPERATION IDLE and waiting for the RSENTnMST.OMS bits to transition to OPERATION IDLE.

However, when the SPC mode is enabled ($CC.SPCE = 1$) and the SPC trigger transmission has not been requested after the previous SPC communication has been completed (e.g. successful reception for the previous SPC trigger transmission), the RSENT module can directly enter the CONFIGURATION mode.

The transition between OPERATION ACTIVE and OPERATION IDLE depends on the setting of the $RSENTnCC.SPCE$ bit.

(1) $RSENTnCC.SPCE = 0$

In case a reception is currently ongoing, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the receive buffer was updated or error was flagged (see **Section 19.6.2.3, Fast Channel Message Reception**).

In case no reception is ongoing, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place immediately.

(2) $RSENTnCC.SPCE = 1$

In case a reception is ongoing, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the falling edge of the end pulse is received.

In case a no response error is flagged, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place at the same time as the error flagging.

The mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the sequence of making a SPC trigger and receiving the response has been completed. This means when a response was already received, the transition takes place immediately. When the response is still pending, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the falling edge of the end pulse is received.

CONFIGURATION mode can be entered by writing CONFIGURATION to the $RSENTnMDC.OMC$ bits and waiting for the $RSENTnMST.OMS$ to transition to CONFIGURATION.

Once CONFIGURATION mode is entered, the remaining status and message information stored in the RSENT module is lost since status and message information is cleared in CONFIGURATION mode.

Figure 19.7 shows the communication disable flow assuming that the RSENT module is in OPERATION ACTIVE mode.

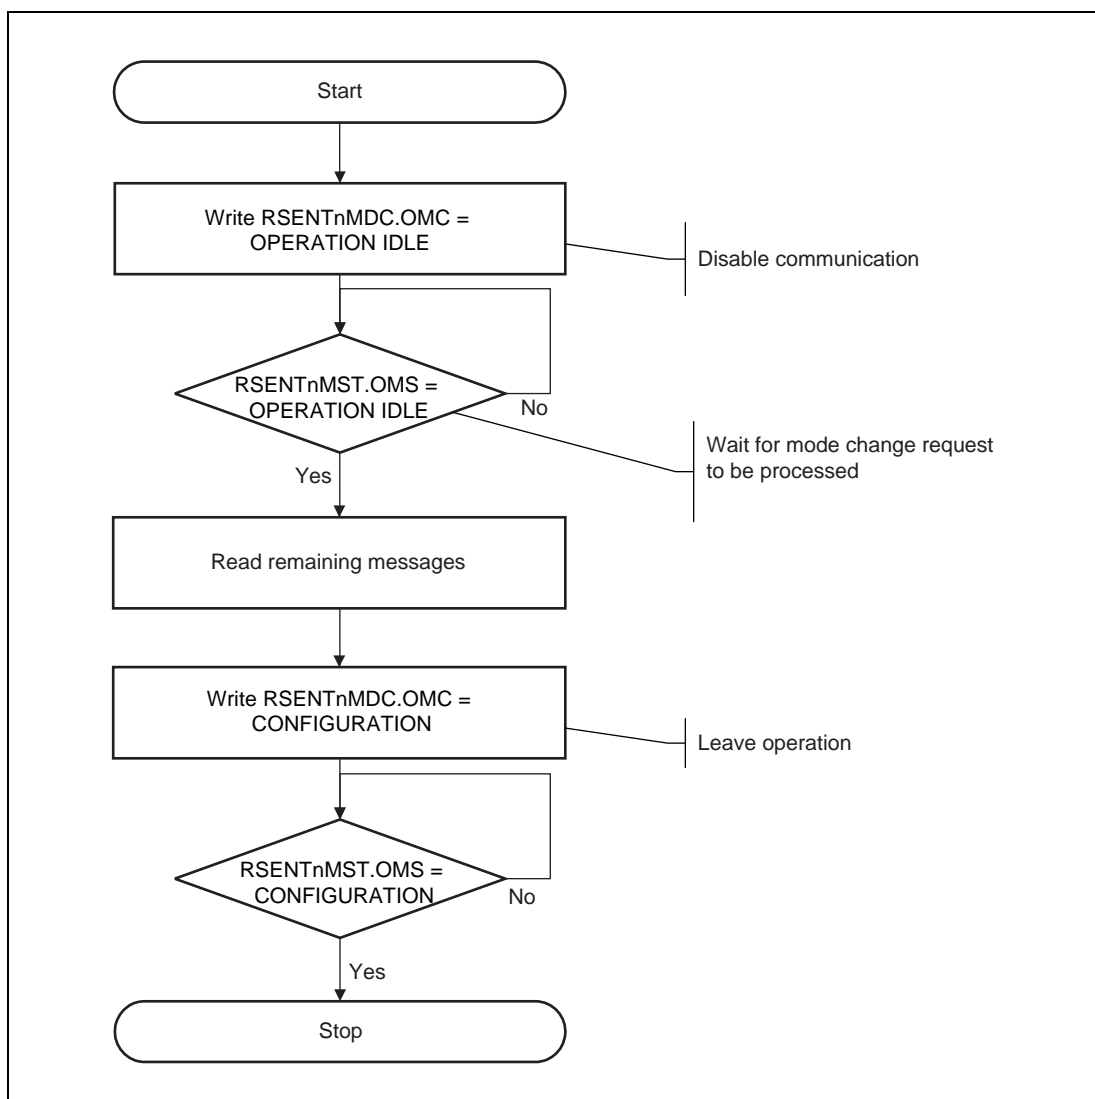

Figure 19.7 Communication Stop Flow

19.6.2 Message Reception

RSENT message reception is composed of the calibration pulse reception followed by the data nibble pulse reception.

Figure 19.8 RSENT Received Message Structure

19.6.2.1 Calibration Pulse Reception

Within the calibration pulse reception phase the internally generated clock tick is adjusted to the transmit clock speed.

In addition, the calibration pulse is used to end the previous message and perform message diagnostics. The RSENT module supports automatic calibration pulse length diagnostics in variable message length modes (RSENTnCC.PPTC = 0). In case the calibration pulse ratio check fails, the calibration pulse length variation error flag (RSENTnCS.CVS) is set to 1.

19.6.2.2 Data Nibble Reception

The receive function of the RSENT module is a straightforward capture and compare function. The RSENT module receives sensor information encoded by the temporal distance of two consecutive falling edges on the data line. The temporal distance (the number of clock ticks) is captured and compared against a set of values to determine the actual nibble value. The data encoding is illustrated in Table 19.27 below.

Table 19.27 Data Nibble Encoding

Nibble Period (Number of Clock Ticks)	Nibble Value (Binary)
12	0000 _B
13	0001 _B
14	0010 _B
15	0011 _B
16	0100 _B
17	0101 _B
18	0110 _B
19	0111 _B
20	1000 _B
21	1001 _B
22	1010 _B
23	1011 _B
24	1100 _B
25	1101 _B
26	1110 _B
27	1111 _B

The received data nibbles are composed into an RSENT message which is then stored in the fast channel message reception buffer.

Any other received nibble period during the reception of data nibbles will cause a fast channel nibble encoding error.

19.6.2.3 Fast Channel Message Reception

Messages received on the fast message channel are stored in a receive buffer.

A fast channel message reception buffer is composed of the calibration pulse length register (RSENTnCPL), the message length register (RSENTnML), the fast channel receive timestamp register (RSENTnFRTS), and the fast channel receive data register (RSENTnFRXD).

These registers are arranged on successive addresses for a transfer of the register content into memory using DMA.

The RSENT module is equipped with a double receive buffer structure that allows the storage of two complete RSENT messages including the related timestamp and message length information. Message decoding and assembling are done in a separate register stage.

Figure 19.9 Fast Channel Message Reception Buffer

The first received message is placed into the message buffer that can be accessed by the CPU. This buffer (except the RSENTnFRXD.SNDM bit) is not updated any more until the RSENTnFRXD.FND bit was read.

When a new message is placed into a receive buffer, the RSENTnFRXD.FND bit is set. At the same time, the RSENTnCS.FRS bit is set and, if enabled, a receive interrupt request is generated.

When receive buffer 1 is holding an unprocessed message (the RSENTnFRXD.FND bit is 1), any further incoming message is placed in receive buffer 2. Receive buffer 2 is updated with any further incoming messages. In case an unprocessed message in receive buffer 2 is overwritten, the RSENTnCS.FMS bit is set to 1.

When the CPU reads the RSENTnFRXD.FND bit and there is valid data in buffer 2, the data previously located in receive buffer 2 becomes available in the receive buffer and is accessible by the CPU. If enabled, a new interrupt request for fast channel data is generated and RSENTnCS.FRS is set.

When the RSENTnFRXD.FND/ RSENTnCS.FRS bit is not set, the data in the receive buffer is not defined and the CPU should not access the receive buffer.

Figure 19.10 Fast Channel Message Reception Buffer Update Timing

The update timing of the receive buffer depends on the applied configuration as depicted in **Figure 19.11** to **Figure 19.14**.

The RSENTnFRTS register is updated with the current timestamp counter register value when the calibration pulse is detected.

The data alignment in the RSENTnFRXD register depends on the nibble data count (RSENTnCC.NDN).

Table 19.28 Data Nibble Alignment in RSENTnFRXD Register

RSENTnCC.NDN	23:20	19:16	15:12	11:8	7:4	3:0
000 _B	Undefined	Undefined	Undefined	Undefined	Undefined	Nibble 1
001 _B	Undefined	Undefined	Undefined	Undefined	Nibble 1	Nibble 2
010 _B	Undefined	Undefined	Undefined	Nibble 1	Nibble 2	Nibble 3
011 _B	Undefined	Undefined	Nibble 1	Nibble 2	Nibble 3	Nibble 4
100 _B	Undefined	Nibble 1	Nibble 2	Nibble 3	Nibble 4	Nibble 5
101 _B	Nibble 1	Nibble 2	Nibble 3	Nibble 4	Nibble 5	Nibble 6

**(1) SAE operation with variable message length and preferred check method
(RSENTnCC.SPCE = 0, RSENTnCC.PPTC = 0, RSENTnCC.FCM = 0)**

In this operation mode, the RSENT module automatically performs the check for successive calibration pulse variation according to the preferred option in the J2716 2010 specification. In this mode, message diagnostics is done after the calibration pulse was received following a message.

If this check is passed, the message reception buffer is updated.

If this check is not passed, the message reception buffer is not updated and RSENTnCS.CVS is set to 1.

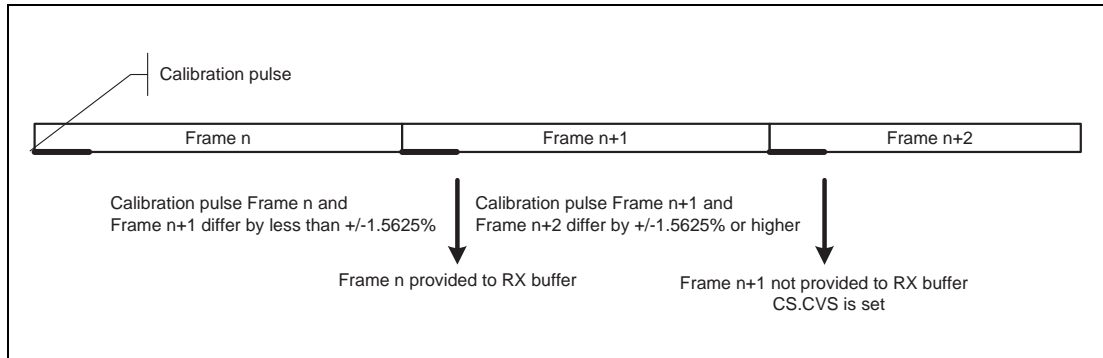

Figure 19.11 Buffer Update in Variable Message Length Mode and Preferred Check Method

**(2) SAE operation with variable message length and optional check method
(RSENTnCC.SPCE = 0, RSENTnCC.PPTC = 0, RSENTnCC.FCM = 1)**

In this operation mode, the RSENT module automatically performs the check for successive calibration pulse variation according to the optional frame check method as described in the J2716 2010 specification. In this mode, the calibration pulse of the current frame is compared to the calibration pulse of the last valid preceding frame.

If this check is passed, the message reception buffer is updated.

If this check is not passed, the message reception buffer is not updated and RSENTnCS.CVS is set to 1.

Figure 19.12 Buffer Update in Variable Message Length Mode and Optional Check Method

(3) SAE operation with fixed message length (RSENTnCC.SPCE = 0, RSENTnCC.PPTC = 1)

In this mode, the RSENT module does not perform the check for calibration pulse and message length ratio according to the preferred option in the J2716 2010 specification. In this mode, the RSENT module provides the calibration pulse length in the RSENTnCPL register and the message length information in the RSENTnML register. The numbers provided are based on samples.

The message buffer is updated at the beginning of the following calibration pulse irrespective of the values in the RSENTnCPL and RSENTnML registers. The CPU needs to calculate the ratio and either accept or discard the message.

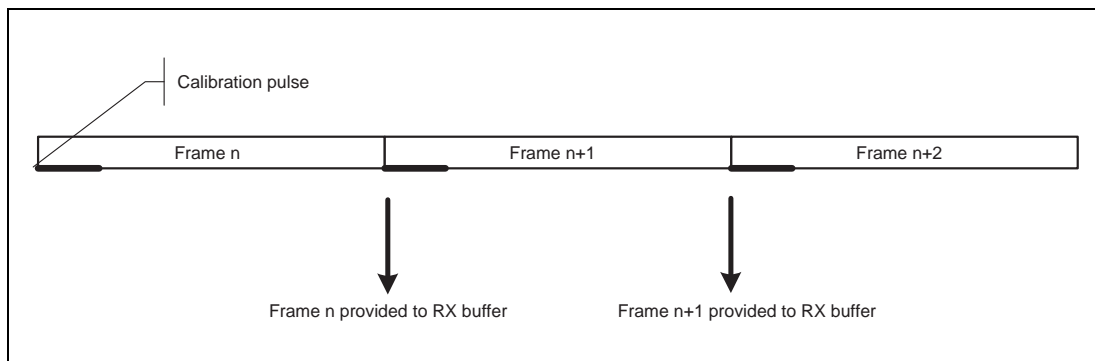

Figure 19.13 Buffer Update in Fixed Message Length Mode

The RSENTnCS.CVS (calibration pulse width variation error status) bit is never set in this mode.

(4) SPC operation (RSENTnCC.SPCE = 1)

In this operation mode, sensor data transmission is done following a SPC master trigger pulse. Within SAE SENT communication, the calibration pulse or pause pulse is aborting the previous message. In SPC communication, the sensor is only sending data following a SPC trigger request. An end pulse sent by the sensor is aborting the message. The message buffer is updated at the beginning of the end pulse.

Figure 19.14 Buffer Update in SPC Mode

The RSENTnCS.CVS (calibration pulse width variation error status) bit is never set in this mode.

The RSENT module provides the calibration pulse length in the RSENTnCPL register and the message length information in the RSENTnML register. The numbers provided are based on samples. The CPU needs to calculate the ratio of calibration pulses and/or message length and either accept or discard the message.

In case of variable message length mode, the RSENT module cannot perform this check because the receive timing of the next calibration pulse depends on the next SPC trigger timing.

19.6.2.4 Fast Channel Reception Flow

In **Figure 19.15**, the recommended reception flow for the fast channel message reception buffer is shown.

When using a polling or event driven method, the CPU should only read the setting of the RSENTnCS.FRS bit to check the availability of new fast channel data.

Figure 19.15 Fast Channel Reception Flow

In any case, the CPU should keep the order in reading the receive buffer registers as shown in the flow. The RSENTnFRXD register should be the last register to be accessed.

The handling of the slow channel message reception buffer is described in **Section 19.6.2.6, Slow Channel Reception Flow**.

In case of SAE communication with pause pulse and fixed message length, the flow must be extended by checking of the ratio of the calibration pulse to message length. This variation check must be performed by the CPU. In case the variation check fails, the CPU must discard the received message.

19.6.2.5 Slow Channel Message Reception

The RSENT module supports extraction of the slow message out of the fast channel messages by using the status and communications nibble bits 3 and 2 out of the status and communications nibble. In order to enable the slow channel extraction, the CPU should set the RSENTnCC.SMF bits to the expected serial message format.

When no serial message extraction is selected (RSENTnCC.SMF = 00_B), the RSENTnSRXD register becomes part of the fast channel message reception buffer structure (including buffer 2) and RSENTnSRTS register should be ignored. The communications and status nibble is placed in the RSENTnSRXD.IDD bits. Furthermore no slow channel new data and slow channel message lost flags are generated.

In order to receive the slow channel serial message, all fast channel serial messages contributing to a slow channel serial message must be received successfully and the received slow channel serial message must comply with the selected serial message format.

A message lost on the fast channel does not impact the reception on the slow channel.

A slow channel message reception buffer is composed of the slow channel receive timestamp register (RSENTnSRTS) and the slow channel receive data register (RSENTnSRXD).

In opposite to the fast channel message reception buffer, the slow channel message reception buffer does not support a double receive buffer structure; only a single receive buffer structure is available.

Message decoding and assembling is done in a separate register stage.

Figure 19.16 Slow Channel Message Reception Buffer

The slow channel message reception buffer is updated at the same time as the fast channel message reception buffer that holds the last status and communications nibble required for the slow channel message. The RSENTnSRXD.SND bit is set to 1 at the same time.

Further updates to the buffer are not carried out until after the RSENTnSRXD.SND bit has been read.

When the receive buffer is holding an unprocessed message (RSENTnSRXD.SND is 1), any further incoming message is lost (the slow channel message reception buffer is not updated) and RSENTnCS.SMS is set to 1.

When the CPU reads the RSENTnSRXD register, RSENTnSRXD.SND is automatically cleared.

The RSENTnSRTS register is updated with the current timestamp counter register value of the last frame contributing to the slow channel message.

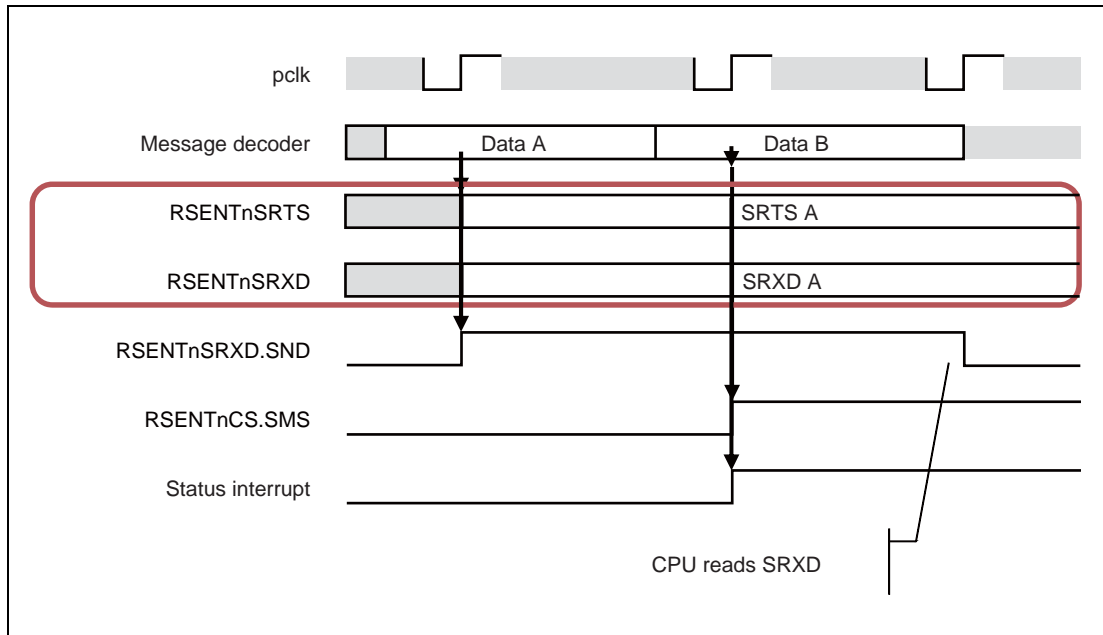

Figure 19.17 Slow Channel Message Reception Buffer Update Timing

The data alignment in the SRDX register depends on the slow channel message format (RSENTnCC.SMF) and the received configuration bit.

Table 19.29 Data Alignment in RSENTnSRXD Register

RSENTn CC.SMF	RSENTnSRXD.SMGC	RSENTnSRXD.IDD [19:16]	RSENTnSRXD.IDD [15:12]	RSENTnSRXD.IDD [11:8]	RSENTnSRXD.IDD [7:4]	RSENTnSRXD.IDD [3:0]
00 _B	Undefined	Undefined	Undefined	Undefined	Undefined	C & S nibble
01 _B	Undefined	Undefined	Undefined	Message ID[3:0]	DATA[7:4]	DATA[3:0]
10 _B	0	Message ID[7:4]	Message ID[3:0]	DATA[11:8]	DATA[7:4]	DATA[3:0]
10 _B	1	Message ID[3:0]	DATA[15:12]	DATA[11:8]	DATA[7:4]	DATA[3:0]

19.6.2.6 Slow Channel Reception Flow

In **Figure 19.18**, the recommended reception flow for the slow channel message reception buffer is shown. When the slow channel receive data is required, this process should be executed as part of the fast channel reception flow.

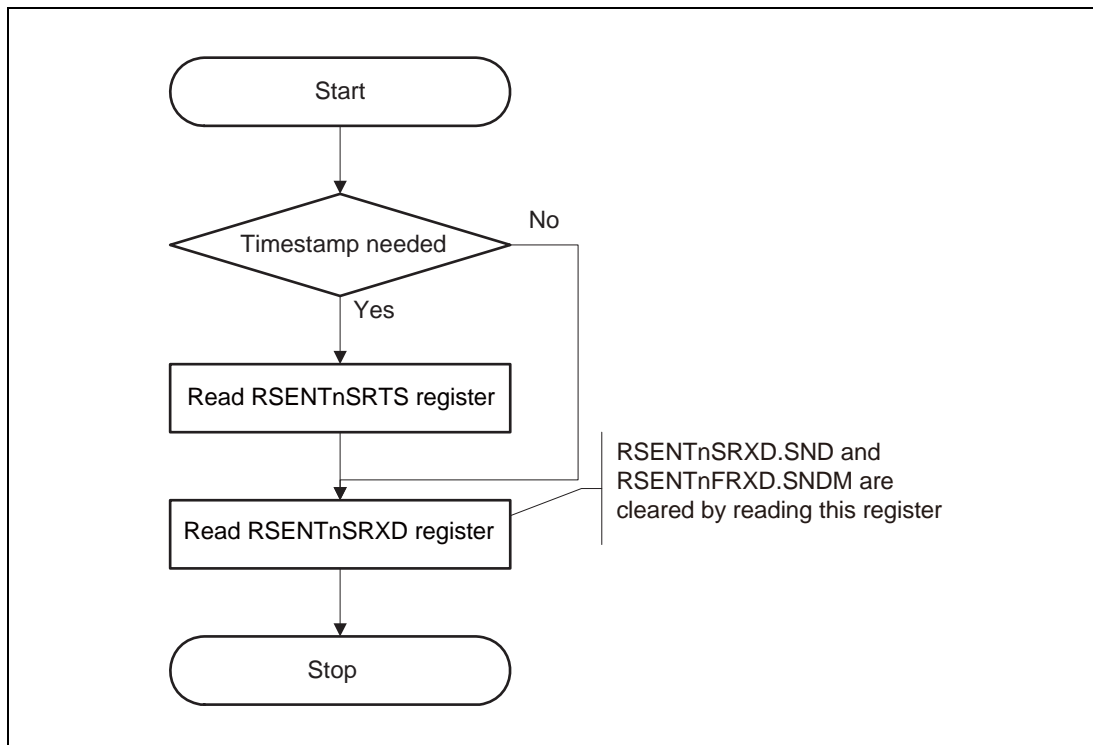

Figure 19.18 Slow Channel Reception Flow

In any case, the CPU should keep the order in reading the slow channel message reception buffer registers as shown in the flow. The RSENTnSRXD.SND bit should be accessed as last.

19.6.2.7 DMA Flow

In case of DMA usage, the start address for the DMA usage and the number of transfers define which part of the receive buffer will be transferred. The RSENTnFRXD register should be the last register to be accessed using a 32 bit access method.

In case of SAE communication with pause pulse and fixed message length, the flow must be extended by checking of the ratio of the calibration pulse to message length. This variation check must be performed by the CPU. In case the variation check fails, the CPU must discard the received message.

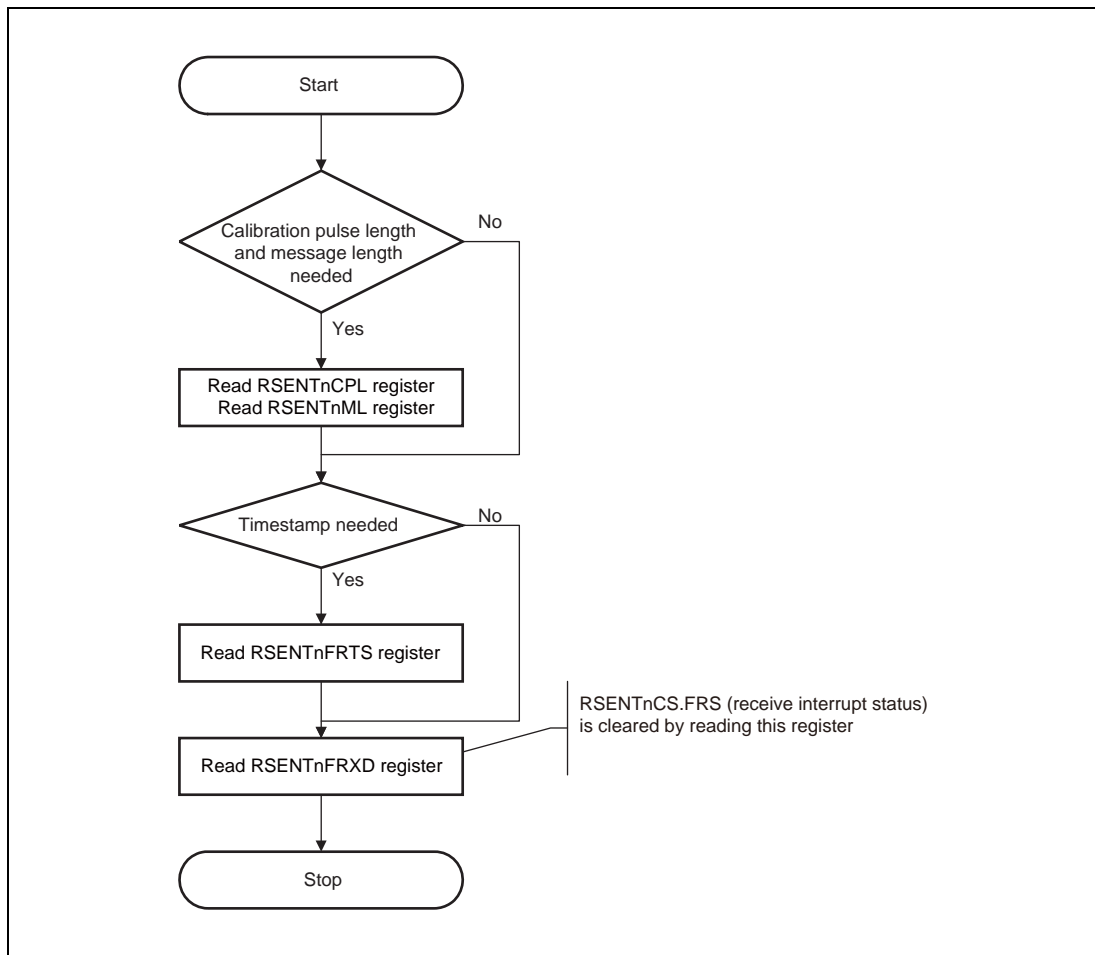

Figure 19.19 DMA Reception Flow

In the software processing, when the transferred data set, the CPU should check the status of the transferred RSENTnFRXD.SNDM bit. If this bit is set to 1, then the user needs to read the slow channel message reception buffer if needed.

19.6.2.8 Error Flagging

The message lost error flag (RSENTnCS.SMS or RSENTnCS.FMS) is set when a new message's diagnostics pass before the previous message is read.

The no response error flag (RSENTnCS.NRS) is set when the CPU has written to RSENTnSPTC.TLL before or during response reception.

The timing at which the fast channel reception error flags (RSENTnCS.CVS, RSENTnCS.CLS, RSENTnCS.FNS, RSENTnCS.FES, and RSENTnCS.FCS) and the slow channel reception error flags (RSENTnCS.SCS, and RSENTnCS.SES) are updated varies with the setting of bits in the communications configuration register (RSENTnCC.SPCE, RSENTnCC.FCM, RSENTnCC.PPC, and RSENTnCC.PPTC).

Table 19.30 and **Table 19.31** list the timings with which the error flags corresponding to each setting are updated.

When a fast channel nibble encoding error or calibration pulse length error is detected, message reception is aborted immediately. No further error flagging for the given message is done. Message decoding starts again after the detection of a valid calibration pulse.

When OPERATION IDLE mode is entered in response to the setting of RSENTnMDC.OMC, error flags of errors for the calibration or the fast channel reception which have been detected in a message being received are not set. A received message is also discarded.

If a fast channel nibble encoding error or calibration pulse length error is detected, entry to OPERATION IDLE mode is immediate.

If a fast channel nibble count error, fast channel CRC error, or calibration pulse length variation error is detected, entry to OPERATION IDLE mode proceeds at the end of the next status and communications nibble.

The fast channel nibble count error flag (RSENTnCS.FNS) is only set when a valid calibration pulse is detected and the subsequent data nibble has a valid length (≥ 12 ticks and ≤ 27 ticks) or no data nibble has been received between two valid calibration pulses.

The fast channel nibble encoding error flag (RSENTnCS.FES) is only set when an encoding error has occurred in a status and communications nibble, CRC nibble, or data nibble.

When the SPC function is enabled (i.e. RSENTnCC.SPCE = 1), the calibration pulse length error flag (RSENTnCS.CLS) is set when the width of a pulse at the expected calibration pulse position is not a valid pulse width for a calibration pulse. When the SPC function is disabled (i.e. RSENTnCC.SPCE = 0), the calibration pulse length error flag (RSENTnCS.CLS) is set when the width of a pulse at a next expected calibration pulse position after the reception of a valid calibration pulse is not a valid pulse width for a calibration pulse.

An additional error flag being set while seeking a valid calibration pulse does not affect the reception of subsequent frames.

Table 19.30 Timing to Set Error Flag (RSENTnCC.SPCE = 0)

RSENTnCC.SPCE	0							
RSENTnCC.FCM	0				1			
RSENTnCC.PPC	0		1		0		1	
RSENTnCC.PPTC	0	1	0	1	0	1	0	1
RSENTnCS.FCS	EC	x	EC	IM	IM	x	IM	IM
RSENTnCS.FES	EC	x	EC	IM	IM	x	IM	IM
RSENTnCS.FNS	EC	x	EC	—	—	x	—	—
RSENTnCS.SCS	IM	x	IM	IM	IM	x	IM	IM
RSENTnCS.SES	IM	x	IM	IM	IM	x	IM	IM
RSENTnCS.CLS	IM	x	IM	IM	IM	x	IM	IM
RSENTnCS.CVS	EC	x	EC	—	EC	x	EC	—

Note: EC: End of calibration pulse (on the falling edge of a valid calibration pulse)
IM: Immediately upon detection (immediately when the error is detected)
—: Error flag not detected
x: Setting prohibited

Table 19.31 Timing to Set Error Flag (RSENTnCC.SPCE = 1)

RSENTnCC.SPCE	1							
RSENTnCC.FCM	0				1			
RSENTnCC.PPC	0		1		0		1	
RSENTnCC.PPTC	0	1	0	1	0	1	0	1
RSENTnCS.FCS	IM	x	IM	IM	IM	x	IM	IM
RSENTnCS.FES	IM	x	IM	IM	IM	x	IM	IM
RSENTnCS.FNS	—	x	—	—	—	x	—	—
RSENTnCS.SCS	IM	x	IM	IM	IM	x	IM	IM
RSENTnCS.SES	IM	x	IM	IM	IM	x	IM	IM
RSENTnCS.CLS	IM	x	IM	IM	IM	x	IM	IM
RSENTnCS.CVS	—	x	—	—	—	x	—	—

Note: EC: End of calibration pulse (on the falling edge of a valid calibration pulse)
IM: Immediately upon detection (immediately when the error is detected)
—: Error flag not detected
x: Setting prohibited

NOTE

When the sensor stops communications, the reception buffer and the state will not be updated after reception of the last message. Confirm the timeout by software.

19.7 SPC Function

The RSENT module supports an extension of the J2716 specification known as SPC, whereby the RSENT module can pull down the RX line to initiate RSENT message transmission.

The user can configure the polarity of the sent_spc port.

The text below describes the behavior of the sent_spc port with the default settings of RSENTnCC.SOPC. When the value of RSENTnCC.SOPC after a reset is changed, the sent_spc port operates with inverted polarity.

The user can enable or disable the SPC extension by setting the RSENTnCC.SPCE bit. When the RSENTnCC.SPCE bit is set to 0, SPC is disabled. The sent_spc port is driven low by the RSENT module, allowing normal RSENT reception to take place. When the RSENTnCC.SPCE bit is set to 1, SPC is enabled and the sent_spc port can be driven high by the RSENT module to request a frame transmission by the sensor.

The transmission function of the RSENT module is a straightforward PWM function. The purpose of this function is to communicate in direction to the sensor by the output sent_spc. With the sent_spc output, the RSENT module can pull down the signal line by an external transistor. The signal line will be held low for a configured length of tick time specified in the RSENTnSPCT.TLL bits.

The tick time is configured with the RSENTnBRP.TTI bits and the RSENTnBRP.TTF bits which are equal to the transmission tick time. For details, see **Section 19.5.2.2, RX and SPC Tick Settings**.

In a single sensor system, this function can be used to trigger data transmission from the sensor. Further data can be sent to the sensor by varying the trigger pulse length. In a multi sensor system, this function can be used to address a dedicated sensor and request a data transmission.

Once RSENT SPC initialization is complete, transmission can be triggered by writing the trigger pulse width to the RSENTnSPCT.TLL register. When a transmission is triggered, the trigger pulse with the configured length is sent. Then a frame reception is expected. After frame reception was done, a new trigger pulse can be sent.

Writing to RSENTnSPCT.TLL requests a SPC trigger transmission. After writing to RSENTnSPCT.TLL, the CPU should read RSENTnCS.NRS to check whether the previous request was completed or not.

In case RSENTnCS.NRS is set, no SPC trigger is sent and any potentially ongoing reception at this time is aborted. The CPU should clear RSENTnCS.NRS by writing 1'b1 to RSENTnCS.NRC. The CPU can write again to RSENTnSPCT.TLL to request a SPC trigger transmission.

In case RSENTnCS.NRS is not set, the CPU should set a reception timeout counter in software. If a reception occurs before the timeout counter elapses, the user should process the received slow and fast channel data as shown in the fast channel reception flow (**Figure 19.15**) and slow channel reception flow (**Figure 19.18**).

When the timeout counter elapses without any successful reception, the addressed sensor seems not to send any valid response. The CPU should analyze the RSENTnCS register to analyze the reason for no successful reception. A new request can be made considering that when RSENTnCS.NRS gets set no SPC trigger is sent.

Purpose of the timeout function is to define a timeout window for response reception in software.

Figure 19.20 shows a transmission flow with a timeout function implemented in software. The timeout function is optional and can be omitted if not needed.

Figure 19.20 Transmission Flow

19.7.1 Multiplexing of the SENTnRX and SENTnSPCO Pin Functions

The SENTnRX input pin and SENTnSPCO output pin functions are assigned to the same multiplexed pin. Two functions can be used on the pin, when it is set for an N-ch open-drain configuration.

Figure 19.21 is a block diagram of multiplexing of the SENTnRX and SENTnSPCO pin functions.

Figure 19.21 Multiplexing of the SENTnRX and SENTnSPCO Pin Functions

Connect the sent_spc signal, which is an RSENT macro output signal, to an N-ch open drain I/O buffer. The RSENT hardware macro is able to control the polarity of sent_spc output and the polarity of the pin output by setting the SOPC bit and the PINVn register of the I/O buffer, respectively. These registers must be set in an appropriate combination.

Table 19.32 lists the register settings when the SENTnRX and SENTnSPCO pin functions share the same pin.

Table 19.32 Setting for Multiplexing of the SENTnRX and SENTnSPCO Pin Functions

Register Name	Setting	Description	
PMcN	Port mode control register	1	Alternative mode
PMn	Port mode register	0	Output mode (output enabled)
PIPcN	Port IP control register	0	I/O mode is controlled by PMn.PMn_m (software or hardware I/O control)
PBDCn	Port bi-direction control register	1	Bi-direction mode is enabled
PODCn	Port open-drain control register	1	N-ch open drain (PODCn_m = 1 or PODCEn_m = 0)
PODCEn	Port open-drain expansion register	0	N-ch open drain (PODCn_m = 1 or PODCEn_m = 0)
PINVn	Port output level inversion register	0	The pin output level is not inverted (active low when RSENTnCC.SOPC = 1)
		1	The pin output level is inverted (active high when RSENTnCC.SOPC = 0)
PFCn	Port function control register	—	Specify an alternative function of the pins. For details, see Table 2.6, Outline of Alternative Mode Selection (PMcN.PMcN_m = 1) .
PFCEn	Port function control expansion register		
PFCAEn	Port function control addition expansion register		

19.8 Interrupts and Checks

The RSENT module provides two interrupt lines.

The successful fast channel receive interrupt notifies the CPU that the fast channel message reception buffer was updated and is holding a set of valid received data. Also, the reception status bit is set (RSENTnCS.FRS).

The status interrupt notifies the CPU that at least one of the error flags or message lost flags in the RSENTnCS register is set.

Whether a status flag in the RSENTnCS register is contributing to the generation of an interrupt event or not can be set individually.

The execution of the CRC checks can be disabled for the slow channel and fast channel individually. In case a check is disabled, the CRC of the received message is not checked and the related error flag is never set.

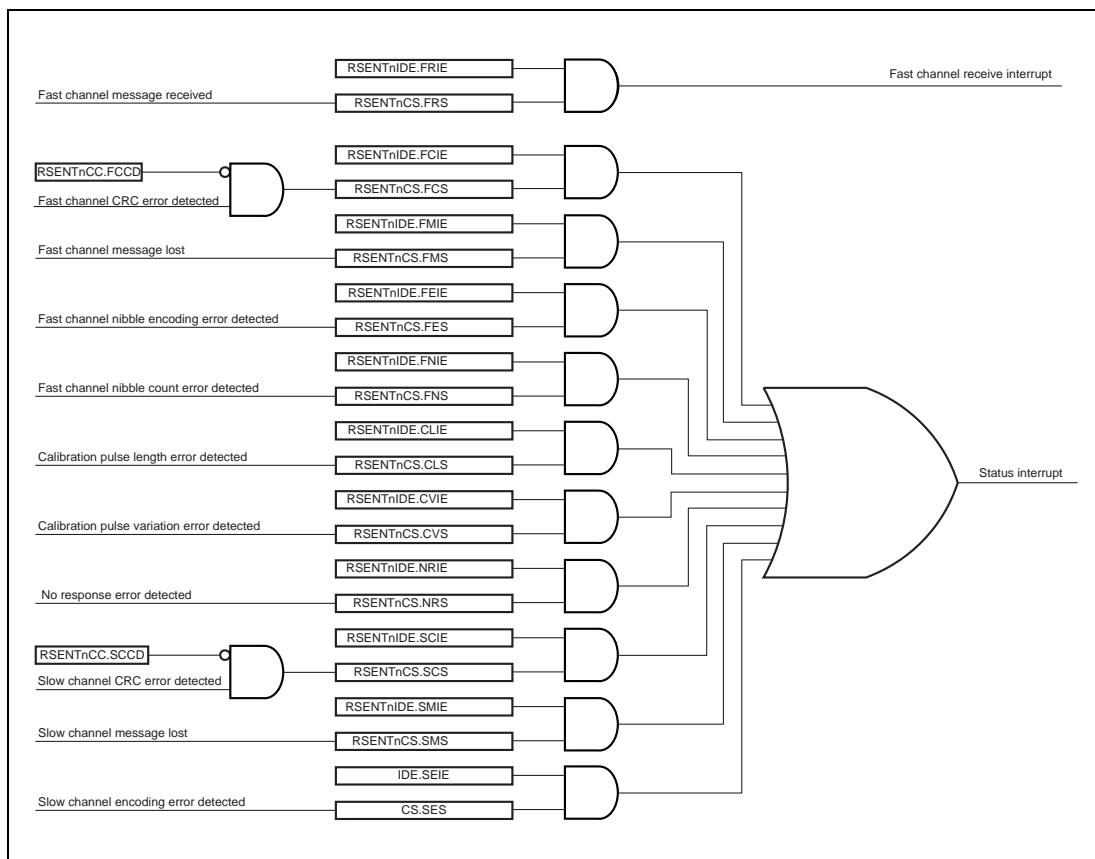

Figure 19.22 Interrupt Structure

Table 19.33 gives an overview about the relationship between set status flags and the buffer update.

Table 19.33 Status Flag Influence to Receive Buffer Behavior

RSENTnCS	Fast Channel Message Reception Buffer	Slow Channel Message Reception Buffer
FRS	Updated	Updated if all status and communications nibbles of slow channel messages are received and RSENTnCS.SES=0 and RSENTnCS.SCS=0
FCS	Not updated	Receive process aborted. Search for new start condition
FMS	Message lost	Not impacted
FES	Not updated	Receive process aborted. Search for new start condition
FNS	Not updated	Receive process aborted. Search for new start condition
CLS	Not updated	Receive process aborted. Search for new start condition
CVS	Not updated	Receive process aborted. Search for new start condition
NRS	Not updated	Receive process aborted. Search for new start condition
SCS	Not impacted	Not updated
SMS	Not impacted	Message lost
SES	Not impacted	Receive process aborted. Search for new start condition

Section 20 PSI5

The Peripheral Sensor Interface 5 (PSI5) is a function of interface the PSI5 (PSI5 v2.0) standard for sensor. PSI5 is implemented 2 channels.

20.1 Features of RH850/P1M-E PSI5

20.1.1 Number of Channels

This microcontroller has the following number of PSI5 channels.

Table 20.1 Number of Channels

Product	RH850/P1M-E 100 pins	RH850/P1M-E 144 pins
Number of channels	2	2
Name	PSI5n (n = 0, 1)	PSI5n (n = 0, 1)

Table 20.2 Index

Index	Meaning
n	Throughout this section, the individual channels of the PSI5 are identified by the index "n" (n = 0, 1).

20.1.2 Register Base Address

PSI5n base addresses are listed in the following table. PSI5n register addresses are given as offsets from the base address in general.

Table 20.3 Register Base Address

Base address Name	Base Address
<PSI50_base>	FFE0 0000 _H
<PSI51_base>	FFE0 1000 _H

20.1.3 Clock Supply

Clock supply by and to PSI5n is listed in the following table.

Table 20.4 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
PSI5n	PCLK psi5_com_clk	High-speed peripheral clock CLK_HSB

20.1.4 Interrupt Requests

The PSI5 can generate the interrupt requests shown in the following table.

Table 20.5 Interrupt Requests

Unit Interrupt Name	Outline	Interrupt	DMA/DTS Trigger
PSI50			
INTPSI50SI* ¹	PSI50 status interrupt	226	—
INTPSI50RI	PSI50 receive interrupt	227	117
INTPSI50TI	PSI50 transfer interrupt	228	—
PSI51			
INTPSI51SI* ¹	PSI51 status interrupt	229	—
INTPSI51RI	PSI51 receive interrupt	230	118
INTPSI51TI	PSI51 transfer interrupt	231	—

Note 1. A set of multiple interrupts.

20.1.5 Reset Sources

Please refer to **Section 8, Reset Controller**.

20.1.6 External Input/Output Signals

The external input/output signals of the PSI5 are listed in the following table.

Table 20.6 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
PSI50			
psi5_rx_data	I	PSI50 data input	Port PSI50DIN
psi5_tx_data	O	PSI50 data output	Port PSI50DOUT
PSI51			
psi5_rx_data	I	PSI51 data input	Port PSI51DIN
psi5_tx_data	O	PSI51 data output	Port PSI51DOUT

20.2 Functions

Features and functions

Among the main functions defined under the PSI5 standard (PSI5 v2.0), this IP supports the following:

- Communication Mode
 - PSI5-A: Asynchronous mode
 - PSI5-P: Synchronous parallel bus mode
 - PSI5-U: Synchronous parallel universal bus mode
 - PSI5-D: Synchronous daisy chain bus mode
 - PSI5-V: Variable time triggered synchronous operation mode
- Sensor to ECU Communication
 - Data can be received up to eight slots.
 - Bit rates: Low speed (125 Kbps); High speed (189 Kbps)
 - Automatic detection of start bits
 - Manchester to binary code conversion
 - Receivable bit length: 10 to 28 bits
 - Serial message frames can be received up to eight slots.
 - Automatic calculation of check bits for both data and serial message frames
 - Stores CRC and parity bits received with the data.
- ECU to Sensor Communication
 - Tooth Gap Mode
 - Pulse Width Mode
 - Automatic detection of start conditions
 - Frame formats 1 to 4 can be used
 - Automatic appending of synchronization bits
 - Automatic appending of CRCs
- PAS compatibility mode
 - 250 Kbps
 - MSB First reception
 - Parity check
- Appending of a timestamp to receive data and serial message frames
 - Master and slave function for synchronization of timestamp

Table 20.7 List of Operation Modes

Operation Mode	Normal Mode	PAS Compatibility Mode
Bit rate	125 Kbps/189 Kbps	250 Kbps
Data word length	10 to 28 bits	8 to 24 bits
Data direction	LSB first	MSB first
Data transmission parameter		
Value of bit time (TYP.)	8 μ s/5.3 μ s	4 μ s
Value of gap time (MIN.)	8.4 μ s/5.6 μ s	2 μ s
Communication Mode	PSI5-A, PSI5-S, PSI5-U, PSI5-D, PSI5-V	PSI5-A only

20.2.1 Block Configuration

Figure 20.1 is a block diagram of PSI5n.

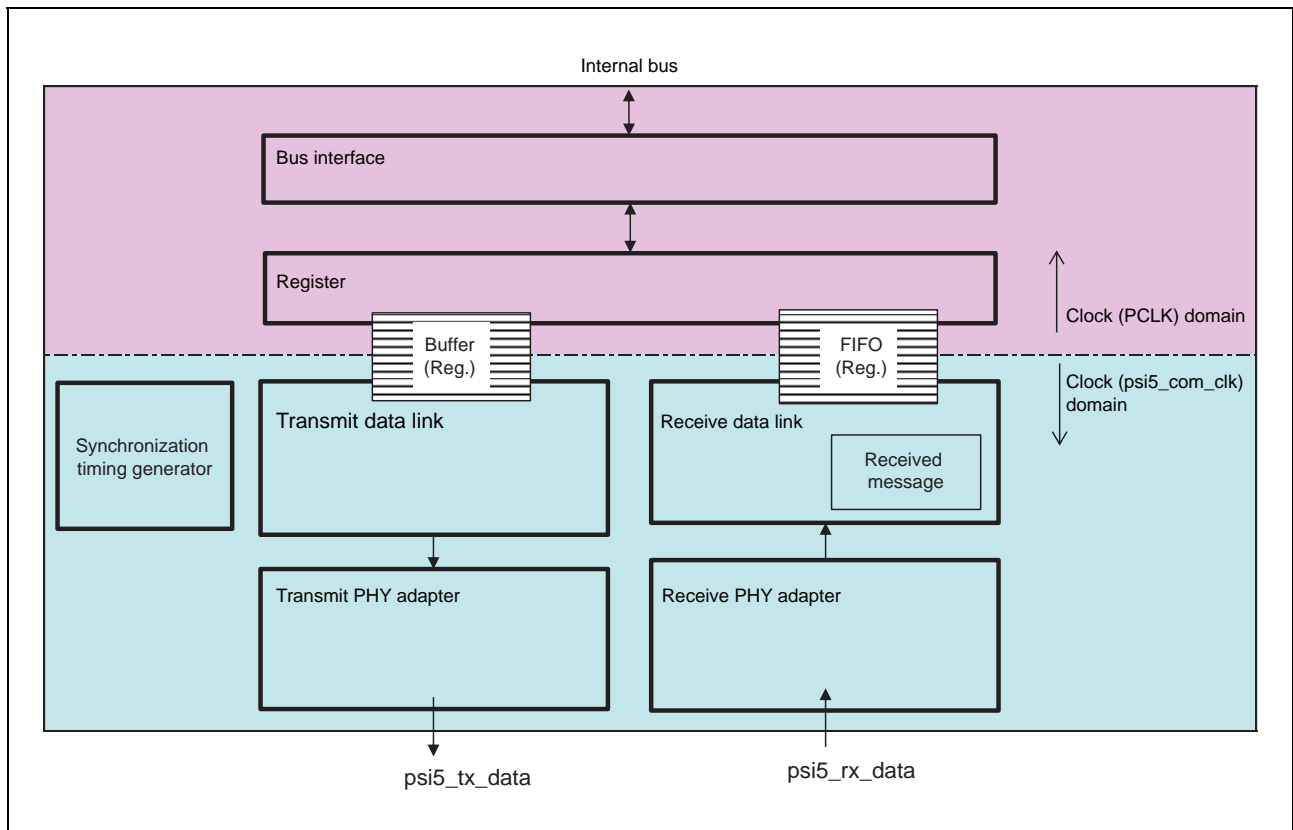

Figure 20.1 Block Diagram of PSI5

20.3 Registers

The PSI5n is controlled and operated by the registers listed in the table below.

For PSI5n base address <PSI5n_base>, see **Section 20.1.2, Register Base Address**.

Table 20.8 PSI5n Register Overview (1/2)

Register Name	Symbol	Address
PSI5 channel control register	PSI5nCHCTRL	<PSI5n_base> + 0000 _H
PSI5 IP timer control register	PSI5nIPTIMERCTRL	<PSI5n_base> + 0010 _H
PSI5 IP timer counter	PSI5nIPTIMER	<PSI5n_base> + 0014 _H
PSI5 operating mode/communication mode register	PSI5nOPMCOMM	<PSI5n_base> + 0020 _H
PSI5 operating-mode bit rate register	PSI5nOPMBITRATE	<PSI5n_base> + 0024 _H
PSI5 operating-mode cycle time register	PSI5nOPMCYCT	<PSI5n_base> + 0028 _H
PSI5 interrupt status register	PSI5nPSI5INT	<PSI5n_base> + 0030 _H
PSI5 receive data emulation register	PSI5nEMRXDATA	<PSI5n_base> + 0040 _H
PSI5 receive data status emulation register	PSI5nEMRXDST	<PSI5n_base> + 0044 _H
PSI5 receive data IP timer emulation register	PSI5nEMRXDTIM	<PSI5n_base> + 0048 _H
PSI5 receive data FIFO emulation register	PSI5nEMRXDFIFO	<PSI5n_base> + 004C _H
PSI5 receive-message receive message emulation register	PSI5nEMRXMRXMSG	<PSI5n_base> + 0050 _H
PSI5 receive-message channel receive status emulation register	PSI5nEMRXMRXST	<PSI5n_base> + 0054 _H
PSI5 receive-message channel receive timestamp emulation register	PSI5nEMRXMRXTIM	<PSI5n_base> + 0058 _H

20.3.1 PSI5nCHCTRL — PSI5 Channel Control Register

This register controls the channel operation.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0000_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CHEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 20.9 PSI5nCHCTRL Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	CHEN	<p>Channel Enable</p> <p>0: Channel disabled</p> <p>1: Channel enabled</p> <p>In synchronous mode, the PSI5 starts to send a synchronization pulse after enabling the channel. In asynchronous mode, the PSI5 sets psi5_tx_data according to PSI5nTXSETTING.DEFTXVAL.</p> <p>When the channel is enabled, writing to the following registers is disabled: PSI5nOPMCOMM, PSI5nOPMBITRATE, PSI5nOPMCYCT, PSI5nTXSETTING, PSI5nRXSPLSET, PSI5nRXSmSET, and PSI5nRXMSET</p> <p>After writing to this bit, check that the setting is reflected by reading the bit by software.</p>

CAUTION

The following registers must be set only when channel operation is enabled (PSI5nCHCTRL.CHEN = 1).

- PSI5nRXMODSTINTEN.RXDEXISTINTEN = 1
- PSI5nTXSTINTEN.TXEMPTYINTEN = 1
- PSI5nTXDATA.TXDATA

20.3.2 PSI5nIPTIMERCTRL — PSI5 IP Timer Control Register

This register controls the IP timer.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0010_H

Value after reset: 0001 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MSTSLV
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TSCLR	—	—	—	—	—	—	—	IPTIMEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Table 20.10 PSI5nIPTIMERCTRL Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is read. When writing, write the value after reset.
16	MSTSLV	Specifies timer master/slave mode. 0: Slave mode is selected 1: Master mode is selected <ul style="list-style-type: none"> In slave mode: The IP timer counts up according to the count-up timing signal (psi5_ts_tick_in) input through the master channel. The value of the PSI5nIPTIME register is cleared when the TSCLR bit is set or in response to the input of the clearing timing signal (psi5_ts_clr_in) through the master channel. In master mode: IPTIMER counts up in response to the clock generated by the internal baud rate generator. PSI5 outputs the count-up timing signal (psi5_ts_tick_out). Setting the TSCLR bit to 1 clears the values in PSI5nIPTIMER (the clearing timing signal (psi5_ts_clr_out) is output).
15 to 9	Reserved	When read, the value after reset is read. When writing, write the value after reset.
8	TSCLR	IP Timer Clear Trigger 0: The IP timer (PSI5nIPTIME register) is not cleared. 1: The IP timer (PSI5nIPTIME register) is cleared. The TSCLR bit setting is valid when the MSTSLV bit is set to 1. Read value is always 0.
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	IPTIMEN	IP Timer Enable 0: IP timer is disabled. 1: IP timer is enabled. In slave mode, set the IPTIMEN bit after enabling the IP timer of the master channel.

20.3.3 PSI5nIPTIMER — PSI5 IP Timer Counter

This is a counter for the IP timer.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0014_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
COUNTVAL[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNTVAL[15:0]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.11 PSI5nIPTIMER Register Contents

Bit Position	Bit Name	Function
31 to 0	COUNTVAL	In master mode, this timer counts up in response to the internal baud rate clock. In slave mode, this timer counts up in response to the input of the count-up timing signal (psi5_ts_tick_in) through the master channel. When writing to this register, the value is reflected after several cycles.

20.3.4 PSI5nOPMCOMM — PSI5 Operating Mode/Communication Mode Register

This register sets the communication mode.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0020_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	COMMODE		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 20.12 PSI5nOPMCOMM Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2 to 0	COMMODE	Specify communication mode. 000 _B : Asynchronous mode 001 _B : Synchronous Parallel Bus Mode 010 _B : Synchronous Universal Bus Mode 011 _B : Synchronous Daisy Chain Bus Mode 100 _B : Variable Time Triggered Synchronous Operation Mode Other than above: Setting prohibited

20.3.5 PSI5nOPMBITRATE — PSI5 Operating-Mode Bit Rate Register

This register sets a bit rate.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0024_H

Value after reset: 0000 029F_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BITRATECNT															
Value after reset	0	0	0	0	0	0	1	0	1	0	0	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.13 PSI5nOPMBITRATE Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	BITRATECNT	<p>Specify the 1-bit clock count considering communication clock tolerance.</p> <ul style="list-style-type: none"> For transfer at 80 MHz (12.5 ns) and 125 Kbps (clock tolerance: 5%: 8.4 μs) psi5_com_clk is used as the counter clock. Counting cycle = 8.4 μs/12.5 ns = 672 = 2A0_H Setting value: 2A0-001_H = 29F_H <p>This value is used to secure the bit length while no edge is detected in bit judgment.</p>

20.3.6 PSI5nOPMCYCT — PSI5 Operating-Mode Cycle Time Register

This register sets a count value.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0028_H

Value after reset: 0000 9C3F_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	TTTTCNT			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TTTTCNT															
Value after reset	1	0	0	1	1	1	0	0	0	0	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.14 PSI5nOPMCYCT Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is read. When writing, write the value after reset.
19 to 0	TTTTCNT	Specify the count value. Specify the count value for the SYNC signal's period. Use psi5_com_clk as the count clock. The default value is 500 μs when counting at 80 MHz (T = 12.5 ns). Count cycle: 500 μs / 12.5 ns = 40000 = 9C40 _H Setting value: 9C40 _H -001 _H = 9C3F _H

20.3.7 PSI5nPSI5INT — PSI5 Interrupt Status Register

This register indicates the status of an interrupt that occurred in the PSI5.

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 0030_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	INT_	INT_	INT_
														SYNCE	SYNCS	TXDEM
														D	T	PTY
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	INT_RX	INT_RX	INT_RX	INT_RX	INT_RX	INT_RX	INT_RX
										DSCNF	DERR	DFOVF	DEXIST	MERR	MFOVF	MEXIST
										ERR						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.15 PSI5nPSI5INT Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is read.
18	INT_SYNCED	INT_SYNCED interrupt generation 0: Was not generated 1: Generated
17	INT_SYNCST	INT_SYNCST interrupt generation 0: Was not generated 1: Generated
16	INT_TXDEMP T	INT_TXDEMP interrupt generation 0: Was not generated 1: Generated
15 to 7	Reserved	When read, the value after reset is read.
6	INT_RXDSCNF ERR	INT_RXDSCNFERR interrupt generation 0: Was not generated 1: Generated
5	INT_RXDERR	INT_RXDERR interrupt generation 0: Was not generated 1: Generated
4	INT_RXDFOVF	INT_RXDFOVF interrupt generation 0: Was not generated 1: Generated
3	INT_RXDEXIST	INT_RXDEXIST interrupt generation 0: Was not generated 1: Generated
2	INT_RXMERR	INT_RXMERR interrupt generation 0: Was not generated 1: Generated
1	INT_RXMFOVF	INT_RXMFOVF interrupt generation 0: Was not generated 1: Generated
0	INT_RXMEXIST	INT_RXMEXIST interrupt generation 0: Was not generated 1: Generated

NOTE

For details about interrupts in the PSI5, see **Section 20.4, Interrupt**.

20.3.8 PSI5nEMRXDATA — PSI5 Receive Data Emulation Register

This is a mirror register of the receive data register (PSI5nRXDATA).

For details on PSI5nRXDATA, see **Section 20.3.25, PSI5nRXDATA — PSI5 Receive Data Register**.

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 0040_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXDATA															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXDATA															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.16 PSI5nEMRXDATA Register Contents

Bit Position	Bit Name	Function
31 to 0	RXDATA	Mirror data of PSI5nRXDATA. Data is not updated even if it is read.

20.3.9 PSI5nEMRXDST — PSI5 Receive Data Status Emulation Register

This is a mirror register of the receive data status register (PSI5nRXDST).

For details on PSI5nRXDST, see **Section 20.3.26, PSI5nRXDST — PSI5 Receive Data Status Register**.

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 0044_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	RXCHKD		RXSLOTNUM				—	—	—	RXSTATUS	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.17 PSI5nEMRXDST Register Contents

Bit Position	Bit Name	Function
30 to 11	Reserved	When read, the value after reset is read.
10 to 8	RXCHKD	These bits act as mirrors of the PSI5nRXDST.RXCHKD bits. Data is not updated even if it is read.
7 to 4	RXSLOTNUM	These bits act as mirrors of the PSI5nRXDST.RXSLOTNUM bits. Data is not updated even if it is read.
3 to 1	Reserved	When read, the value after reset is read.
0	RXSTATUS	This bit acts as a mirror of the PSI5nRXDST.RXSTATUS bit. Data is not updated even if it is read.

20.3.10 PSI5nEMRXDTIM — PSI5 Receive Data IP Timer Emulation Register

This is a mirror register of the receive data IP timer register (PSI5nRXDTIM).

For details on PSI5nRXDTIM, see **Section 20.3.27, PSI5nRXDTIM — PSI5 Receive Data IP Timer Register**.

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 0048_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXDTIM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXDTIM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.18 PSI5nEMRXDTIM Register Contents

Bit Position	Bit Name	Function
31 to 0	RXDTIM	Mirror data of the PSI5nRXDTIM register. Data is not updated even if it is read.

20.3.11 PSI5nEMRXDFIFO — PSI5 Receive Data FIFO Emulation Register

This is a mirror register of the receive data FIFO register (PSI5nRXDFIFO).

For details on PSI5nRXDFIFO, see **Section 20.3.28, PSI5nRXDFIFO — PSI5 Receive Data FIFO Register**.

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 004C_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXDST															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXDST															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.19 PSI5nEMRXDFIFO Register Contents

Bit Position	Bit Name	Function
31 to 0	RXDST	Mirror data of the PSI5nRXDFIFO register. Data is not updated even if it is read.

20.3.12 PSI5nEMRXMRXMSG — PSI5 Receive-Message Receive Message Emulation Register

This is a mirror register of the receive-message receive message register (PSI5nRXMRXMSG).

For details on PSI5nRXMRXMSG, see **Section 20.3.33, PSI5nRXMRXMSG — PSI5 Receive-Message Receive Message Register.**

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 0050_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CONFI GBIT	—	—	—	—	—	—	—	SERIALID

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DATAFIELD															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.20 PSI5nEMRXMRXMSG Register Contents

Bit Position	Bit Name	Function
31	CONFIGBIT	This bit acts as a mirror of the PSI5nRXMRXMSG.CONFIGBIT bit. Data is not updated even if it is read.
30 to 24	Reserved	When read, the value after reset is read.
23 to 16	SERIALID	These bits act as mirrors of the PSI5nRXMRXMSG.SERIALID bits. Data is not updated even if it is read.
15 to 0	DATAFIELD	These bits act as mirrors of the PSI5nRXMRXMSG.DATAFIELD bits. Data is not updated even if it is read.

20.3.13 PSI5nEMRXMRXST — PSI5 Receive-Message Channel Receive Status Emulation Register

This is a mirror register of the receive-message channel receive status register (PSI5nRXMRXST).

For details on PSI5nRXMRXST, see **Section 20.3.34, PSI5nRXMRXST — PSI5 Receive-message Channel Receive Status Register**.

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 0054_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	RXSYNC

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.21 PSI5nEMRXMRXST Register Contents

Bit Position	Bit Name	Function
30 to 19	Reserved	When read, the value after reset is read.
18 to 16	RXSYNC	These bits act as mirrors of the PSI5nRXMRXST.RXSYNC bits. Data is not updated even if it is read.
15, 14	Reserved	When read, the value after reset is read.
13 to 8	RXCRC	These bits act as mirrors of the PSI5nRXMRXST.RXCRC bits. Data is not updated even if it is read.
7 to 4	SLOTNUM	These bits act as mirrors of the PSI5nRXMRXST.SLOTNUM bits. Data is not updated even if it is read.
3 to 1	Reserved	When read, the value after reset is read.
0	RXSTATUS	This bit acts as a mirror of the PSI5nRXMRXST.RXSTATUS bit. Data is not updated even if it is read.

20.3.14 PSI5nEMRXMRXTIM — PSI5 Receive-Message Channel Receive Timestamp Emulation Register

This is a mirror register of the receive-message channel receive timestamp register (PSI5nRXMRXTIM).

For details on PSI5nRXMRXTIM, see **Section 20.3.35, PSI5nRXMRXTIM — PSI5 Receive-message Channel Receive Timestamp Register.**

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 0058_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXMTIM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	RXMTIM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.22 PSI5nEMRXMRXTIM Register Contents

Bit Position	Bit Name	Function
31 to 0	RXMTIM	Mirror data of the PSI5nRXMRXTIM register. Data is not updated even if it is read.

20.3.15 PSI5nEMRXMFIFO — PSI5 Receive-Message Channel FIFO Emulation Register

This is a mirror register of the receive-message channel FIFO register (PSI5nRXMFIFO).

For details on PSI5nRXMFIFO, see **Section 20.3.36, PSI5nRXMFIFO — PSI5 Receive-message Channel FIFO Register**.

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 005C_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXMFIFO

Table 20.23 PSI5nEMRXMFIFO Register Contents

Bit Position	Bit Name	Function
31 to 0	RXMFIFO	Mirror data of the PSI5nRXMFIFO register. Data is not updated even if it is read.

20.3.16 PSI5nTXSETTING — PSI5 Transmission Setting Register

This register specifies transmission settings.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0080_H

Value after reset: 1067 47F7_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	LONGCNT															
Value after reset	0	0	0	1	0	0	0	0	0	1	1	0	0	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PHY MODE	DEF TXVAL	SHORTCNT													
Value after reset	0	1	0	0	0	1	1	1	1	1	1	1	0	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.24 PSI5nTXSETTING Register Contents

Bit Position	Bit Name	Function
31 to 16	LONGCNT	Set the allowable upper limit of “long” synchronization pulse width when synchronous signal is output in the Pulse Width method. The upper limit when psi5_com_clk is at 80 MHz is 52.5 μ s. Counting cycle: 52.5 μ s / 12.5 ns = 4200 = 1068 _H Setting value: 1068 _H - 0001 _H = 1067 _H
15	PHYMODE	Specifies synchronous pulse PHY layer mode. 0: Tooth Gap method is selected. 1: Pulse Width method is selected. When the Pulse Width method is selected, the pulse width should comply with the value within the pulse width specified by the SHORTCNT bits in the Tooth Gap method.
14	DEFTXVAL	Specifies the initial value of synchronization pulse when data is not transmitted. 0: (0) is transmitted. 1: (1) is transmitted.
13 to 0	SHORTCNT	Set the allowable upper limit of “short” synchronization pulse width when synchronous signal is output in the Pulse Width or Tooth Gap method. The upper limit when psi5_com_clk is at 80 MHz is 25.5 μ s. Counting cycle: 25.5 μ s / 12.5 ns = 2040 = 07F8 _H Setting value: 07F8 _H - 0001 _H = 07F7 _H

CAUTION

- The PSI5nTXSETTING.SHORTCNT bit must be set to 1 or higher.
- The setting value below should be used.
PSI5nOPMCYCT.TTTCNT > PSI5nTXSETTING.LONGCNT > PSI5nTXSETTING.SHORTCNT

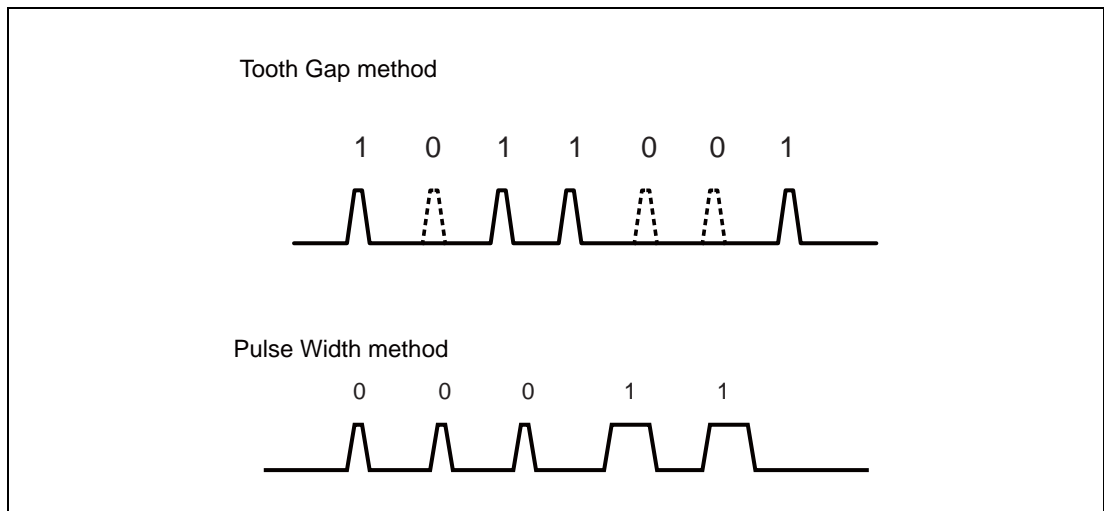

Figure 20.2 Pulse Width Method and Tooth Gap Method

20.3.17 PSI5nSYNCCTRL — PSI5 Synchronization Control Register

This register controls the start trigger in variable time triggered synchronous operation mode.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0084_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VALTIM SYNC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 20.25 PSI5nSYNCCTRL Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	VALTIMSYNC	Synchronization signal send trigger in variable time triggered synchronous operation mode 0: Not effective. 1: The synchronization pulse is issued. This bit is always 0 when it is read. Do not write 1 to the VALTIMSYNC bit in any modes other than variable time triggered synchronous operation mode.

20.3.18 PSI5nTXST — PSI5 Transmission Status Register

This register indicates the transmission status.

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 0088_H

Value after reset: 0000 0001_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.26 PSI5nTXST Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is read.
9	SYNCED	Indicates synchronization signal transmit complete. 0: Synchronization signal transmit is not started or is incomplete. 1: Synchronization signal transmit is complete. When the SYNCED bit is set, the INT_SYNCED interrupt is asserted. The SYNCED bit is set even when 0 is sent in the Tooth Gap method.
8	SYNCST	Indicates start of synchronization signal transmit 0: Synchronization signal is not sent. 1: Synchronization signal is started to send. When the SYNCST bit is set, the INT_SYNCST interrupt is asserted. The SYNCST bit is set even when 0 is sent in the Tooth Gap method.
7 to 1	Reserved	When read, the value after reset is read.
0	TXDEEMPTY	Indicates Tx data buffer empty status. 0: Transmit data buffer is not empty 1: Transmit data buffer is empty When the TXDEEMPTY bit is set, the INT_TXDEEMPTY interrupt is asserted.

20.3.19 PSI5nTXSTCLR — PSI5 Transmission Status Clear Register

This register clears the setting in the PSI5nTXST register.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 008C_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Table 20.27 PSI5nTXSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	SYNCEDCLR	Clears the value of the PSI5nTXST.SYNCED bit. 0: No operation is done. The read value is always 0. 1: Clears the value of the PSI5nTXST.SYNCED bit
8	SYNCSTCLR	Clears the value of the PSI5nTXST.SYNCST bit. 0: No operation is done. The read value is always 0. 1: Clears the value of the PSI5nTXST.SYNCST bit.
7 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

20.3.20 PSI5nTXSTINTEN — PSI5 Transmission Status Interrupt Enable Register

This register controls transmission status interrupts.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0090_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 20.28 TXSINTEN Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	SYNCED INTEN	Controls the INT_SYNCED interrupt. 0: Interrupt disabled (Masked) 1: Interrupt enabled
8	SYNCSTINTEN	Controls the INT_SYNCST interrupt. 0: Interrupt disabled (Masked) 1: Interrupt enabled
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TXDEEMPTYINT EN	Controls the INT_TXDEEMPTY interrupt. 0: Interrupt disabled (Masked) 1: Interrupt enabled

20.3.21 PSI5nTXDCTRL — PSI5 Transmit Data Control Register

This register controls transmission status interrupts.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0094_H

Value after reset: 0000 0001_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 20.29 PSI5nTXDCTRL Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2 to 0	FRMFORMAT	Specify the Tx frame format. 001 _B : Frame 1 (Short) 010 _B : Frame 2 (Long: 4-bit data or 8-bit data) 011 _B : Frame3 (XLong) 100 _B : Frame4 (XXLong) Other than above: Setting prohibited

20.3.22 PSI5nTXDATA — PSI5 Transmit Data Register

This register stores transmit data.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0098_H

Value after reset: Undefined

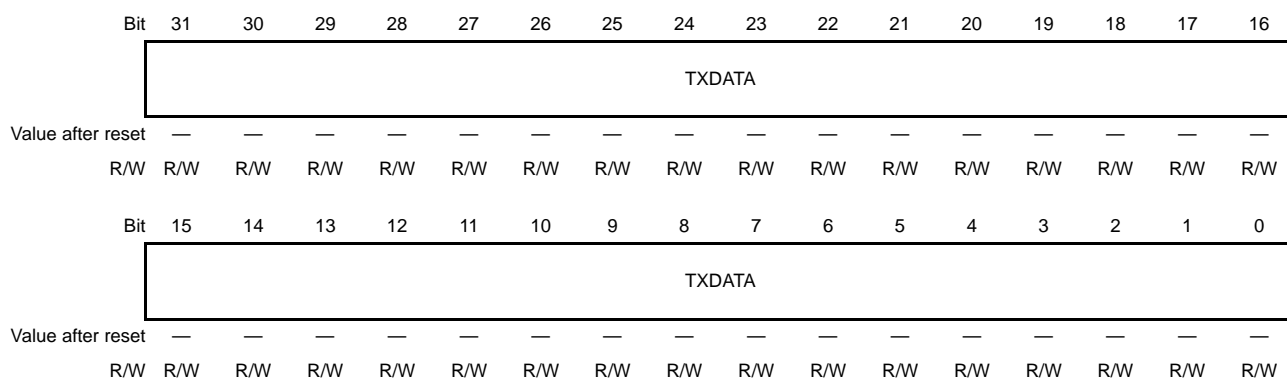

Table 20.30 PSI5nTXDATA Register Contents

Bit Position	Bit Name	Function
31 to 0	TXDATA	<p>Tx Data</p> <p>Write Tx data without the Start field, Synchronization bit, and CRC field (Tx data is written in LSB first).</p> <p>Data arrangement differs depending on the transmit frame format specified in the PSI5nTXDCTRL.FRMFORMAT bit. (See Table 20.31.)</p> <p>The data is sent after these bits are written.</p> <p>Read value is always 0.</p>

20.3.23 PSI5nRXSPLSET — PSI5 Receive Sampling Setting Register

This register controls the sampling timing for received data.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0100_H

Value after reset: 0000 0027_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

250 kHz	13 _H									

20.3.24 PSI5nRXSmSET — PSI5 Receive Slot m Setting Register (m = 1 to 8)

These registers set the receive slots.

Access: This register can be read/written in 32-bit units.

Address: PSI5nRXS1SET: <PSI5n_base> + 0108_H, PSI5nRXS2SET: <PSI5n_base> + 010C_H,
PSI5nRXS3SET: <PSI5n_base> + 0110_H, PSI5nRXS4SET: <PSI5n_base> + 0114_H,
PSI5nRXS5SET: <PSI5n_base> + 0118_H, PSI5nRXS6SET: <PSI5n_base> + 011C_H,
PSI5nRXS7SET: <PSI5n_base> + 0120_H, PSI5nRXS8SET: <PSI5n_base> + 0124_H

Value after reset: 00A0 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SLTEN	—	—	—	—	PAS CMP	ERR DET	LENGTH				OFFSETCNT				
Value after reset	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0

Table 20.33 PSI5nRXSmSET Register Contents

Bit Position	Bit Name	Function
31	SLTEN	Slot Enable 0: Slot m is disabled. 1: Slot m is enabled.
30 to 27	Reserved	When read, the value after reset is read. When writing, write the value after reset.
26	PASCMP	Specifies PAS compatibility mode. 0: PSI5 mode is selected. (LSB first) 1: PAS compatibility mode is selected. (MSB first)
25	ERRDET	Specifies the error detection scheme. 0: 1-bit parity 1: 3-bit CRC
24 to 20	LENGTH	Specify the data length
19 to 0	OFFSETCNT	Specify the count value of the offset timer. When the count value reaches the specified value, the PSI5 starts to receive the data in Slot m. The value counted by psi5_com_clk is used. <ul style="list-style-type: none"> Example settings when psi5_com_clk = 80 MHz Start time: 44 μs psi5_com_clk: 80 MHz (T = 12.5 ns) Offset value: 44 us / 12.5 ns = 3520 = 0DC0_H OFFSETCNT: 0DC0_H- 0001_H = 0DBF_H

CAUTIONS

1. In asynchronous mode (PSI5nOPMCOMM.COMMODE = 000_B), only PSI5nRXS1SET is available.
2. The ERRDET must always be set to 0 in PAS compatibility mode (PASCMP = 1).

20.3.25 PSI5nRXDATA — PSI5 Receive Data Register

This register is the receive data register.

Access: This register can only be read in 32-bit units.

Address: <PSI5n_base> + 0128_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.34 PSI5nRXDATA Register Contents

Bit Position	Bit Name	Function
31 to 0	RXDATA	Received Data These bits hold received data that does not include a start bit and CRC/parity bits (received data is stored in LSB first). These bits are effective only when PSI5nRXMODST.RXDEXIST = 1.

20.3.26 PSI5nRXDST — PSI5 Receive Data Status Register

This register indicates the status of received data.

Access: This register can only be read in 32-bit units.

Address: <PSI5n_base> + 012C_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	RXCHKD		RXSLOTNUM				—	—	—	RXSTAT US	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.35 PSI5nRXDST Register Contents

Bit Position	Bit Name	Function
30 to 11	Reserved	When read, the value after reset is read.
10 to 8	RXCHKD	Raw Data of CRC or Parity In parity mode, setting is as below: RXCHKD[2:1]: 00 _B RXCHKD[0]: Parity value These bits are effective only when PSI5nRXMODST.RXDEXIST bit = 1
7 to 4	RXSLOTNUM	Indicate the slot number of received PSI5nRXDATA.RXDATA. The slot number of the first received data is 1 (the slot number is from 1 to 8). These bits are effective only when PSI5nRXMODST.RXDEXIST = 1.
3 to 1	Reserved	When read, the value after reset is read.
0	RXSTATUS	Indicates the status of Rx data. 0: No error. 1: CRC, parity, or syntax error occurred. Syntax error includes the following three types: <ul style="list-style-type: none"> – An illegal start bit – Data shorter than PSI5RXSnSET.length (A long data error cannot be detected.) – Manchester code error

20.3.27 PSI5nRXDTIM — PSI5 Receive Data IP Timer Register

This register indicates the IPTIMER value in received data.

Access: This register can only be read in 32-bit units.

Address: <PSI5n_base> + 0130_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXDTIM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 20.36 PSI5nRXDTIM Register Contents

Bit Position	Bit Name	Function
31 to 0	RXDTIM	Specify the PSI5nIPTIMER value when the last data (CRC or Parity) is received. These bit fields are effective only when the PSI5RXMODST.RXDEXIST bit is set to 1.

20.3.28 PSI5nRXDFIFO — PSI5 Receive Data FIFO Register

This register is the receive data FIFO register.

Access: This register can only be read in 32-bit units.

Address: <PSI5n_base> + 0134_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXDST															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.37 PSI5nRXDFIFO Register Contents

Bit Position	Bit Name	Function
31 to 0	RXDST	<p>These bits are used for DMA.</p> <p>These bits can be read after data is received (when PSI5nRXMODST.RXDEXIST= 1 and the INT_RXDEXIST interrupt is asserted). This register acts as FIFO whose content includes PSI5nRXDATA, PSI5nRXDST, and PSI5nRXDTIM. Read the receive data three times each. Data is read in the following order: PSI5nRXDATA, PSI5nRXDST, and then PSI5nRXDTIM.</p> <p>Exclusive access is required between PSI5nRXDFIFO and “PSI5nRXDATA, PSI5nRXDST, or PSI5nRXDTIM”.</p>

20.3.29 PSI5nRXMODST — PSI5 Receive Module Status Register

This register is the status register for the receive module.

Access: This register can only be read in 32-bit units.

Address: <PSI5n_base> + 0138_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	RXD SCNF ERR	—	—	—	—	—	—	—	RXD ERR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	RXD FOVF	—	—	—	—	—	—	—	RXD EXIST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.38 PSI5nRXMODST Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is read.
24	RXDSCNFERR	Indicates collision errors of synchronization pulse and reception of sensor data. 0: No error has occurred. 1: An error has occurred. When this bit is set, the INT_RXDSCNFERR interrupt is asserted.
23 to 17	Reserved	When read, the value after reset is read.
16	RXDERR	Indicates the status of receive data. 0: No error. 1: CRC, parity, or syntax error occurred. This bit is set by PSI5nRXDST.RXSTATUS bit. When this bit is set, the INT_RXDERR interrupt is asserted.
15 to 9	Reserved	When read, the value after reset is read.
8	RXDFOVF	Receive Data FIFO Overflow Flag 0: No overflow. 1: Overflow occurred. When this bit is set, the INT_RXDFOVF interrupt is asserted.
3 to 1	Reserved	When read, the value after reset is read.
0	RXDEXIST	Indicates whether or not Rx data exists. 0: No Rx data exists. 1: Rx data exists. When the PSI5nRXDATA, PSI5nRXDST, and PSI5nRXDTIM registers are read, this bit is cleared. When this bit is set, the INT_RXDEXIST interrupt is asserted.

20.3.30 PSI5nRXMODSTCLR — PSI5 Receive Module Status Clear Register

This register is the status clear register for the receive module.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 013C_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	RXDSCNFERR CLR	—	—	—	—	—	—	—	RXDERR CLR

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Table 20.39 PSI5nRXMODSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is read. When writing, write the value after reset.
24	RXDSCNFERR CLR	Clears the PSI5nRXMODST.RXDSCNFERR bit. 0: No operation is done. 1: The RXDSCNFERR bit is cleared. Read value is always 0.
23 to 17	Reserved	When read, the value after reset is read. When writing, write the value after reset.
16	RXDERRCLR	Clears the PSI5nRXMODST.RXDERR bit. 0: No operation is done. 1: The RXDERR bit is cleared. Read value is always 0.
15 to 9	Reserved	When read, the value after reset is read. When writing, write the value after reset.
8	RXDFOVFCLR	Clears the PSI5nRXMODST.RXDFOVF bit. 0: No operation is done. 1: The RXDFOVF bit is cleared. Read value is always 0.
3 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

20.3.31 PSI5nRXMODSTINTEN — PSI5 Receive Module Status Interrupt Enable Register

This register is the status interrupt enable register for the receive module.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0140_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	RXDSCNFERRINTEN	—	—	—	—	—	—	—	RXDERRINTEN

Table 20.40 PSI5nRXMODSTINTEN Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is read. When writing, write the value after reset.
24	RXDSCNFERRINTEN	INT_RXDSCNFERR Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled
23 to 17	Reserved	When read, the value after reset is read. When writing, write the value after reset.
16	RXDERRINTEN	INT_RXDERR Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled
15 to 9	Reserved	When read, the value after reset is read. When writing, write the value after reset.
8	RXDFOVFINTEN	INT_RXDFOVF Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled
3 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	RXDEXISTINTEN	INT_RXDEXIST Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled

20.3.32 PSI5nRXMSET — PSI5 Receive Message Channel Setting Register

This register sets the channels for the receive module.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0180_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RXM8 EN	RXM7 EN	RXM6 EN	RXM5 EN	RXM4 EN	RXM3 EN	RXM2 EN	RXM1 EN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 20.41 PSI5nRXMSET Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is read. When writing, write the value after reset.
7	RXM8EN	Controls the messaging channel for slot 8. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
6	RXM7EN	Controls the messaging channel for slot 7. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
5	RXM6EN	Controls the messaging channel for slot 6. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
4	RXM5EN	Controls the messaging channel for slot 5. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
3	RXM4EN	Controls the messaging channel for slot 4. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
2	RXM3EN	Controls the messaging channel for slot 3. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
1	RXM2EN	Controls the messaging channel for slot 2. 0: Messaging channel is disabled. 1: Messaging channel is enabled.
0	RXM1EN	Controls the messaging channel for slot 1. 0: Messaging channel is disabled. 1: Messaging channel is enabled.

20.3.33 PSI5nRXMRXMSG — PSI5 Receive-Message Receive Message Register

This register is the receive message register.

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 0184_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CONFI GBIT	—	—	—	—	—	—	—	SERIALID

Table 20.42 PSI5nRXMRXMSG Register Contents

Bit Position	Bit Name	Function
31	CONFIGBIT	Configuration Bit in the Received Serial Data Frame See Figure 20.3 .
30 to 24	Reserved	When read, the value after reset is read.
23 to 16	SERIALID	Serial ID in the Received Serial Data Frame See Figure 20.3 .
15 to 0	DATAFIELD	Data Field in the Received Serial Data Frame See Figure 20.3 .

Figure 20.3 Serial Data Frame Configured by the Two Messaging Bits of the Sensor Data Frame (Messaging Channel)

20.3.34 PSI5nRXMRXST — PSI5 Receive-message Channel Receive Status Register

This register is the receive status register for the receive-message channel.

Access: This register can only be read in 32-bit units.

Address: <PSI5n_base> + 0188_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	RXSYNC		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	RXCRC					SLOTNUM					—	—	—	RXSTATUS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.43 PSI5nRXMRXST Register Contents

Bit Position	Bit Name	Function
30 to 19	Reserved	When read, the value after reset is read.
18 to 16	RXSYNC	Received Synchronization Bit Raw Data (the frame numbers 7, 13, and 18 of the sensor frame) For the sensor frame, see Figure 20.3 .
15, 14	Reserved	When read, the value after reset is read.
13 to 8	RXCRC	Received CRC Raw Data
7 to 4	SLOTNUM	Received Serial Data Frame's Slot Number
3 to 1	Reserved	When read, the value after reset is read.
0	RXSTATUS	Indicates the error state of Rx data. 0: No error. 1: CRC or Syntax error occurred. A syntax error also occurs when the receive synchronization bit has received a value other than 0 while RXSYNC = 000 _B .

20.3.35 PSI5nRXMRXTIM — PSI5 Receive-message Channel Receive Timestamp Register

This register indicates the value of the receive-message channel receive timestamp.

Access: This register can be read in 32-bit units.

Address: <PSI5n_base> + 018C_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXMTIM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXMTIM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.44 PSI5nRXMRXTIM Register Contents

Bit Position	Bit Name	Function
31 to 0	RXMTIM	Indicate the PSI5nIPTIMER value when the last data (frame number 18 of the sensor frame) is received. For the sensor frame, see Figure 20.3 . These bits are effective only when PSI5nRXMMST.RXMEXIST = 1.

20.3.36 PSI5nRXMFIFO — PSI5 Receive-message Channel FIFO Register

This register indicates the receive-message channel FIFO information.

Access: This register can only be read in 32-bit units.

Address: <PSI5n_base> + 0190_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXMFIFO															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXMFIFO															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.45 PSI5nRXMFIFO Register Contents

Bit Position	Bit Name	Function
31 to 0	RXMFIFO	<p>These bits can be read after data is received (when PSI5nRXMMST.RXMEXIST= 1: INT_RXMEXIST interrupt is asserted). This register acts as FIFO whose content includes PSI5nRXMRXMSG, PSI5nRXMRXST, and PSI5nRXMTIM. Read the received data three times each.</p> <p>Data is read in the following order: PSI5nRXMRXMSG, PSI5nRXMRXST, and then PSI5nRXMTIM.</p> <p>Exclusive access is required between PSI5nRXMFIFO and "PSI5nRXMRXMSG, PSI5nRXMRXST, or PSI5nRXMTIM".</p>

20.3.37 PSI5nRXMMST — PSI5 Receive-message Channel Module Status Register

This register is the status register for the receive-message channel module.

Access: This register can only be read in 32-bit units.

Address: <PSI5n_base> + 0194_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RXM ERR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.46 PSI5nRXMMST Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is read.
16	RXMERR	Rx Message Error 0: No error. 1: Error occurred. When this bit is set, the INT_RXMERR interrupt is asserted.
15 to 9	Reserved	When read, the value after reset is read.
8	RXMFOVF	Rx Message FIFO Overflow Flag 0: No overflow. 1: Overflow occurred. When this bit is set, the INT_RXMFOVF interrupt is asserted.
3 to 1	Reserved	When read, the value after reset is read.
0	RXMEXIST	Indicates whether Rx Serial Data Frame exists. 0: No Rx serial data exists. 1: Rx serial data exists. When the PSI5nRXMRXMSG, PSI5nRXMRXST, and PSI5nRXMTIM registers are read, this bit is cleared. When this bit is set, the INT_RXMEXIST interrupt is asserted.

20.3.38 PSI5nRXMMSTCLR— PSI5 Receive-message Channel Module Status Clear Register

This register is used to clear the receive-message channel module status register.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 0198_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RXMERR CLR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

	—	—	—	—	—	—	—	RXMFOVF CLR	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Table 20.47 PSI5nRXMMSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is read. When writing, write the value after reset.
16	RXMERRCLR	Clears the status of the PSI5nRXMMST.RXMERR bit. 0: No operation is done. 1: The RXMERR bit is cleared. Read value is always 0.
15 to 9	Reserved	When read, the value after reset is read. When writing, write the value after reset.
8	RXMFOVFCLR	Clears the status of the PSI5nRXMMST.RXMFOVF bit. 0: No operation is done. 1: The RXMFOVF bit is cleared. Read value is always 0.
3 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

20.3.39 PSI5nRXMMSTINTEN — PSI5 Receive-message Channel Module Status Interrupt Enable Register

This register controls interrupts from the receive-message channel module.

Access: This register can be read/written in 32-bit units.

Address: <PSI5n_base> + 019C_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RXM ERR INTEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 20.48 PSI5nRXMMSTINTEN Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is read. When writing, write the value after reset.
16	RXMERR INTEN	INT_RXMERR Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled
15 to 9	Reserved	When read, the value after reset is read. When writing, write the value after reset.
8	RXMFOVF INTEN	INT_RXMFOVF Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled
3 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	RXMEXIST INTEN	INT_RXMEXIST Interrupt Enable 0: Interrupt disabled (Masked) 1: Interrupt enabled

20.3.40 PSI5TSSEL — PSI5 Timestamp Function Mode Selection Register

This register specifies the timestamp setting.

This register can be controlled when the PSI5 is stopped (PSI5nCHCTRL.CHEN = 0).

Access: This register can be read/written in 32-bit units.

Address: <PSI50_base> + 3000_H

Value after reset: 0000 0000_H This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 20.49 PSI5TSSEL Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	PSI5MSSEL0	Timestamp Mode Selection 0: Inputs the timestamp count-up timing and clearing signals from PSI51 to PSI50. 1: Inputs the timestamp count-up timing and clearing signals from PSI50 to PSI51.

20.4 Interrupt

The PSI5 has 10 interrupt signals.

Table 20.50 PSI5 Interrupt Signals and Corresponding Registers

Interrupt Signal	Function	Source Register	Interrupt Enable Register
		Bit	Bit
INT_SYNCED	Synchronization end interrupt	PSI5nTXST. SYNCED	PSI5nTXSTINTEN. SYNCEDINTEN
INT_SYNCST	Synchronization start interrupt	PSI5nTXST. SYNCST	PSI5nTXSTINTEN. SYNCSTINTEN
INT_TXEMPTY	Transmit data empty interrupt	PSI5nTXST. TXEMPTY	PSI5nTXSTINTEN. TXEMPTYINTEN
INT_RXDSCNFERR	Synchronization pulse and receive data conflict error interrupt	PSI5nRXMODST. RXDSCNFERR	PSI5nRXMODSTINTEN. RXDSCNFINTEN
INT_RXDERR	Receive data error interrupt	PSI5nRXMODST. RXDERR	PSI5nRXMODSTINTEN. RXDERRINTEN
INT_RXDFOVF	Receive data FIFO overflow interrupt	PSI5nRXMODST. RXDFOVF	PSI5nRXMODSTINTEN. RXDFOVFINTEN
INT_RXDEXIST	Receive data exist interrupt	PSI5nRXMODST. RXDEXIST	PSI5nRXMODSTINTEN. RXDEXISTINTEN
INT_RXMFOVF	Receive message FIFO overflow interrupt	PSI5nRXMMST. RXMFOVF	PSI5nRXMMSTINTEN. RXMFOVFINTEN
INT_RXMERR	Receive message error interrupt	PSI5nRXMMST. RXMERR	PSI5nRXMMSTINTEN. RXMERRINTEN
INT_RXMEXIST	Receive message exist interrupt	PSI5nRXMMST. RXMEXIST	PSI5nRXMMSTINTEN. RXMEXISTINTEN

The following figure shows the relationship between the PSI5 interrupt signals, and RH850/P1M-E's interrupt controller INTC and DMA.

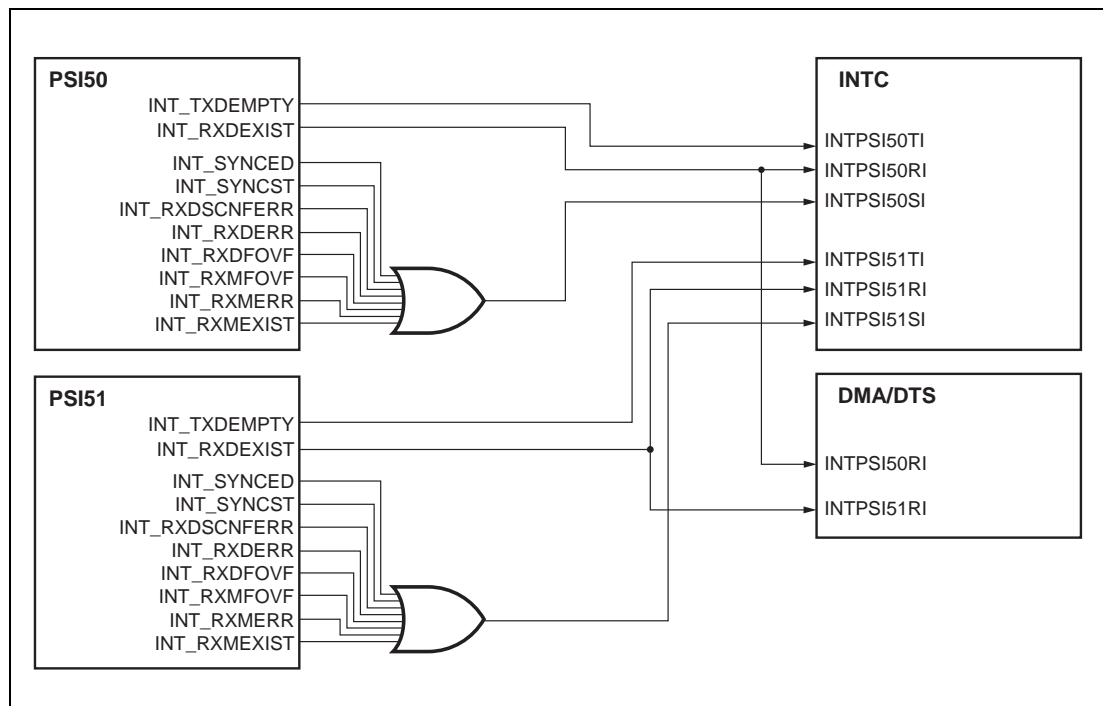

Figure 20.4 PSI5 Interrupt Signals

20.5 Operation

20.5.1 Setting Operation Mode

Before the PSI5n starts operating, initial settings including the sensor connection status and operation mode must be configured. The following describes necessary initial settings.

Figure 20.5 Setting PSI5 Operation Mode

Table 20.51 Setting Operation Mode

Item		Description
Communication Modes	A	Asynchronous Mode
	P	Synchronous Parallel Bus Mode
	U	Synchronous Universal Bus Mode
	D	Synchronous Daisy Chain Bus Mode
	V	Variable Time Triggered Synchronous Operation Mode
Number of data bits	dd	Data length of each slot specified in the PSI5nRXSmSET.LENGTH bit (10 to 28 bits)
Error Detection	P	One Parity Bit
	CRC	Three Bits CRC
Cycle time	tttt	Cycle Time (Minimum cycle time allowed in variable time triggered synchronous operation mode)(µs)
Slot count/cycle (n)	n	Select the slot to be used in the PSI5nRXMSET.
Bit Rate	L	125 Kbps
	H	189 Kbps

20.5.1.1 Setting for Transmit/Receive Mode

Set PSI5nOPMCOMM, PSI5nOPMBITRATE, and PSI5nOPMCYCT to the value corresponding to the specification of the PS15 sensor and its connection status.

20.5.1.2 Setting for Data Reception

The RH850/P1M-E receives data on psi5_com_clk.

A 16-times sampling is used for bit detection.

The bit length depends on the setting of PSI5nRXSPLSET.SMPLPROD[7:0].

- PSI5nRXSPLSET.SMPLPROD[7:0]: Set the sampling interval.

Set the value counted by psi5_com_clk. The RH850/P1M-E uses a 16-times sampling.

20.5.1.3 Initial Setting for Asynchronous Mode

In asynchronous mode, only PSI5nRXS1SET is available. Writing 1 to SLTEN in PSI5nRXS2SET to PSI5nRXS8SET is prohibited (so disable them).

In asynchronous mode, set the SLTEN, PASCMP, ERRDET, and LENGTH fields in PSI5nRXS1SET. The OFFSETCNT field is not available.

20.5.1.4 Initial Setting for Synchronous Mode

In synchronous mode, specify all fields of PSI5nRXS1SET to PSI5nRXS8SET appropriately.

The recommended setting values for PSI5nRXS1SET.OFFSETCNT and PSI5nRXS2SET to PSI5nRXS8SET.OFFSETCNT can be obtained as the results of the formula in **Figure 20.6** and **Figure 20.7**. In these figures, tcom_clk indicates the time for one psi5_com_clk cycle. Other variables are the variables specified by the PSI5 standard.

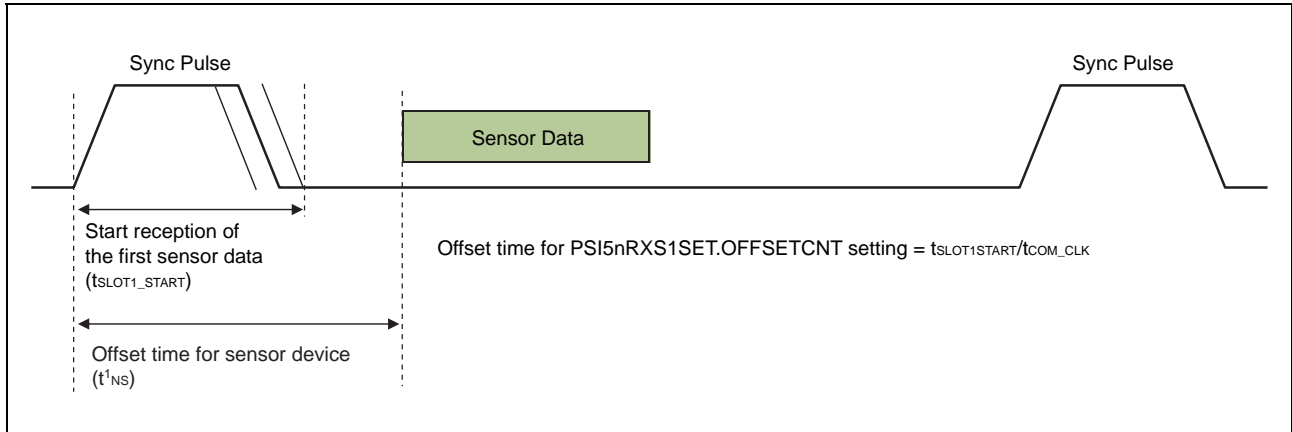

Figure 20.6 Recommended Setting of PSI5nRXS1SET.OFFSETCNT

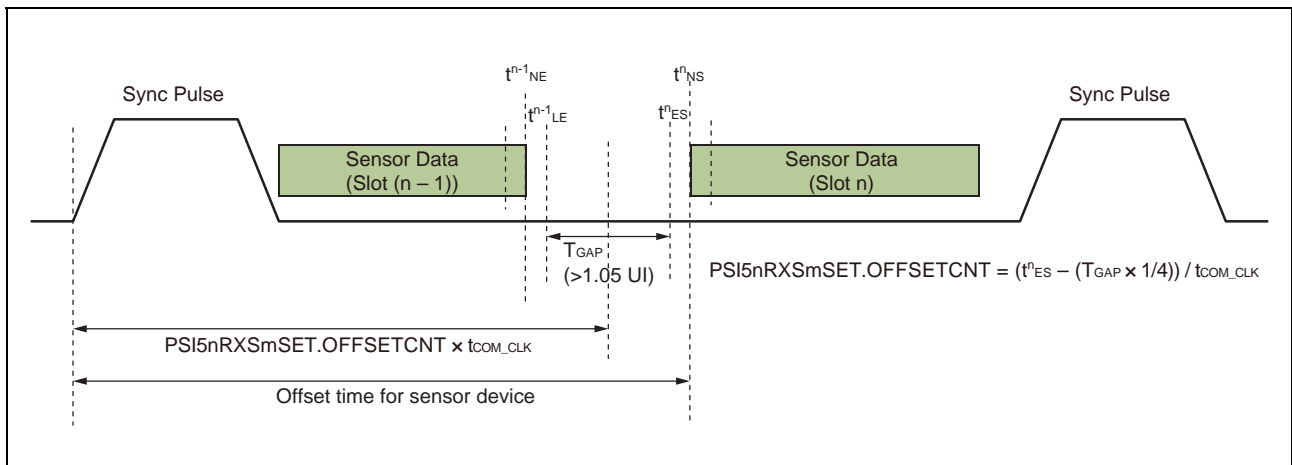

Figure 20.7 Recommended Setting of PSI5nRXSmSET.OFFSETCNT (m = 2 to 8)

20.5.1.5 Setting for Serial Message Reception

To receive a serial message, write 1 to PSI5nRXMSET. RXMmEN (m = 1 to 8) in the corresponding slot.

20.5.1.6 Initial Setting in Asynchronous Mode

In asynchronous mode, registers for transmission are disabled except PSI5nTXSETTING.DEFTXVAL fields. Use the value after reset.

The PSI5 outputs the value set in PSI5nTXSETTING.DEFTXVAL after the start of operation (although the standard does not define output data in asynchronous mode). The value after reset is 1.

20.5.1.7 Initial Setting in Synchronous Mode

Set the value in PSI5nTXSETTING.

PSI5nTXSETTING.DEFTXVAL sets a synchronization pulse value for the period during which data is not transmitted. In Tooth GAP mode, set PSI5nTXSETTING.DEFTXVAL to 1. In pulse width mode, the value is not specified in the standard. Set the value specified by a system designer.

In variable time triggered synchronous operation mode, the user must specify the timing for synchronization pulse output.

When issuing a synchronization pulse, write 1 to the PSI5nSYNCCTRL.VALTIMSYNC bits.

Set the data format to be transmitted to the sensor in PSI5nTXDCTRL.FRMFORMAT.

20.5.1.8 Setting for Timestamping

A timestamp is appended to the received data so that the order of the received data and messages can be identified.

Timestamping is available in two modes: master mode for generation of the timing for counting up within the PSI5, and slave mode for counting with an input signal from the master. In master mode, the count-up timing is output to the output signal psi5_ts_tick_out. In slave mode, the input signal psi5_ts_tick_in is used for counting up.

To use a timestamp, set PSI5nIPTIMERCTRL.IPTIMEN to 1. Specify master or slave in PSI5nIPTIMERCTRL.MSTSLV.

In master mode, the count-up timing is complete when the internal baud rate counter is complete. The value to complete the baud rate counter is the setting of PSI5nOPMBITRATE.BITRATECNT.

The timestamp can be cleared by writing 1 to PSI5nIPTIMERCTRL.TSCLR irrespective of master or slave. In master mode, the clearing timing is output to the output signal psi5_ts_clr_out. In slave mode, the input signal psi5_ts_clr_in from the master can be used to clear the timestamp.

(1) Setting of Master/Slave Mode in Timestamp Mode

For PSI50 and PSI51, the timestamp mode can be selected from master mode and slave mode.

The following shows the setting of master or slave mode.

Table 20.52 Setting of Master/Slave Mode

PSI5TSSEL. PSI5MSSEL0 Bit	IPTIMERCTRL. MSTSLV Bit in PSI50	IPTIMERCTRL. MSTSLV Bit in PSI51	Timestamp Mode		Operation
			PSI50	PSI51	
1	1	0	Master of PSI51	Slave of PSI50	PSI50 operates as master and PSI51 operates as slave.
1	1	1	Master (No slave)	Master (No slave)	PSI50 and PSI51 operate in master mode without slaves.
0	0	1	Slave of PSI51	Master of PSI50	PSI51 operates as master, and PSI50 operates as slave.
0	1	1	Master (No slave)	Master (No slave)	PSI50 and PSI51 operates in master mode without slaves.
Other than above			Setting prohibited		

Figure 20.8 Relationship Between PSI50 and PSI51

20.5.2 Operation Flow

20.5.2.1 Starting Operation

Figure 20.9 shows the flow from initialization to the start of operation. When resetting the sensor or releasing it from reset, issue instructions to the PHY as these operations are performed by the PHY.

Figure 20.9 Flow of Starting Operation

20.5.2.2 Flow of Data Reception

Figure 20.10 shows the flow of data reception. The interrupt enable (PSI5nRXMODSTINTEN.RXDEXISTINTEN = 1) in the flowchart is not required when polling is used for detection of reception, or when it is always enabled (this applies to enabling of other interrupts in the subsequent sections).

The received data without the start bit and CRC/parity bits can be read out from PSI5nRXDATA.RXDATA.

Regarding the FIFO buffer shown in **Figure 20.10**, when data are received, that state is retained, and even if the register is empty, the received data are set from the FIFO buffer to the register. In cases of overflow because of delays in the reading out of data, new data are written to the buffer.

When reading data from the FIFO buffer, check that the value of PSI5nRXMDST.RXDEXIST is 0. Since PSI5nRXMDST.RXDEXIST being 1 indicates that data which have not been read out remain in the FIFO buffer, repeat the processing for reading.

The PSI5nRXDST.RXSTATUS is set to 1 in response to a start-bit error, Manchester code error, CRC error, or parity error during data reception. Specifically, in cases where multiple errors are detected during the reception of a single frame, the FIFO buffer for received data is updated every time an error occurs.

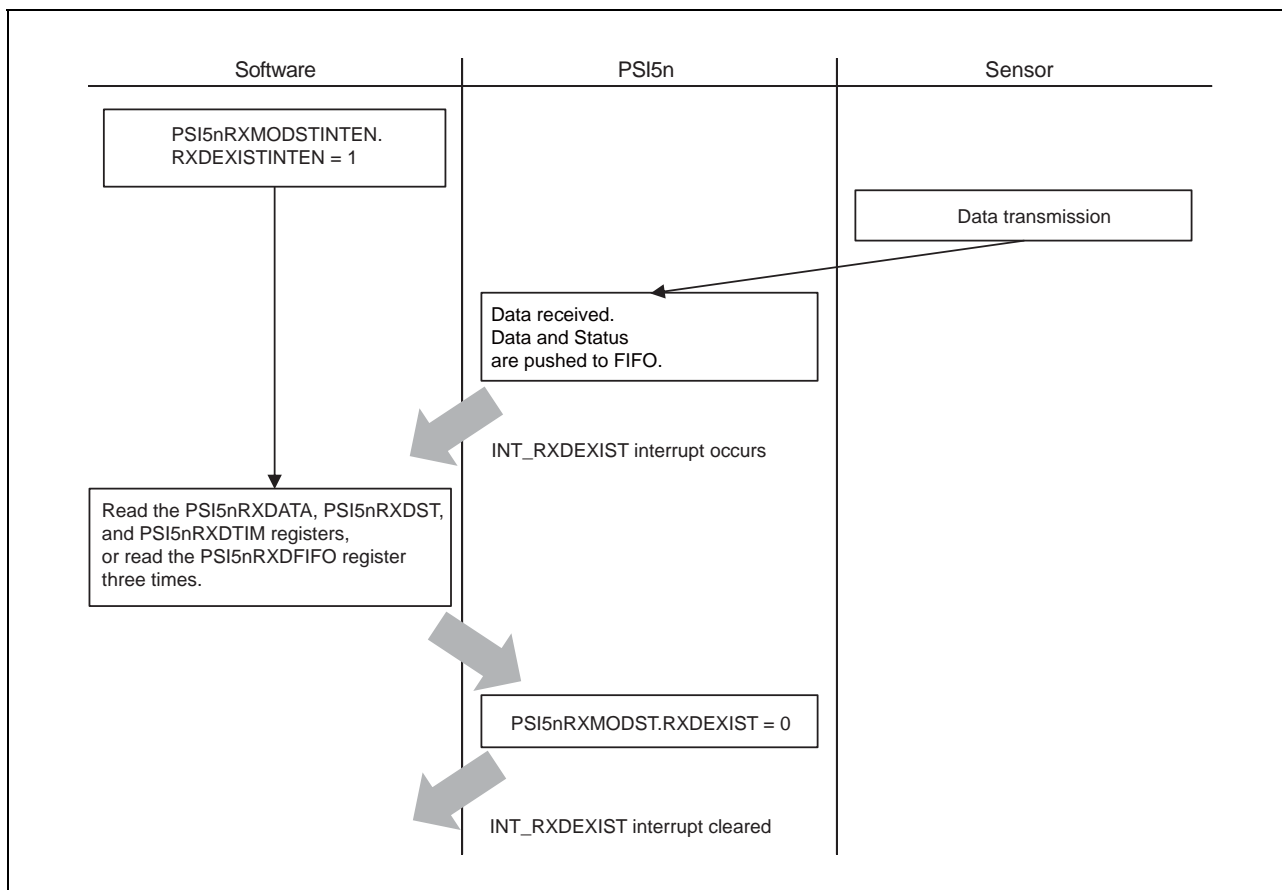

Figure 20.10 Data Reception Flow

20.5.2.3 Flow of Data Transmission

Figure 20.11 shows the flow of data transmission.

Transmit data arrangement to be written to the PSI5nTXDATA.TXDATA differs depending on the transmit frame format specified in the PSI5nTXDCTRL.FRMFORMAT bit (See **Table 20.31**). The data must not include a start bit, synchronization bit, or CRC (these are automatically appended).

Once PSI5nTXDCTRL.FRMFORMAT has been set, it does not need to be set again after that.

The PSI5 module does not have a FIFO buffer for transmission, so processing for transmission is sequential. When you intend to write to the transmission buffer, read the state of the buffer empty flag to check if it currently indicates the buffer empty state (PSI5nTXST.TXDEEMPTY = 1). If the transmission buffer holds data to be transmitted at the time of writing (PSI5nTXST.TXDEEMPTY = 0), transmitted data become undefined when data are written to the transmission buffer.

PSI5nTXST.TXDEEMPTY becomes 1 to indicate the completion of transmission when reading of the last bit of the data from the transmission buffer starts.

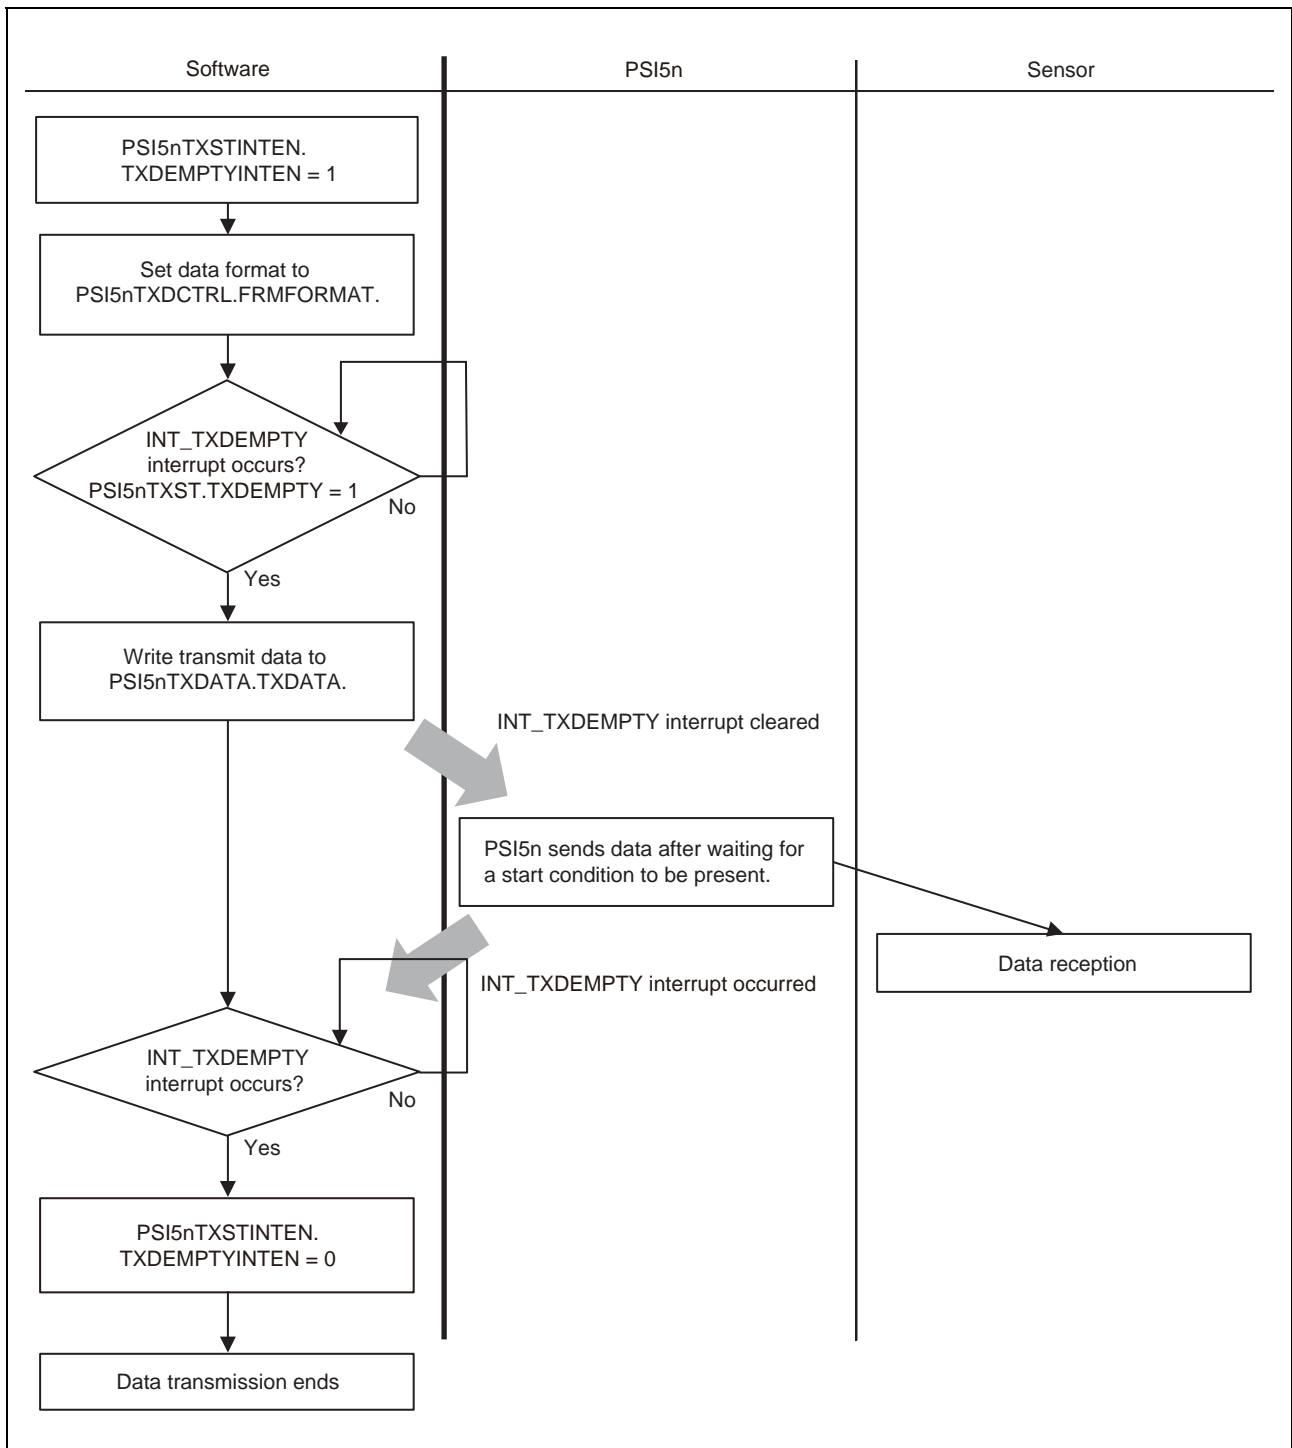

Figure 20.11 Data Transmission Flow

20.5.2.4 Serial Message Reception Flow

Figure 20.12 shows the flow of serial message reception.

The received serial message can be read out from PSI5nRXMRXMSG.RXDATA.

In Figure 20.12, the FIFO buffer holds the serial message and its state and the received data are set from the FIFO buffer to the register if the register is empty. In cases of overflow because of delays in the reading out of data, new data are written to the buffer.

When reading data from the FIFO buffer, check that the value of PSI5nRXMMST.RXMEXIST is 0. Since PSI5nRXMMST.RXMEXIST being 1 indicates that data which have not been read out remain in the FIFO buffer, repeat the processing for reading.

If either a CRC error or a receive data error occurs after the detection of the start bit in the message (after reception of M1 (Frame No.) = 11111_B), PSI5nRXMRXST.RXSTATUS is set to 1. In this case, handling of the received message is system-dependent. When an receive data error occurs, the message up to that data is stored in order from the least-significant bit of PSI5nRXMRXMSG.

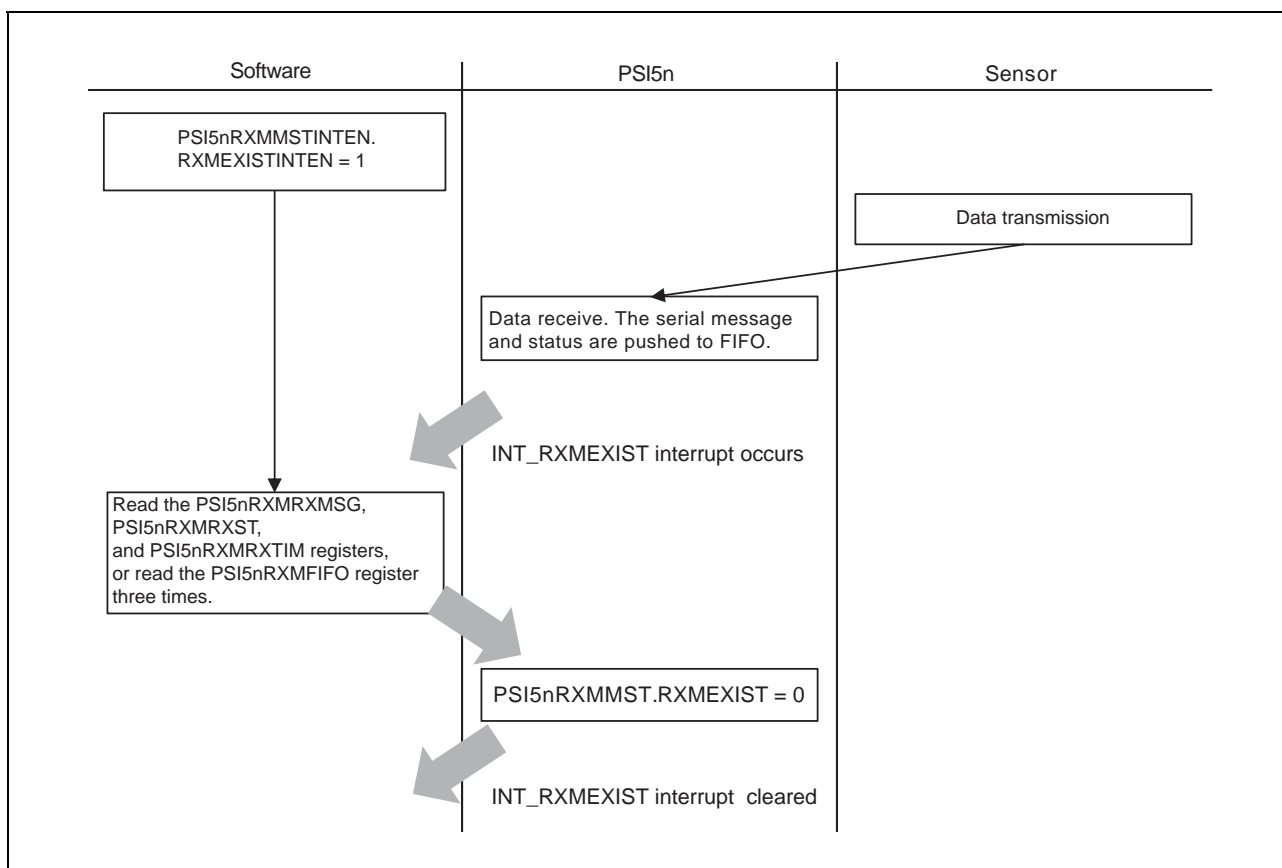

Figure 20.12 Serial Message Reception Flow

20.5.2.5 Parity and CRC Errors in Received Data

Error flags (PSI5nRXMODST.RXDERR and PSI5nRXMMST.RXMERR) are set in response to the detection of parity or CRC errors in received data. Reception operations proceed whether or not errors are detected.

Each of the error flags has a corresponding clearing bit (PSI5nRXMODSTCLR.RXDERRCLR and PSI5nRXMMSTCLR.RXMERRCLR).

20.5.2.5.1 Operation after Error Detection in Asynchronous Mode and PAS Compatibility Mode

When external noise and so on lead to errors in the Manchester code during the reception of data while the PSI5 is in the asynchronous mode or PAS compatibility mode, reception of the data being received is assumed to be complete, the parity or CRC error flag is set, and the data are stored in the reception FIFO buffer. Even when a Manchester code error occurs, the next data reception starts immediately. Due to this specification, even if a Manchester code error occurs for one bit because of external noise during data reception, the following data bit is assumed to be the start bit, and reception starts. In this situation, multiple Manchester code errors may occur and multiple receptioncomplete interrupts can be generated. In such cases, the maximum number of errors corresponds to the number of bits in the unit of data.

Accordingly, this raises the possibility of producing an overflow. If an overflow occurs even though the data retrieval assumed during system designing is performed, the transfer may be malfunctioning due to factors such as noise.

In synchronous mode, data reception is halted at slot $n + 1$ in response to an error in the Manchester code while reception in slot n is in progress. For this reason, even if further errors occur or data is resent while in slot n , they are ignored.

20.5.3 PAS Compatibility Mode

The RH850/P1M-E has a PAS compatibility mode. The PAS compatibility mode supported by the RH850/P1M-E is as shown in **Table 20.7**.

In PAS compatibility mode, set 1 in PSI5nRXS1SET.PASCMP. At that time, set 0 (parity) in PSI5nRXS1SET.ERRDET.

20.5.4 Baud Rate

The communication clock is generated, by dividing 1 cycle of psi5_com_clk by 1 to 2¹⁶.

1 bit cycle waveform = (value set in PSI5nOPMBITRATE.BITRATECNT) / psi5_com_clk
 Baud rate = 1/1 bit cycle waveform

The following shows an example baud rate setting.

Table 20.53 Example Baud Rate Setting

Baud Rate [Kbps]	psi5_com_clk		Value Set in PSI5nOPMBITRATE.BITRATECNT	Bit Time [μs]
	Frequency [MHz]	Cycle [ns]		
125	80	12.5	29F _H	8.4
189	80	12.5	1BC _H	5.57
250	80	12.5	14F _H	4.2

Section 21 Window Watchdog Timer A (WDTA)

The purpose of the Window Watchdog Timer A (WDTA) is to detect deadlock of CPU operation. WDTA is implemented 1 unit. This timer generates an error signal if the counter is not cleared by CPU within a certain counter value. If the timer is cleared, MCU can keep normal operation.

21.1 Features of RH850/P1M-E WDTA

21.1.1 Units and Channels

This microcontroller has the following number of WDTA units.

Table 21.1 Number of Units

Product	RH850/P1M-E 100 pins	RH850/P1M-E 144 pins
Number of Units	1	1
Name	WDTA0	WDTA0

Table 21.2 Unit Configurations and Channels

Unit Name WDTAn	Channels per Unit	RH850/P1M-E 100 pins (1 ch)	RH850/P1M-E 144 pins (1 ch)
WDTA0	1	√	√

Note: The channel names are same as those of the corresponding units.

Table 21.3 Index

Index	Description
n	Throughout this section, the individual WDTA units are identified by the index "n" (n = 0): for example, WDTAnWDTE (n = 0) is the WDTAn enable register.

21.1.2 Register Base Address

WDTAn base addresses are listed in the following table.

WDTAn register addresses are given as offsets from the base addresses throughout the section.

Table 21.4 Register Base Address

Base Address Name	Base Address
<WDTA0_base>	FFD7 4000 _H

21.1.3 Clock Supply

Clock supply by and to WDTAn is listed in the following table.

Table 21.5 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
WDTA0	WDTATCKI	High-speed mode: CLK_IOSC: 8 MHz Low-speed mode: CLK_IOSC/32: 250 kHz
	PCLK	High-speed peripheral clock CLK_HSB

21.1.4 Interrupt Request

WDTAn interrupt requests are listed in the following table.

Table 21.6 Interrupt Requests

Unit Interrupt Name	Description	Interrupt Number	DMA/DTS Trigger Number
WDTA0			
INTWDTA0	WDTA0 75% interrupt	9	—

21.1.5 Reset Sources

Please refer to **Section 8, Reset Controller**.

21.1.6 External Input/Output Signals

WDTAn has no external pin.

21.2 Overview

21.2.1 Functional Overview

The WDTA has the following functions:

- Selection of the operation mode after release from the reset state, by using start-up options

Starting/stopping of the counter after reset, the setting of the overflow time of the counter, enabling/disabling of the VAC function, and clock mode can be selected. WDTA startup options are described in **Table 21.7, WDTA Start-up Options**.

- WDTA trigger function

Writing an activation code to the WDTA trigger register starts WDTA and restarts the counter. Activation codes include fixed activation codes and variable activation codes (VAC function). In a variable activation code, a different value from the previous time (variable value) is written to the WDTA trigger register, which causes the counter to be restarted.

- 75% interrupt request signals

An interrupt request signal can be generated when the WDTA counter reaches 75% of the overflow interval time (this function can be enabled or disabled by the setting of WDTAnMD.WDTAnWIE).

- Window function

The period during which writing to the WDTA trigger register is valid (window-open period) can be set. Writing to the WDTA trigger register at a time outside the window-open period causes an error.

- WDTA error detection function

When an error is detected, an error signal WDTAnTERR is generated. The error signal WDTAnTERR is connected to the ECM module.

For details about the error sources, refer to **Section 21.5.3, WDTA Error Detection**.

Table 21.7 WDTA Start-up Options

Start-up Option	Function	Description	Option Byte
OPWDRUN	Start mode setting	Specifies the start mode. 0: Software trigger start mode 1: Default start mode For details, refer to Section 21.5.1, WDTA after Release from the Reset State.	OPBT0.OPBT0[31]
OPWDOVF[2:0]	Overflow interval time reset value setting	Specifies the reset value of the overflow interval time control bits WDTAnMD.WDTAnOVF[2:0].	OPBT0.OPBT0[27:25]
OPWDVAC	Variable Activation Code (VAC) selection	Specifies the trigger register for the generation of counter re-start triggers to keep the counter from overflowing. 0: WDTAnWDTE (fixed) 1: WDTAnEVAC (variable) When WDTAnWDTE is selected, the value to be written to the register (activation code) is fixed (AC_H). When WDTAnEVAC is selected, the activation code to be written to the register is variable. For details, refer to Section 21.5.2, WDTA Trigger, Section 21.5.2.1, Calculating an Activation Code when the VAC Function is Used.	OPBT0.OPBT0[22]
OPWDMDS	Clock mode selection	Selects the counter clock source of WDTAn. 0: High-speed mode (high-speed internal oscillation: 8 MHz) 1: Low-speed mode (high-speed internal oscillation/32: 250 kHz)	OPBT0.OPBT0[21]

21.2.2 Block Diagram

Figure 21.1 shows the main components of the WDTA.

Figure 21.1 Block Diagram of the WDTA

21.3 Registers

21.3.1 List of Registers

WDTA registers are listed in the following table.

For details about <WDTAn_base>, see **Section 21.1.2, Register Base Address**.

Table 21.8 List of Registers

Module Name	Register Name	Symbol	Address
WDTAn	WDTA enable register	WDTAnWDTE	<WDTAn_base> + 0000 _H
WDTAn	WDTA enable VAC register	WDTAnEVAC	<WDTAn_base> + 0004 _H
WDTAn	WDTA reference value register	WDTAnREF	<WDTAn_base> + 0008 _H
WDTAn	WDTA mode register	WDTAnMD	<WDTAn_base> + 000C _H

21.3.2 WDTAnWDTE — WDTA Enable Register

This register is the WDTA trigger register if the VAC function is not used (start-up option OPWDVAC = 0).

Writing AC_H to this register generates a WDTA trigger and starts or restarts the WDTA counter. Refer to **Section 21.5.2, WDTA Trigger**, for details.

The behavior of this register depends on the setting of the start-up option (OPWDVAC). Refer to **Table 21.11, WDTAnWDTE Behavior**.

Access: This register can be read/written in 8-bit units.

Address: <WDTAn_base> + 0000_H

Value after reset: The initial value depends on the start-up options OPWDRUN and OPWDVAC. Refer to **Table 21.10, WDTAnRUN Value after a Reset**. This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	WDTAnRUN[7:0]							
Value after reset		0	1	0	1	1	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.9 WDTAnWDTE Register Contents

Bit Position	Bit Name	Function
7 to 0	WDTAnRUN [7:0]	Writing a fixed activation code (AC _H) generates a WDTA trigger to control WDTAn count start and restart. Writing a value other than AC _H generates an error. After WDTAn starts, it cannot be stopped. When these bits are read or written, see Table 21.11, WDTAnWDTE Behavior .

The WDTAnRUN7 bit is only valid if the VAC function is disabled (OPWDVAC = 0). **Table 21.10** lists the values of the WDTAnRUN7 bit after reset according to the start-up options.

Table 21.10 WDTAnRUN Value after a Reset

Start-up options		Start Mode	Value of WDTAnRUN7 after Reset
OPWDVAC	OPWDRUN		
0	1	Default start	1
	0	Software trigger start	0

The behavior of WDTAnWDTE during read/write accesses depends on the OPWDVAC setting, as shown in **Table 21.12, WDTAnWDTE Behavior**.

Table 21.11 WDTAnWDTE Behavior

OPWDVAC	Description	WDTAnWDTE	
		Read	Write
0	The VAC function is disabled. WDTAnWDTE is enabled.	2C _H is read (before WDTAn starts in software trigger start mode). AC _H is read (after WDTAn has started).	WDTA trigger Write AC _H *1
1	The VAC function is enabled. WDTAnWDTE is disabled.	2C _H is read.	Writing is ignored.

Note 1. Any other write value will cause an error.

21.3.3 WDTAnEVAC — WDTA Enable VAC Register

This register is the WDTA trigger register when the VAC function is used (start-up option OPWDVAC = 1).

Writing a correct activation code to this register generates a WDTA trigger and starts or restarts the WDTA counter. For details, see **Section 21.5.2, WDTA Trigger**. For details about the activation codes when the VAC function is used, see **Section 21.5.2.1, Calculating an Activation Code when the VAC Function is Used**.

The behavior of this register depends on the setting of the start-up option (OPWDVAC). Refer to **Table 21.14, WDTAnEVAC Behavior**.

Access: This register can be read/written in 8-bit units.

Address: <WDTAn_base> + 0004_H

Value after reset: The initial value depends on the start-up options (OPWDRUN and OPWDVAC). Refer to **Table 21.13, WDTAnEVAC7 Value after a Reset**.
This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	WDTAnEVAC[7:0]							
Value after reset		0	1	0	1	1	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.12 WDTAnEVAC Register Contents

Bit Position	Bit Name	Function
7 to 0	WDTAnEVAC [7:0]	Writing a variable activation code generates a WDTA trigger to control WDTAn count start and restart. Writing an incorrect value generates an error. After WDTAn starts, it cannot be stopped. When these bits are read or written, see Table 21.14, WDTAnEVAC Behavior

The WDTAnEVAC7 bit is only valid if the VAC function is enabled (OPWDVAC = 1). **Table 21.13** lists the values of the WDTAnEVAC7 bit after reset according to the start-up options.

Table 21.13 WDTAnEVAC7 Value after a Reset

Start-up options		Start Mode	Value of WDTAnEVAC7 after a Reset
OPWDVAC	OPWDRUN		
1	1	Default start	1
	0	Software trigger start	0

The behavior of WDTAnEVAC during read/write accesses depends on the OPWDVAC setting, as shown in **Table 21.14**.

Table 21.14 WDTAnEVAC Behavior

OPWDVAC	Description	WDTAnEVAC	
		Read	Write
0	The VAC function is disabled. WDTAnEVAC is disabled.	2C _H is read.	Writing is ignored.
1	The VAC function is enabled. WDTAnEVAC is enabled.	2C _H is read (before WDTAn starts in software trigger start mode). The variable activation code written last is returned (after WDTAn has started).	Write the variable activation code* ¹ . For details, see Section 21.5.2.1, Calculating an Activation Code when the VAC Function is Used .

Note 1. Any other write value will cause an error.

21.3.4 WDTAnREF — WDTA Reference Value Register

This register contains the reference value for calculating the activation code of the VAC function. It is automatically updated after every trigger operation. For details, see **Section 21.5.2.1, Calculating an Activation Code when the VAC Function is Used**.

If VAC function is disabled (OPWDVAC = 0), reading this register returns 00_H.

Access: This register can be read in 8-bit units.

Address: <WDTAn_base> + 0008_H

Value after reset: 00_H This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	WDTAnREF[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.15 WDTAnREF Register Contents

Bit Position	Bit Name	Function
7 to 0	WDTAnREF[7:0]	Reference value to calculate activation code of VAC function.

21.3.5 WDTAnMD — WDTA Mode Register

This register specifies the overflow interval time, 75% interrupt enable/disable, and the window-open period.

The value of this register can be updated only once after release from the reset state and before the first WDTA trigger is generated. The updated value will be effective after the WDTA trigger register is written to.

When this register is updated after the first WDTA trigger has been generated, an error occurs. No error occurs when the same value is written to it.

Access: This register can be read/written in 8-bit units.

Address: <WDTAn_base> + 000C_H

Value after reset: The initial value depends on the start-up options (OPWDOVF[2:0]). Refer to **Table 21.7, WDTA Start-up Options**. This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	—	WDTAnOVF[2:0]			WDTAnWIE	—	WDTAnWS[1:0]	
Value after reset	0	*1	*1	*1	0	1	1	1
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. The WDTAnOVF[2:0] value after reset can be set by the start-up options OPWDOVF[2:0].

Table 21.16 WDTAnMD Register Contents (1/2)

21.4 Interrupt Sources

The WDTA checks the status of the WDTA counter value, detects accesses to the WDTA-related registers, and generates an interrupt request. The following are WDTA interrupt requests:

- (1) INTWDTAn (WDTA timer count 75% interrupt request)
An interrupt request signal is generated at 75% of the counter overflow time of the WDTA timer.
An interrupt request signal can be enabled or disabled by using the WDTA mode register (WDTAnMD).
- (2) WDTAnTERR (WDTA error signal)
Detection of a WDTA error generates an error signal WDTAnTERR.
The WDTAnTERR signal is connected to the ECM module.

21.5 Function

21.5.1 WDTA after Release from the Reset State

21.5.1.1 Start Modes

There are two start modes (software start mode and default start mode) when WDTA starts after release from the reset state. The start mode can be selected by the start-up option. The start modes are listed in **Table 21.17**.

Table 21.17 Start Mode Selection

Start-up Option	Start mode	Description
OPWDRUN		
0	Software trigger	<ul style="list-style-type: none"> The WDTA counter stops (0000_H) after release from the reset state. Writing an activation code to the WDTA trigger register starts WDTA.
1	Default start mode	The WDTA counter starts after release from the reset state.

21.5.1.2 Count Clock Selection

The count clock WDTATCKI can be selected by the start-up options.

The selection of the count clock WDTATCKI is listed in **Table 21.18**.

Table 21.18 Count Clock Selection

Start-up Options	Mode	Count Clock
OPWDMDS		
0	High-speed mode	High-speed internal oscillation (8 MHz)
1	Low-speed mode	High-speed internal oscillation/32 (250 kHz)

21.5.1.3 WDTA Settings after Release From The Reset State,

Table 21.19 shows the WDTA settings after release from the Reset State,.

Table 21.19 WDTA Settings after Release From The Reset State,

Function	Setting	Remark
Start mode	Specified by start-up options	
VAC function		
Count clock selection		
WDTA overflow interval time	Specified by start-up options	Modification is possible only once by the setting of the WDTA mode register (WDTAnMD).
75% interrupt mode	75% interrupt disabled	
Behavior on error detection	Error signal WDTAnTERR generation	
Window-open period	100%	

The setting of the WDTA mode register (WDTAnMD) is enabled when the first WDTA trigger is generated (writing an activation code to WDTAnWDTE and WDTAnEVAC). Change the setting of the WDTAnMD register before a WDTA trigger is generated.

Setting of WDTA by using WDTAnMD is possible only once. If the value set in WDTAnMD is changed after a WDTA trigger is generated, an error occurs. However, an error does not occur if the same value is set.

21.5.1.4 Default Start Mode Timing

The default start mode timing and the changes to the WDTA settings are illustrated in **Figure 21.2**.

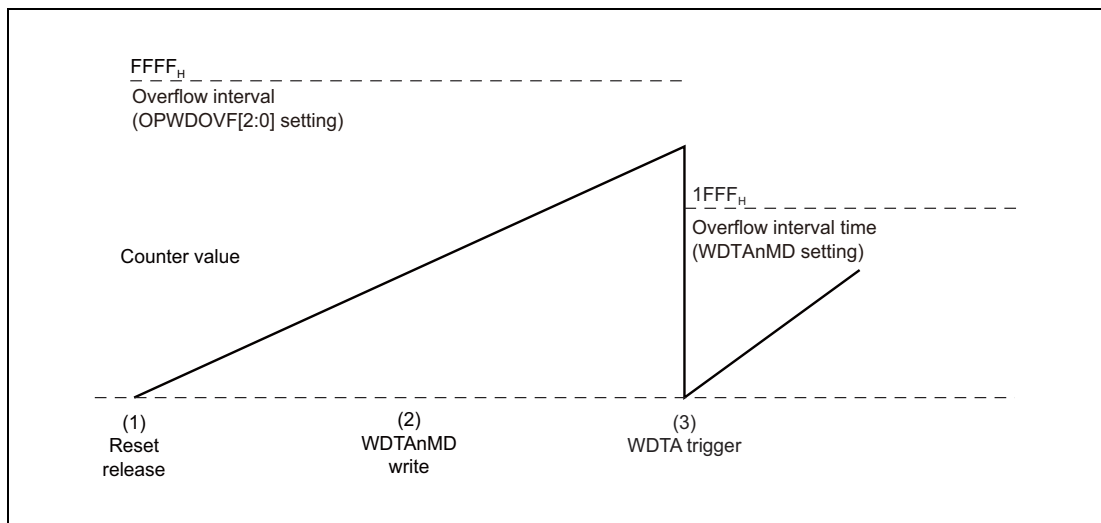

Figure 21.2 Timing Diagram of WDTA Start in Default Start Mode

The timing diagram shown in **Figure 21.2** shows the following behaviors:

- (1) In default start mode, the WDTA counter starts after release from the reset state. The overflow interval time after release from the reset state, is set by start-up options.
Example: Overflow interval time after release from the reset state,

$$= 2^{16}/\text{WDTATCKI} (\text{OPWDOVF}[2:0] = 111_{\text{B}})$$
- (2) WDTAnMD is set before a WDTA trigger is generated. Note that the setting is not applied immediately.
- (3) Write to the WDTA trigger register before the WDTA counter overflows. The WDTAnMD setting is applied by the generation of a WDTA trigger.
Example: Overflow interval time after a WDTA trigger is generated

$$= 2^{13}/\text{WDTATCKI}$$

21.5.1.5 Software Trigger Start Mode Timing

The software trigger start mode timing and the changes to the WDTA settings are illustrated in **Figure 21.3**.

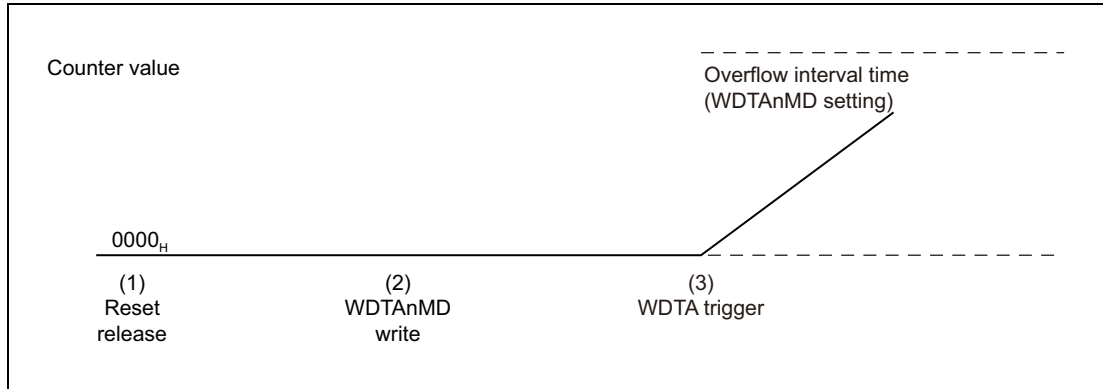

Figure 21.3 Timing Diagram of WDTA Start in Software Trigger Start Mode

The timing diagram above shows the following:

- (1) After release from the reset state, the counter remains 0000_H until the first trigger. The count clock is specified by the start-up options, but this setting has no effect because the counter is not operating.
- (2) WDTAnMD is written before the first trigger. However, the settings are not applied immediately.
- (3) The WDTA counter starts by the generation of a WDTA trigger. The overflow interval time and other settings specified in WDTAnMD are applied.

21.5.2 WDTA Trigger

Writing a special value called an activation code to the WDTA enable register (WDTAnWDTE) and the WDTA enable VAC register (WDTAnEVAC) leads to generation of a WDTA trigger.

The WDTA trigger has the following functions:

- Starting the WDTA counter in software trigger start mode
- Restarting the WDTA counter
- Setting the WDTA mode specified by the WDTAnMD register (only for the first WDTA trigger after release from the reset state,)

The WDTA trigger register, which generates a WDTA trigger, is specified by the start-up option OPWDVAC.

Table 21.20 lists the WDTA trigger registers and activation codes.

Table 21.20 WDTA Trigger Registers and Activation Codes

Type of activation code	Trigger register	Activation code
Fixed (OPWDVAC = 0)	WDTAnWDTE	AC _H
Variable (OPWDVAC = 1)	WDTAnEVAC	For details, refer to Section 21.5.2.1, Calculating an Activation Code when the VAC Function is Used.

21.5.2.1 Calculating an Activation Code when the VAC Function is Used

Use the following expression to calculate the variable activation code (ExpectWDTE) to be set to the WDTA trigger register (WDTAnEVAC) when the VAC function is used, by using the WDTA reference value register (WDTAnREF):

$$\text{ExpectWDTE} = \text{AC}_H - \text{WDTAnREF (old)}$$

Note that the value in the WDTAnREF register is updated every time a activation code is written to the trigger register WDTAnEVAC. Use the following expression to calculate the updated value of the WDTAnREF register:

$$\text{WDTAnREF (new)} = (\text{rotate the value of ExpectWDTE to the left by 1 bit})$$

Table 21.21 lists the variable activation codes according to the number of WDTA triggers.

Table 21.21 Expected Variable Activation Code Development

No ^{*1}	WDTAnREF (old)		ExpectWDTE (AC _H - WDTAnREF)		WDTAnREF (new)	
0	0000 0000	00 _H	1010 1100	AC _H	0101 1001	59 _H
1	0101 1001	59 _H	0101 0011	53 _H	1010 0110	A6 _H
2	1010 0110	A6 _H	0000 0110	06 _H	0000 1100	0C _H
...

Note 1. Number of triggers after reset

NOTE

Writing an incorrect activation code generates an error.

21.5.3 WDTA Error Detection

WDTA detects an error, including generation of WDTA count overflow or illegal operations.

The following events are detected as errors:

- WDTA counter overflow
- Wrong activation code is written to the WDTA trigger register
- Writing to the trigger register at a time outside the window-open period
- When it is attempted to change the setting value of the WDTA mode register WDTAnMD after the first WDTA trigger has been generated
- When updating the setting value of the WDTA mode register WDTAnMD twice before the first WDTA trigger is generated

Figure 21.4 shows generation of an error signal WDTAnTERR when default mode is selected and the counter overflows.

Figure 21.4 Timing Diagram of WDTA Error Signal WDTAnTERR Generation

The timing diagram above shows the following:

- (1) In default start mode, the WDTA counter starts after release from the reset state. The overflow interval time after release from the reset state, is set by start-up options.
- (2) WDTAnMD is set before a WDTA trigger is generated. In this case, $2^{16}/\text{WDTATCKI}$ is set for the overflow interval time.
- (3) The WDTAnMD setting is applied due to the WDTA trigger.
- (4) When the counter overflows, an error is detected. An error signal WDTAnTERR is generated. The counter value remains until a reset is performed.
- (5) When the reset is performed, the counter is cleared and stopped until release from the reset state.

21.5.4 75% Interrupt Request Signals

When the WDTA counter reaches 75% of the time set for the overflow interval, the interrupt request INTWDTAn is generated.

By use of WDTAnMD.WDTAnWIE this function can be enabled or disabled afterwards.

Figure 21.5 shows the 75% interrupt request generation under following conditions:

- Default start mode selected
- 75% interrupt request is enabled after the first WDTA trigger is generated
- WDTA overflow interval time: $2^{16}/\text{WDTATCKI}$

Figure 21.5 Timing Diagram of WDTA 75% Interrupt Request Signals

- (1) In default start mod, WDTA count starts after reset is released.
The overflow interval time period after reset is released is set by the start-up options.
- (2) WDTAnMD is set before the WDTA trigger is generated. In this figure, $2^{16}/\text{WDTATCKI}$ is set as the overflow interval time period.
- (3) The WDTAnMD setting is applied at the WDTA trigger.
- (4) When the WDTA counter reaches 75% of the set overflow interval time, an interrupt request INTWDTAn is generated.
- (5) The count restarts at the WDTA trigger.
- (6) When the WDTA counter reaches 75% of the set overflow interval time, an interrupt request INTWDTAn is generated.
- (7) When the counter overflows, an error is detected. An error signal WDTAnTERR is generated. The counter value remains unchanged until a reset is performed.

21.5.5 Window Function

The period when a WDTA trigger is valid (window-open period) can be set. If the window-open period is set to the value less than 100%, an error occurs by the WDTA trigger generated not in the window-open period. The window-open period after release from the reset state, is 100%. The period is set to the value by the WDTAnMD.WDTAnWS[1:0] setting after the first WDTA trigger is generated.

Figure 21.6 shows window function operations under the following conditions.

- Default start mode is selected.
- The 25% window open period is valid (WDTAnWS[1:0] = 00_B) after the first WDTA trigger
- WDTA overflow interval time period: $2^{16}/\text{WDTATCKI}$

Figure 21.6 Timing Diagram of WDTA Window Function

- (1) In default start mode, WDTA count starts after reset is released.
The overflow interval time period after reset is released is set by the start-up options.
- (2) WDTAnMD is set before the WDTA trigger is generated. In this figure, $2^{16}/\text{WDTATCKI}$ is set as the overflow interval time period.
- (3) The WDTAnMD setting is applied at the WDTA trigger.
- (4) WDTA count restarts at the WDTA trigger during the window open period.
- (5) An error is detected at the WDTA trigger during the window close period.
An error signal WDTAnTERR is generated. The counter value remains unchanged until a reset is performed.
- (6) When the reset is performed, the counter is cleared and stops until the reset is released.

Section 22 OS Timer (OSTM)

The OS Timer (OSTM) is a 32-bit timer/counter. OSTM is implemented 7 units.

OSTM can be used in interval timer mode or in free-running comparison mode. The settings for operating mode specify the direction of counting (up or down) in control of the generation of interrupt requests.

The OSTM is synchronized with other peripheral functions by the count clock enable signal and the count start signal.

22.1 Features of RH850/P1M-E OSTM

22.1.1 Number of Units

This microcontroller has the following number of units of the OSTM_n.

Table 22.1 Number of Units

Product	RH850/P1M-E
Number of Units	7
Name	OSTM0, OSTM1, and OSTM3 to OSTM7

Table 22.2 Index

Index	Meaning
n	Throughout this section, the individual OSTM _n units are identified by the index "n": for example, OSTM _n CNT is the OSTM _n counter register.

22.1.2 Register Base Address

OSTMn base addresses are listed in the following table.

OSTMn register addresses are given as offsets from these base addresses.

Table 22.3 Register Base Address

Base Address Name	Base Address
<OSTM0_base>	FFDD 8000 _H
<OSTM1_base>	FFDD 9000 _H
<OSTM3_base>	FFD7 0000 _H
<OSTM4_base>	FFD7 0040 _H
<OSTM5_base>	FFD7 0080 _H
<OSTM6_base>	FFD7 00C0 _H
<OSTM7_base>	FFD7 0100 _H

22.1.3 Clock Supply

Clock supply by and to OSTMn is listed in the following table.

Table 22.4 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
OSTM0	PCLK	High speed peripheral clock CLK_HSB*1
OSTM1	PCLK	High speed peripheral clock CLK_HSB*1
OSTM3	PCLK	High speed peripheral clock CLK_HSB
OSTM4	PCLK	High speed peripheral clock CLK_HSB
OSTM5	PCLK	High speed peripheral clock CLK_HSB
OSTM6	PCLK	High speed peripheral clock CLK_HSB
OSTM7	PCLK	High speed peripheral clock CLK_HSB

Note 1. OSTMnTCKE is selectable as the counter source clock.

22.1.4 Interrupt Requests

OSTMn interrupt requests are listed in the following table.

Table 22.5 Interrupt Requests

Unit Interrupt Name	Description	Interrupt Number	DMA/DTS Trigger Number
OSTM0			
INTOSTM0	OSTM0 interrupt	74	—
OSTM1			
INTOSTM1	OSTM1 interrupt	75	—
OSTM3			
INTOSTM3	OSTM3 interrupt	(FEINT)	—
OSTM4			
INTOSTM4	OSTM4 interrupt	(FEINT)	—
OSTM5			
INTOSTM5	OSTM5 interrupt	(FEINT)	—
OSTM6			
INTOSTM6	OSTM6 interrupt	(FEINT)	—
OSTM7			
INTOSTM7	OSTM7 interrupt	(FEINT)	—

22.1.5 Reset Sources

Please refer to **Section 8, Reset Controller**.

22.1.6 External Input/Output Signals

An OSTMn input/output signals are listed in the following table.

Table 22.6 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
OSTM0:			
OSTM0TTOUT	O	OSTM0 output	OSTM0O
OSTM1:			
OSTM1TTOUT	O	OSTM1 output	OSTM1O

22.2 Overview

Each OSTMn is a 32-bit timer/counter.

OSTMn can be used in interval timer mode or in free-running comparison mode. The settings for operating mode determine the direction of counting (up or down) that is used for the generation of interrupt requests.

The OSTMn is synchronized with other peripheral modules by the counter-clock-enable signal (OSTMnTCKE) and the count start signal (OSTMnTSST).

22.2.1 Functional Overview

The OSTMn has the following features.

- Two operating modes
 - Interval timer mode
 - Free-running comparison mode
- INTOSTMn interrupt
- Generation of an output signal from the OSTMnO pin (OSTM0, OSTM1)
 - Software control mode
 - Timer output toggle mode
- Using the timing protection timer (TPT) to monitor times
 - Monitoring of the times taken in processing tasks and interrupts is possible by using INTOSTM3 to INTOSTM7 assigned as FEINT interrupts.

22.2.2 Block Diagram

The following block diagram shows the main components of the OSTMn.

Figure 22.1 Block Diagram of the OSTMn (OSTM0, OSTM1)

Figure 22.2 Block Diagram of the OSTMn (OSTM3 to OSTM7)

22.2.3 Counter clock

The clock signals for counting by OSTM0 and OSTM1 are defined by PCLK and OSTMnTCKE in the following ways. The count signals for counting by OSTM3 to OSTM7 are always defined by PCLK.

- If C0KSELn.IC0TMENn = 0, the OSTMnTCKE signal being at the high level (logical 1) selects counting of cycles of PCLK.
- IC0KSELn.IC0TMENn being set to 1 selects the TAUDn or TAUJn signal as the counter-clock-enable signal, OSTMnTCKE. The cycles of the clock signals for counting by OSTMn are synchronized with the cycles of the clock signals generated as TAUDn or TAUJn (any from among CK0 to CK3).

This is illustrated in the following figures.

Figure 22.3 Counting when OSTMnTCKE is Fixed to H

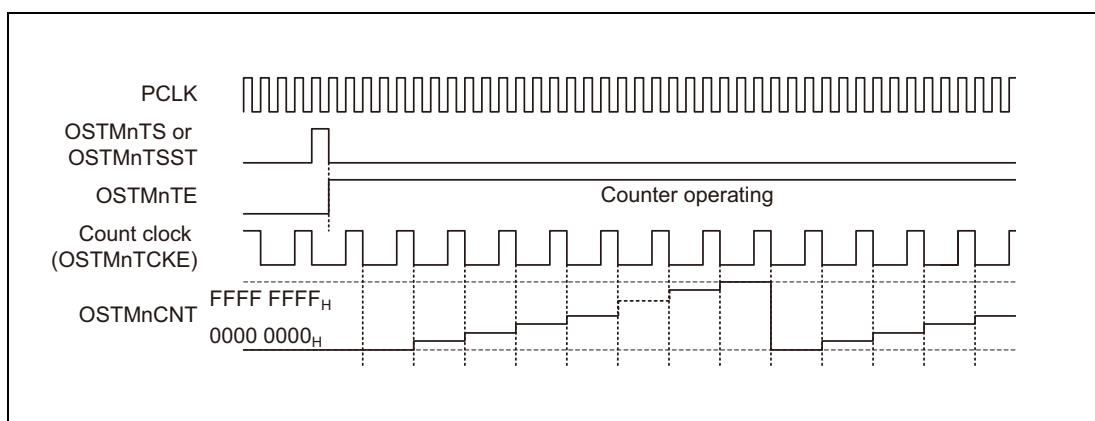

Figure 22.4 Counting in Response to Transitions of the OSTMnTCKE Input Signal

The counter-clock-enable signal (OSTMnTCKE) for each OSTMn can be selected by the IC0CKSEL0 or IC0CKSEL1 register from among 40 channels: 16 channels from each of TAUD0 and TAUD1, and 4 channels from each of TAUJ0 and TAUJ1.

For the counter-clock-enable signals for TAUDn and TAUJn (TAUDnTCKENm and TAUJnTCKENm) and the clock signals generated in TAUDn and TAUJn (CK0 to CK3), see **Figure 22.2** and **Figure 23.2**.

CAUTIONS

1. Select a counter-clock-enable signal for OSTMn while the operation of OSTMn is stopped (the OSTMnTE.OSTMnTE bit is 0).
2. After using the IC0CKSELn.IC0TMSELn[1:0], IC0CKSELn.IC0CKSELn3[1:0], IC0CKSELn.IC0CKSELn2[1:0], IC0CKSELn.IC0CKSELn1[3:0], and IC0CKSELn.IC0CKSELn0[3:0] bits to select the counter-clock-enable signal for OSTMn, set the IC0CKSELn.IC0TMENn bit to 1.
3. If TAUDn or TAUJn is selected as the source of the counter-clock-enable signal for OSTMn (the IC0CKSELn.IC0TMENn bit is 1), do not change the operation of TAUDn or TAUJn while the OSTMn is operating (the OSTMnTE.OSTMnTE bit is 1).

[Setting procedure]

- (1) Confirm that the OSTMnTE.OSTMnTE bit is 0 (OSTMn operation is stopped).
 - (2) Set the IC0CKSELn.IC0TMSELn[1:0], IC0CKSELn.IC0CKSELn3[1:0], IC0CKSELn.IC0CKSELn2[1:0], IC0CKSELn.IC0CKSELn1[3:0], and IC0CKSELn.IC0CKSELn0[3:0] bits to select the counter-clock enable signal for the OSTMn.
 - (3) Set the IC0CKSELn.IC0TMENn bit to 1.
 - (4) Enable OSTMn operation by setting the OSTMnTS.OSTMnTS bit to 1.
4. Operating system timers OSTM3 to OSTM7 do not have IC0CKSELn registers. Only PCLK is available as the clock for counting.
-

22.2.4 Output Modes (OSTM0 and OSTM1)

The OSTMn has the following output modes. The mode is selected by the setting of the OSTMnTOE.OSTMnTOE bit.

- Software control mode (the OSTMnTOE.OSTMnTOE bit is 0): The value set in the OSTMnTO.OSTMnTO bit is output to OSTMnTTOUT.
- Timer-output toggling mode (the OSTMnTOE.OSTMnTOE bit is 1): The OSTMnTTOUT output is toggled each time an INTOSTMn request is generated.

Both output modes are illustrated in the following figure.

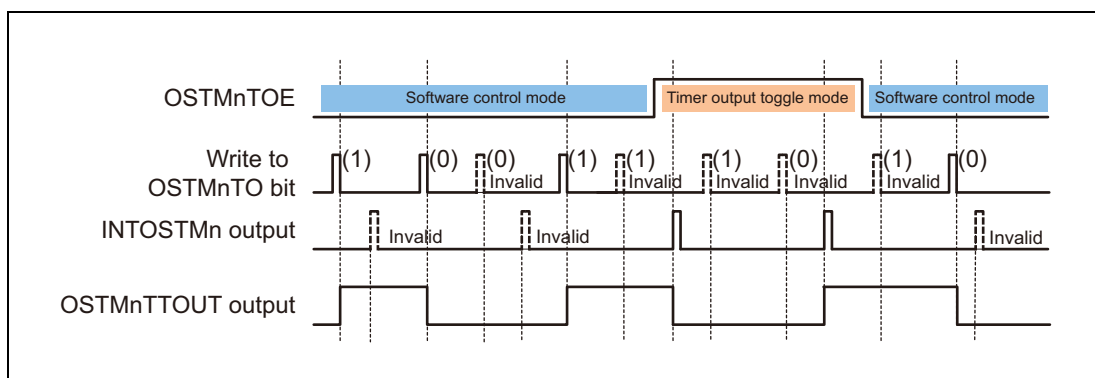

Figure 22.5 Timing Diagram of Output Modes

The above timing diagram shows the following operations.

- In software control mode, the level of the OSTMnTTOUT output changes in accord with the value set in the OSTMnTO.OSTMnTO bit.
- In timer-output toggling mode, the value of the OSTMnTO.OSTMnTO bit and level of the OSTMnTTOUT output are toggled each time an INTOSTMn interrupt request is generated.

22.2.5 Interrupt Requests (INTOSTMn)

An INTOSTMn interrupt request is generated on counter underflow (interval timer mode) or when the counter matches the compare value (free-running comparison mode).

An interrupt request can also be generated on starting and restarting of the counter. This is controlled by the OSTMnCTL.OSTMnMD0 bit.

The INTOSTMn is the trigger for toggling of the OSTMnTTOUT output in the timer output toggling mode (OSTMnTOE.OSTMnTOE = 1), so the setting of the OSTMnCTL.OSTMnMD0 bit also affects OSTMnTTOUT output.

This is illustrated in the following figure.

Figure 22.6 Generating an Interrupt when Counting Starts (Interval Timer Mode)

22.3 Registers

22.3.1 List of Registers

OSTMn registers are listed in the following table.

For details about <OSTMn_base>, see **Section 22.1.2, Register Base Address**.

Table 22.7 List of Registers

Module Name	Register Name	Symbol	Address
OSTMn	OSTMn compare register	OSTMnCMP	<OSTMn_base> + 00 _H
OSTMn	OSTMn counter register	OSTMnCNT	<OSTMn_base> + 04 _H
OSTMn	OSTMn output register	OSTMnTO	<OSTMn_base> + 08 _H
OSTMn	OSTMn output enable register	OSTMnTOE	<OSTMn_base> + 0C _H
OSTMn	OSTMn count enable status register	OSTMnTE	<OSTMn_base> + 10 _H
OSTMn	OSTMn count start trigger register	OSTMnTS	<OSTMn_base> + 14 _H
OSTMn	OSTMn count stop trigger register	OSTMnTT	<OSTMn_base> + 18 _H
OSTMn	OSTMn control register	OSTMnCTL	<OSTMn_base> + 20 _H
OSTM	OSTM0 clock select register	IC0CKSEL0	FFDD 6000 _H
OSTM	OSTM1 clock select register	IC0CKSEL1	FFDD 6004 _H

22.3.2 Details of OSTMn Registers

22.3.2.1 OSTMnCMP — OSTMn Compare Register

This register stores the start value of the down-counter or the value with which the counter is compared, depending on the mode of operation.

Access: This register can be read/written in 32-bit units.

Address: <OSTMn_base> + 00_H

Value after reset: 0000 0000_H. This register is initialized by a reset of any type.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OSTMnCMP[31:16]

Bit Position	Bit Name	Function
31 to 0	OSTMnCMP [31:0]	<ul style="list-style-type: none"> In interval timer mode: start value of the down-counter In free-running comparison mode: compare value

22.3.2.2 OSTMnCNT — OSTMn Counter Register

This register indicates the counter value of the timer.

Access: This register can be read in 32-bit units.

Address: <OSTMn_base> + 04_H

Value after reset: FFFF FFFF_H. This register is initialized by a reset of any type.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 0	OSTMnCNT [31:0]	Timer counter value

Table 22.10 shows the correspondence between OSTM operating mode, counting direction and start value of the OSTMn. The start value is the value read from the counter after a change to the operating mode.

Table 22.10 Correspondence between Operating Mode, Counting Direction and Start Value

Timer operating mode	OSTMnCTL.OSTMnMD1	Counting direction	Start value
Interval timer mode	0*1	Down	FFFF FFFF _H
Free-running comparison mode	1	Up	0000 0000 _H

Note 1. Value after reset.

OSTMnCNT is loaded with the value in the OSTMnCMP register if it is in interval timer mode or with the counter value 0000 0000_H if it is in free-running comparison mode at the start of a cycle of counting after OSTMnTE has become 1.

22.3.2.3 OSTMnTO — OSTMn Output Register

The OSTM Output Register is used to specify and read the level of an OSTMnTTOUT output signal. The setting of this register is only valid in OSTMn (n = 0, 1).

Access: This register can be read/written in 8-bit units. Writing can only proceed when the software control mode is selected (OSTMnTOE.OSTMnTOE = 0).

Address: <OSTMn_base>+ 08_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTO
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 22.11 OSTMnTO Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	OSTMnTO	This bit specifies or indicates the level of the OSTMnTTOUT output signal. 0: Low level 1: High level

22.3.2.4 OSTMnTOE — OSTMn Output Enable Register

The OSTM Output Enable Register specifies OSTMnTTOUT output mode. The setting of this register is only valid in OSTMn (n = 0, 1).

Access: This register can be read/written in 8-bit units.

Address: <OSTMn_base>+ 0C_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTOE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 22.12 OSTMnTOE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	OSTMnTOE	This bit specifies the OSTMnTTOUT output mode. 0: Software control mode: The level corresponding to the setting of OSTMnTO.OSTMnTO is output to OSTMnTTOUT. 1: Timer-output toggling mode: OSTMnTTOUT output is toggled whenever an INTOSTMn interrupt request is generated.

22.3.2.5 OSTMnTE — OSTMn Count Enable Status Register

This register indicates whether the counter is enabled or disabled.

Access: This register can only be read in 8-bit units.

Address: <OSTMn_base> + 10_H

Value after reset: 00_H. This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 22.13 OSTMnTE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read.
0	OSTMnTE	Indicates whether the counter is enabled or disabled: 0: Counter disabled 1: Counter enabled This bit is set to 1 in response to OSTMnTS.OSTMnTS being set to 1, or to OSTMnTSST being 1. Setting OSTMnTT.OSTMnTT to 1 resets this bit to 0.

NOTE

If the counter is disabled, the counter OSTMnCNT retains its value.

If the counter is restarted:

- It restarts counting down from the value in the OSTMnCMP register if it is in interval timer mode or
- It restarts counting up from the counter value 0000 0000_H if it is in free-running comparison mode.

22.3.2.6 OSTMnTS — OSTMn Count Start Trigger Register

This register starts the counter.

Access: This register can only be written in 8-bit units. It is always read as 00_H.

Address: <OSTMn_base> + 14_H

Value after reset: 00_H. This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 22.14 OSTMnTS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	OSTMnTS	Starts the counter: 0: This setting is invalid. 1: Starts the counter and sets OSTMnTE.OSTMnTE = 1. <ul style="list-style-type: none"> • In interval timer mode, a forced restart is executed if this bit is set while OSTMnTE.OSTMnTE = 1. • In free-running comparison mode, setting this bit is ignored as long as OSTMnTE.OSTMnTE = 1.

22.3.2.7 OSTMnTT — OSTMn Count Stop Trigger Register

This register stops the counter.

Access: This register can only be written in 8-bit units. It is always read as 00_H.

Address: <OSTMn_base> + 18_H

Value after reset: 00_H. This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 22.15 OSTMnTT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	OSTMnTT	Stops the counter: 0: This setting is invalid. 1: Stops the counter and clears the OSTMnTE.OSTMnTE bit.

22.3.2.8 OSTMnCTL — OSTMn Control Register

This register specifies the operating mode for the counter and controls the generation of INTOSTMn interrupt requests when counting starts.

Although this register is readable and writable, writing to it is only possible when OSTMnTE.OSTMnTE = 0; that is, the register becomes read-only when OSTMnTE.OSTMnTE = 1.

Access: This register can be read/written in 8-bit units.

Address: <OSTMn_base> + 20_H

Value after reset: 00_H. This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OSTMnMD1	OSTMnMD0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 22.16 OSTMnCTL Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	OSTMnMD1	Specifies the operating mode for the counter: 0: Interval timer mode 1: Free-running comparison mode
0	OSTMnMD0	Controls the generation of INTOSTMn interrupt requests at the start of counting: 0: Interrupts when counting starts are disabled. 1: Interrupts when counting starts are enabled.

22.3.2.9 IC0CKSEL0 — OSTM0 Clock Select Register

This register selects the counter-clock-enable signal as the clock source to drive counting for the OSTM0 counter.

Access: This register can be read/written in 16-bit units.

Address: FFDD 6000_H

Value after reset: 0000_H. This register is initialized by a reset of any type.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

22.4 Operation

22.4.1 Starting and Stopping OSTMn

The OSTMn is started and stopped as follows:

Starting the timer

The timer is started in either of the following ways:

- setting the OSTMnTS.OSTMnTS bit to 1 or
- transitions of the OSTMnTSST signal from 0 to 1

The OSTMnTE.OSTMnTE status flag is set to 1.

The counter starts to count up or down in accord with the settings for operating mode. For details, refer to **Section 22.4.2, Interval Timer Mode** and **Section 22.4.3, Free-Running Comparison Mode**.

If the OSTMnTS.OSTMnTS bit is to be used to start the timer, the OSTMnTSST input must correspond to logical zero.

Stopping the timer

Setting the OSTMnTT.OSTMnTT bit to 1 stops the OSTMn.

This also clears the OSTMnTE.OSTMnTE status flag.

When the counter is stopped, the OSTMnTO register and the OSTMnCNT register retain their current values and the output signal OSTMnTTOUT stays at the same level until the next time counting is started.

Synchronous start

The OSTMnTSST signal can be used to start the timer in synchronization with other peripheral functions. Refer to **Section 29.2.3.1, Simultaneous Start Trigger Function**.

22.4.2 Interval Timer Mode

In interval timer mode, the OSTMn can be used as a reference timer generating interrupt requests at fixed intervals.

22.4.2.1 Basic Operation in Interval Timer Mode

In interval timer mode, the timer counts down from the value specified in the OSTMnCMP register. An INTOSTMn interrupt request is generated when the counter underflows (reaches 0000 0000_H).

To select interval timer mode, set OSTMnCTL.OSTMnMD1 = 0.

New values can be written to the OSTMnCMP register at any time. When a new value is written while counting is in progress, the new OSTMnCMP value will only be loaded the next time the counter reaches 0000 0000_H. The counter then continues with the new value.

Intervals for INTOSTMn and OSTMnTTOUT output

The intervals for INTOSTMn and OSTMnTTOUT output are as follows.

- INTOSTMn generation cycle = counter-clock cycle × (OSTMnCMP + 1)
- OSTMnTTOUT output cycle = INTOSTMn generation cycle × 2

The following figure shows the basic operation of the OSTMn in interval timer mode with counter-start interrupts enabled.

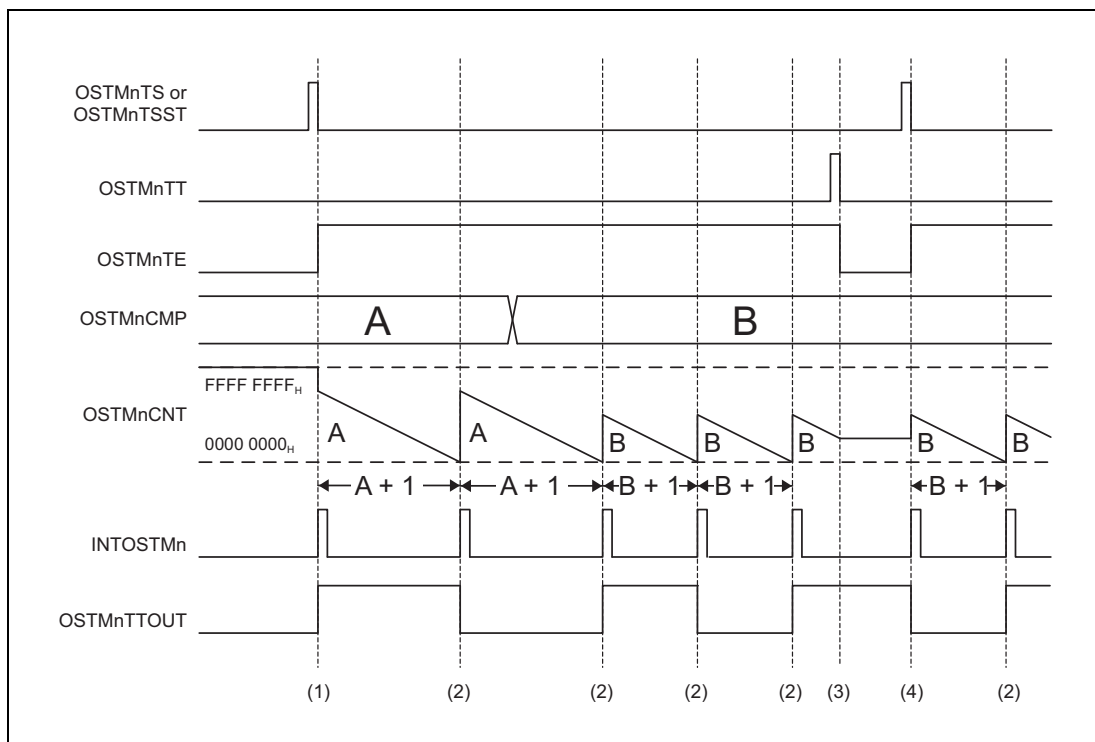

Figure 22.7 Timing Diagram of OSTMn in Interval Timer Mode

The timing diagram above shows the following:

- (1) The counter starts counting when OSTMnTS.OSTMnTS = 1 or OSTMnTSST = 1. The OSTMnTE.OSTMnTE bit is set to indicate enabling of the counter. The counter starts counting-down from the value of OSTMnCMP. If OSTMnCTL.OSTMnMD0 is 1, INTOSTMn interrupt requests are generated at the start of counting and the OSTMnTTOUT signal is toggled. The OSTMnCNT register indicates the counter value.
- (2) When the counter reaches 0000 0000_H, an INTOSTMn interrupt request is generated and the OSTMnTTOUT signal is toggled. The counter loads the new start value from OSTMnCMP and continues counting down.
- (3) When the counter is stopped (OSTMnTT.OSTMnTT = 1), the OSTMnTE.OSTMnTE bit is cleared to indicate disabling of the counter. The counter retains its current value until it is restarted.
- (4) When counting is restarted (OSTMnTS.OSTMnTS = 1, or OSTMnTSST = 1), the counter loads the new start value from OSTMnCMP and starts counting down.

Forced restart

The counter is forcibly restarted by setting $OSTMnTS.OSTMnTS = 1$ or by a transition of the $OSTMnTSST$ signal from 0 to 1 during counting.

The counter loads the start value from the $OSTMnCMP$ register and continues counting down.

The following figure shows a timing diagram in interval timer mode, with counter-start interrupts enabled ($OSTMnCTL.OSTMnMD0 = 1$), and in timer output toggling mode, where $OSTMnTTOUT$ is toggled ($OSTMnTOE.OSTMnTOE = 1$).

Figure 22.8 Timing Diagram of Forced Restart in Interval Timer Mode

The timing diagram above shows the following operations:

- (1) The counter is started and stopped as described under **Figure 22.7, Timing Diagram of OSTMn in Interval Timer Mode**.
- (2) Setting $OSTMnTS.OSTMnTS = 1$ or $OSTMnTSST = 1$ restarts the counter while counting is in progress (i.e. while $OSTMnTE.OSTMnTE = 1$).
The counter immediately restarts counting down, starting with the current value of $OSTMnCMP$. When $OSTMnCTL.OSTMnMD0 = 1$, an $INTOSTMn$ interrupt request is generated when counting starts and the $OSTMnTTOUT$ signal is toggled.

22.4.2.2 Operation when $OSTMnCMP = 0000\ 0000_H$

When PCLK is selected as the source of the clock signal for counting and $OSTMnCMP = 0000\ 0000_H$, the OSTMn behaves as follows.

- If the counter is enabled, the INTOSTMn interrupt request will always be set to 1. The INTOSTMn interrupt request is generated only when the counter starts counting. However, the timer (OSTMnTTOUT) output signal can still be used. Timer (OSTMnTTOUT) output using timer output toggling mode results in OSTMnTTOUT being toggled on every cycle of the counter clock.

The following figure shows operations of the OSTMn when PCLK is selected as the source of the clock signal for counting and $OSTMnCMP = 0000\ 0000_H$, the counter start interrupt is enabled ($OSTMnCTL.OSTMnMD0 = 1$), and the timer is in timer output toggling mode, where OSTMnTTOUT is toggled ($OSTMnTOE.OSTMnTOE = 1$).

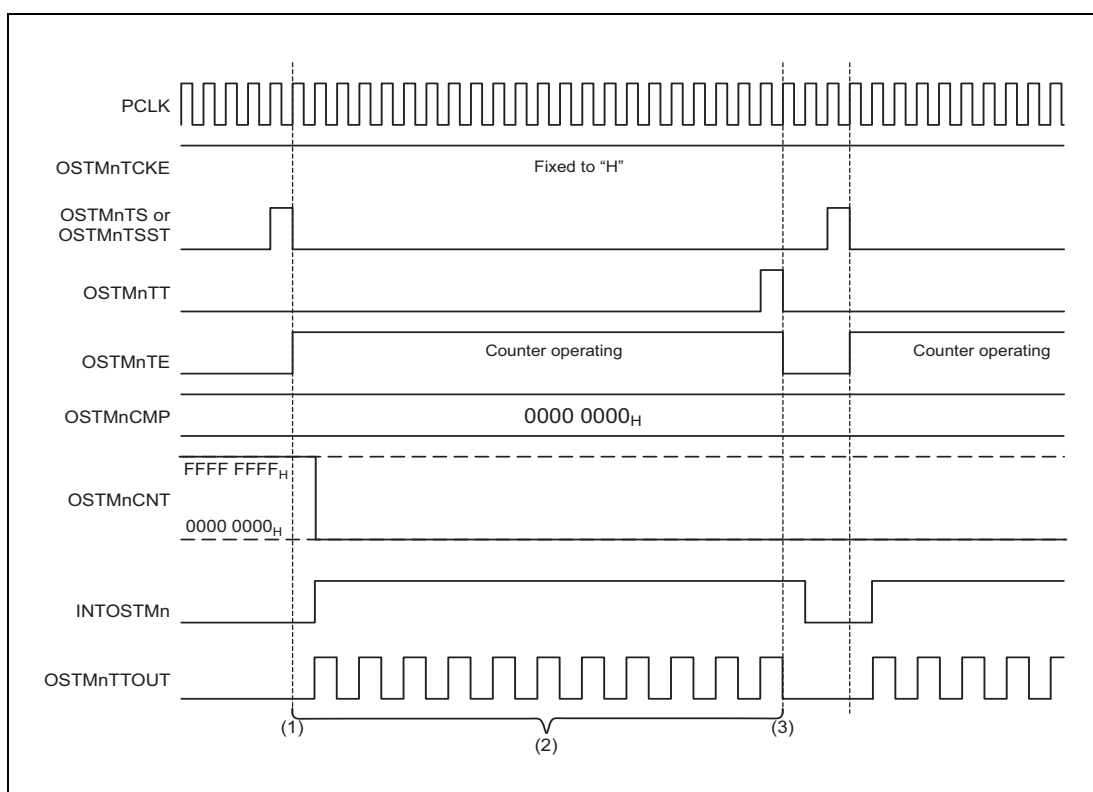

Figure 22.9 Timing Diagram when Counter Clock = PCLK (OSTMnTCKE is at High Level) and $OSTMnCMP = 0000\ 0000_H$ in Interval Timer Mode

The timing diagram above shows the following operations:

- (1) The counter is reloaded with the value in OSTMnCMP as soon as it starts counting, so the value $0000\ 0000_H$ is retained in OSTMnCMP.
- (2) While the INTOSTMn interrupt request signal is continuously asserted, OSTMnTTOUT is toggled (in **Figure 22.9**, INTOSTMn is fixed to the high level because PCLK is selected as the counter clock).
- (3) After the counter stops, the INTOSTMn interrupt request signal is deasserted and the output level of the OSTMnTTOUT signal is maintained.

When an interrupt is prohibited when the counter starts, 1 clock cycle of the counter clock is not generated at the start timing of the counter.

22.4.2.3 Setting Procedure for Interval Timer Mode

The procedure for setting up interval timer mode after release from the reset state is described below.

Setting procedure

- (1) Set the start value of the counter in the OSTMnCMP register.
- (2) To output OSTMnTTOUT:
 - Initialize the OSTMnTO register in software control mode (OSTMnTOE.OSTMnTOE = 0).
 - Select timer output toggle mode (OSTMnTOE.OSTMnTOE = 1).
- (3) Select interval timer mode by setting the OSTMnCTL.OSTMnMD1 bit to 0.
- (4) Select by using the OSTMnCTL.OSTMnMD0 bit whether to enable or disable an interrupt when counting starts.

22.4.3 Free-Running Comparison Mode

22.4.3.1 Basic Operation in Free-Running Comparison Mode

In free-running comparison mode, the counter counts up from $0000\ 0000_H$ to $FFFF\ FFFF_H$. When the value of the OSTMnCMP register matches the current counter value, an INTOSTMn interrupt request is generated.

When the free-running comparison mode is used, set the OSTMnCTL.OSTMnMD1 to 1.

New values can be written to the OSTMnCMP register at any time.

The following figure shows the basic operation of the OSTMn in free-running compare mode with the start of counting enabled (OSTMnCTL.OSTMnMD0 = 1) and with the timer in timer output toggling mode, where OSTMnTTOUT is toggled (OSTMnTOE.OSTMnTOE = 1).

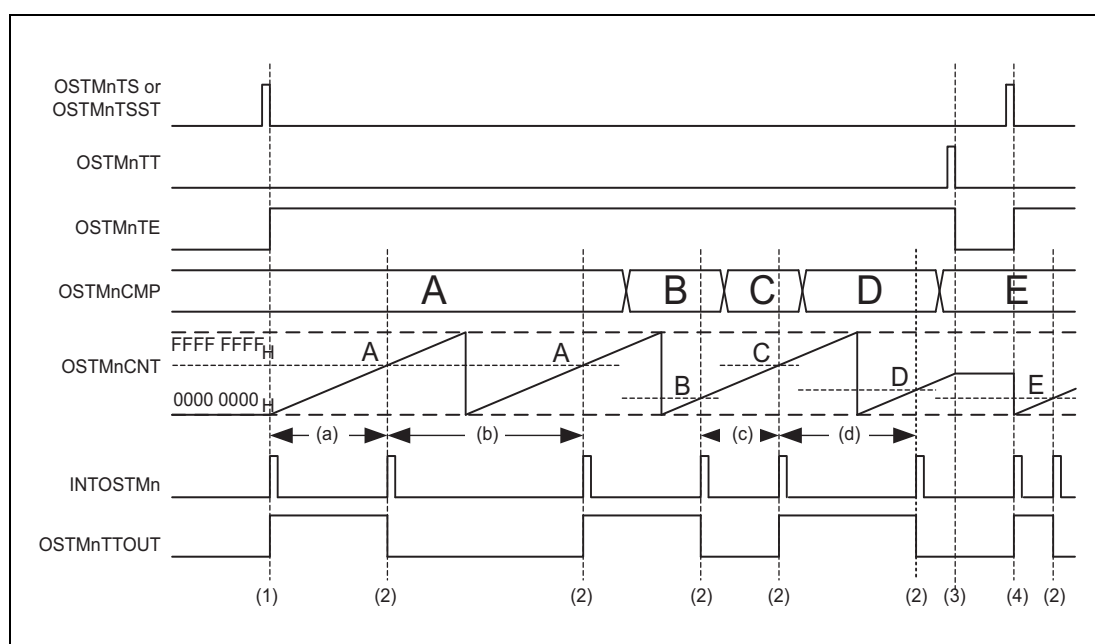

Figure 22.10 Timing Diagram of OSTMn in Free-Running Comparison Mode

The timing diagram above shows the following:

- (1) The counter starts counting when OSTMnTS.OSTMnTS = 1, or when OSTMnTSST = 1. The OSTMnTE.OSTMnTE bit is set to indicate enabling of the counter. The counter counts up from $0000\ 0000_H$ to $FFFF\ FFFF_H$. The OSTMnCNT register indicates the counter value. When the OSTMnCTL.OSTMnMD0 set to 1, the interrupt request INTOSTMn is generated when the counting starts.
- (2) When the current counter value matches the value in the OSTMnCMP register, an INTOSTMn interrupt request is generated and the OSTMnTTOUT signal is toggled.
- (3) When the counter is stopped (OSTMnTT.OSTMnTT = 1), the OSTMnTE.OSTMnTE bit is cleared to indicate disabling of the counter. The counter retains its current value until it is restarted.
- (4) Counting by the counter restarts from $0000\ 0000_H$ when OSTMnTS.OSTMnTS = 1, or when OSTMnTSST = 1.

INTOSTMn Period

The INTOSTMn generation interval depends on whether or not it is the first time after start counting or not, and if OSTTMnCMP is rewritten during operation, the INTOSTMn generation interval also depends on the counter value at timing of rewriting, the old comparison value and the new comparison value.

Table 22.19 Interval of INTOSTMn Generation

Old value for comparison	New value for comparison	Counter value at time of rewriting	Interval to generate the next INTOSTMn	Label in timing diagram
		Counter starts	$(A + 1) \times \text{counter clock period}$	(a)
A	A	No rewriting	$(\text{FFFF FFFF}_H + 1) \times \text{counter clock period}$	(b)
B	$C > B$	$B < \text{counter value} < C$	$(C - B) \times \text{counter clock period}$	(c)
C	$D < C$	Counter value $> D, C$	$(\text{FFFF FFFF}_H - C + D + 1) \times \text{counter clock period}$	(d)

Forced restart

Forced restart is not performed when the OSTMnTS.OSTMnTS bit is set or OSTMnTSST = 1 during counting. The counter ignores the attempted setting and continues counting.

22.4.3.2 Operation when OSTMnCMP = 0000 0000_H

The following figure shows the operation of the OSTMn when PCLK is selected as the source of the clock signal for counting and OSTMnCMP = 0000 0000_H, counter-start interrupts are enabled (OSTMnCTL.OSTMnMD0 = 1) and the timer is in timer output toggling mode, where OSTMnTTOUT is toggled (OSTMnTOE.OSTMnTOE = 1).

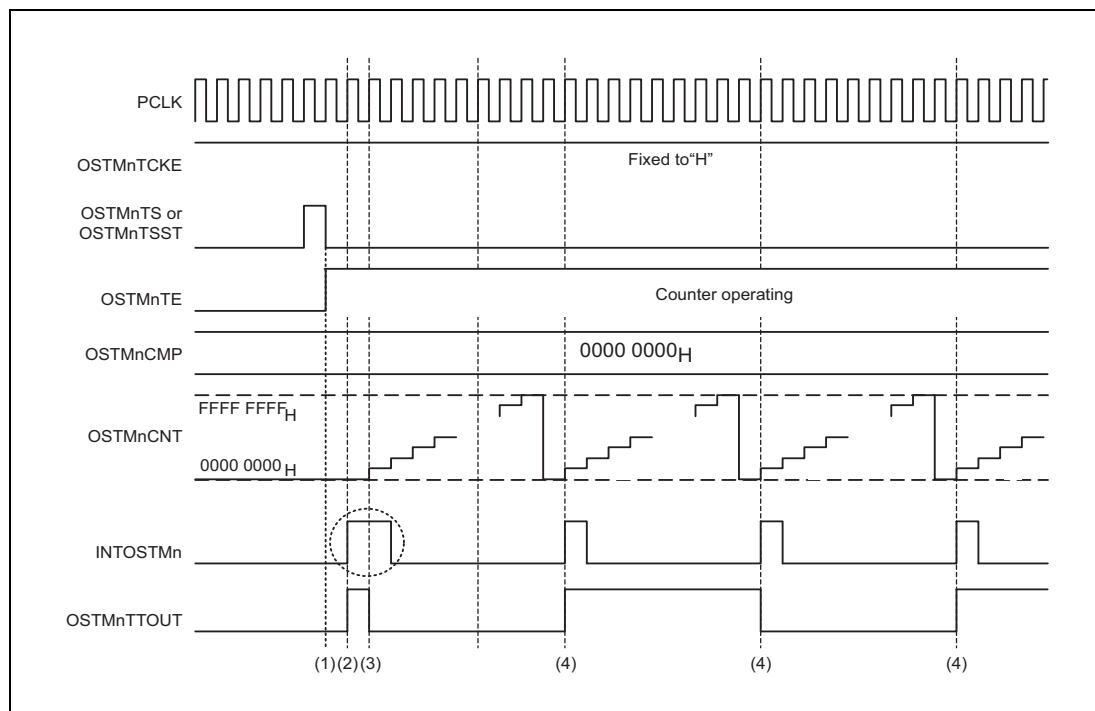

Figure 22.11 Timing Diagram when Counter Clock = PCLK (OSTMnTCKE is at High Level) and OSTMnCMP = 0000 0000_H in Free-Running Comparison Mode

The timing diagram above shows the following operations.

- (1) Once the counter starts, it counts up from 0000 0000_H to FFFF FFFF_H.
- (2) An INTOSTMn interrupt request is generated when counting starts and the OSTMnTTOUT signal is toggled. Though INTOSTMn is at the high level for the period of two cycles of PCLK at the start of counting operations, only a single interrupt request is generated on the rising edge of INTOSTMn.
- (3) If the current counter value matches OSTMnCMP, the interrupt request INTOSTMn is generated. If OSTMnCMP = 0000 0000_H as shown above, INTOSTMn is generated over two clock cycles and the OSTMnTTOUT signal is toggled.
- (4) For every (FFFF FFFF_H + 1) clock cycles the INTOSTMn interrupt request signal is asserted and the OSTMnTTOUT signal is toggled.

When an interrupt is prohibited when the counter starts, 1 clock cycle of the counter clock is not generated at the start timing of the counter.

22.4.3.3 Setting Procedure for Free-Running Comparison Mode

The setting procedure in free-running compare mode after reset release is described below:

Initialization

- (1) Set the comparison value in the OSTMnCMP register.
- (2) To output OSTMnTTOUT:
 - Initialize the OSTMnTO register in software control mode (OSTMnTOE.OSTMnTOE = 0).
 - Select timer output toggle mode (OSTMnTOE.OSTMnTOE = 1).
- (3) Select free-running compare mode by setting the OSTMnCTL.OSTMnMD1 bit to 1.
- (4) Enable or disable an interrupt when counting is started by the OSTMnCTL.OSTMnMD0 bit.

Section 23 Timer Array Unit D (TAUD)

The Timer Array Unit D (TAUD) is multifunction timer unit with several 16-bit timers (16-bit timer array unit). TAUD is implemented 3 units with the channel interface of 16 per one unit.

23.1 Features of RH850/P1M-E TAUD

23.1.1 Units and Channels

This microcontroller has the following number of TAUD units.

Table 23.1 Number of Units

Product	RH850/P1M-E 100 pins	RH850/P1M-E 144 pins
Number of Units	3	3
Name	TAUDn (n = 0 to 2)	TAUDn (n = 0 to 2)

TAUDn has the following timers for the quantity of channels of timers.

Table 23.2 TAUDn Unit Configurations and Channels

Unit Name (Channel Name)	Channels per Unit	RH850/P1M-E 100 pins (48 ch)	RH850/P1M-E 144 pins (48 ch)
TAUD0	16	√	√
TAUD1	16	√	√
TAUD2	16	√	√

Table 23.3 Index

Index	Description
n	Throughout this section, the individual TAUD units are identified by the index "n" (n = 0 to 2)
m	The TAUD has 16 channels. Throughout this section, the individual channels are identified by the index "m" (m = 0 to 15), thus a certain channel is denoted as CHm. The even numbered channels (m = 0, 2, 4, 6, 8, 10, 12, 14) are denoted as CHm_even. The odd numbered channels (m = 1, 3, 5, 7, 9, 11, 13, 15) are denoted as CHm_odd.

23.1.2 Register Base Address

TAUDn base addresses are listed in the following table.

TAUDn register addresses are given as offsets from the base addresses throughout the section.

Table 23.4 Register Base Address

Base Address Name	Base Address
<TAUD0_base>	FFE2 0000 _H
<TAUD1_base>	FFE2 1000 _H
<TAUD2_base>	FFE2 2000 _H

23.1.3 Clock Supply

Clock supply by and to TAUDn is listed in the following table.

Table 23.5 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
TAUDn	PCLK	High-speed peripheral clock CLK_HSB

23.1.4 Interrupt Requests

TAUDn interrupt requests are listed in the following table.

Table 23.6 Interrupt Requests (1/2)

Unit Interrupt Name	Description	Interrupt Number	DMA/DTS Trigger Number
TAUD0			
INTTAUD0I0	Channel 0 interrupt	141	13
INTTAUD0I1	Channel 1 interrupt	142	14
INTTAUD0I2	Channel 2 interrupt	143	15
INTTAUD0I3	Channel 3 interrupt	144	16
INTTAUD0I4	Channel 4 interrupt	145	17
INTTAUD0I5	Channel 5 interrupt	146	18
INTTAUD0I6	Channel 6 interrupt	147	19
INTTAUD0I7	Channel 7 interrupt	148	20
INTTAUD0I8	Channel 8 interrupt	149	21
INTTAUD0I9	Channel 9 interrupt	150	22
INTTAUD0I10	Channel 10 interrupt	151	23
INTTAUD0I11	Channel 11 interrupt	152	24
INTTAUD0I12	Channel 12 interrupt	153	25
INTTAUD0I13	Channel 13 interrupt	154	26
INTTAUD0I14	Channel 14 interrupt	155	27
INTTAUD0I15	Channel 15 interrupt	156	28
TAUD1			
INTTAUD1I0	Channel 0 interrupt	158	29
INTTAUD1I1	Channel 1 interrupt	159	30

Table 23.6 Interrupt Requests (2/2)

Unit Interrupt Name	Description	Interrupt Number	DMA/DTS Trigger Number
INTTAUD1I2	Channel 2 interrupt	160	31
INTTAUD1I3	Channel 3 interrupt	161	32
INTTAUD1I4	Channel 4 interrupt	162	33
INTTAUD1I5	Channel 5 interrupt	163	34
INTTAUD1I6	Channel 6 interrupt	164	35
INTTAUD1I7	Channel 7 interrupt	165	36
INTTAUD1I8	Channel 8 interrupt	166	37
INTTAUD1I9	Channel 9 interrupt	167	38
INTTAUD1I10	Channel 10 interrupt	168	39
INTTAUD1I11	Channel 11 interrupt	169	40

INTTAUD2I9	Channel 9 interrupt	269	54
INTTAUD2I10	Channel 10 interrupt	270	—
INTTAUD2I11	Channel 11 interrupt	271	—
INTTAUD2I12	Channel 12 interrupt	272	—
INTTAUD2I13	Channel 13 interrupt	273	—
INTTAUD2I14	Channel 14 interrupt	274	—
INTTAUD2I15	Channel 15 interrupt	275	—

23.1.5 Reset Sources

Please refer to **Section 8, Reset Controller**.

23.1.6 External Input/Output Signals

External input/output signals of TAUDn are listed below.

Table 23.7 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
TAUD0			
TAUD0TTIN0 to TAUD0TTIN15* ²	I	Inputs for channel 0 to 15	TAUD0I0 to TAUD0I15
TAUD0TTOUT0 to TAUD0TTOUT15	O	Outputs for channel 0 to 15	TAUD0O0 to TAUD0O15
TAUD1			
TAUD1TTIN0 to TAUD1TTIN15* ²	I	Inputs for channel 0 to 15	TAUD1I0 to TAUD1I15
TAUD1TTOUT0 to TAUD1TTOUT15	O	Outputs for channel 0 to 15	TAUD1O0 to TAUD1O15
TAUD2			
TAUD2TTIN0 to TAUD2TTIN15* ²	I	Inputs for channel 0 to 15	TAUD2I0 to TAUD2I15* ¹
TAUD2TTOUT0 to TAUD2TTOUT15	O	Outputs for channel 0 to 15	TAUD2O0 to TAUD2O15

Note 1. The input signals can be switched by PIC. For details, see **Section 29.2.3.11, TAUD Input Select Function**, and **Section 29.2.3.13, Timer Output Monitor Function (PWM-Diag)**.

Note 2. Setting of the noise filter for the port is required when the channel input pin is used. For details, **Section 2.6, Noise Filter and Edge Level Detection Circuit**.

23.1.7 Internal Input/Output Signals

The internal input/output signals of TAUDn are listed below.

Table 23.8 Internal Input/Output Signals

Unit Signal Name	Description	Connected to
TAUDnTSSTm* ¹	Simultaneous channel start trigger input	PIC

Note 1. n = 0, 1 only. TAUD2TSSTm is not connected to PIC.

23.2 Overview

23.2.1 Functional Overview

The TAUD has the following functions:

- 16 channels
- 16-bit counter and 16-bit data register per channel
- Independent channel operation
- Synchronous channel operation (master and slave operation)
- Generation of different types of output signal
- Real-time output
- Counter can be triggered by external signal
- Interrupt generation

The Timer Array Unit D is used to perform various count or timer operations and to output a signal which depends on the result of the operation. It contains one prescaler block for count clock generation and 16 channels, each equipped with a 16 bit counter TAUDnCNTm and a 16-bit data register TAUDnCDRm to hold the start or compare value of the counter.

It also contains several control and status registers.

Independent and synchronous operation

Every channel can operate in different operation modes, either independently or in combination with other channels (synchronously). When one master channel and one or more slave channels operate in combination, the slave channels depend on the master channel.

When a channel is operated independently, its operation mode and functions are not affected by those of other channels. When a channel is operated synchronously it is either a master or a slave. A master channel can have multiple slaves, and the state of one channel affects that of the other channels. For example, this means that one channel can control when another starts to count, is reset, etc.

23.2.2 Terms

In this chapter, the following terms are used:

Independent / synchronous channel operation

Independent or synchronous channel operation describes the dependency of channels on each other:

- If a channel operates independent of all other channels, this is called independent channel operation.
- If a channel operates depending on other channels, this is called synchronous channel operation.

Channel group

In synchronous channel operation, all channels that depend on each other are referred to as a “channel group”.

A channel group has one master channel and one or more slave channels.

Operation mode

An operation mode can be selected for every channel m . The operation mode defines the basic operation and features of a channel.

In synchronous channel operation, every channel in the channel group can operate in a different operation mode.

Examples are “Capture Mode”, “Event Count Mode”, and “Interval Timer Mode”.

Channel output mode

The channel output mode defines the operation of $TAUDnTTOUTm$

- of a single channel (independent output operation) or
- of all channels in a channel group (synchronous output operation).

Examples are “Independent Channel Output Mode 1” and “Synchronous Channel Output Mode 2 with Dead Time Output”.

Channel operation function

The channel operation function defines the complete function and all features

- of a single channel (independent channel operation) or
- of all channels in a channel group (synchronous channel operation).

Upper / lower channel

Depending on the channel number m , a channel with a smaller number or with a larger number is referred to as “upper” or “lower” channel, respectively.

- Upper channel: Channel with a smaller channel number
- Lower channel: Channel with a larger channel number

Example:

For channel 5, channel 3 is an upper channel and channel 9 is a lower channel.

23.2.3 Functional List of Timer Operations

This timer provides the following functions by operating each channel independently or by combining multiple channels.

Table 23.9 Functional List of TAUD Operations

Function of Independent Operation	Example

23.2.4 TAUD I/O and Interrupt Request Signals

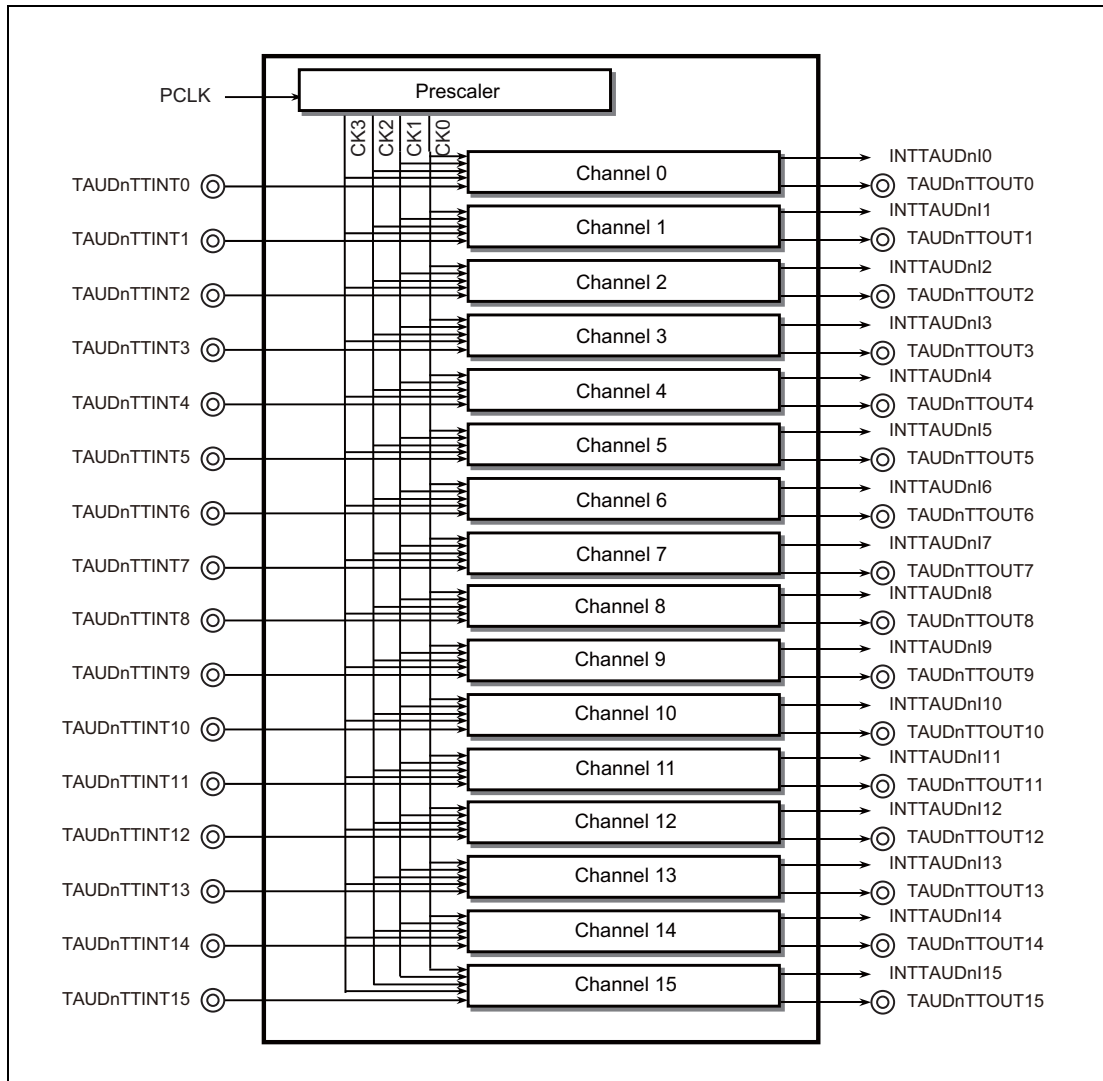

Figure 23.1 TAUD I/O and Interrupt Request Signals

23.2.5 Block Diagram

Figure 23.2 shows the main components of the TAUD:

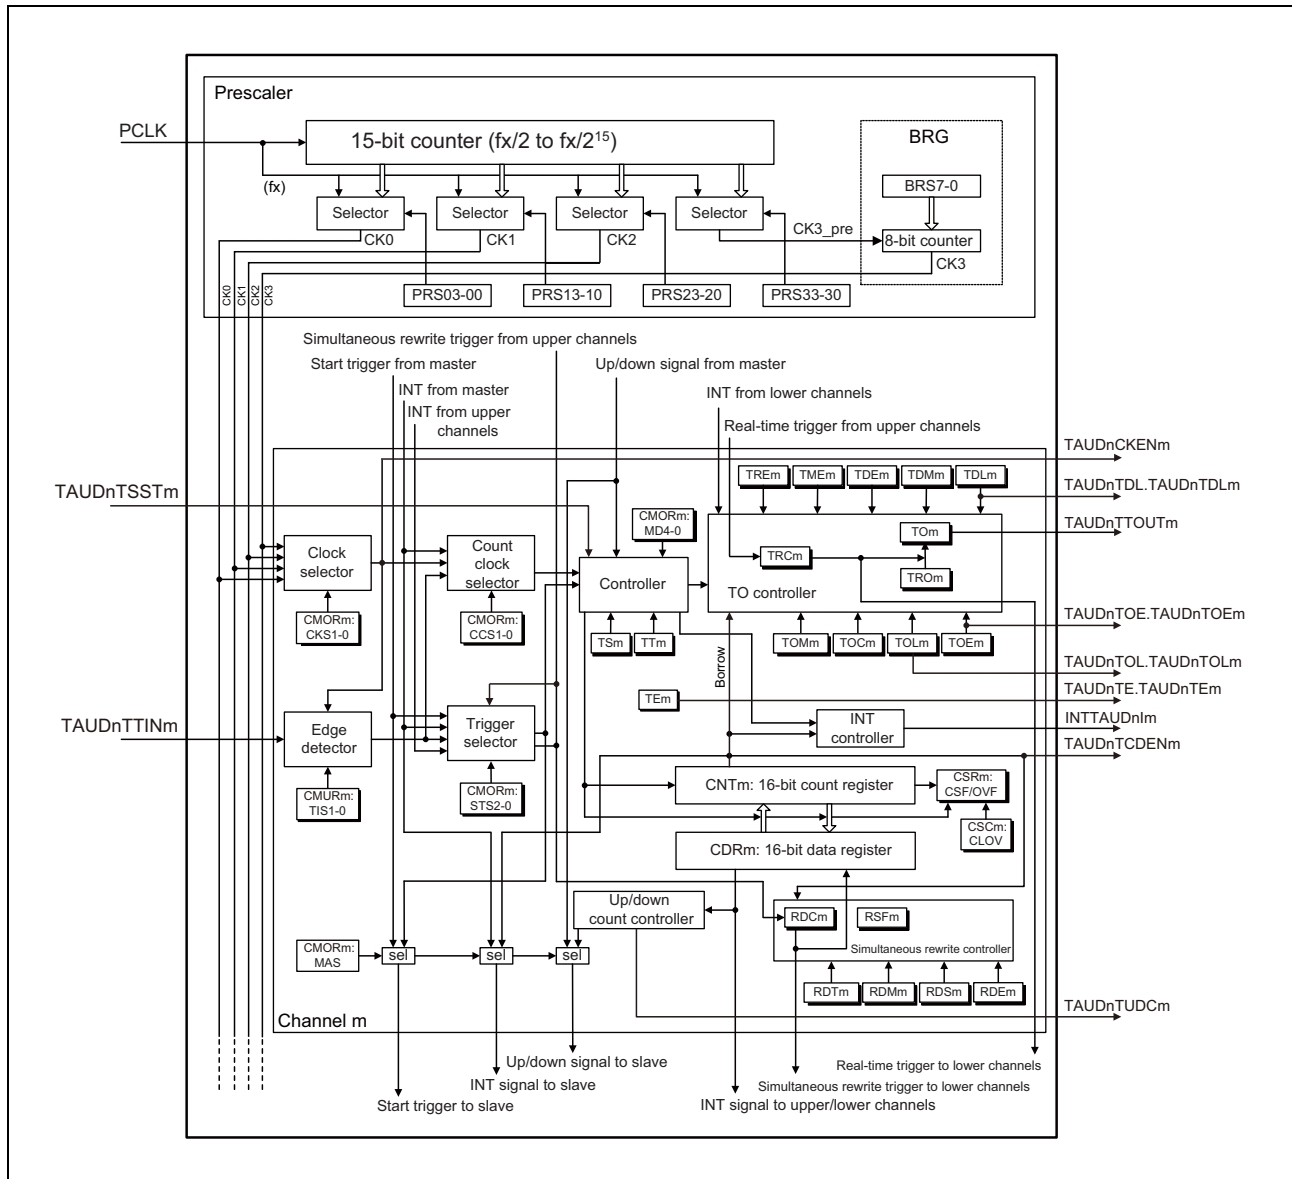

Figure 23.2 Block Diagram of the TAUD

The prefix “TAUDn” has been omitted from the module names for the sake of clarity in the above figure.

23.2.6 Description of Blocks

The following describes the functional blocks:

Prescaler

The prescaler provides up to 4 clock signals (CK0 to CK3) that can be used as count clocks for all channels.

Count clocks CK0 to CK2 are derived from PCLK by configurable prescaler division factors of 2^0 to 2^{15} . The fourth count clock CK3 can be adjusted more precisely by using the BRG to set an additional division factor that is not a power of 2.

Clock and count clock selection

For every channel, the count clock selector selects which of the following is used as the clock source:

- One of the clocks CK0 to CK3 (selected by the clock selector)
- INTTAUDnIm from master channel
- TAUDnTTINm input signal valid edge

Controller

The controller controls the main operations of the counter:

- Operation mode (selected by bits TAUDnCMORm.TAUDnMD[4:0])
- Counter start enable (TAUDnTS.TAUDnTSM) and counter stop (TAUDnTT.TAUDnTTm)

When counter start is enabled, status flag TAUDnTE.TAUDnTEm is set.

- Count direction (up/down) (can be controlled by master channel)

Trigger selector

Depending on the selected operation mode, the counter starts automatically when it is enabled (TAUDnTE.TAUDnTEm = 1), or it waits for an external start trigger signal. Any of the following signals can be used as the start trigger:

- Synchronous channel start trigger input TAUDnTSSTm
- INTTAUDnIm from the master or any upper channel
- Up/down output trigger signal of the master channel
- Dead-time output signal of the TAUDnTTOUTm generation
- TAUDnTTINm input signal valid edge

Simultaneous rewrite controller

Simultaneous rewrite control is a special function that can be used in synchronous operation modes. The data registers (TAUDnCDRm) of all channels in a channel group can be rewritten at any time. The simultaneous rewrite controller ensures that new data register values of all channels become effective at the same time.

TAUDnTO controller

The output control of every channel enables the generation of various output signal forms such as PWM signals or triangular waves.

23.3 Registers

23.3.1 List of Registers

TAUDn registers are listed in the following table.

For details about <TAUDn_base>, see **Section 23.1.2, Register Base Address**.

Table 23.10 Registers

Module	Register	Symbol	Address
TAUDn prescaler registers			
TAUDn	TAUDn prescaler clock select register	TAUDnTPS	<TAUDn_base> + 240 _H
TAUDn	TAUDn prescaler baud rate setting register	TAUDnBRS	<TAUDn_base> + 244 _H
TAUDn control registers			
TAUDn	TAUDn channel data register m	TAUDnCDRm	<TAUDn_base> + m × 4 _H
TAUDn	TAUDn channel counter register m	TAUDnCNTm	<TAUDn_base> + 80 _H + m × 4 _H
TAUDn	TAUDn channel mode OS register m	TAUDnCMORm	<TAUDn_base> + 200 _H + m × 4 _H
TAUDn	TAUDn channel mode user register m	TAUDnCMURm	<TAUDn_base> + C0 _H + m × 4 _H
TAUDn	TAUDn channel status register m	TAUDnCSRm	<TAUDn_base> + 140 _H + m × 4 _H
TAUDn	TAUDn channel status clear register m	TAUDnCSCm	<TAUDn_base> + 180 _H + m × 4 _H
TAUDn	TAUDn channel start trigger register	TAUDnTS	<TAUDn_base> + 1C4 _H
TAUDn	TAUDn channel enable status register	TAUDnTE	<TAUDn_base> + 1C0 _H
TAUDn	TAUDn channel stop trigger register	TAUDnTT	<TAUDn_base> + 1C8 _H
TAUDn output registers			
TAUDn	TAUDn channel output enable register	TAUDnTOE	<TAUDn_base> + 5C _H
TAUDn	TAUDn channel output register	TAUDnTO	<TAUDn_base> + 58 _H
TAUDn	TAUDn channel output mode register	TAUDnTOM	<TAUDn_base> + 248 _H
TAUDn	TAUDn channel output configuration register	TAUDnTOC	<TAUDn_base> + 24C _H
TAUDn	TAUDn channel output active level register	TAUDnTOL	<TAUDn_base> + 040 _H
TAUDn	TAUDn channel dead time output enable register	TAUDnTDE	<TAUDn_base> + 250 _H
TAUDn	TAUDn channel dead time output mode register	TAUDnTDM	<TAUDn_base> + 254 _H
TAUDn	TAUDn channel dead time output level register	TAUDnTDL	<TAUDn_base> + 54 _H
TAUDn	TAUDn channel real-time output register	TAUDnTRO	<TAUDn_base> + 4C _H
TAUDn	TAUDn channel real-time output enable register	TAUDnTRE	<TAUDn_base> + 258 _H
TAUDn	TAUDn channel real-time output control register	TAUDnTRC	<TAUDn_base> + 25C _H
TAUDn	TAUDn channel modulation output enable register	TAUDnTME	<TAUDn_base> + 50 _H
TAUDn reload data registers			
TAUDn	TAUDn channel reload data enable register	TAUDnRDE	<TAUDn_base> + 260 _H
TAUDn	TAUDn channel reload data mode register	TAUDnRDM	<TAUDn_base> + 264 _H
TAUDn	TAUDn channel reload data control CH select register	TAUDnRDS	<TAUDn_base> + 268 _H
TAUDn	TAUDn channel reload data control register	TAUDnRDC	<TAUDn_base> + 26C _H
TAUDn	TAUDn channel reload data trigger register	TAUDnRDT	<TAUDn_base> + 44 _H
TAUDn	TAUDn channel reload status register	TAUDnRSF	<TAUDn_base> + 48 _H

23.3.2 Details of TAUDn Prescaler Registers

23.3.2.1 TAUDnTPS — TAUDn Prescaler Clock Select Register

This register specifies clocks CK0, CK1, CK2, and CK3_PRE for all channels of the PCLK prescaler. CK3 is generated by dividing CK3_PRE by the factor specified in TAUDnBRS.

Access: Readable/writable in 16-bit units. Write to this register when TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 240_H

Value after reset: FFFF_H This register is initialized by any reset source.

Table 23.11 TAUDnTPS Register Contents (1/3)

Bit Position	Bit Name	Function
15 to 12	TAUDnPRS3 [3:0]	Specify the CK3_PRE clock. CK3_PRE clock is an input clock to BRG unit which supplies the CK3 operating clock to all channels.
TAUDnPRS3[3:0]		CK3_PRE Clock
	0000 _B	PCLK/2 ⁰
	0001 _B	PCLK/2 ¹

The above bits are rewritable only when all the counters using CK0 are stopped (TAUDnTE.TAUDnTEm = 0).

NOTE

The TAUDn clock input PCLK is specified in the first part of this section, **Section 23.1.3, Clock Supply**.

23.3.2.2 TAUDnBRS — TAUDn Prescaler Baud Rate Setting Register

This register specifies the division factor of prescaler clock CK3.

CK3 is generated by dividing CK3_PRE by the factor specified in this register plus one. The PCLK prescaler for CK3_PRE is specified in TAUDnTPS.TAUDnPRS3[3:0].

Access: Readable/writable in 8-bit units. Write to this register when TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 244_H

Value after reset: 00_H This register is initialized by any reset source.

Bit	7	6	5	4	3	2	1	0
	TAUDnBRS[7:0]							
Value after reset	0	0	0	0	0	0	0	0

23.3.3 Details of TAUDn Control Registers

23.3.3.1 TAUDnCDRm — TAUDn Channel Data Register

This register functions either as a compare register or as a capture register, depending on the operating mode specified in TAUDnCMORm.TAUDnMD[4:1].

Access: Readable/writable in 16-bit units.
When this register functions as a capture register, only reading is possible. Any write operation is ignored.
When this register functions as a compare register, reading and writing is possible.

Address: <TAUDn_base> + m × 4_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 23.13 TAUDnCDRm Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnCDR [15:0]	Data register for capture/compare values

23.3.3.2 TAUDnCNTm — TAUDn Channel Counter Register

This is a channel m counter register.

Access: Readable in 16-bit units.

Address: <TAUDn_base> + 80_H + m × 4_H

Value after reset: FFFF_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCNT[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.14 TAUDnCNTm Register Contents

Bit Position	Bit Name	Function
15 to 0	TAUDnCNT [15:0]	16-bit counter value

A read value depends on a counter value, a changed operating mode, TAUDnTS.TAUDnTSM or TAUDnTT.TAUDnTTm bit value.

The initial read value of the counter depends on an operating mode and how the counter is stopped.

- Stop by a reset
- Stop by a counter stop trigger (TAUDnTT.TAUDnTTm = 1)

Table 23.15 lists the initial counter read values after the counter is stopped (TAUDnTE.TAUDnTEm = 0) and re-enabled (TAUDnTS.TAUDnTSM = 1).

The table also contains the counter read value one count after the counter is enabled (TAUDnTS.TAUDnTSM = 1) with the counter waiting for a start trigger.

Table 23.15 TAUDnCNTm Read Values after Re-Enabling Counter

Mode Name	Count Method (Up/Down)	TAUDnCNTm Value		
		Start value*1	After Stop Trigger	After One Count
Interval timer mode	Count down	FFFF _H	Stop value	—
Judge mode	Count down	FFFF _H	Stop value	—
Capture mode	Count up	0000 _H	Stop value	—
Event count mode	Count down	FFFF _H	Stop value	—
One-count mode	Count down	FFFF _H	Stop value	Stop value
Capture and one-count mode	Count up	0000 _H	Stop value	Capture value + 1 (TAUDnCDRm)
Judge and one-count mode	Count down	FFFF _H	Stop value	TAUDnCNTm value – 1
Up/down count mode	Count down/up	FFFF _H	Stop value	—
Pulse one count mode	Count down	FFFF _H	Stop value	0000 _H
Count capture mode	Count up	0000 _H	Stop value	—
Capture and gate count mode	Count up	0000 _H	Stop value	Stop value

Note 1. The value set in TAUDnCNTm when operation mode is changes after reset release.

23.3.3.3 TAUDnCMORm — TAUDn Channel Mode OS Register

This register controls channel m operation.

Access: Readable/writable in 16-bit units. Write to this register when TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 200H + m × 4H

Value after reset: 0000H This register is initialized by any reset source.

23.3.3.4 TAUDnCMURm — TAUDn Channel Mode User Register

This register specifies a type of valid edge detection used for TAUDnTTINm input.

Access: Readable/writable in 8-bit units.

Address: <TAUDn_base> + C0_H + m × 4_H

Value after reset: 00_H This register is initialized by any reset source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 23.17 TAUDnCMURm Register Contents

Bit position	Bit name	Function															
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.															
1, 0	TAUDnTIS[1:0]	Specify a valid edge of TAUDnTTINm input signal.															
		<table border="1"> <thead> <tr> <th>TAUDnTIS1</th> <th>TAUDnTIS0</th> <th>Functional Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Detection of rising and falling edges (selects low width measurement) <ul style="list-style-type: none"> Start trigger: Falling edge Stop trigger (capture): Rising edge </td> </tr> <tr> <td>1</td> <td>1</td> <td>Detection of rising and falling edges (selects high width measurement) <ul style="list-style-type: none"> Start trigger: Rising edge Stop trigger (capture): Falling edge </td> </tr> </tbody> </table>	TAUDnTIS1	TAUDnTIS0	Functional Description	0	0	Falling edge	0	1	Rising edge	1	0	Detection of rising and falling edges (selects low width measurement) <ul style="list-style-type: none"> Start trigger: Falling edge Stop trigger (capture): Rising edge 	1	1	Detection of rising and falling edges (selects high width measurement) <ul style="list-style-type: none"> Start trigger: Rising edge Stop trigger (capture): Falling edge
TAUDnTIS1	TAUDnTIS0	Functional Description															
0	0	Falling edge															
0	1	Rising edge															
1	0	Detection of rising and falling edges (selects low width measurement) <ul style="list-style-type: none"> Start trigger: Falling edge Stop trigger (capture): Rising edge 															
1	1	Detection of rising and falling edges (selects high width measurement) <ul style="list-style-type: none"> Start trigger: Rising edge Stop trigger (capture): Falling edge 															
Edge detection of TAUDnTTINm input signal is based on the operating clock selected by TAUDnCMORm.TAUDnCKS[1:0].																	

23.3.3.5 TAUDnCSRm — TAUDn channel status register

This register indicates the up/down count and overflow status of channel m counter.

Access: Readable in 8-bit units.

Address: <TAUDn_base> + 140H + m × 4H

Value after reset: 00H This register is initialized by any reset source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnCSF	TAUDnOVF
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 23.18 TAUDnCSRm Register Contents

Bit position	Bit name	Function
7 to 2	Reserved	When read, the value after reset is read.
1	TAUDnCSF	Indicates a count direction. 0: Count-up 1: Count-down The read value of this bit is valid only in up/down count mode. In other modes, an undefined value is read.
0	TAUDnOVF	Indicates counter overflow status. 0: No overflow occurs. 1: Overflow occurs. This bit is used only in the following modes: <ul style="list-style-type: none"> • Capture mode • Capture and one-count mode <p>The function of this bit depends on the setting of control bit TAUDnCMORm.TAUDnCOS[1:0]. In other modes, an undefined value is read.</p>

23.3.3.6 TAUDnCSm - TAUDn Channel Status Clear Register

This is a trigger register for clearing the overflow flag TAUDnCSRm.TAUDnOVF of channel m.

Access: Writable in 8-bit units. This value is always read as 00_H.

Address: <TAUDn_base> + 180_H + m × 4_H

Value after reset: 00_H This register is initialized by any reset source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAUDnCLOV
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 23.19 TAUDnCSm Register Contents

Bit position	Bit name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAUDnCLOV	This bit clears the overflow flag of channel m. Writing 1 to this bit clears the overflow flag TAUDnCSRm.TAUDnOVF, though writing 0 is ignored.

23.3.3.7 TAUDnTS — TAUDn Channel Start Trigger Register

This register enables the counter operation of each channel.

Access: Writable in 16-bit units. This value is always read as 0000_H.

Address: <TAUDn_base> + 1C4_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnTS15	TAUDnTS14	TAUDnTS13	TAUDnTS12	TAUDnTS11	TAUDnTS10	TAUDnTS09	TAUDnTS08	TAUDnTS07	TAUDnTS06	TAUDnTS05	TAUDnTS04	TAUDnTS03	TAUDnTS02	TAUDnTS01	TAUDnTS00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 23.20 TAUDnTS Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnTSM	Enables the counter operation of channel m. Writing 1 to this bit enables the counter operation and sets TAUDnTE.TAUDnTEm to 1, though writing 0 is ignored.

23.3.3.8 TAUDnTE — TAUDn Channel Enable Status Register

This register indicates the enable/disable state of the counter operation.

Access: Readable in 16-bit units.

Address: <TAUDn_base> + 1C0_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnTE15	TAUDnTE14	TAUDnTE13	TAUDnTE12	TAUDnTE11	TAUDnTE10	TAUDnTE09	TAUDnTE08	TAUDnTE07	TAUDnTE06	TAUDnTE05	TAUDnTE04	TAUDnTE03	TAUDnTE02	TAUDnTE01	TAUDnTE00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.21 TAUDnTE Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnTE _m	Indicates the enable/disable state of the counter operation of channel m. 0: The counter operation is disabled. 1: The counter operation is enabled. This bit is set to 1 when trigger input of TAUDnTSST _m (synchronous channel start trigger signal) is detected or when TAUDnTS.TAUDnTS _m is set to 1. This bit is set to 0 when TAUDnTT.TAUDnTT _m is set to 1.

23.3.3.9 TAUDnTT — TAUDn Channel Stop Trigger Register

This register stops the counter operation of each channel.

Access: Writable in 16-bit units. This value is always read as 0000_H.

Address: <TAUDn_base> + 1C8_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnTT15	TAUDnTT14	TAUDnTT13	TAUDnTT12	TAUDnTT11	TAUDnTT10	TAUDnTT09	TAUDnTT08	TAUDnTT07	TAUDnTT06	TAUDnTT05	TAUDnTT04	TAUDnTT03	TAUDnTT02	TAUDnTT01	TAUDnTT00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 23.22 TAUDnTT Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnTT _m	Stops the counter operation of channel m. Writing 1 to this bit stops the counter operation and clears TAUDnTE.TAUDnTE _m to 0, though writing 0 is ignored. TAUDnCNT _m , TAUDnTO.TAUDnTO _m , and TAUDnTTO _m retain the values provided before the counter is stopped.

23.3.4 Details of TAUDn Simultaneous Rewrite Registers

23.3.4.1 TAUDnRDE — TAUDn Channel Reload Data Enable Register

This register enables/disables simultaneous rewrite of TAUDnCDRm/TAUDnTOLm data register.

Access: Readable/writable in 16-bit units. Writable only while TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 260_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnRDE15	TAUDnRDE14	TAUDnRDE13	TAUDnRDE12	TAUDnRDE11	TAUDnRDE10	TAUDnRDE09	TAUDnRDE08	TAUDnRDE07	TAUDnRDE06	TAUDnRDE05	TAUDnRDE04	TAUDnRDE03	TAUDnRDE02	TAUDnRDE01	TAUDnRDE00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.23 TAUDnRDE Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnRDEm	Enables/disables simultaneous rewrite of the data register of channel m. 0: Disables simultaneous rewrite (Loaded by the detection of its own channel match) 1: Enables simultaneous rewrite

23.3.4.2 TAUDnRDS — TAUDn Channel Reload Data Control Channel Select Register

This register selects a channel that controls simultaneous rewrite.

Access: Readable/writable in 16-bit units. Writable only while TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 268_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnRDS15	TAUDnRDS14	TAUDnRDS13	TAUDnRDS12	TAUDnRDS11	TAUDnRDS10	TAUDnRDS09	TAUDnRDS08	TAUDnRDS07	TAUDnRDS06	TAUDnRDS05	TAUDnRDS04	TAUDnRDS03	TAUDnRDS02	TAUDnRDS01	TAUDnRDS00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.24 TAUDnRDS Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnRDSm	Selects a channel that controls a simultaneous rewrite trigger. 0: Master channel 1: Another upper channel (The channel when TAUDnRDE.TAUDnRDEm = 1)

23.3.4.3 TAUDnRDM — TAUDn Channel Reload Data Mode Register

This register selects the timing for generating a simultaneous rewrite control signal.

Access: Readable/writable in 16-bit units. Writable only while TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 264_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnRDM15	TAUDnRDM14	TAUDnRDM13	TAUDnRDM12	TAUDnRDM11	TAUDnRDM10	TAUDnRDM09	TAUDnRDM08	TAUDnRDM07	TAUDnRDM06	TAUDnRDM05	TAUDnRDM04	TAUDnRDM03	TAUDnRDM02	TAUDnRDM01	TAUDnRDM00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.25 TAUDnRDM Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnRDMm	Selects the timing for generating a simultaneous rewrite trigger signal. 0: When the master channel counter starts to count 1: At the peak of cycle of triangular wave These bit settings are applied to the channel when TAUDnRDE.TAUDnRDEm = 1 and TAUDnRDS.TAUDnRDSm = 0.

23.3.4.4 TAUDnRDC — TAUDn Channel Reload Data Control Register

This register specifies a channel which generates an INTTAUDnIm signal to trigger simultaneous rewrite.

Access: Readable/writable in 16-bit units. Writable only while TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 26C_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnRDC15	TAUDnRDC14	TAUDnRDC13	TAUDnRDC12	TAUDnRDC11	TAUDnRDC10	TAUDnRDC09	TAUDnRDC08	TAUDnRDC07	TAUDnRDC06	TAUDnRDC05	TAUDnRDC04	TAUDnRDC03	TAUDnRDC02	TAUDnRDC01	TAUDnRDC00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.26 TAUDnRDC Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnRDCm	Specify whether the channel generates a simultaneous rewrite trigger signal or not. 0: Not operate as a simultaneous rewrite trigger channel. 1: Operates as a simultaneous rewrite trigger channel. These bit settings are applied to the channel when TAUDnRDE.TAUDnRDEm = 1 and TAUDnRDS.TAUDnRDSm = 1.

23.3.4.5 TAUDnRDT — TAUDn Channel Reload Data Trigger Register

This register triggers the enabling state of simultaneous rewrite.

Access: Writable in 16-bit units. This value is always read as 0000_H.

Address: <TAUDn_base> + 044_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnRDT15	TAUDnRDT14	TAUDnRDT13	TAUDnRDT12	TAUDnRDT11	TAUDnRDT10	TAUDnRDT09	TAUDnRDT08	TAUDnRDT07	TAUDnRDT06	TAUDnRDT05	TAUDnRDT04	TAUDnRDT03	TAUDnRDT02	TAUDnRDT01	TAUDnRDT00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 23.27 TAUDnRDT Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnRDTm	These bits specify the trigger to the enabling state of simultaneous rewrite. 0: No function 1: The simultaneous rewrite enabling flag (TAUDnRSFm) is set to 1. The system waits for the simultaneous rewrite trigger. The setting of these bits is applied to the channel when TAUDnRDE.TAUDnRDEm is 1.

23.3.4.6 TAUDnRSF — TAUDn Channel Reload Status Register

This flag register indicates simultaneous rewrite status.

Access: Readable in 16-bit units.

Address: <TAUDn_base> + 048_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnRSF15	TAUDnRSF14	TAUDnRSF13	TAUDnRSF12	TAUDnRSF11	TAUDnRSF10	TAUDnRSF09	TAUDnRSF08	TAUDnRSF07	TAUDnRSF06	TAUDnRSF05	TAUDnRSF04	TAUDnRSF03	TAUDnRSF02	TAUDnRSF01	TAUDnRSF00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.28 TAUDnRSF Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnRSFm	Indicates simultaneous rewrite status. 0: Indicates that a simultaneous rewrite has completed by the generation of a simultaneous rewrite trigger. 1: Indicates that a simultaneous rewrite trigger is waited in a simultaneous rewrite enable state (TAUDnRDTm = 1).

23.3.5 Details of TAUDn Output Registers

23.3.5.1 TAUDnTOE — TAUDn Channel Output Enable Register

This register enables/disables the independent channel output mode controlled by software.

Access: Readable/writable in 16-bit units.

Address: <TAUDn_base> + 5C_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnTOE15	TAUDnTOE14	TAUDnTOE13	TAUDnTOE12	TAUDnTOE11	TAUDnTOE10	TAUDnTOE09	TAUDnTOE08	TAUDnTOE07	TAUDnTOE06	TAUDnTOE05	TAUDnTOE04	TAUDnTOE03	TAUDnTOE02	TAUDnTOE01	TAUDnTOE00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.29 TAUDnTOE Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnTOEm	Enables or disables the independent channel output mode. 0: Disables the independent timer output function (software control) 1: Enables the independent timer output function.

23.3.5.2 TAUDnTO — TAUDn Channel Output Register

This register specifies and reads a TAUDnTTOUTm level.

Access: Readable/writable in 16-bit units.

Address: <TAUDn_base> + 58_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnTOO15	TAUDnTOO14	TAUDnTOO13	TAUDnTOO12	TAUDnTOO11	TAUDnTOO10	TAUDnTOO09	TAUDnTOO08	TAUDnTOO07	TAUDnTOO06	TAUDnTOO05	TAUDnTOO04	TAUDnTOO03	TAUDnTOO02	TAUDnTOO01	TAUDnTOO00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.30 TAUDnTO Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnTOM	Specify and reads a TAUDnTTOUTm level. 0: Low level 1: High level Writing to these bits is enabled only when TAUDnTOE.TAUDnTOEm is 0.

23.3.5.3 TAUDnTOM — TAUDn Channel Output Mode Register

This register specifies the output mode of each channel.

Access: Readable/writable in 16-bit units. Writable only while the counter is stopped (TAUDnTE.TAUDnTEm = 0).

Address: <TAUDn_base> + 248_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnTOM15	TAUDnTOM14	TAUDnTOM13	TAUDnTOM12	TAUDnTOM11	TAUDnTOM10	TAUDnTOM09	TAUDnTOM08	TAUDnTOM07	TAUDnTOM06	TAUDnTOM05	TAUDnTOM04	TAUDnTOM03	TAUDnTOM02	TAUDnTOM01	TAUDnTOM00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.31 TAUDnTOM Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnTOMm	Specify an output mode. 0: Independent channel operation 1: Synchronous channel operation

23.3.5.4 TAUDnTOC — TAUDn Channel Output Configuration Register

This register specifies the output mode of each channel in combination with TAUDnTOM.TAUDnTOMm.

Access: Readable/writable in 16-bit units. Writable only while the counter is stopped (TAUDnTE.TAUDnTEm = 0).

Address: <TAUDn_base> + 24C_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 23.32 TAUDnTOC Register Contents

Bit position	Bit name	Function	
15 to 0	TAUDnTOCm	Specify an output mode. 0: Operating mode 1 1: Operating mode 2 These bits specify the operating mode of TAUDnTOUTm by the setting of TAUDnTOM.TAUDnTOMm and TAUDnTOC.TAUDnTOCm.	
	TOMm	TOCm	Functional Description
	0	0	Toggle mode: Toggle operation is conducted when INTTAUDnIm occurs.
	0	1	Set/reset mode: Set when INTTAUDnIm occurs at the beginning of count operation, and reset when INTTAUDnIm is caused by detection of a match between TAUDnCNTm and TAUDnCDRm.
	1	0	Synchronous channel operating mode 1: Set when INT occurs on master channels, and reset when INT occurs on slave channels.
	1	1	Synchronous channel operating mode 2: <ul style="list-style-type: none"> Set when INTTAUDnIm occurs in count-down status. Reset when INTTAUDnIm occurs in count-up status.

23.3.5.5 TAUDnTOL — TAUDn Channel Output Active Level Register

This register specifies the output logic of channel output bit (TAUDnTO.TAUDnTOm).

Access: Readable/writable in 16-bit units.

Address: <TAUDn_base> + 040H

Value after reset: 0000H This register is initialized by any reset source.

Table 23.33 TAUDnTOL Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnTOLm	Specify the output logic of channel m output bit (TAUDnTO.TAUDnTOm). 0: Positive logic (active high) 1: Negative logic (active low) The value of these bits are enabled when the combination of following three conditions is enabled and TAUDnTOE.TAUDnTOEm = 1. <ul style="list-style-type: none"> • TAUDnTOM.TAUDnTOMm = 0, TAUDnTOC.TAUDnTOCm = 1 • TAUDnTOM.TAUDnTOMm = 1, TAUDnTOC.TAUDnTOCm = 1 • TAUDnTOM.TAUDnTOMm = 1, TAUDnTOC.TAUDnTOCm = 0

23.3.6 Details of TAUDn Dead Time Output Registers

23.3.6.1 TAUDnTDE — TAUDn Channel Dead Time Output Enable Register

This register enables/disables the dead time operation of every channel.

Access: Readable/writable in 16-bit units. Writable only while the counter is stopped (TAUDnTE.TAUDnTE_m = 0).

Address: <TAUDn_base> + 250_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 23.37 TAUDnTRE Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnTREm	Enables or disables real-time output of channel m. 0: Disables real-time output 1: Enables real-time output. These bit settings are applied only when TAUDnTOE.TAUDnTOEm = 1. When TAUDnTRE.TAUDnTREm = 0, TAUDnTTOUTm is not affected by real-time output. When TAUDnTRE.TAUDnTREm = 1, TAUDnTTOUTm outputs the value of real-time output bit TAUDnTRO.TAUDnTROm in response to a timer operation.

23.3.7.2 TAUDnTRC — TAUDn Channel Real-time Output Control Register

This register controls the real-time output trigger of each channel.

Access: Readable/writable in 16-bit units. Writable only while TAUDnTE.TAUDnTEm = 0.

Address: <TAUDn_base> + 25C_H

Value after reset: 0000_H This register is initialized by any reset source.

Table 23.39 TAUDnTRO Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnTROm	Sets a value which is output to TAUDnTTOUTm. 0: Low 1: High TAUDnTROm value is not output to TAUDnTTOUTm when TAUDnTRE.TAUDnTREM = 0, even if a real-time output trigger occurs.

23.3.7.4 TAUDnTME — TAUDn Channel Modulation Output Enable Register

This register enables/disables modulation output for timer output and real-time output.

Access: Readable/writable in 16-bit units.

Address: <TAUDn_base> + 050_H

Value after reset: 0000_H This register is initialized by any reset source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnTME15	TAUDnTME14	TAUDnTME13	TAUDnTME12	TAUDnTME11	TAUDnTME10	TAUDnTME09	TAUDnTME08	TAUDnTME07	TAUDnTME06	TAUDnTME05	TAUDnTME04	TAUDnTME03	TAUDnTME02	TAUDnTME01	TAUDnTME00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.40 TAUDnTME Register Contents

Bit position	Bit name	Function
15 to 0	TAUDnTME _m	Enables/disables modulation output for timer output and real-time output of channel m. 0: Disables modulation 1: Enables modulation These bit settings are applied only when TAUDnTOE.TAUDnTOEm and TAUDnTRE.TAUDnTREM = 1.

23.4 Operating Procedure

The following lists the general operation procedure for the TAUDn:

After reset release, the operation of each channel is stopped. Clock supply is started and writing to each register is enabled. All circuits and registers of all channels are initialized. The control register of TAUDnTTOUTm is also initialized and outputs a low level.

- (1) Set the TAUDnTPS and TAUDnBRS registers to specify the clock frequency of CK0 to CK3.
- (2) Configure the desired TAUDn function:
 - Set the operation mode
 - Set the channel output mode
 - Set any other control bits
- (3) Enable the counter by setting the TAUDnTS.TAUDnTSM bit to 1.
The counter starts to count immediately, or when an appropriate trigger is detected, depending on the bit settings.
- (4) If desired, and if possible for the configured function, stop the counter or perform a forced restart operation during count operation. The counter can be stopped by setting the TAUDnTT.TAUDnTTm bit to 1. The counter can be forcibly restarted by setting the TAUDnTS.TAUDnTSM bit to 1.
- (5) Stop the function by setting the TAUDnTT.TAUDnTTm bit to 1.

NOTES

1. A detailed description of the required control bits and the operation of the individual functions is given below:
 - **Section 23.12, Independent Channel Operation Functions**
 - **Section 23.13, Synchronous Channel Operation Functions**
2. Change function while count operation is stopped (TAUDnTE.TAUDnTEm = 0).

23.5 Concepts of Synchronous Channel Operation

The synchronous channel operation function is implemented using a combination of channel groups (consisted of master and slave channels). Several rules apply to the settings of channels. These rules are detailed in **Section 23.5.1, Rules of Synchronous Channel Operation**.

Two special features for synchronous channel operation are detailed in the following subchapters:

- **Section 23.5.2, Simultaneous Start and Stop of Synchronous Channel Counters**
- **Section 23.6, Simultaneous Rewrite**

23.5.1 Rules of Synchronous Channel Operation

Number of master and slave channels

- Only even-numbered channels (CH0, CH2, CH4, ...) can be set as master channels. Any channel apart from CH0 can be set as a slave channel.
- Only channels lower than the master channel can be set as slave channels, and several slave channels can be set for one master channel.
Example: If CH2 is a master channel, CH3 and the lower channels (CH4, CH5, ...) can be set as slave channels.
- If multiple master channels are used, slave channels cannot cross the master channels.
Example: If CH0 and CH4 are master channels, CH1 to CH3 can be set as slave channels for CH0, but CH5 to CH15 cannot.

Operating clock

- The same operating clock must be set for the slave channel and the master channel. This is achieved by setting the TAUDnCMORm.TAUDnCKS[1:0] bits of the slave and master channel.

The basic concepts of master/slave usage and operating clocks are illustrated in **Figure 23.3**.

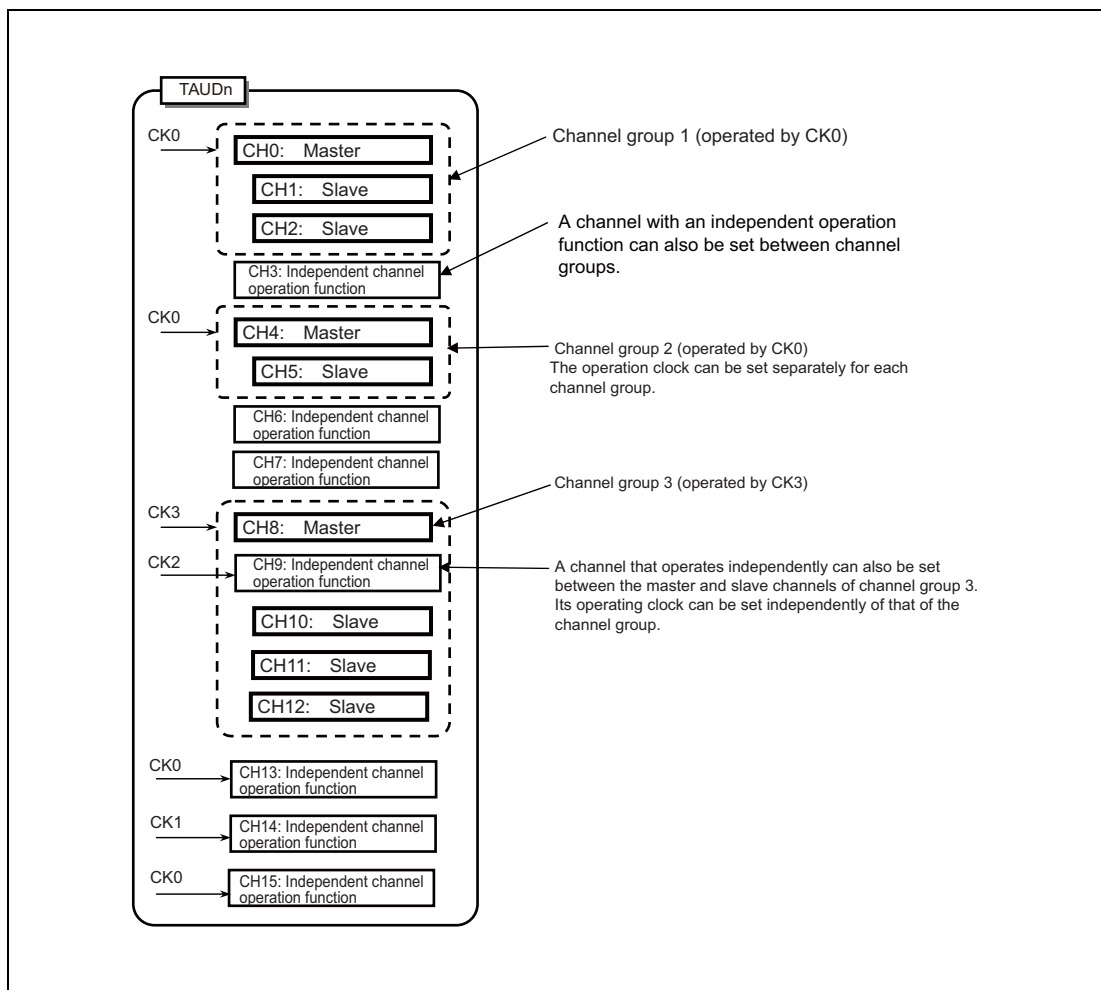

Figure 23.3 Grouping of Channels and Assignment of Operating Clocks

Control trigger signal for master/slave channels

- Master channels can output control trigger signals to slave channels.
- Slave channels can use control trigger signals from master channels but cannot output control trigger signals of their own to lower channels.
- Master channels cannot use control trigger signals from upper master channels.

23.5.2 Simultaneous Start and Stop of Synchronous Channel Counters

Channels that are operated synchronously can be started and stopped simultaneously within the same unit and between the units.

23.5.2.1 Simultaneous Start and Stop within the Same Unit

- To simultaneously start synchronized channels, the TAUDnTS.TAUDnTSM bits of the channels should be set at the same time.
- To simultaneously stop synchronized channels, the TAUDnTT.TAUDnTTM bits of the channels should be set at the same time.

Setting to the TAUDnTS.TAUDnTSM bits to 1 also sets the corresponding TAUDnTE.TAUDnTEM bits to 1, enabling counting. The count start timing depends on operating mode.

23.5.2.2 Simultaneous Start between the Units

Counters in different units can also be started simultaneously if the corresponding counters are enabled before receiving the simultaneous trigger signal.

For details on simultaneous start between the units and other timer functions, **Section 29, Peripheral Interconnection (PIC), 29.2.3.1, Simultaneous Start Trigger Function.**

23.6 Simultaneous Rewrite

23.6.1 Overview of Operations

Simultaneous rewrite describes the ability to change the compare/start value and the output logic of multiple channels at the same time.

The corresponding data and control registers (TAUDnCDRm and TAUDnTOLm) can nevertheless be written at any time. The new value does not affect the counter operation or the output signal until simultaneous rewrite is triggered.

Simultaneous rewrite can be triggered by:

- The counter on the master channel or upper channel (depending on the selected operation mode) reaching a certain value
- INTTAUDnIm being issued on the upper channel specified by TAUDnRDC.TAUDnRDCm

There are four methods for simultaneous rewrite. These are listed in **Table 23.41**, along with how to specify them and when they cause simultaneous rewrite to be triggered.

Table 23.41 Simultaneous Rewrite Methods and when They are Triggered

Method	Simultaneous Rewrite Triggered when	TAUDnRDE. TAUDnRDEm	TAUDnRDS. TAUDnRDSm	TAUDnRDM. TAUDnRDMm
—	There is no simultaneous rewrite	0	0	0
A	The master channel (re)starts counting	1	0	0
B	The master channel starts counting down at the peaks of the triangular waves in the corresponding slave channel.	1	0	1
C1	INTTAUDnIm is generated on an upper channel specified by TAUDnRDC.TAUDnRDCm	1	1	0/1
C2	INTTAUDnIm is generated on an upper channel specified by TAUDnRDC.TAUDnRDCm that in turn is triggered by an external signal	1	1	0/1

Table 23.42 lists which of these four methods is available for each channel operation function. For more information about the individual channel operation functions, see the corresponding sections in **Section 23.12, Independent Channel Operation Functions**, **Section 23.13, Synchronous Channel Operation Functions** and **Section 23.14, Synchronous Non-Complementary and Complementary Modulation Output Functions**.

Table 23.42 Channel Functions and the Methods They Use for Simultaneous Rewrite

23.6.2 How to Control Simultaneous Rewrite

Figure 23.4 shows the general procedure for simultaneous rewrite. The three main blocks (initial settings, start and counter count operation, and simultaneous rewrite) are explained afterwards.

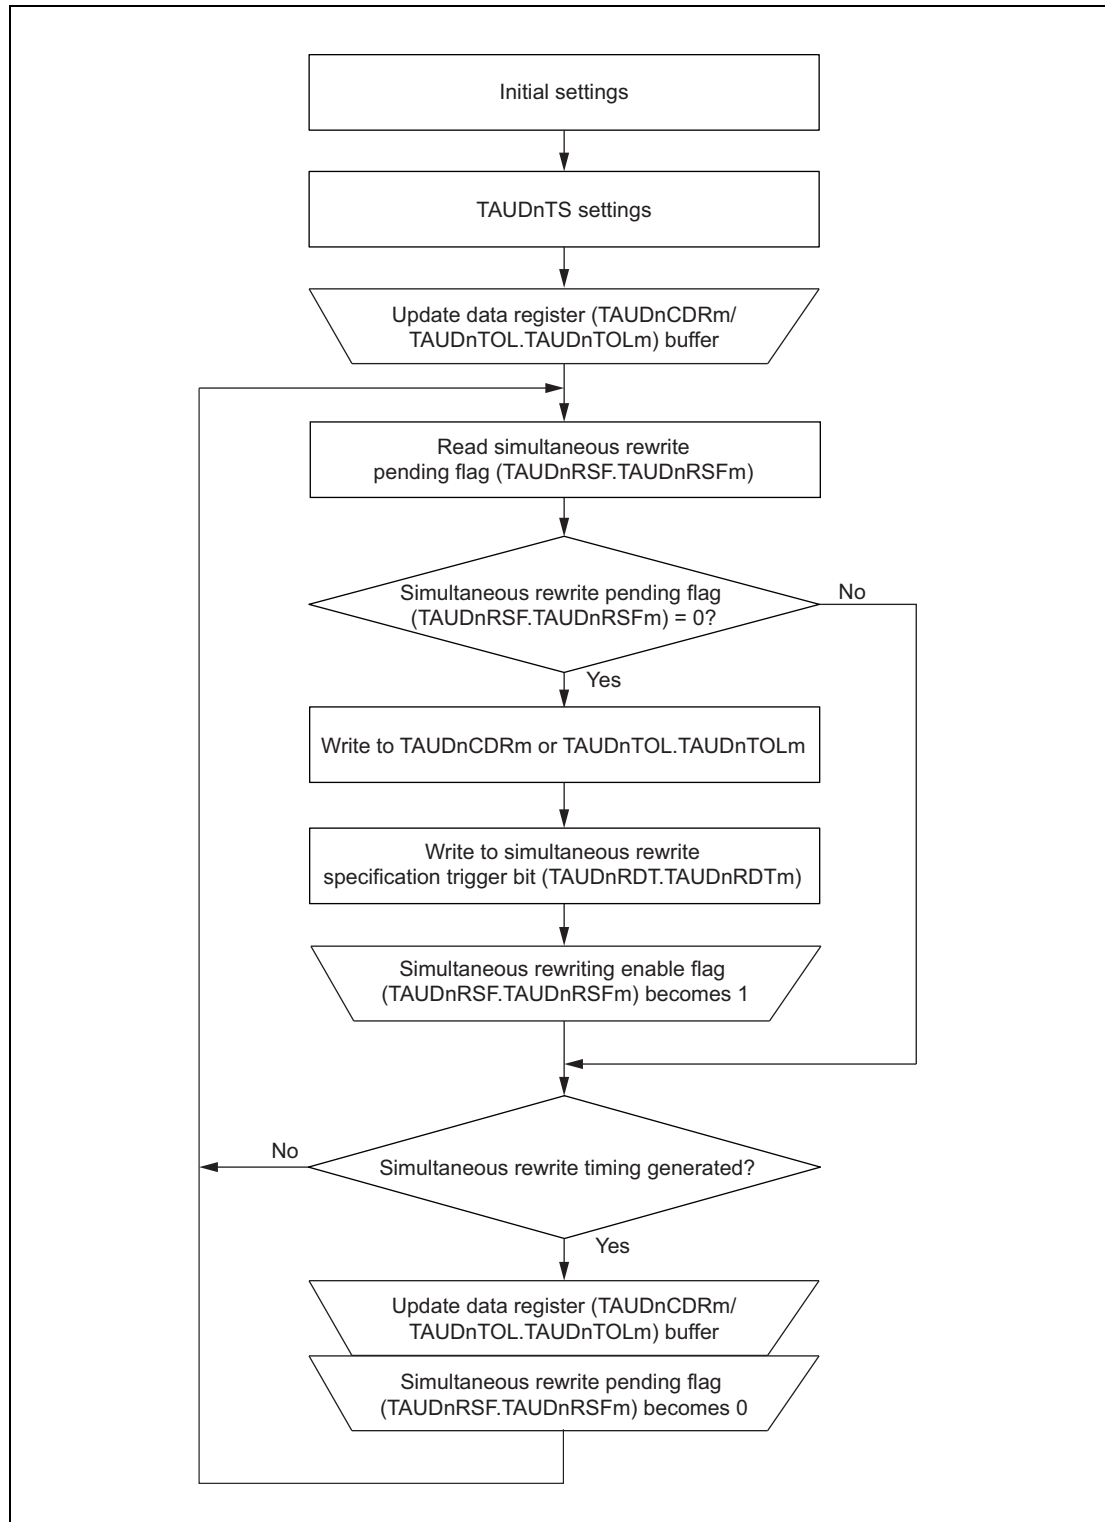

Figure 23.4 General Procedure for Simultaneous Rewrite

23.6.2.1 Initial Settings

- To enable simultaneous rewrite in channel m, set $TAUDnRDE.TAUDnRDEm = 1$
- To select the type of simultaneous rewrite, set $TAUDnRDM.TAUDnRDMm$ and $TAUDnRDS.TAUDnRDSm$ according to the values listed in **Table 23.41, Simultaneous Rewrite Methods and when They are Triggered**.
- Specify a simultaneous rewrite trigger channel by using $TAUDnRDC.TAUDnRDCm$.
(Prerequisite: $TAUDnRDS.TAUDnRDSm$ has been set to the upper channel.)

23.6.2.2 Start Counter and Count Operation

- To start all the $TAUDnCNTm$ counters of the channel group, set the corresponding $TAUDnTS.TAUDnTSm$ bits to 1. The values of $TAUDnTOL.TAUDnTOLm$ and the data registers ($TAUDnCDRm$) are loaded into the corresponding $TAUDnTOL.TAUDnTOLm$ buffer ($TAUDnTOL.TAUDnTOLm$ buf) and data buffer registers ($TAUDnCDRm$ buf) and the counters start.
- Setting the reload data trigger bit ($TAUDnRDT.TAUDnRDTm$) to 1 sets the reload flag ($TAUDnRSF.TAUDnRSFm$) to 1, enabling simultaneous rewrite. $TAUDnRSF.TAUDnRSFm$ remains set to 1 until simultaneous rewrite is completed.
- When the specified trigger for simultaneous rewrite is detected, the $TAUDnRSF.TAUDnRSFm$ bit is checked to see if simultaneous rewrite is enabled ($TAUDnRSF.TAUDnRSFm = 1$). If it is, simultaneous rewrite is carried out. Otherwise the simultaneous rewrite is not carried out and waits for the next trigger detection.

23.6.2.3 Simultaneous Rewrite

- When simultaneous rewrite is enabled ($TAUDnRSF.TAUDnRSFm = 1$) and the simultaneous rewrite trigger is detected, the current values of the data registers are copied to their buffers. These values are then loaded into the corresponding counters and are applied the next time the counter starts or restarts.
- When simultaneous rewrite is complete, the $TAUDnRSF.TAUDnRSFm$ bit is set to 0, and the system awaits the next simultaneous rewrite trigger.

23.6.3 Other General Rules of Simultaneous Rewrite

The following rules also apply:

- TAUDnRDE.TAUDnRDEm, TAUDnRDS.TAUDnRDSm, TAUDnRDM.TAUDnRDMm, and TAUDnRDC.TAUDnRDCm cannot be changed while the counter is in operation (TAUDnTE.TAUDnTEm = 1).
- TAUDnTOL.TAUDnTOLm can only be rewritten during operation with PWM output function or triangle PWM output function. For all other output functions, TAUDnTOL.TAUDnTOLm should be written before the counter starts. If it is rewritten while any other function is used, TAUDnTTOUTm outputs an invalid wave.
- When an upper channel is used as a channel issuing the simultaneous rewrite trigger (TAUDnRDS.TAUDnRDSm = 1), the TAUDnRDC.TAUDnRDCm bit controls all the lower channels. This means that if the TAUDnRDC.TAUDnRDCm bits of CH2 and CH7 are set to 1 and the TAUDnRDC.TAUDnRDCm bits of other channels are set to 0, CH2 and CH7 serve as simultaneous rewrite trigger generation channels. CH2 controls the lower channels CH3 to CH6, and CH7 controls the lower channels CH8 to CH15.
- If simultaneous rewrite is enabled and an upper channel is selected as the channel to generate the simultaneous rewrite trigger (TAUDnRDE.TAUDnRDEm and TAUDnRDS.TAUDnRDSm = 1) but no upper channel is set (TAUDnRDC.TAUDnRDC[15:0] = 0), simultaneous rewrite cannot take place.

23.6.4 Types of Simultaneous Rewrite

In the following section, the four simultaneous rewrite methods are explained using timing diagrams.

23.6.4.1 Simultaneous Rewrite when the Master Channel (Re)starts Counting (Method A)

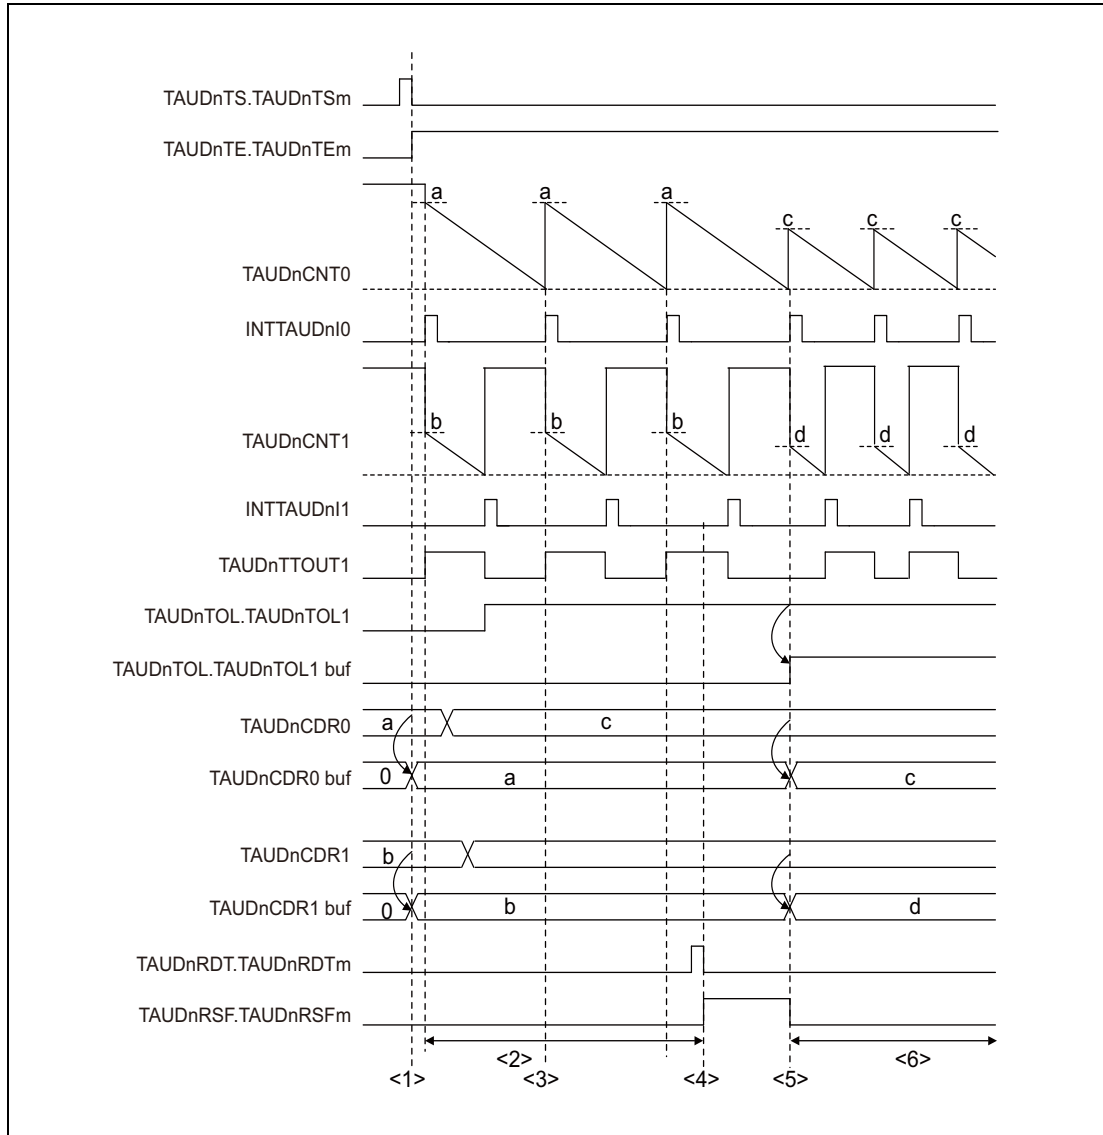

Figure 23.5 Simultaneous Rewrite when the Master Channel (Re)starts Counting

Setup:

CH0 is the master channel, which starts counting down, and CH1 represents an arbitrary slave channel. The simultaneous rewrite method A is applied.

Description:

- (1) When $\text{TAUDnTS.TAUDnTSM} = 1$ is set, the value of TAUDnCDRm is copied to the TAUDnCDRm buffer and the value of $\text{TAUDnTOL.TAUDnTOLm}$ is copied to the $\text{TAUDnTOL.TAUDnTOLm}$ buffer.
- (2) The TAUDnCDRm and $\text{TAUDnTOL.TAUDnTOLm}$ registers can be written at any time.
- (3) CH0 restarts counting, but simultaneous rewrite does not occur because it is disabled ($\text{TAUDnRSF.TAUDnRSFm} = 0$).
- (4) The reload data trigger bit ($\text{TAUDnRDT.TAUDnRDTm}$) is set to 1 which sets the status flag ($\text{TAUDnRSF.TAUDnRSFm} = 1$), enabling simultaneous rewrite.
- (5) Because simultaneous rewrite is enabled, it is triggered when CH0 restarts counting. The TAUDnCDRm value is loaded into the TAUDnCDRm buffer and the $\text{TAUDnTOL.TAUDnTOLm}$ value is loaded into the $\text{TAUDnTOL.TAUDnTOLm}$ buffer.
- (6) The counters count down and await the next simultaneous rewrite trigger. The values of TAUDnCDRm and $\text{TAUDnTOL.TAUDnTOLm}$ can be changed again.

23.6.4.2 Simultaneous Rewrite at the Peak of a Triangular Wave of Slave Channel (Method B)

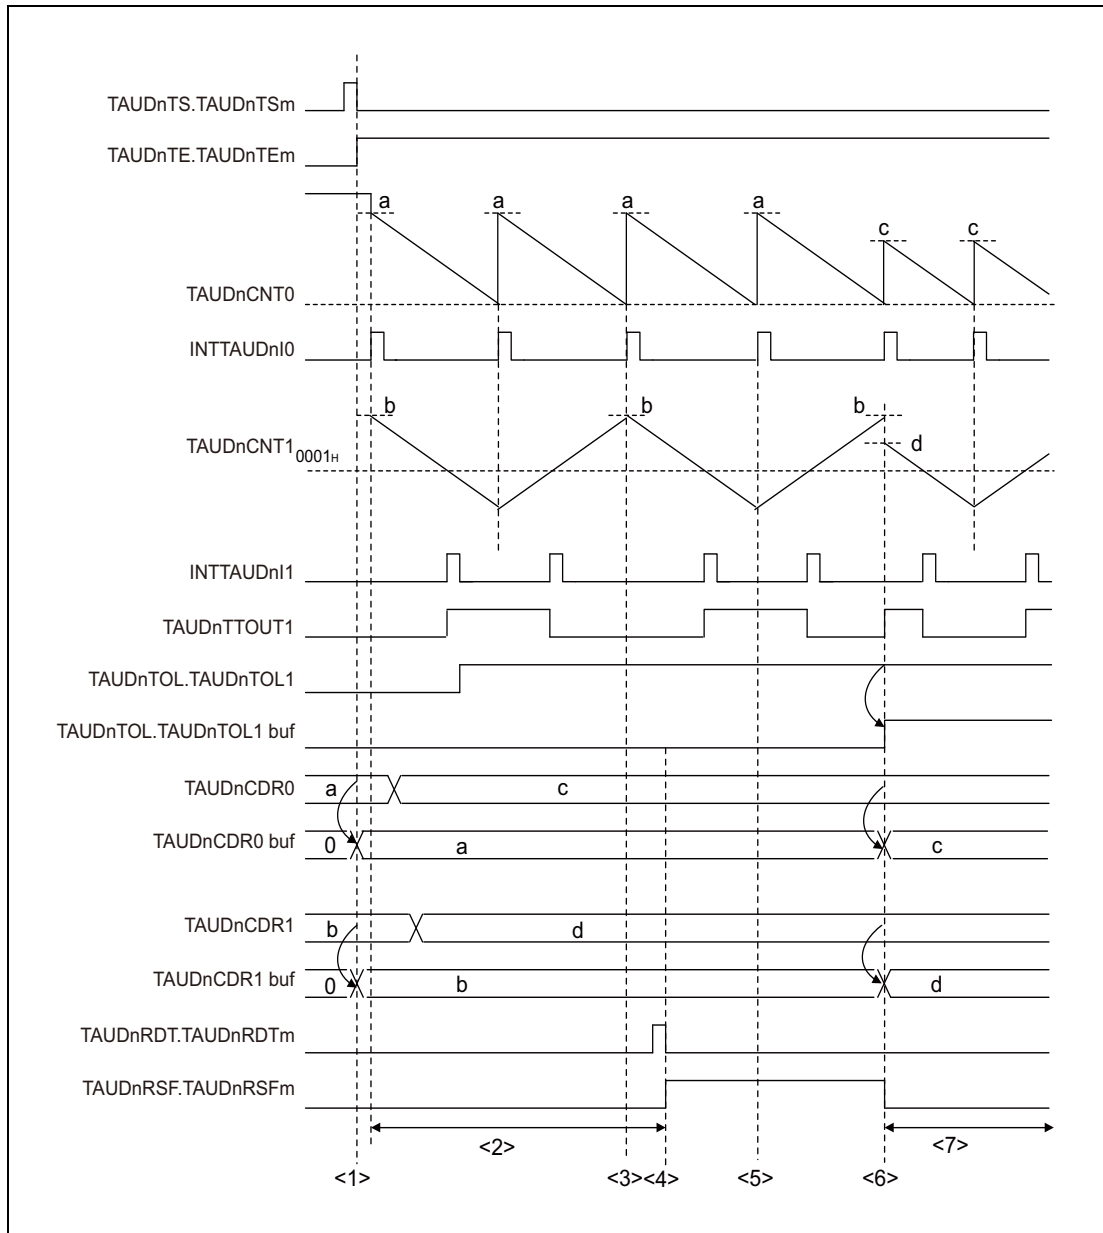

Figure 23.6 Simultaneous Rewrite at the Peak of a Triangular Wave of Slave Channel

Setting

CH0 is the master channel which performs counting down, and CH1 represents an arbitrary slave channel. The simultaneous rewrite method B is applied.

Description:

- (1) When $\text{TAUDnTS.TAUDnTSM} = 1$ is set, the value of TAUDnCDRm is copied to the TAUDnCDRm buffer.
- (2) The TAUDnCDRm and TAUDnTOL registers can be written at any time.
- (3) Simultaneous rewrite does not occur because it is disabled ($\text{TAUDnRSF.TAUDnRSFm} = 0$).
- (4) The reload data trigger bit ($\text{TAUDnRDT.TAUDnRDTm}$) is set to 1 which sets the status flag ($\text{TAUDnRSF.TAUDnRSFm} = 1$), enabling simultaneous rewrite.
- (5) Simultaneous rewrite does not take place at the bottom of the triangular cycle.
- (6) Simultaneous rewrite takes place at the top of the triangular cycle. The TAUDnCDRm value is loaded into the TAUDnCDRm buffer, the $\text{TAUDnTOL.TAUDnTOLm}$ value is loaded into the $\text{TAUDnTOL.TAUDnTOLm}$ buffer.
- (7) The counters count down and await the next simultaneous rewrite trigger. The values of TAUDnCDRm and $\text{TAUDnTOL.TAUDnTOLm}$ can be changed again.

23.6.4.3 Simultaneous Rewrite when INTTAUDnIm is Generated on an Upper Channel Specified by TAUDnRDC.TAUDnRDCm (Method C1)

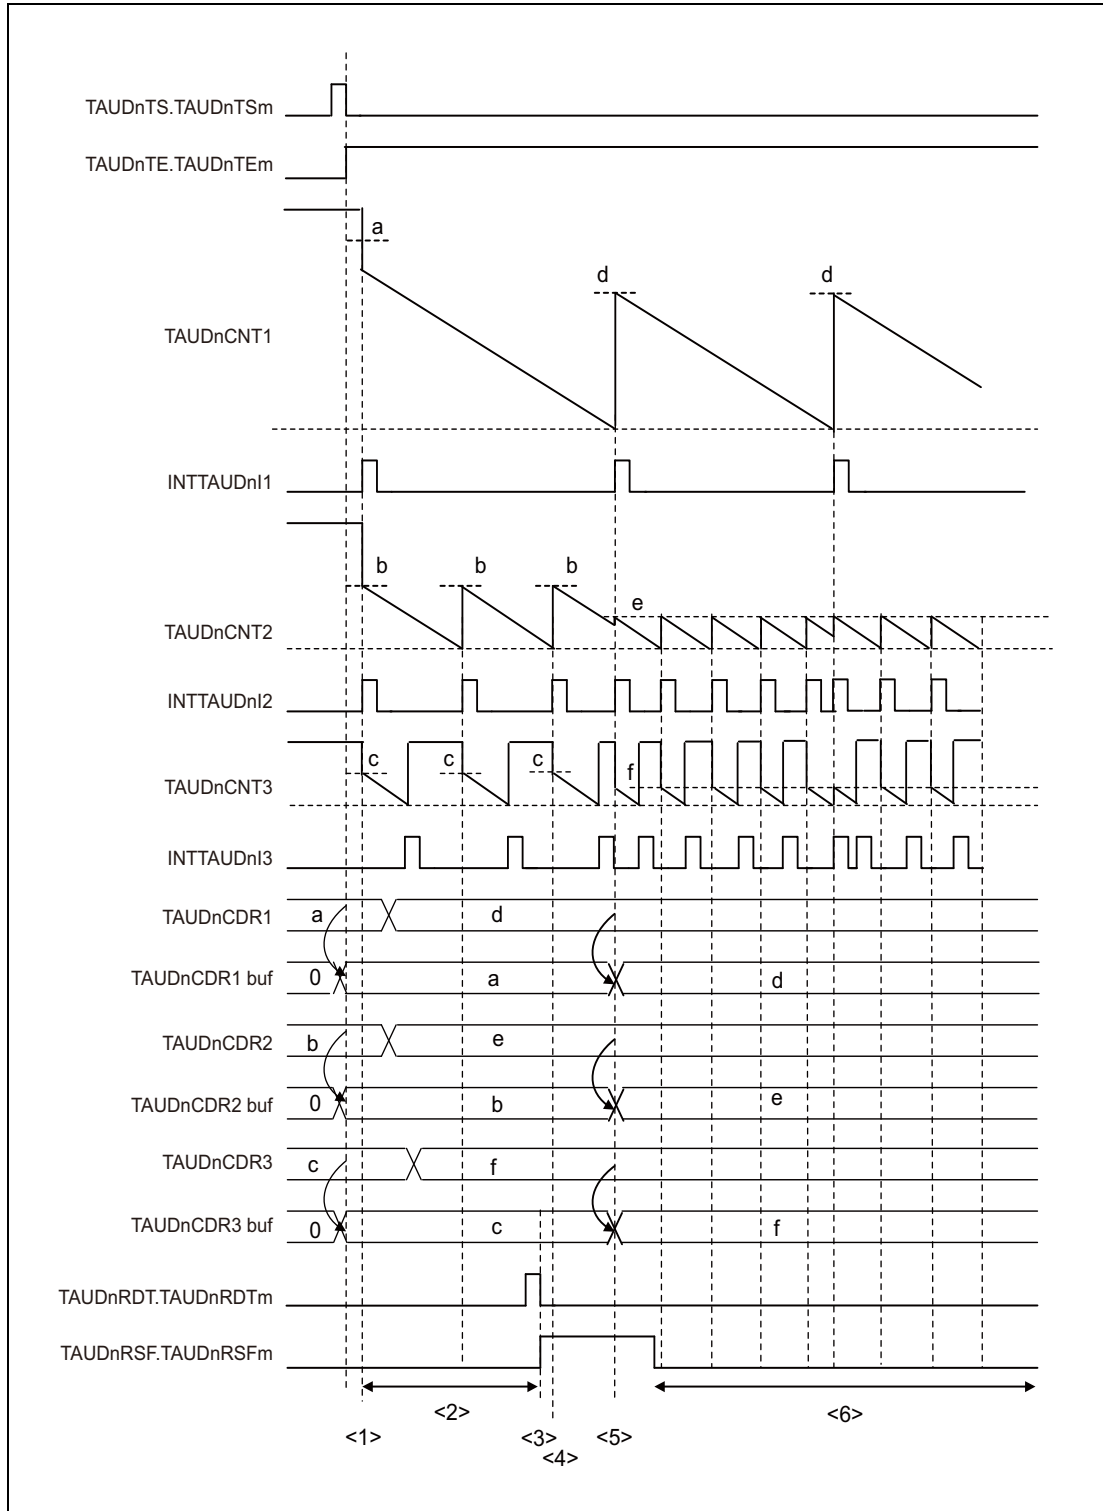

Figure 23.7 Simultaneous Rewrite When INTTAUDnIm Is Generated on an Upper Channel Specified by TAUDnRDC.TAUDnRDCm

Setting

CH1 is an upper channel used counting down, CH2 is a master channel, and CH3 is the slave channel. The simultaneous rewrite method C1 is applied. The TAUDnRDC register specifies a channel which generates simultaneous rewrite triggers.

Description:

- (1) When TAUDnTS.TAUDnTSM is set to 1, TAUDnCDRm value is copied to the TAUDnCDRm buffer.
- (2) The TAUDnCDRm register is always ready to write.
- (3) By setting the reload data trigger bit (TAUDnRDT.TAUDnRDTm) to 1, the status flag is set (TAUDnRSF.TAUDnRSFm = 1) to enable simultaneous rewrite.
- (4) Simultaneous rewrite is triggered only by a CH1 interrupt. Therefore, simultaneous rewrite is not conducted even if enabled.
- (5) Simultaneous rewrite is triggered by INT1 which is generated when counter 1 reaches 0000_H. The TAUDnCDRm values are loaded into the corresponding TAUDnCDRm buffers.
- (6) The counter counts down and awaits the next simultaneous rewrite trigger. The values of the TAUDnCDRm registers can be changed again.

23.6.4.4 Simultaneous Rewrite when INTTAUDnIm is Generated on an Upper Channel Specified by TAUDnRDC.TAUDnRDCm that in Turn is Triggered by an External Signal (Method C2)

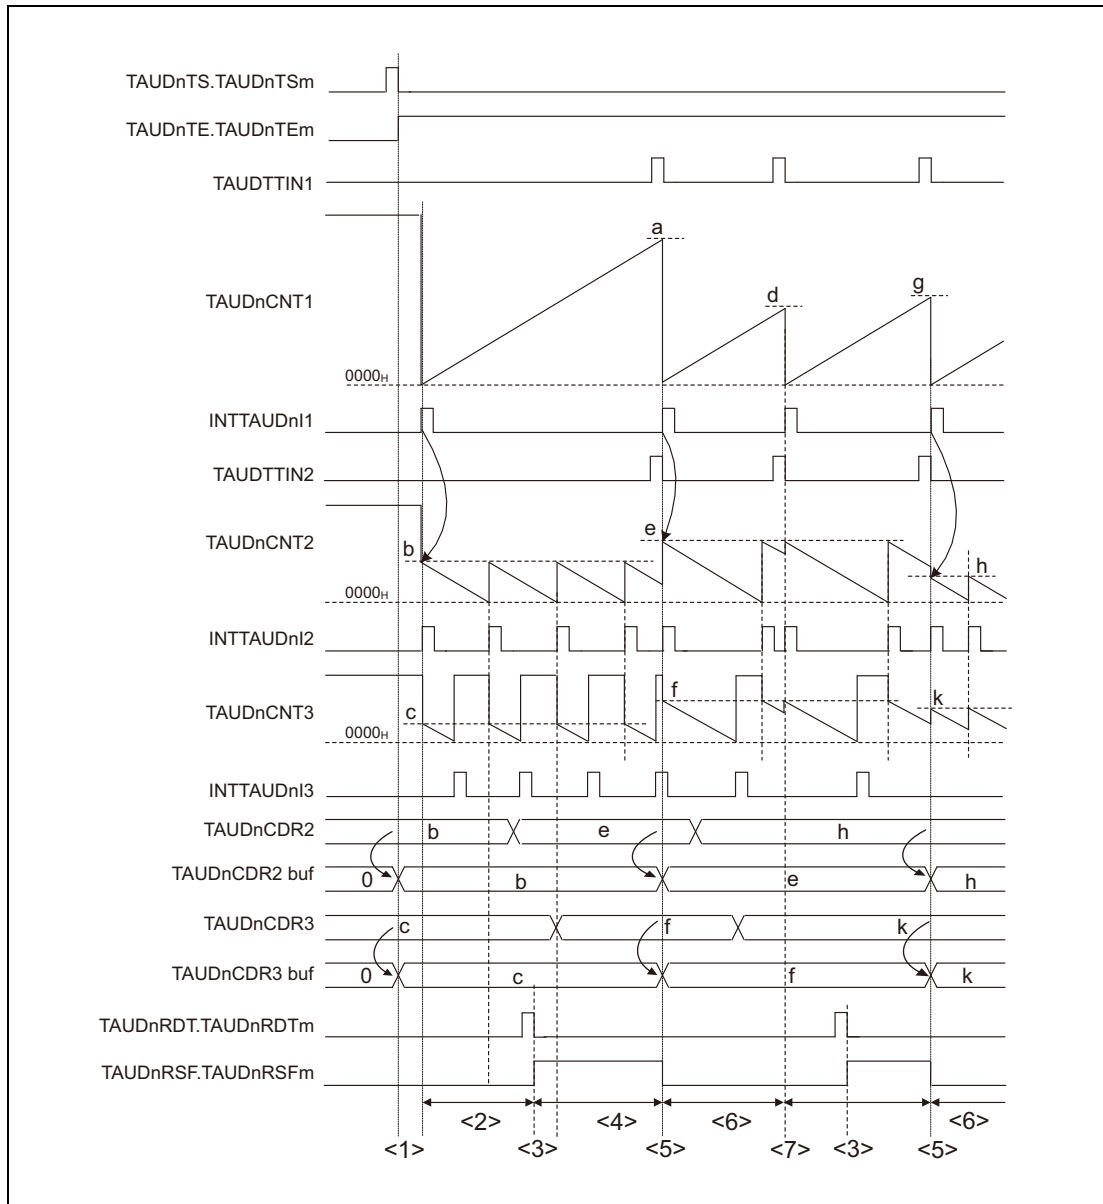

Figure 23.8 Simultaneous Rewrite when INTTAUDnIm is Generated on an Upper Channel Specified by TAUDnRDC.TAUDnRDCm that in Turn is Triggered by an External Signal

Setup:

CH1 is an upper channel used counting up, CH2 is a master channel, and CH3 is the slave channel. The synchronous channel operation method C2 is applied. The TAUDnRDC register specifies which upper channel is monitored for an INTTAUDnIm trigger.

Description:

- (1) When TAUDnTS.TAUDnTSM is set to 1, TAUDnCDRm value is copied to the TAUDnCDRm buffer. However, the TAUDnCDR1 value is not copied to the TAUDnCDR1 buffer because TAUDnCDR1 is in capture mode.
- (2) The TAUDnCDRm register is always ready to write.
- (3) By setting the reload data trigger bit (TAUDnRDT.TAUDnRDTm) to 1, the status flag is set (TAUDnRSF.TAUDnRSFm = 1) to enable simultaneous rewrite.
- (4) Simultaneous rewrite is triggered only by a CH1 interrupt. Therefore, simultaneous rewrite is not conducted even if enabled.
- (5) Simultaneous rewrite is triggered by INT1 which is caused by external signal TIN1. The TAUDnCDRm values are written to the corresponding TAUDnCDRm buffers.
- (6) The counters count down and await the next simultaneous rewrite trigger. The values of the TAUDnCDRm registers can be changed again.
- (7) An external signal occurs at TIN2 but simultaneous rewrite does not take place because it is disabled (TAUDnRSF.TAUDnRSFm = 0).

23.7 Channel Output Modes

The output of the TAUDnTTOUTm pin can be controlled in two ways, the latter of which can be further split into individual modes.

- By software (TAUDnTOE.TAUDnTOEm = 0)
When controlled by software, the value written in the output register bit (TAUDnTO.TAUDnTOm) is sent out of the output pin (TAUDnTTOUTm).
- By TAUD signals (TAUDnTOE.TAUDnTOEm = 1)
When controlled by TAUD signals, the output level of TAUDnTTOUTm is set or reset or toggled by internal signals. The value of TAUDnTO.TAUDnTOm is updated accordingly to reflect the value of TAUDnTTOUTm
 - Independently (TAUDnTOM.TAUDnTOMm = 0)
In case of independent operation, the output of the TAUDnTTOUTm pin is only affected by settings of channel m. Therefore, independent channel operation should be selected (TAUDnTOM.TAUDnTOMm = 0).
 - Synchronously (TAUDnTOM.TAUDnTOMm = 1)
In case of synchronous operation, the output of the TAUDnTTOUTm pin is affected by settings of channel m and those of other channels. Therefore, synchronous channel operation should be selected for all synchronized channels (TAUDnTOM.TAUDnTOMm = 1).

The TAUDnTO.TAUDnTOm bit can always be read to determine the current value of TAUDnTTOUTm, regardless of whether the pin is controlled by software, operated independently, or operated synchronously.

Control bits

The settings of the control bits required to select a specific channel output mode are listed in **Table 23.43, Channel Output Modes**.

The channel output modes are described in details below.

- **Section 23.7.2, Channel Output Modes Controlled Independently by TAUDn Signals**
- **Section 23.7.3, Channel Output Modes Controlled Synchronously by TAUDn Signals**

Batch operation of TAUDnTOm bit

Whether a set value is reflected to the TAUDnTOm bit or not is controlled by the TAUDnTOE.TAUDnTOEm bit.

The TAUDnTOm setting is written only to the bit (channel) set with TAUDnTOE.TAUDnTOEm bit = 0 when a write to the TAUDnTO register is attempted. No TAUDnTOm setting is reflected to the bit (channel) set with TAUDnTOE.TAUDnTOEm bit = 1.

NOTE

TAUDnTO.TAUDnTOm bit is placed so that its bit number corresponds to a channel number.

Output logic

Positive logic or negative logic of the output is specified by control bit TAUDnTOL.TAUDnTOLm.

The value of TAUDnTOL.TAUDnTOLm bit should be set before the counter is started. It can only be changed during operation with PWM output function or triangle PWM output function. Otherwise, changes to TAUDnTOL.TAUDnTOLm result in an invalid TAUDnTTOUTm signal output.

See **Section 23.6, Simultaneous Rewrite**.

The various channel output modes and the channel output control bits are listed in **Table 23.43**.

Table 23.43 Channel Output Modes

Channel Output Mode	TAUDn TOE. TAUDn TOEm	TAUDn TOM. TAUDn TOMm	TAUDn TOC. TAUDn TOCm	TAUDn TDE. TAUDn TDEm	TAUDn TRE. TAUDn TREM	TAUDn TME. TAUDn TMEm	TAUDn TDM. TAUDn TDMm			
By software										
Independent channel output mode controlled by software	0					X				
By TAUD signals, independently										
Independent channel output mode 1	1	0	0	0	0	0	0			
with real-time output					1					
Independent channel output mode 2			1		0					
By TAUD signals, synchronously										
Synchronous channel output mode 1	1	1	0	0	0	0	0			
with non-complementary modulation output					1			X		
Synchronous channel output mode 2			1		0			0	0	0
with dead time output					1					
with one-phase PWM output										
with complementary modulation output									1	1
with non-complementary modulation output			1	0						

- All combinations not listed in this table are forbidden.
- Bits marked with an x can be set to any value.

NOTES

1. The following bits cannot be changed during count operation (TAUDnTE.TAUDnTEm = 1):
 - TAUDnTOM.TAUDnTOMm
 - TAUDnTOC.TAUDnTOCm
 - TAUDnTDE.TAUDnTDEm
 - TAUDnTRE.TAUDnTREm
 - TAUDnTDM.TAUDnTDMm
2. The following bits cannot be changed during count operation (TAUDnTE.TAUDnTEm = 1) except in channel output modes with modulation output:
 - TAUDnTME.TAUDnTMEm
 - TAUDnTDL.TAUDnTDLm

23.7.1 General Procedures for Specifying a Channel Output Mode

This section describes the general procedures for specifying a TAUDnTTOUTm channel output mode. The prerequisite is that timer output operation is disabled (TAUDnTOE.TAUDnTOEm = 0).

- (1) Set TAUDnTO.TAUDnTOm to specify the initial level of the TAUDnTTOUTm output.
- (2) Set channel output mode according to **Table 23.43, Channel Output Modes**, and the output logic using the TAUDnTOL.TAUDnTOLm bit.
- (3) Start the counter (TAUDnTS.TAUDnTSm = 1).

Figure 23.9 General Procedure for Specifying a TAUDnTTOUTm Channel Output Mode

23.7.2 Channel Output Modes Controlled Independently by TAUDn Signals

This section lists the channel output modes that are controlled independently by TAUDn signals. The control bits used to specify a mode are listed in **Table 23.43, Channel Output Modes**.

23.7.2.1 Independent Channel Output Mode 1

Set/reset conditions

In this output mode, TAUDnTTOUTm toggles when INTTAUDnIm is detected. The value of TAUDnTOL.TAUDnTOLm is ignored.

Prerequisites

There are no prerequisites other than those shown in **Table 23.43, Channel Output Modes**

23.7.2.2 Independent Channel Output Mode 1 with Real-Time Output

In this output mode, the value of TAUDnTRO.TAUDnTROm bit of the trigger channel is output to TAUDnTTOUTm. The trigger channel is specified by setting the corresponding TAUDnTRC.TAUDnTRCm bit to 1. It controls all lower channels for which TAUDnTRC.TAUDnTRCm = 0.

Set/reset conditions

The value of TAUDnTRO.TAUDnTROm bit is sent to TAUDnTTOUTm only when an INTTAUDnIm interrupt occurs on the trigger channel. The interrupt is generated either:

- at certain specified intervals or
- on detection of a valid TAUDnTTINm input edge/counter start

The type of trigger is set using the TAUDnCMORm.TAUDnMD[4:1] bits.

Prerequisites

Both master and slave channels can be set as a trigger generation channel. A channel for which TAUDnTRC.TAUDnTRCm is set to 1 serves as a trigger generation channel regardless of the value of TAUDnTRE.TAUDnTREM.

If there is no channel for which TAUDnTRC.TAUDnTRCm is set to 1 or if TAUDnTRC.TAUDnTRC0 = 0, real-time output cannot take place.

This can be seen in **Figure 23.10**.

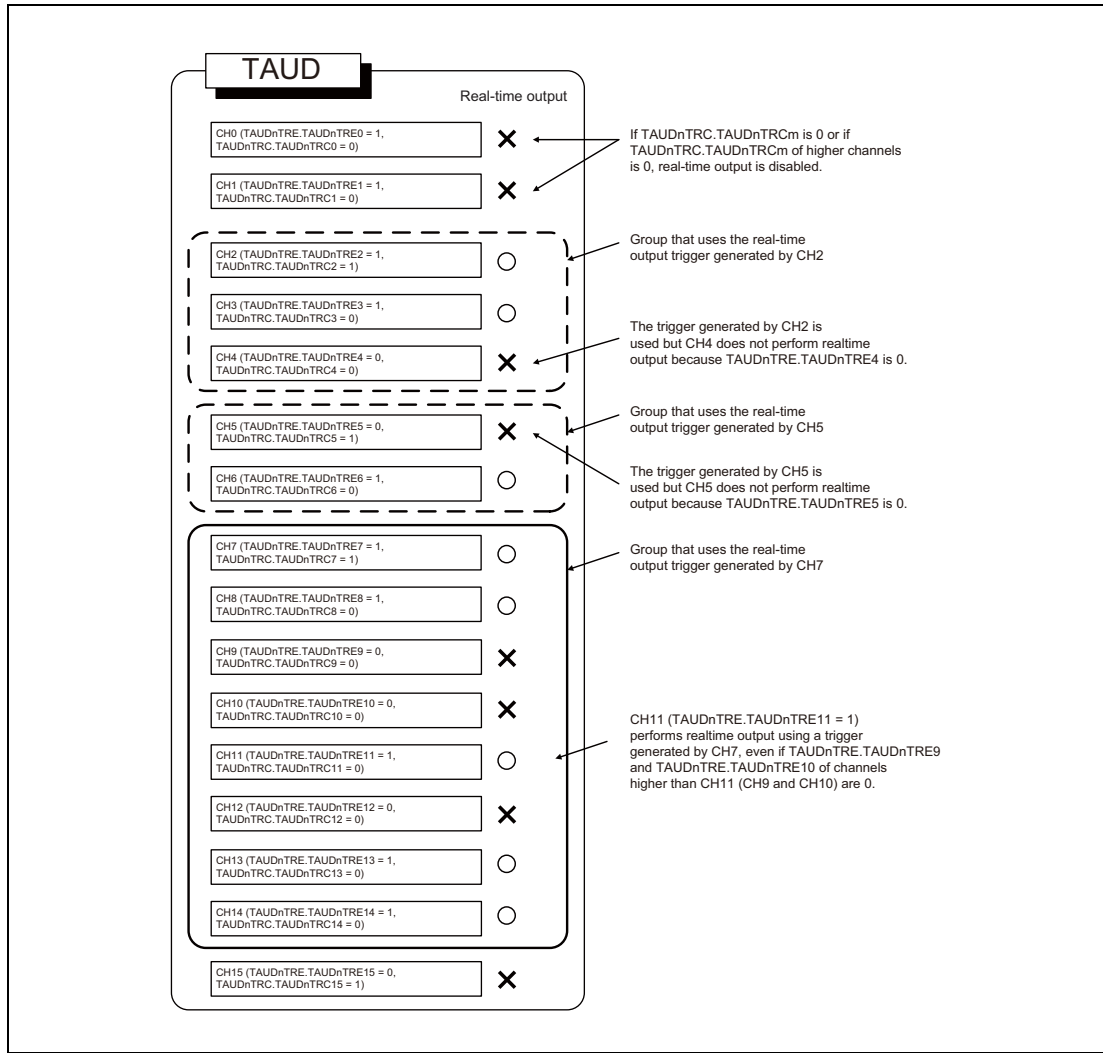

Figure 23.10 Real-Time Output

23.7.2.3 Independent Channel Output Mode 2

Set/reset conditions

In this output mode, TAUDnTTOUTm is set when INTTAUDnIm occurs at the time of count start, and reset when INTTAUDnIm occurs due to a match between TAUDnCNTm and TAUDnCDRm.

Prerequisites

There are no prerequisites other than those shown in **Table 23.43, Channel Output Modes**.

23.7.3 Channel Output Modes Controlled Synchronously by TAUDn Signals

This section lists the channel output modes that are controlled synchronously by TAUDn signals. The control bits used to specify a mode are listed in **Table 23.43, Channel Output Modes**.

23.7.3.1 Synchronous Channel Output Mode 1

Set/reset conditions

In this output mode, INTTAUDnIm of master channel serves as a set signal and INTTAUDnIm of the slave channel as a reset signal. If INTTAUDnIm of master channel and INTTAUDnIm of the slave channel are generated at the same time, INTTAUDnIm of the slave channel (reset signal) has priority over INTTAUDnIm (set signal) of master channel, i.e., the master channel is ignored.

Prerequisites

There are no prerequisites other than those shown in **Table 23.43, Channel Output Modes**.

23.7.3.2 Synchronous Channel Output Mode 1 with Non-Complementary Modulation Output

Set/reset conditions

In this output mode, TAUDnTTOUTm outputs the result of an AND operation between the PWM output and the real-time output bit (TAUDnTRO.TAUDnTROm) of a channel.

The phase period to which the dead time is added is specified using the TAUDnTDL.TAUDnTDLm bit; for positive phase set TAUDnTDL.TAUDnTDLm = 0 and for negative phase set TAUDnTDL.TAUDnTDLm = 1.

Prerequisites

A set of at least three channels is required to generate the PWM output. The master channel and slave channel 1 generate a period, and slave channel 2 generates the duty cycle. In typical applications, five more slave channels are also used that operate in the same manner as slave channel 2.

Only the PWM output and the real-time output bit of the same channel can be combined.

TAUDnTRO.TAUDnTROm, TAUDnTME.TAUDnTMEem, and TAUDnTDL.TAUDnTDLm can only be changed during count operation.

- If TAUDnTME.TAUDnTMEem is changed, its new value is applied upon detection of INTTAUDnIm on the specified channel.
- If TAUDnTME.TAUDnTMEem and TAUDnTDL.TAUDnTDLm are changed, their new values are applied upon detection of INTTAUDnIm on the master channel.

23.7.3.3 Synchronous Channel Output Mode 2

In this output mode, the operating mode should be set to up/down count mode. The result is a triangle PWM output at $TAUDnTTOUTm$. For details, see **Section 23.13.6, Triangle PWM Output Function**.

Set/reset conditions

$TAUDnCNTm$ of the slave channel counts down and up alternatively. When it passes 0001_H it generates an interrupt, causing $TAUDnTTOUTm$ to toggle.

Prerequisites

A set of two channels is required to generate the triangle PWM output. $TAUDnTTOUTm$ should be set to 0 before the function starts.

23.7.3.4 Synchronous Channel Output Mode 2 with Dead Time Output

In this output mode, a dead time delay is added to $TAUDnTTOUTm$. The set/reset conditions are shown in **Figure 23.11**.

Set/reset conditions

Figure 23.11 Set/Reset Conditions for Synchronous Channel Output Mode 2 with Dead Time Output

With regard to the edge to which dead time is added, set $TAUDnTDL.TAUDnTDLm = 0$ for rising edges and $TAUDnTDL.TAUDnTDLm = 1$ for falling edges.

Prerequisites

Dead time control requires a set of three channels, each operating in the following modes:

- One master channel
The master channel should be set to interval timer mode.
- One even-numbered slave channel
The even-numbered slave channel should be set up/down count mode.
- One odd-numbered slave channel (even-numbered channel + 1)
The odd-numbered slave channel should be set to one-count mode.

The values of the following bits should be the same for the odd-numbered channel and the even-numbered channel:

- TAUDnTOE.TAUDnTOEm
- TAUDnTME.TAUDnTME_m
- TAUDnTRE.TAUDnTRE_m
- TAUDnTOM.TAUDnTOM_m
- TAUDnTOC.TAUDnTOC_m
- TAUDnTDE.TAUDnTDE_m
- TAUDnTDM.TAUDnTDM_m

23.7.3.5 Synchronous Channel Output Mode 2 with One-Phase PWM Output

In this output mode, a dead time delay is added to TAUDnTTOUT_m. The set/reset conditions are shown in **Figure 23.12**.

Set/reset conditions

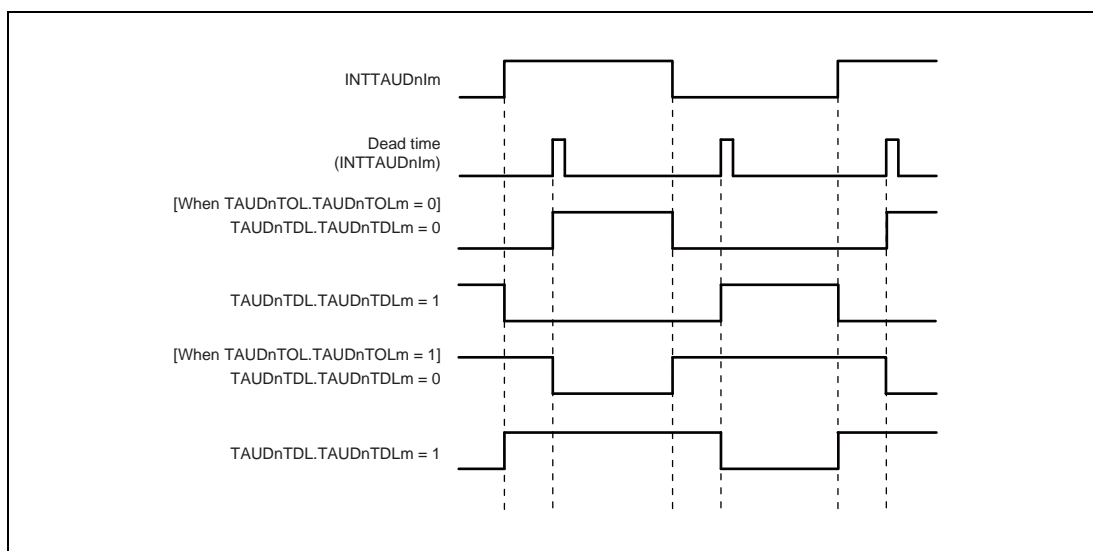

Figure 23.12 Set/Reset Conditions for Synchronous Channel Output Mode 2 with One-Phase PWM Output

With regard to the edge to which dead time is added, set TAUDnTDL.TAUDnTDL_m = 0 for rising edges and TAUDnTDL.TAUDnTDL_m = 1 for falling edges.

Prerequisites

One-phase PWM output control requires a set of two channels:

- One even-numbered slave channel
- One odd-numbered slave channel (even-numbered channel + 1)
The odd-numbered slave channel should be set to one-count mode.

The values of the following bits should be the same for the odd-numbered channel and the even-numbered channel:

- TAUDnTOE.TAUDnTOEm
- TAUDnTME.TAUDnTMEm
- TAUDnTRE.TAUDnTREm
- TAUDnTOM.TAUDnTOMm
- TAUDnTOC.TAUDnTOCm
- TAUDnTDE.TAUDnTDEm
- TAUDnTDM.TAUDnTDMm

23.7.3.6 Synchronous Channel Output Mode 2 with Complementary Modulation Output**Set/reset conditions**

In this output mode, TAUDnTTOUTm outputs a PWM signal, a high signal, or a low signal depending on the value of real-time output bit (TAUDnTRO.TAUDnTROm), the modulation output bit (TAUDnTME.TAUDnTMEm), and the output level bit (TAUDnTOL.TAUDnTOLm) of a pair of slave channels.

For details, see **Section 23.14.3, Complementary Modulation Output Function**.

Prerequisites

A set of at least four channels is required for this mode. The master channel and slave channel 1 generate a period, slave channel 2 generates a duty cycle, and slave channel 3 generates dead time. Slave channels 2 and 3 are a pair. In typical applications, 4 more channels are also used, which operates in the same manner as slave channels 2 and 3 respectively.

TAUDnTRO.TAUDnTROm, TAUDnTME.TAUDnTMEm, and TAUDnTDL.TAUDnTDLm can only be changed during count operation.

- If TAUDnTME.TAUDnTMEm is changed during operation, its new value is applied upon detection of INTTAUDnIm at the specified channel.
- If TAUDnTME.TAUDnTMEm and TAUDnTDL.TAUDnTDLm are changed, their new values are applied upon detection of INTTAUDnIm on an even-numbered slave channel.

23.7.3.7 Synchronous Channel Output Mode 2 with Non-Complementary Modulation Output

The difference from synchronous channel output mode 1 with non-complementary modulation output is the PWM wave shape.

Mode 1 has a square wave while mode 2 has a triangular wave.

23.8 Start Timing in Each Operating Modes

This section describes the timing at which the counter starts after TAUDnTS.TAUDnTSM is set to 1 in each operating mode.

In all modes, the value of data register and whether or not an interrupt occurs depends on mode and register settings.

CAUTION

The count start timing described in this section is for your reference. Actually, the count start timing depends on the count clock timing.

23.8.1 Interval Timer Mode, Judge Mode, Capture Mode, and Up/Down Count Mode

The counter starts operating with the next count clock after TAUDnTS.TAUDnTSM is set to 1. The value of data register is also loaded when the counter starts.

Figure 23.13 Start Timing in Interval Timer Mode, Judge Mode, Capture Mode, and Up/Down Count Mode

NOTE

Make sure to set TAUDnCMORm.TAUDnMD0 = 0 when using the up/down count mode.

23.8.2 Event Count Mode

The value of data register is loaded as soon as TAUDnTS.TAUDnTSM is set to 1. The counter also starts immediately. The value of data register decrements when the subsequent count clock cycle starts.

Figure 23.14 Start Timing in Event Count Mode

23.8.3 Other Operating Modes

In other operating modes, the counter operation start timing is triggered only upon detection of a valid edge of TAUDnTTINm. Once the counter starts, the value of data register is also loaded. The count clock cycles, which are irrelevant to start of counter operation, determine the frequency with which all operations take place.

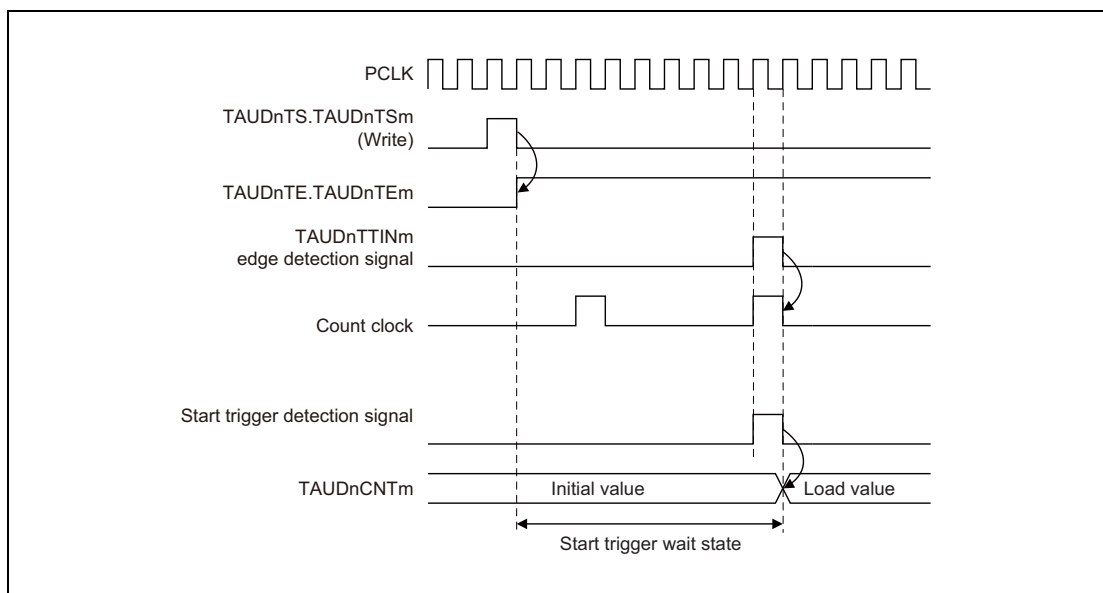

Figure 23.15 Count Start Timing in Other Operating Modes

23.9 TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts

When the counter starts, it is possible to specify whether an INTTAUDnIm is generated using the TAUDnCMOR.TAUDnMD0 bit. The way in which the setting of the TAUDnCMORm.TAUDnMD0 bit determines whether an INTTAUDnIm interrupt is generated at the start of counting and the operation of TAUDnTTOUTm depends on the selected mode. For details, see the description of TAUDnCMORm.TAUDnMD0 in the relevant individual functional blocks.

Figure 23.16 INTTAUDnIm Generation Timing (When TAUDnCMORm.TAUDnMD0 = 0)

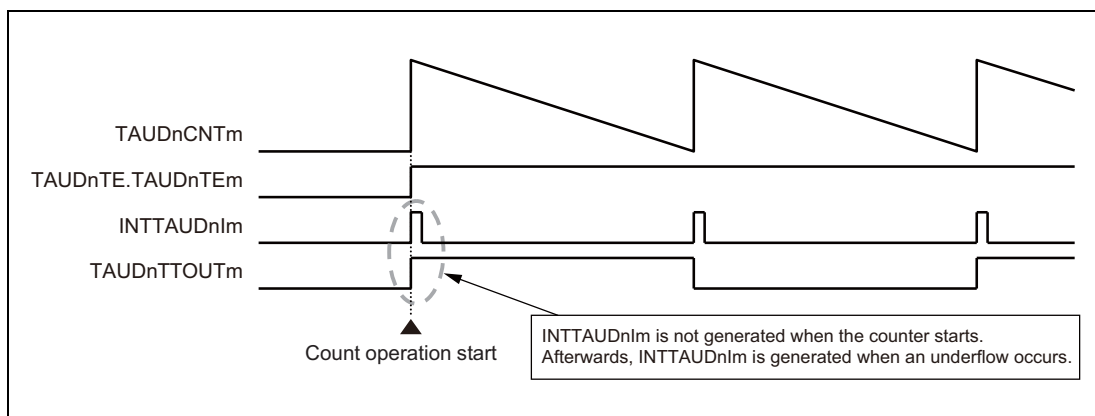

Figure 23.17 INTTAUDnIm Generation Timing (When TAUDnCMORm.TAUDnMD0 = 1)

23.10 Interrupt Generation upon Overflow

In certain independent functions, an interrupt is not generated when the counter value reaches $FFFF_H$ and an overflow occurs during count-up. This section describes how to generate an interrupt by combining channel operation in a mode that counts up and in a mode that counts down.

The appropriate operation mode for the second channel depends on the operation mode of the first channel. Nevertheless, the principle is the same for all combinations:

- Find an operation mode for the second channel that counts down in such a manner, that it reaches 0000_H at the same time as the first channel overflows ($TAUDnCNTm = FFFF_H$).
- Set $TAUDnCDRm$ of the second channel to $FFFF_H$.
- The two channels must count at the same speed (i.e. they must have the same count clock).
- Both channels are triggered by the same $TAUDnTTINm$ input signal.
- The trigger detection settings ($TAUDnCMORm.TAUDnSTS[2:0]$ and $TAUDnCMURm.TAUDnTIS[1:0]$) must be identical for both channels.

Result:

The down-counter of the second channel reaches 0000_H at exactly the same time as the up-counter of the first channel overflows ($TAUDnCNTm = FFFF_H$). Thus the second channel generates the desired interrupt.

The following sections list the operating modes that count down that are required to match specific operating modes that count up, as well as example timing diagrams.

23.10.1 Combination of TAUDTTINm Input Pulse Interval Measuring Function and TAUDTTINm Input Interval Timer Function

When a capture trigger is input to TAUDTTINm of both channels simultaneously, an overflow from FFFF_H in TAUDnCNTm of the TAUDTTINm input pulse interval measuring function is detected by INTTAUDnIm from the TAUDTTINm input interval timer function.

Figure 23.18 Combination of TAUDTTINm Input Pulse Interval Measuring Function and TAUDTTINm Input Interval Timer Function

Timing diagram

Figure 23.19 Interrupt Generation via Combination of TAUDTTINm Input Pulse Interval Measuring Function and TAUDTTINm Input Interval Timer Function

23.10.2 Combination of TAUDTTINm Input Signal Width Measuring Function and Overflow Interrupt Output Function (during TAUDTTINm Width Measurement)

When a capture trigger is input to TAUDTTINm of both channels simultaneously, an overflow from FFFF_H in TAUDnCNTm of the TAUDTTINm input signal width measuring function is detected by INTTAUDnIm from the overflow interrupt output function (during TAUDTTINm width measurement).

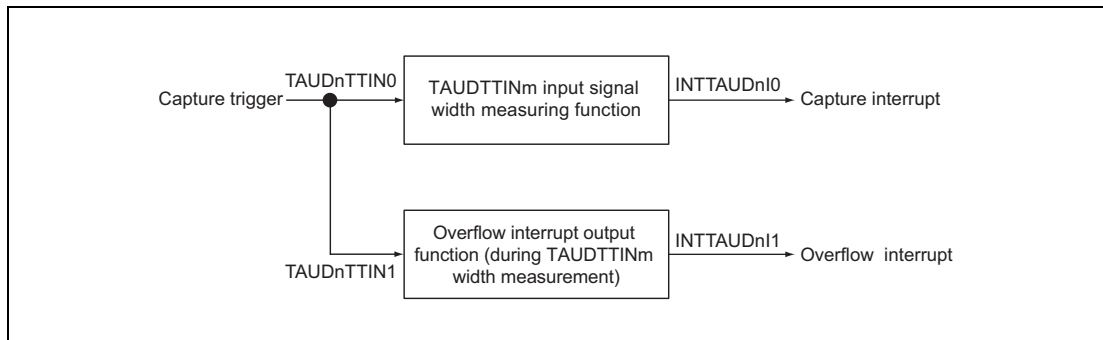

Figure 23.20 Combination of TAUDTTINm Input Signal Width Measuring Function and Overflow Interrupt Output Function (during TAUDTTINm Width Measurement)

Timing diagram

Figure 23.21 Interrupt Generation via Combination of TAUDTTINm Input Signal Width Measuring Function and Overflow Interrupt Output Function (during TAUDTTINm Width Measurement)

23.10.3 Combination of TAUDTTINm Input Position Detecting Function and Interval Timer Function

When the counters of both channels are started simultaneously, an overflow from $FFFF_H$ in TAUDnCNTm of the TAUDTTINm input position detecting function is detected by INTTAUDnIm from the interval timer function.

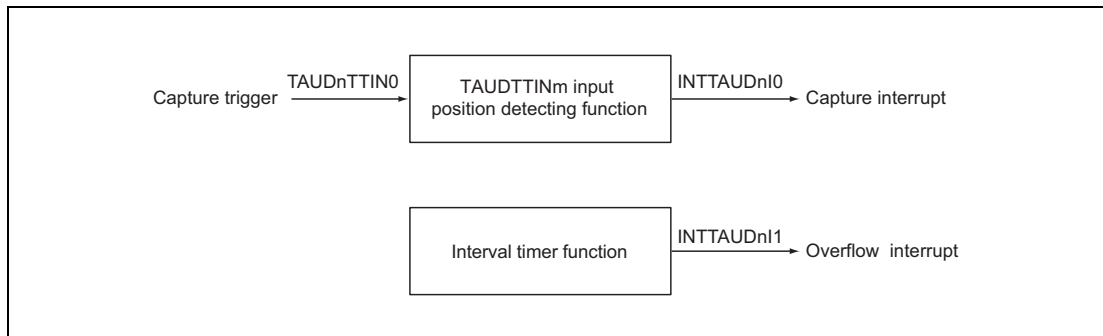

Figure 23.22 Combination of TAUDTTINm Input Position Detecting Function and Interval Timer Function

Timing diagram

Figure 23.23 Interrupt Generation via Combination of TAUDTTINm Input Position Detecting Function and Interval Timer Function

23.10.4 Combination of TAUDTTINm Input Period Count Detecting Function and Overflow Interrupt Output Function (during TAUDTTINm Input Period Count Detection)

When a capture trigger is input to TAUDTTINm of both channels simultaneously, an overflow from $FFFF_H$ in TAUDnCNTm of the TAUDTTINm input period count detecting function is detected by INTTAUDnIm from the overflow interrupt output function (during TAUDTTINm input period count detection).

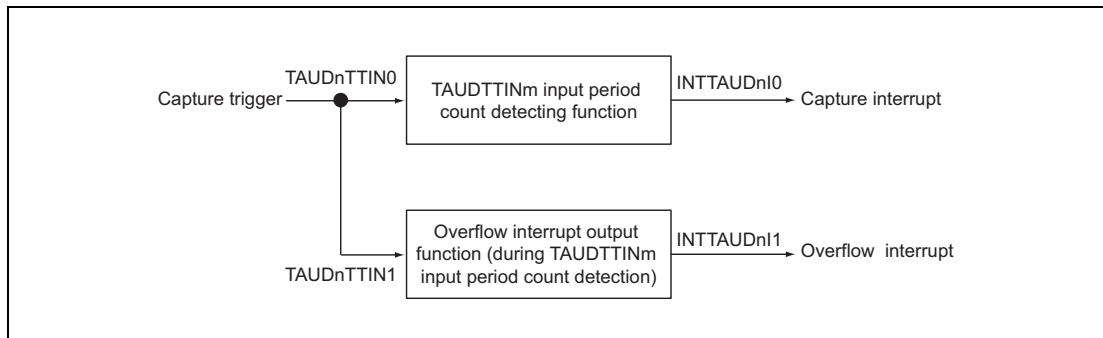

Figure 23.24 Combination of TAUDTTINm Input Period Count Detecting Function and Overflow Interrupt Output Function (during TAUDTTINm Input Period Count Detection)

Timing diagram

Figure 23.25 Interrupt Generation via Combination of TAUDTTINm Input Period Count Detecting Function and Overflow Interrupt Output Function (during TAUDTTINm Input Period Count Detection)

23.11 TAUDnTTINm Edge Detection

Edge detection is based on the operating clock. This means that an edge can only be detected at the next rising edge of the operating clock. This can lead to a maximum delay of one operating clock cycle.

Figure 23.26 shows when edge detection takes place.

Figure 23.26 Basic Edge Detection Timing

Figure 23.26 shows an operation timing image. Actually, a noise filter or synchronization circuit which is located between the TAUDnIm pin and TAUDn causes a delay time.

23.12 Independent Channel Operation Functions

The following sections list the independent channel operation functions provided by the Timer Array Unit D. For a general overview of independent channel operation, see **Section 23.2, Overview**.

This section describes functions that generate interrupts at regular intervals or with a specified delay.

23.12.1 Interval Timer Function

23.12.1.1 Overview

Summary

This function is used as a reference timer for generating timer interrupts (INTTAUDnIm) at regular intervals. When an interrupt is generated, the TAUDnTTOUTm signal toggles, resulting in a square wave.

Prerequisites

- The operation mode must be set to Interval Timer Mode, refer to **Table 23.44, Contents of the TAUDnCMORm register for Interval Timer Function**
- The channel output mode must be set to Independent Channel Output Mode 1, refer to **Section 23.7, Channel Output Modes**

Functional description

The counter is started by setting the channel trigger bit (TAUDnTS.TAUDnTSM) to 1. This in turn sets TAUDnTE.TAUDnTEM = 1, enabling count operation. The current value of TAUDnCDRm is written to TAUDnCNTm and the counter starts to count down from this value.

When the counter reaches 0000_H, INTTAUDnIm is generated and the TAUDnTTOUTm signal toggles. TAUDnCNTm then reloads the TAUDnCDRm value and subsequently continues operation.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1, which in turn sets TAUDnTE.TAUDnTEM to 0. TAUDnCNTm and TAUDnTTOUTm stop but retain their values. The counter can be restarted by setting TAUDnTS.TAUDnTSM to 1. The counter can also be forcibly restarted (without stopping it first) by setting TAUDnTS.TAUDnTSM to 1 during operation.

Conditions

If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt after a start or restart is not generated, and therefore TAUDnTTOUTm does not toggle. This results in an inverted TAUDnTTOUTm signal compared to when TAUDnCMORm.TAUDnMD0 is set to 1. For details refer to **Section 23.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts**.

23.12.1.2 Equations

$$\text{INTTAUDnIm cycle} = \text{count clock cycle} \times (\text{TAUDnCDRm} + 1)$$

$$\text{TAUDnTTOUTm square wave cycle} = \text{count clock cycle} \times (\text{TAUDnCDRm} + 1) \times 2$$

23.12.1.3 Block Diagram and General Timing Diagram

Figure 23.27 Block Diagram of Interval Timer Function

The following settings apply to the general timing diagram.

- INTTAUDnIm is generated at the beginning of operation (TAUDnCMORm.TAUDnMD0 = 1)

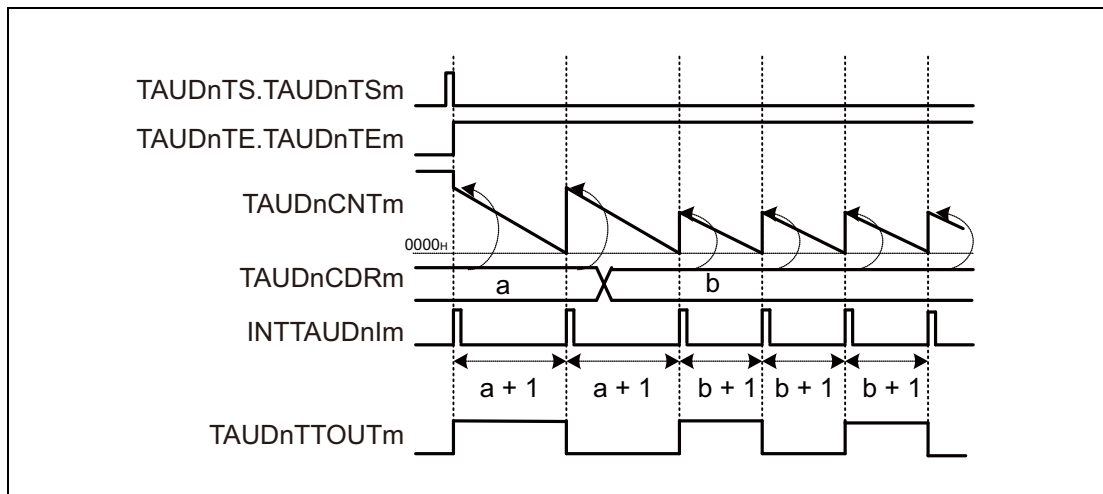

Figure 23.28 General Timing Diagram of Interval Timer Function

Table 23.45 Contents of the TAUDnCMURm register for Interval Timer Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode**Table 23.46 Control Bit Settings in Independent Channel Output Mode 1**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode. (the value after reset).
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROM	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	
TAUDnTME.TAUDnTMEm	0: Disables modulation

NOTE

The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUDnTOE.TAUDnTOEm = 0. TAUDnTOUTm can then be controlled independently of the interrupts. For details, see **Section 23.7, Channel Output Modes**.

(4) Simultaneous rewrite

The simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the interval timer function. Therefore, these registers should be set to 0.

Table 23.47 Simultaneous Rewrite Settings for Interval Timer Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

23.12.1.5 Operating Procedure for Interval Timer Function

Table 23.48 Operating Procedure for Interval Timer Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in Table 23.44, Contents of the TAUDnCMORm register for Interval Timer Function , and Table 23.45, Contents of the TAUDnCMURm register for Interval Timer Function .	Channel operation is stopped.
	Set the value of TAUDnCDRm register.	
	Set channel output mode by setting the control bits as described in Table 23.46, Control Bit Settings in Independent Channel Output Mode 1 .	
Start Operation	Set TAUDnTS.TAUDnTSM to 1. TAUDnTS.TAUDnTSM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is set to 1 and the counter starts. The TAUDnCDRm value is loaded in TAUDnCNTm. When TAUDnCMORm.TAUDnMD0 = 1, INTTAUDnIm is generated and TAUDnTTOUTm toggles.
	During Operation	<p>The TAUDnCDRm register value can be changed at any time. The TAUDnCNTm register can be read at all times.</p> <p>TAUDnCNTm counts down. When the counter reaches 0000_H:</p> <ul style="list-style-type: none"> The TAUDnCDRm value is loaded in TAUDnCNTm again and count operation continues. INTTAUDnIm is generated and TAUDnTTOUTm toggles.
Stop Operation	Set TAUDnTT.TAUDnTTM to 1. TAUDnTT.TAUDnTTM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart

23.12.1.6 Specific Timing Diagrams

(1) $TAUDnCDRm = 0000_H$, count clock = $PCLK/2$

Figure 23.29 $TAUDnCDRm = 0000_H$, Count Clock = $PCLK/2$

- If $TAUDnCDRm = 0000_H$ and the count clock = $PCLK/2$, the $TAUDnCDRm$ value is loaded into $TAUDnCNTm$ every count clock, meaning that $TAUDnCNTm$ is always 0000_H .
- $INTTAUDnIm$ is generated every count clock, resulting in $TAUDnTTOUTm$ toggling every count clock.

(2) TAUDnCDRm = 0000_H, count clock = PCLK**Figure 23.30 TAUDnCDRm = 0000_H, Count Clock = PCLK**

- If TAUDnCDRm = 0000_H and the count clock = PCLK, the TAUDnCDRm value is loaded into TAUDnCNTm every PCLK clock, meaning that TAUDnCNTm is always 0000_H.
- Though the first interrupt is generated, subsequent interrupts are not generated. TAUDTTOUTm is toggled every PCLK clock.

NOTE

INTTAUDnIm is fixed to the high level.

(3) Operation stop and restart

Figure 23.31 Operation Stop and Restart (TAUDnCMORM.TAUDnMD0 = 1)

- The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1. This sets TAUDnTE.TAUDnTEm to 0.
- TAUDnCNTm and TAUDnTTOUTm stop but retain their values.
- The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1.

(4) Forced restart (TAUDnCMORm.TAUDnMD0 = 1)

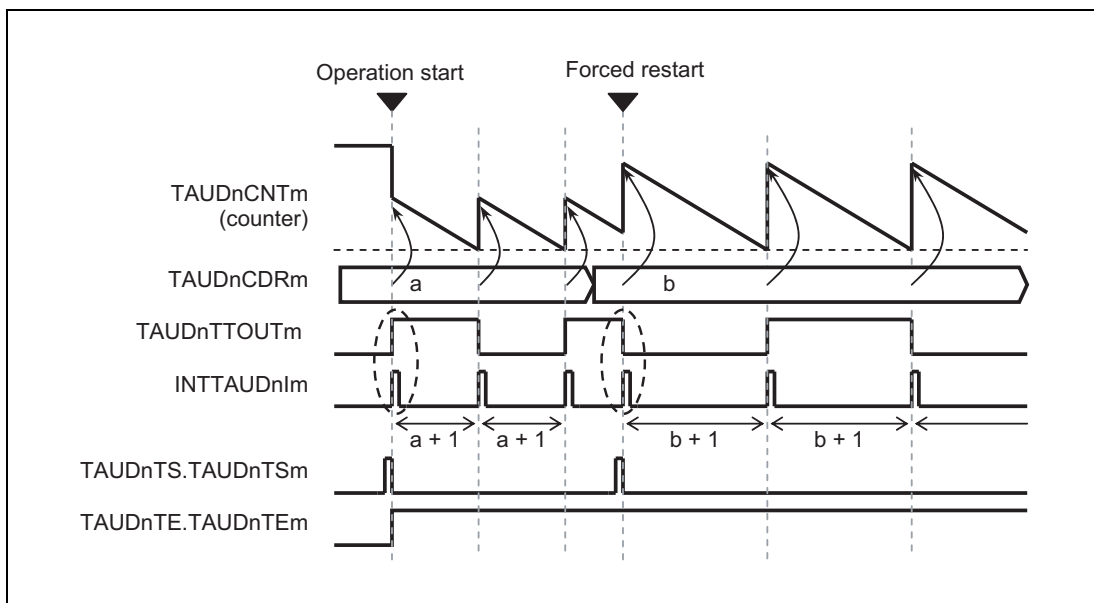

Figure 23.32 Forced Restart Operation (TAUDnCMORm.TAUDnMD0 = 1)

- The counter can be forcibly restarted (without stopping it first) by setting TAUDnTS.TAUDnTSm to 1 during operation.
- If the TAUDnCMORm.TAUDnMD0 bit is set to 1, the first interrupt after a start or restart is generated.
- When the counter is forcibly restarted, the TAUDnCDRm value is reflected in TAUDnCNTm and the counter starts.
A forced restart causes immediate reflection of changes to the value of TAUDnCDRm.
- When the counter is forcibly restarted, an interrupt (INTTAUDnIm) is generated and TAUDnTTOUTm is inverted.

(5) Forced restart ($TAUDnCMORm.TAUDnMD0 = 0$)

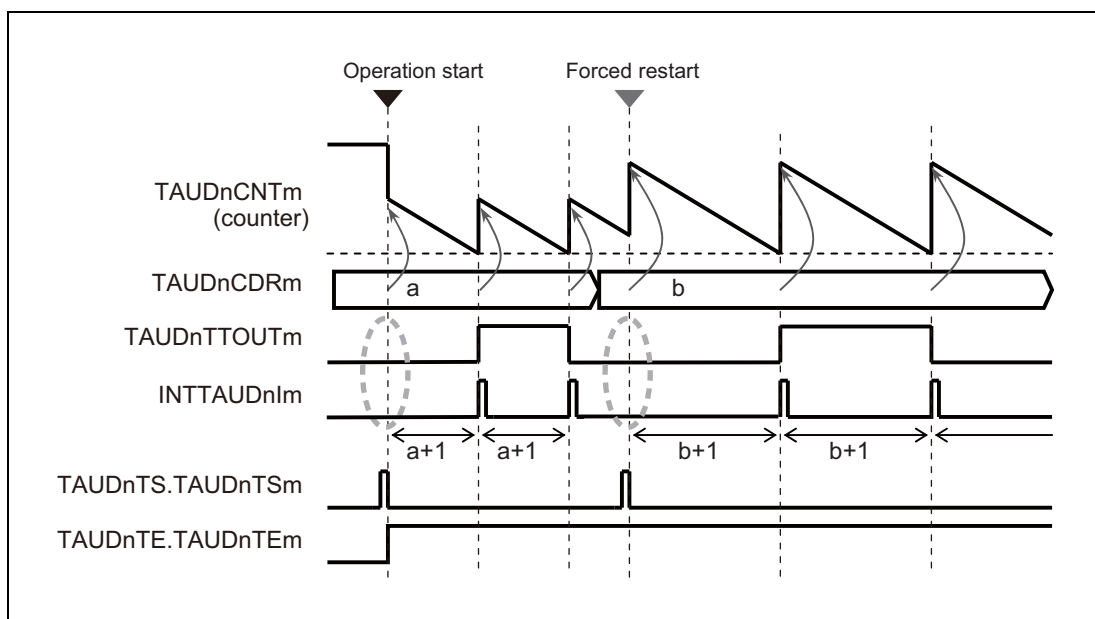

Figure 23.33 Forced Restart Operation ($TAUDnCMORm.TAUDnMD0 = 0$)

- When the counter is forcibly restarted, an interrupt (INTTAUDnIm) is not generated or TAUDnTOUTm is not inverted.

23.12.2 TAUDnTTINm Input Interval Timer Function

23.12.2.1 Overview

Summary

This function is used as a reference timer for generating timer interrupts (INTTAUDnIm) at regular intervals or when a valid TAUDnTTINm input edge is detected. When an interrupt is generated, the TAUDnTTOUTm signal toggles, resulting in a square wave.

Prerequisites

- The operating mode should be set to interval timer mode. See **Table 23.49, Contents of the TAUDnCMORm register for TAUDnTTINm Input Interval Timer Function.**
- The channel output mode should be set to independent channel output mode 1. See **Section 23.7, Channel Output Modes.**

Functional description

This function operates in an identical manner to the interval timer function (see **Section 23.12.1, Interval Timer Function**) except that this function is restarted by a valid TAUDnTTINm input edge. The type of edge used as a trigger is specified using the TAUDnCMURm.TAUDnTIS[1:0] bits. Either rising edge, falling edge, or rising and falling edge can be selected.

23.12.2.2 Equations

$$\text{INTTAUDnIm cycle} = \text{count clock cycle} \times (\text{TAUDnCDRm} + 1)$$

$$\text{TAUDnTTOUTm square wave cycle} = \text{count clock cycle} \times (\text{TAUDnCDRm} + 1) \times 2$$

23.12.2.3 Block Diagram and General Timing Diagram

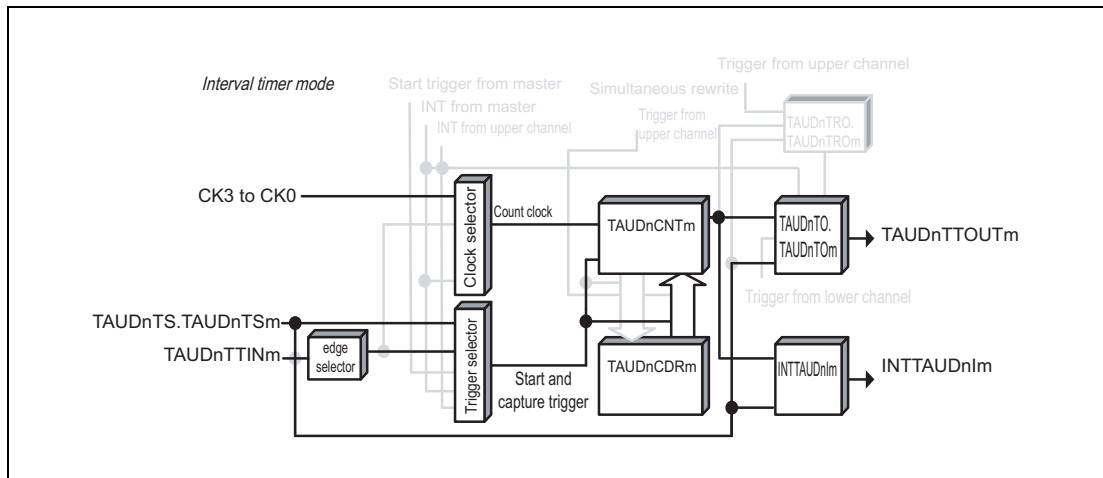

Figure 23.34 Block Diagram of TAUDnTTINm Input Interval Timer Function

The following settings apply to the general timing diagram.

- INTTAUDnIm is generated at the beginning of operation (TAUDnCMORm.TAUDnMD0 = 1).
- Rising edge detection (TAUDnCMURm.TAUDnTIS[1:0] = 01_B)

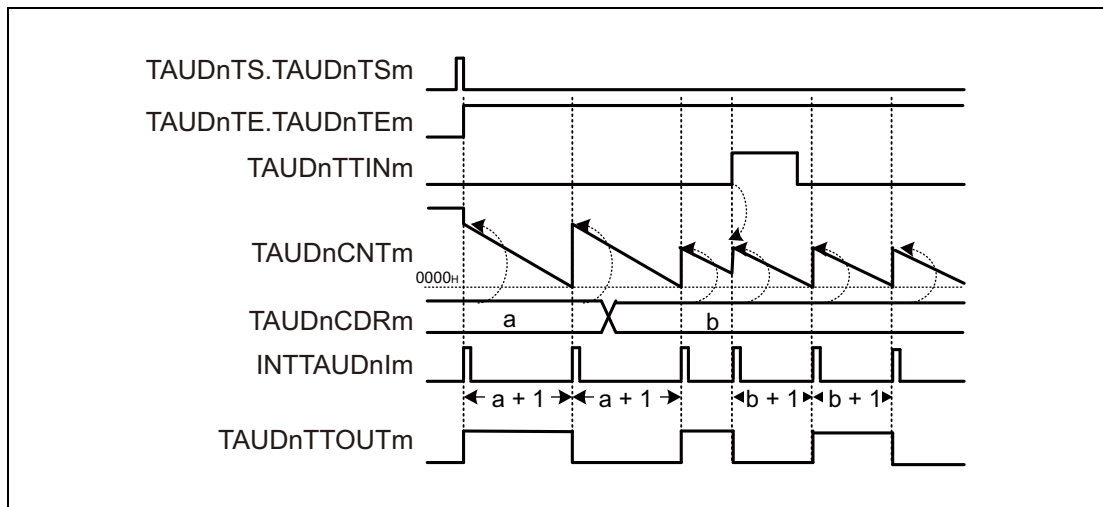

Figure 23.35 General Timing Diagram of TAUDnTTINm Input Interval Timer Function

TAUDnTRC.TAUDnTRCm	(TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTME.TAUDnTMEm	0: Disables modulation

NOTE

The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUDnTOE.TAUDnTOEm = 0. TAUDnTTOUTm can then be controlled independently of the interrupts. For details, see **Section 23.7, Channel Output Modes**.

(4) Simultaneous rewrite

The simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the TAUDnTTINm Input Interval Timer Function. Therefore, these registers should be set to 0.

Table 23.52 Simultaneous Rewrite Settings for TAUDnTTINm Input Interval Timer Function

23.12.2.4 Operating Procedure for TAUDnTTINm Input Interval Timer Function

Table 23.53 Operating Procedure for TAUDnTTINm Input Interval Timer Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in Table 23.49, Contents of the TAUDnCMORm register for TAUDnTTINm Input Interval Timer Function, and Table 23.50, Contents of the TAUDnCMURm register for TAUDnTTINm Input Interval Timer Function.	Channel operation is stopped.
	Set the value of TAUDnCDRm register.	
	Set channel output mode by setting the control bits as described in Table 23.51, Control Bit Settings in Independent Channel Output Mode 1.	
Restart	Start Operation Set TAUDnTS.TAUDnTSM to 1. TAUDnTS.TAUDnTSM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is set to 1 and the counter starts. The TAUDnCDRm value is loaded in TAUDnCNTm. When TAUDnCMORm.TAUDnMD0 = 1, INTTAUDnIm is generated and TAUDnTTOUTm toggles.
	During Operation The values of the TAUDnCMURm.TAUDnTIS[1:0] and the TAUDnCDRm register are changeable at any time. The TAUDnCNTm register can be read at all times. Detection of TAUDnTTINm edge	TAUDnCNTm counts down. When the counter reaches 0000H: <ul style="list-style-type: none"> The TAUDnCDRm value is loaded in TAUDnCNTm again and count operation continues. INTTAUDnIm is generated and TAUDnTTOUTm toggles. When a TAUDnTTINm input valid edge is detected during count operation, the TAUDnCDRm value is loaded in TAUDnCNTm and count operation continues. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTM to 1. TAUDnTT.TAUDnTTM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

23.12.2.5 Specific Timing Diagrams

The timing diagrams in **Section 23.12.1, Interval Timer Function** apply, and in addition, the counter can also be restarted by a valid TAUDnTTINm input edge without using this function.

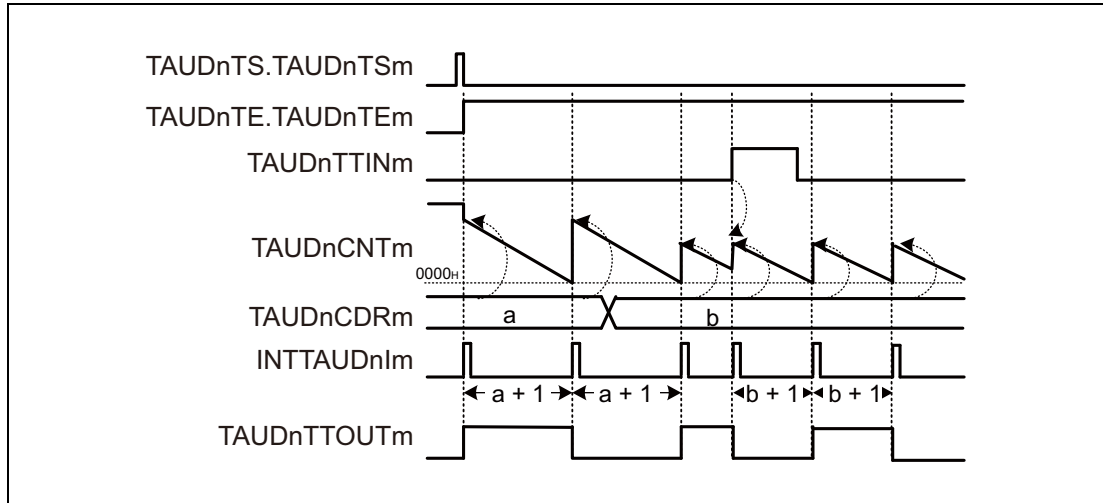

Figure 23.36 Counter Triggered by Rising TAUDnTTINm Input Edge
(TAUDnCMURm.TAUDnTIS[1:0] = 01_B), TAUDnCMORm.TAUDnMD0 = 1

- If a valid TAUDnTTINm input edge is detected, an interrupt is generated which causes TAUDnTTOUTm to toggle. In this example, the valid edge is a rising edge (TAUDnCMURm.TAUDnTIS[1:0] = 01_B).

23.12.3 Clock Divider Function

23.12.3.1 Overview

Summary

This function is used as a frequency divider. The frequency of the input signal TAUDnTTINm is divided by a factor related to TAUDnCDRm, and the resulting signal is output to TAUDnTTOUTm.

Prerequisites

- TAUDnTTINm should have a fixed frequency.
- The operating mode should be set to interval timer mode. (See **Table 23.54, Contents of the TAUDnCMORm register for Clock Divider Function.**)
- The channel output mode should be set to independent channel output mode 1. (See **Section 23.7, Channel Output Modes.**)

Functional description

The counter is started by setting the channel trigger bit (TAUDnTS.TAUDnTSM) to 1. This in turn sets TAUDnTE.TAUDnTEM = 1, enabling count operation. The current value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from this value, using TAUDnTTINm as a count clock.

When the counter value reaches 0000_H, INTTAUDnIm occurs and TAUDnTTOUTm signal is toggled. Then, TAUDnCDRm value is loaded into TAUDnCNTm to continue operation subsequently.

The value of TAUDnCDRm can be rewritten at any time. The changed value of TAUDnCDRm is applied when the counter starts to count down next time.

The counter can be stopped by setting TAUDnTT.TAUDnTTm = 1. This sets TAUDnTE.TAUDnTEM = 0. TAUDnCNTm and TAUDnTTOUTm stop but retain their values. The function can be restarted by setting TAUDnTS.TAUDnTSM = 1. The counter can also be forcibly restarted without making a stop by setting TAUDnTS.TAUDnTSM = 1 during operation (forced restart).

Conditions

If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt after a start or restart is not generated, and therefore TAUDnTTOUTm does not toggle. This results in an inverted TAUDnTTOUTm signal compared to when TAUDnCMORm.TAUDnMD0 is set to 1. For details, see **Section 23.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts.**

NOTE

TAUDnTTINm input signals are sampled at the frequency of the operating clock set by TAUDnCMORm.TAUDnCKS[1:0] bits. Therefore, the TAUDnTTOUTm output clock cycle has an error of ± 1 operating clock cycle.

23.12.3.2 Equations

- When rising edge detection is selected:
 $TAUDnTTOUTm \text{ frequency} = TAUDnTTINm \text{ frequency} / [(TAUDnCDRm + 1) \times 2]$
- When falling edge detection is selected:
 $TAUDnTTOUTm \text{ frequency} = TAUDnTTINm \text{ frequency} / [(TAUDnCDRm + 1) \times 2]$
- When falling and rising edge detection is selected:
 $TAUDnTTOUTm \text{ frequency} = TAUDnTTINm \text{ frequency} / (TAUDnCDRm + 1)$

23.12.3.3 Block Diagram and General Timing Diagram

Figure 23.37 Block Diagram of Clock Divider Function

The following settings apply to the general timing diagram.

- INTTAUDnIm generated at the beginning of operation. ($TAUDnCMORm.TAUDnMD0 = 1$)
- Detection of rising edge ($TAUDnCMURm.TAUDnTIS[1:0] = 01_B$)

23.12.3.5 Operating Procedure for Clock Divider Function

Table 23.58 Operating Procedure for Clock Divider Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in Table 23.54, Contents of the TAUDnCMORm register for Clock Divider Function , and Table 23.55, Contents of the TAUDnCMURm register for Clock Divider Function .	Channel operation is stopped.
	Set the value of TAUDnCDRm register.	
	Set channel output mode by setting the control bits as described in Table 23.56, Control Bit Settings in Independent Channel Output Mode 1 .	
Restart	Start Operation Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCNTm loads TAUDnCDRm value. If TAUDnCMORm.TAUDnMD0 is set to 1, INTTAUDnIm occurs and TAUDnTTOUTm is toggled.
	During Operation The value of TAUDnCDRm is changeable at any time. The TAUDnCNTm register can be read at all times.	TAUDnCNTm counts down each time TAUDnTTINm input edge is detected. When the counter reaches 0000 _H : <ul style="list-style-type: none"> • TAUDnCDRm value is loaded in TAUDnCNTm and count operation continues. • INTTAUDnIm is generated. • TAUDnTTOUTm is toggled. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops. TAUDnCNTm and TAUDnTTOUTm retain their current values.

23.12.3.6 Specific Timing Diagrams

(1) TAUDnCDRm = 0000H

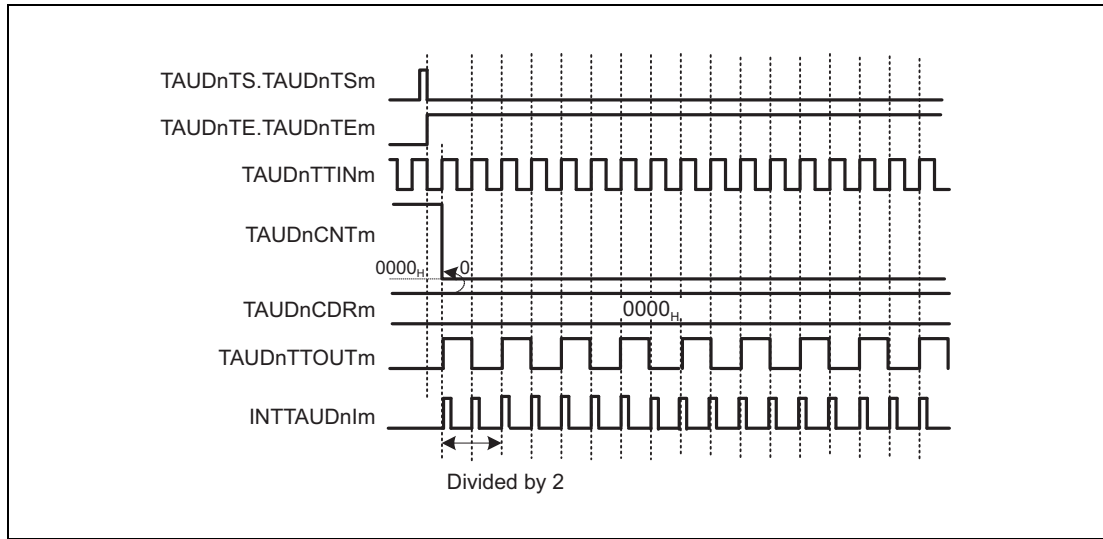

Figure 23.39 TAUDnCDRm = 0000H, TAUDnCMORm.TAUDnMD0 = 1, TAUDnCMURm.TAUDnTIS[1:0] = 01B

- If TAUDnCDRm is 0000H, TAUDnCNTm is always 0000H.
- INTTAUDnIm is generated every count clock, resulting in TAUDnTTOUTm toggling every count clock

Figure 23.39 shows an operation timing example. Actually, there is a delay from TINm detection until TOUTm output because of the delay time of a noise filter or synchronization circuit placed between the TAUDnIm pin and TAUDn.

(2) Operation restart

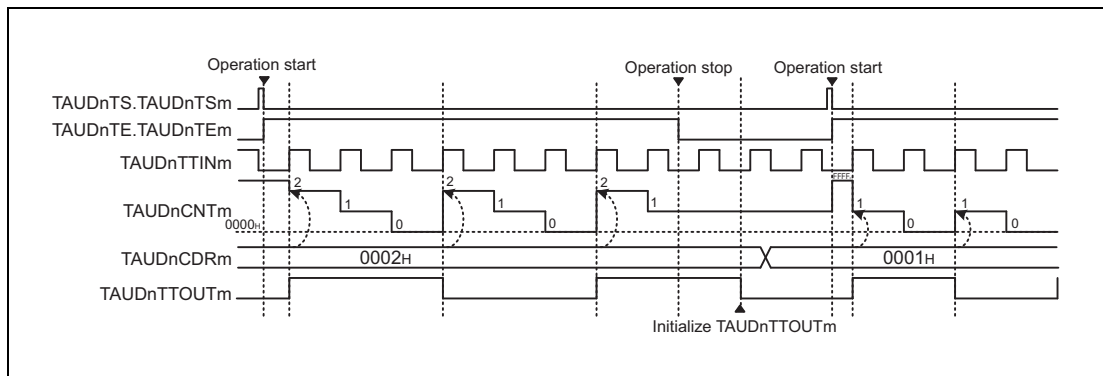

Figure 23.40 Operation Restart (TAUDnCMORm.TAUDnMD0 = 1, TAUDnCMURm.TAUDnTIS[1:0] = 01B)

To reset the value of TAUDnTTOUTm:

- Set TAUDnTOE.TAUDnTOEm = 0 when the counter is stopped (TAUDnTE.TAUDnTEm = 0).
- Then, write either 0 or 1 to TAUDnTO.TAUDnTOM to set the new start value of TAUDnTTOUTm.

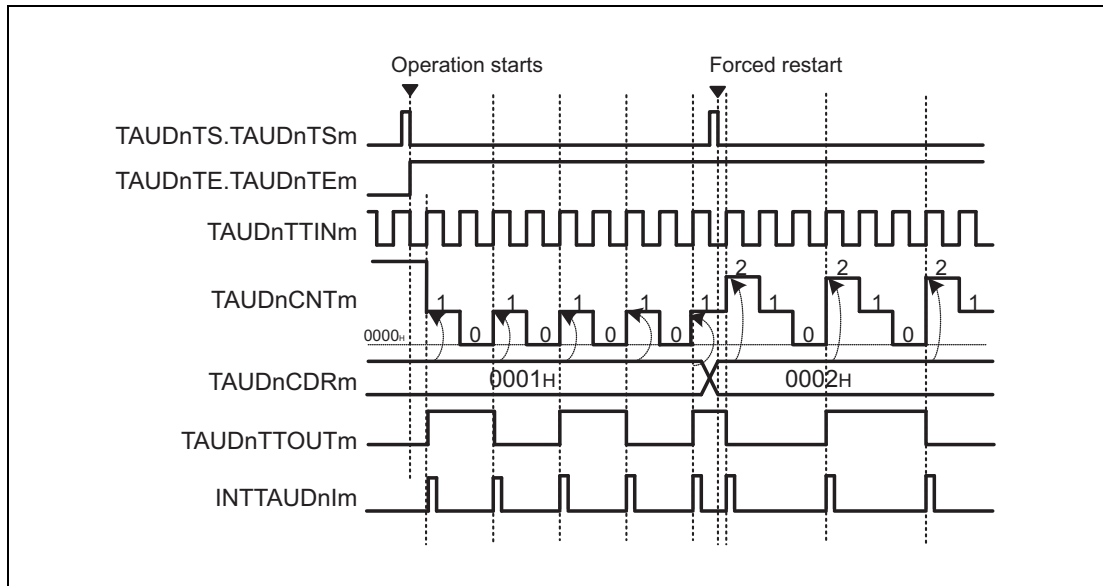

(3) Forced restart

Figure 23.41 Forced Restart Operation
 (TAUDnCMORm.TAUDnMD0 = 1, TAUDnCMURm.TAUDnTIS[1:0] = 01_B)

- The counter can be forcibly restarted (without stopping it first) by setting TAUDnTS.TAUDnTSm = 1 during operation.
- The value of TAUDnCDRm is written to TAUDnCNTm and the count operation restarts.
- TAUDnTTOUTm restarts at the same level as before the forced restart.

23.12.4 External Event Count Function

23.12.4.1 Overview

Summary

This function is used as an event timer, which generates an interrupt (INTTAUDnIm) when a specific number of TAUDnTTINm input valid edge has been detected.

Prerequisites

- The operating mode should be set to the event count mode. (See **Table 23.59, Contents of the TAUDnCMORm register for External Event Count Function.**)
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSM) to 1. This in turn sets TAUDnTE.TAUDnTEM = 1, enabling count operation. When the counter starts, the current value of TAUDnCDRm is loaded into TAUDnCNTm.

When a valid TAUDnTTINm input edge is detected, the value of TAUDnCNTm decrements by 1. TAUDnCNTm retains this value until a valid TAUDnTTINm input edge is detected or the counter is restarted.

When the valid edge is detected for the (TAUDnCDRm + 1) times, INTTAUDnIm is generated. Then, TAUDnCDRm value is loaded into TAUDnCNTm to continue operation subsequently.

The counter can be stopped by setting TAUDnTT.TAUDnTTM to 1. This sets TAUDnTE.TAUDnTEM to 0. The counter can be restarted by setting TAUDnTS.TAUDnTSM to 1. The counter can also be restarted without stopping it first (forced restart) by setting TAUDnTS.TAUDnTSM to 1 during operation.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

Conditions

An edge type used as a trigger is specified by TAUDnCMURm.TAUDnTIS[1:0] bits.

- When TAUDnCMURm.TAUDnTIS[1:0] = 00_B, falling edges are counted.
- When TAUDnCMURm.TAUDnTIS[1:0] = 01_B, rising edges are counted.
- When TAUDnCMURm.TAUDnTIS[1:0] = 10_B, both edges are counted.

23.12.4.2 Equations

Number of valid edges detected before INTTAUDnIm generation = TAUDnCDRm + 1

23.12.4.5 Operating Procedure for External Event Count Function**Table 23.62 Operating Procedure for External Event Count Function**

Operation	TAUDn Status
Initial Channel Setting Set TAUDnCMORm and TAUDnCMURm registers as described in Table 23.59, Contents of the TAUDnCMORm register for External Event Count Function , and Table 23.60, Contents of the TAUDnCMURm register for External Event Count Function . Set the value of TAUDnCDRm register.	Channel operation is stopped.
Restart Start Operation Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCNTm loads TAUDnCDRm value and waits for TAUDnTTINm input edge detection.
During Operation Detection of TAUDnTTINm edge The value of TAUDnCDRm is changeable at any time. The TAUDnCNTm register can be read at any time.	TAUDnCNTm counts down each time TAUDnTTINm input edge is detected. When an effective edge is detected (TAUDnCDRm + 1) times: <ul style="list-style-type: none"> • TAUDnCDRm value is loaded in TAUDnCNTm and count operation continues. • INTTAUDnIm is generated. Afterwards, this procedure is repeated.
Stop Operation Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

23.12.4.6 Specific Timing Diagrams

(1) TAUDnCDRm = 0000_H

Figure 23.44 TAUDnCDRm = 0000_H, TAUDnCMURm.TAUDnTIS[1:0] = 01_B

- If 0000_H = TAUDnCDRm, 0000_H is loaded into TAUDnCNTm each time a valid TAUDnTTINm input edge is detected.
In other words, INTTAUDnIm occurs each time a valid TAUDnTTINm input edge is detected.

(2) Operation stop and restart

Figure 23.45 Operation Stop and Restart (TAUDnCMURm.TAUDnTIS[1:0] = 01_B)

- The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1. This sets TAUDnTE.TAUDnTEM to 0.
- TAUDnCNTm stops and retains its current value. TAUDnTTINm continues and TAUDnCNTm ignores the valid edge.
- The counter can be restarted by setting TAUDnTS.TAUDnTSM to 1. TAUDnCNTm loads the TAUDnCDRm value and restarts count operation.

(3) Forced restart

Figure 23.46 Forced Restart Operation (TAUDnCMURm.TAUDnTIS[1:0] = 01_B)

Once a forced restart is made, the changed TAUDnCDRm value is applied to TAUDnCNTm.

- The counter can be restarted without making a stop by setting TAUDnTS.TAUDnTSm to 1 during operation.
- The value of TAUDnCDRm is loaded into TAUDnCNTm and the counter awaits the next valid TAUDnTTINm input edge.

23.12.5 Delay Count Function

23.12.5.1 Overview

Summary

This function generates interrupts (INTTAUDnIm), which have a defined delay to the TAUDnTTINm input signal. TAUDnTTINm input signal pulses that occur within the delay period are ignored.

Prerequisites

- The operating mode should be set to one-count mode. See **Table 23.63, Contents of the TAUDnCMORm register for Delay Count Function.**
- TAUDnTTOUTm is not used with this function.
- Start trigger detection should be disabled during counting (TAUDnCMORm.TAUDnMD0 = 0).

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation.

The counter starts when a valid TAUDnTTINm input start edge is detected. The value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from the TAUDnCDRm value.

When the counter reaches 0000_H, an interrupt is generated. The counter returns to FFFF_H and awaits the next valid TAUDnTTINm input edge.

When the counter is counting down, further TAUDnTTINm input signals are ignored, i.e., the counter does not reset.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

Conditions

The type of edge used as a trigger is specified by the TAUDnCMURm.TAUDnTIS[1:0] bits:

- If TAUDnCMURm.TAUDnTIS[1:0] = 00_B, falling edges trigger the counter.
- If TAUDnCMURm.TAUDnTIS[1:0] = 01_B, rising edges trigger the counter.
- If TAUDnCMURm.TAUDnTIS[1:0] = 10_B, rising and falling edges trigger the counter.

23.12.5.2 Equations

Delay between TAUDnTTINm and INTTAUDnIm = count clock cycle × (TAUDnCDRm + 1)

	Set the value of TAUDnCDRm register.	
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and TAUDnCNTm waits for detection of the TAUDnTTINm start edge.
	Detection of TAUDnTTINm start edge	When a start edge is detected, the TAUDnCDRm value is loaded in TAUDnCNTm.
During Operation	The TAUDnCDRm register value can be changed at any time. The TAUDnCNTm register can be read at all times.	TAUDnCNTm counts down. When the counter reaches 0000 _H , INTTAUDnIm is generated. TAUDnCNTm stops counting, returns FFFF _H , and waits for a trigger.
		If a trigger occurs while TAUDnCNTm is counting, the trigger is ignored. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its value.

Restart

23.12.6 One-Pulse Output Function

23.12.6.1 Overview

Summary

This function generates an interrupt (INTTAUDnIm) when a valid TAUDnTTINm input edge is detected and at a defined interval afterward. TAUDnTTINm input signal pulses that occur within the defined interval are ignored. When an interrupt is generated, the TAUDnTTOUTm signal toggles, resulting in a square wave.

Prerequisites

- The operating mode should be set to pulse one-count mode. (See **Table 23.67, Contents of the TAUDnCMORm register for One-Pulse Output Function.**)
- The channel output mode should be set to independent channel output mode 2. (See **Section 23.7, Channel Output Modes.**)

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSM) to 1. This in turn sets TAUDnTE.TAUDnTEM = 1, enabling count operation.

The counter starts when a valid TAUDnTTINm input edge is detected. The value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from the TAUDnCDRm value. An interrupt is generated and TAUDnTTOUTm is set to the active level.

When the counter reaches 0001_H, an interrupt is generated and TAUDnTTOUTm is set to the inactive level. The counter stops at 0000_H and awaits the next valid TAUDnTTINm input edge.

When the counter is counting down, further TAUDnTTINm input signals are ignored, i.e., the counter does not reset.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

Conditions

The type of edge used as a trigger is specified by the TAUDnCMURm.TAUDnTIS[1:0] bits:

- If TAUDnCMURm.TAUDnTIS[1:0] = 00_B, falling edges trigger the counter.
- If TAUDnCMURm.TAUDnTIS[1:0] = 01_B, rising edges trigger the counter.
- If TAUDnCMURm.TAUDnTIS[1:0] = 10_B, rising and falling edges trigger the counter.

23.12.6.2 Equations

Interval between TAUDnTTINm and INTTAUDnIm = TAUDnTTOUTm (timer output) width = count clock cycle × TAUDnCDRm

23.12.6.5 Operating Procedure for One-Pulse Output Function

Table 23.71 Operating Procedure for One-Pulse Output Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in Table 23.67, Contents of the TAUDnCMORm register for One-Pulse Output Function, and Table 23.68, Contents of the TAUDnCMURm register for One-Pulse Output Function.	Channel operation is stopped.
	Set the value of TAUDnCDRm register.	
	Set channel output mode by setting the control bits as described in Table 23.69, Control Bit Settings in Independent Channel Output Mode 2.	
Start Operation	Set TAUDnTS.TAUDnTSM to 1. TAUDnTS.TAUDnTSM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is set to 1 and TAUDnCNTm waits for detection of the TAUDnTTINm start edge.
	Detection of TAUDnTTINm start edge	When a start edge is detected, TAUDnCNTm loads the TAUDnCDRm value.
During Operation	The value of TAUDnCDRm is changeable at any time. The TAUDnCNTm register can be read at all times.	INTTAUDnIm is generated when TAUDnCNTm starts and TAUDnTTOUTm is set to its active level. TAUDnCNTm counts down. When the counter reaches 0001 _H : <ul style="list-style-type: none"> • INTTAUDnIm is generated. • TAUDnTTOUTm is set to its inactive level. TAUDnCNTm stops counting and waits for a trigger.
		If a trigger occurs while TAUDnCNTm is counting, the trigger is ignored.
Stop Operation	Set TAUDnTT.TAUDnTTM to 1. TAUDnTT.TAUDnTTM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

23.12.7 TAUDnTTINm Input Pulse Interval Measurement Function

23.12.7.1 Overview

Summary

This function captures the count value and uses this value and the overflow bit TAUDnCSRm.TAUDnOVF to measure the interval of the TAUDnTTINm input signals.

Prerequisites

- The operating mode should be set to capture mode. See **Table 23.73, Contents of the TAUDnCMORm register for TAUDnTTINm Input Pulse Interval Measurement Function**.
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is started by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The counter TAUDnCNTm starts to count up from 0000_H. When a valid TAUDnTTINm edge is detected, the value of TAUDnCNTm is captured, transferred to TAUDnCDRm, and an interrupt INTTAUDnIm is generated. The counter resets to 0000_H and subsequently continues operation.

If the counter reaches FFFF_H before a valid TAUDnTTINm edge is detected, it overflows. The counter is reset to 0000_H and subsequently continues operation. The values transferred to TAUDnCDRm and TAUDnCSRm.TAUDnOVF respectively depend on the values of bits TAUDnCMORm.TAUDnCOS[1:0].

Table 23.72 Effects of Overflow

TAUDnCMORm. TAUDnCOS[1:0]	When Overflow Occurs		When a Valid TAUDnTTINm Input is Detected	
	TAUDnCDRm	TAUDnCSRm. TAUDnOVF	TAUDnCDRm, TAUDnCNTm	TAUDnCSRm. TAUDnOVF
00	Unchanged	0	TAUDnCNTm loaded into TAUDnCDRm	1
01		1		
10	Set to FFFF _H	0	TAUDnCNTm set to 0, TAUDnCDRm unchanged	Unchanged
11		1		

When TAUDnCMORm.TAUDnCOS[0] = 1, the overflow bit (TAUDnCSRm.TAUDnOVF) can be cleared only by setting TAUDnCSCm.TAUDnCLOV = 1.

The combination of the value of TAUDnCDRm and TAUDnCSRm.TAUDnOVF can be used to deduce the interval of the TAUDnTTINm signal. However, if an overflow occurs multiple times before a valid TAUDnTTINm input is detected, the overflow bit TAUDnCSRm.TAUDnOVF cannot indicate the occurrence of multiple overflows.

The function can be stopped by setting TAUDnTT.TAUDnTTm = 1. This sets TAUDnTE.TAUDnTEm = 0. TAUDnCNTm stops but retains its value. While the function is stopped, valid TAUDnTTINm input edge detection and TAUDnCNTm capture are not performed.

Conditions

If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details, see **Section 23.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts.**

NOTE

When TAUDnCMORm.TAUDnCOS[1] = 1, the value of TAUDnCNTm is not loaded into TAUDnCDRm when the first valid TAUDnTTINm input edge occurs after an overflow. However, an interrupt is generated.

23.12.7.2 Equations

TAUDnTTINm input pulse interval = count clock cycle \times [(TAUDnCSRm.TAUDnOVF \times (FFFF_H + 1)) + TAUDnCDRm capture value + 1]

23.12.7.3 Block Diagram and General Timing Diagram

Figure 23.51 Block Diagram of TAUDnTTINm Input Pulse Interval Measurement Function

The following settings apply to the general timing diagram.

- INTTAUDnIm not generated at the beginning of operation (TAUDnCMORm.TAUDnMD0 = 0)
- Falling edge detection (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)
- When a valid TAUDnTTINm input is detected after an overflow, TAUDnCDRm is changed and TAUDnCSRm.TAUDnOVF is set to 1 (TAUDnCMORm.TAUDnCOS[1:0] = 00_B)

(3) Channel output mode

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used with this function.

(4) Simultaneous rewrite

The simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the TAUDnTTINm input pulse interval measurement function. Therefore, these registers should be set to 0.

Table 23.75 Simultaneous Rewrite Settings for TAUDnTTINm Input Pulse Interval Measurement Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

23.12.7.5 Operating Procedure for TAUDnTTINm Input Pulse Interval Measurement Function

Table 23.76 Operating Procedure for TAUDnTTINm Input Pulse Interval Measurement Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORM and TAUDnCMURm registers as described in Table 23.73, Contents of the TAUDnCMORM register for TAUDnTTINm Input Pulse Interval Measurement Function , and Table 23.74, Contents of the TAUDnCMURm register for TAUDnTTINm Input Pulse Interval Measurement Function .	Channel operation is stopped.
	TAUDnCDRm register operates as a capture register.	
Restart	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCNTm is cleared to 0000 _H . INTTAUDnIm is generated when TAUDnCMORM.TAUDnMD0 is set to 1.
During Operation	Detection of TAUDnTTINm edge The TAUDnCMURm.TAUDnTIS[1:0] bits can be changed at any time. The TAUDnCDRm and TAUDnCSRm registers can be read at any time. TAUDnCSCm.TAUDnCLOV can be written to 1. (TAUDnCSRm.TAUDnOVF bit is cleared to 0.)	TAUDnCNTm starts to count up from 0000 _H . When a TAUDnTTINm valid edge is detected: <ul style="list-style-type: none"> TAUDnCNTm transfers (captures) its value to TAUDnCDRm, and returns to 0000_H. INTTAUDnIm is then generated. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and both it and TAUDnCSRm.TAUDnOVF retain their current values.

23.12.7.6 Specific Timing Diagrams: Overflow Operation

(1) TAUDnCMORm.TAUDnCOS[1:0] = 00_B

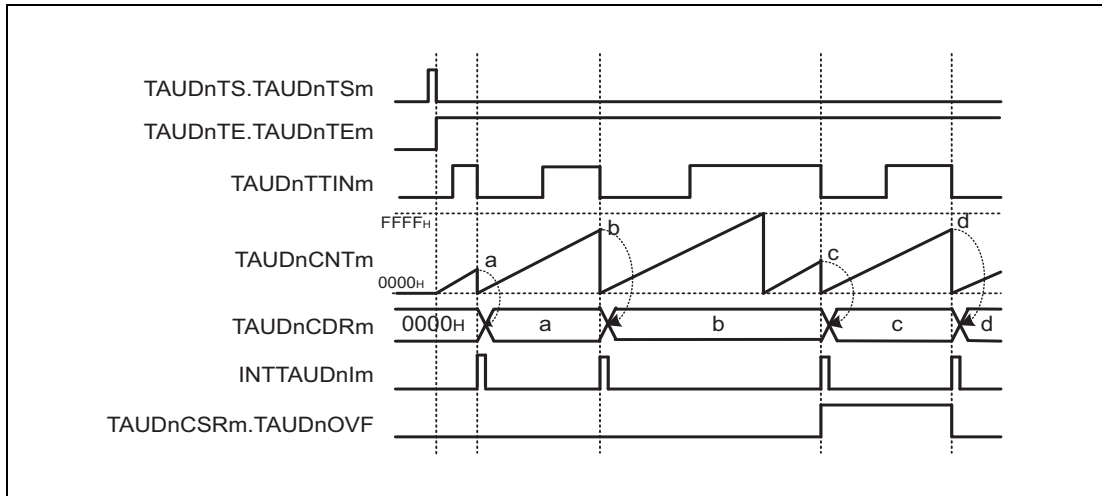

Figure 23.53 TAUDnCMORm.TAUDnCOS[1:0] = 00_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUDnCDRm remains unchanged and TAUDnCSRm.TAUDnOVF remains = 0.
- Upon detection of the next valid TAUDnTTINm input edge, the value of TAUDnCNTm is loaded into TAUDnCDRm and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge with no overflow occurring, TAUDnCSRm.TAUDnOVF is cleared to 0.

(2) TAUDnCMORm.TAUDnCOS[1:0] = 01_B

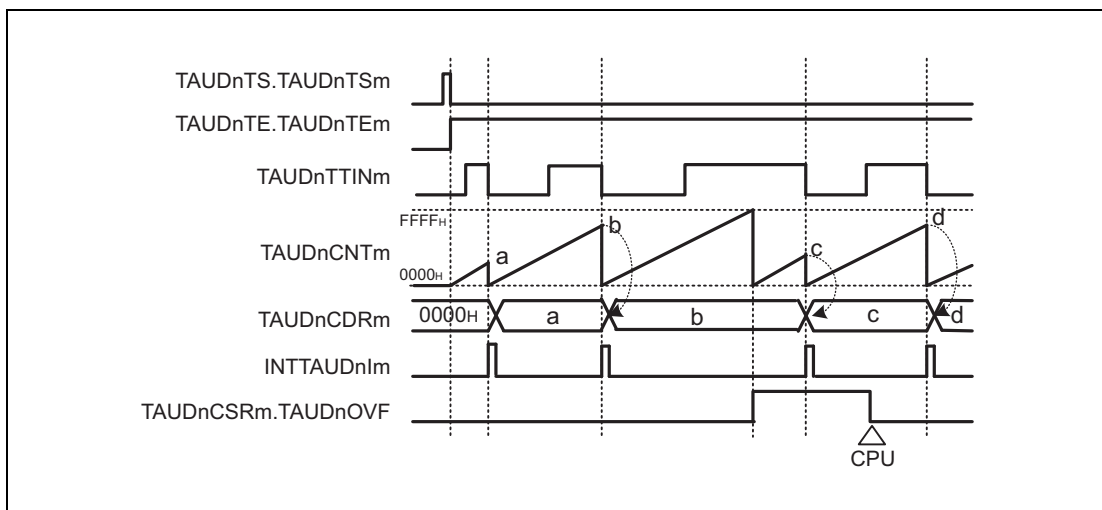

Figure 23.54 TAUDnCMORm.TAUDnCOS[1:0] = 01_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUDnCDRm remains unchanged and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge, the value of TAUDnCNTm is loaded into TAUDnCDRm.
- TAUDnCSRm.TAUDnOVF is only cleared by a CPU command (by setting TAUDnCSCm.TAUDnCLOV bit to 1).

(3) TAUDnCMORm.TAUDnCOS[1:0] = 10_B

Figure 23.55 TAUDnCMORm.TAUDnCOS[1:0] = 10_B, TAUDnCMORm.TAUDnMDO = 0, TAUDnCMURm.TAUDnTIS[1:0] = 00_B

- When an overflow occurs, TAUDnCDRm is set to FFFF_H and TAUDnCSRm.TAUDnOVF remains = 0.
- Upon detection of the next valid TAUDnTTINm input edge, TAUDnCNTm is reset to 0, but TAUDnCDRm and TAUDnCSRm.TAUDnOVF remain unchanged.
- Thus, the next valid TAUDnTTINm input edge after the overflow is ignored.

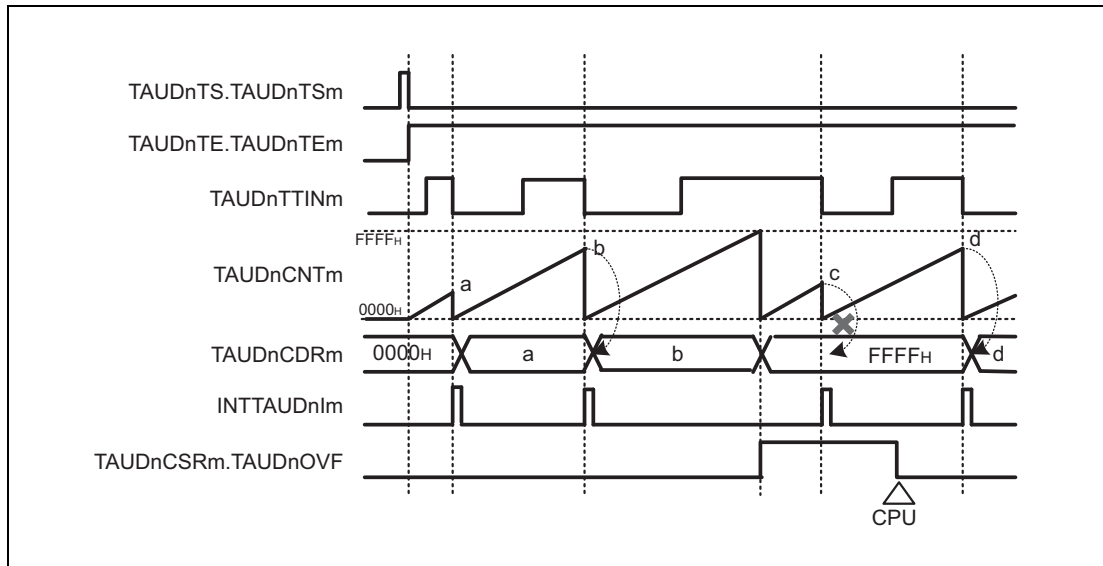

(4) TAUDnCMORm.TAUDnCOS[1:0] = 11_B

Figure 23.56 TAUDnCMORm.TAUDnCOS[1:0] = 11_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 00_B

- When an overflow occurs, TAUDnCDRm is set to FFFF_H and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge, TAUDnCNTm is reset to 0, but TAUDnCDRm and TAUDnCSRm.TAUDnOVF remain unchanged.
- Thus, the next valid TAUDnTTINm input edge after the overflow is ignored.
- TAUDnCSRm.TAUDnOVF is cleared by setting TAUDnCSCm.TAUDnCLOV to 1.

23.12.8 TAUDnTTINm Input Signal Width Measurement Function

23.12.8.1 Overview

Summary

This function measures the width of a TAUDnTTINm signal, by starting the count at one edge of TAUDnTTINm and capturing the count value at the other edge.

Prerequisites

- The operating mode should be set to capture and one-count mode. See **Table 23.78, Contents of the TAUDnCMORm register for TAUDnTTINm Input Signal Width Measurement Function**.
- TAUDnTTOUTm is not used with this function.
- TAUDnCMORm.TAUDnMD0 should be set to 0.

Functional description

The counter is started by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation. When a valid TAUDnTTINm start edge is detected, the counter TAUDnCNTm starts to count up from 0000_H. When a valid TAUDnTTINm stop edge is detected, the value of TAUDnCNTm is captured, transferred to TAUDnCDRm, and an interrupt INTTAUDnIm is generated. The counter retains its value (CDRn + 1) and awaits the next valid TAUDnTTINm input start edge.

If the counter reaches FFFF_H before a valid TAUDnTTINm stop edge is detected, it overflows. The counter is reset to 0000_H and subsequently continues operation. The values transferred to TAUDnCDRm and TAUDnCSRm.TAUDnOVF respectively depend on the values of bits TAUDnCMORm.TAUDnCOS[1:0].

Table 23.77 Effects of Overflow

TAUDnCMORm. TAUDnCOS[1:0]	When Overflow Occurs		When a Valid TAUDnTTINm Input Stop Edge is Detected	
	TAUDnCDRm	TAUDnCSRm. TAUDnOVF	TAUDnCDRm, TAUDnCNTm	TAUDnCSRm. TAUDnOVF
00	Unchanged	0	TAUDnCNTm loaded into TAUDnCDRm	1
01		1		
10	Set to FFFF _H	0	TAUDnCNTm stops counting TAUDnCDRm unchanged	Unchanged
11		1		

When TAUDnCMORm.TAUDnCOS[0] = 1, overflow bit TAUDnCSRm.TAUDnOVF can be cleared only by setting TAUDnCSCm.TAUDnCLOV to 1.

The combination of the value of TAUDnCDRm and TAUDnCSRm.TAUDnOVF can be used to deduce the width of the TAUDnTTINm signal. However, if an overflow occurs multiple times before a valid TAUDnTTINm input is detected, overflow bit TAUDnCSRm.TAUDnOVF cannot indicate the occurrence of multiple overflows.

This function cannot be forcibly restarted.

NOTE

When TAUDnCMORm.TAUDnCOS[1] = 1, the value of TAUDnCNTm is not loaded to TAUDnCDRm when the first valid TAUDnTTINm input edge occurs after an overflow. However, an interrupt is generated.

23.12.8.2 Equations

$$\text{TAUDnTTINm input signal width} = \text{count clock cycle} \times [(\text{TAUDnCSRm.TAUDnOVF} \times (\text{FFFF}_H + 1)) + \text{TAUDnCDRm capture value} + 1]$$

23.12.8.3 Block Diagram and General Timing Diagram

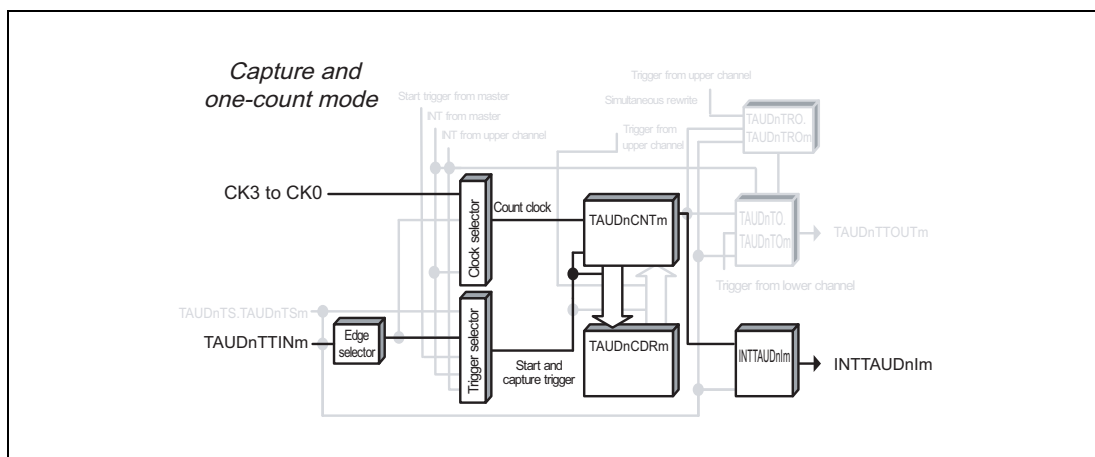

Figure 23.57 Block Diagram of TAUDnTTINm Input Signal Width Measurement Function

The following settings apply to the general timing diagram.

- Detection of rising and falling edges = high width measurement
(TAUDnCMURm.TAUDnTIS[1:0] = 11_B)
- When a valid TAUDnTTINm input is detected after an overflow, TAUDnCDRm is changed and TAUDnCSRm.TAUDnOVF is set to 1. (TAUDnCMORm.TAUDnCOS[1:0] = 00_B)

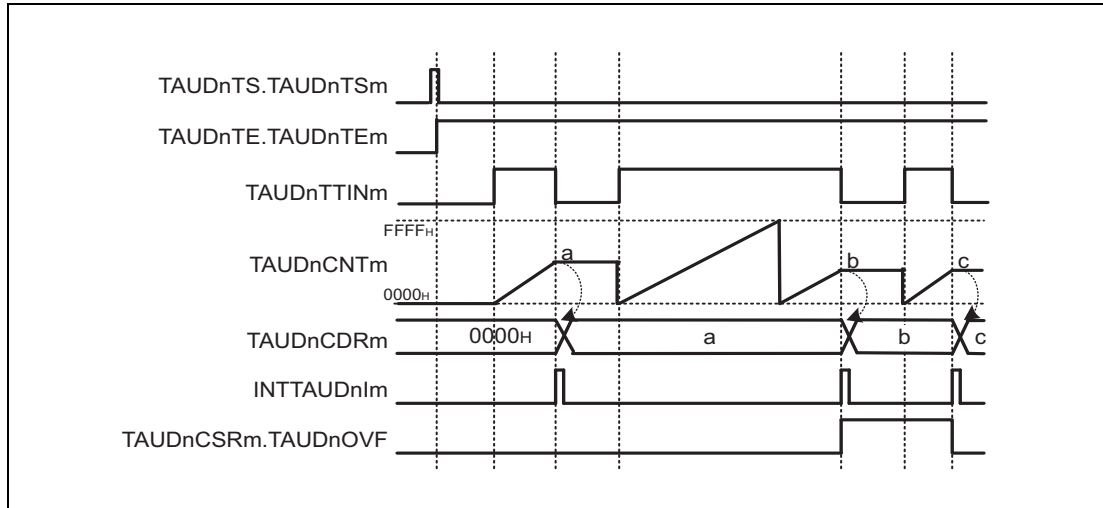

Figure 23.58 General Timing Diagram of TAUDnTTINm Input Signal Width Measurement Function

7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	10: Detection of rising and falling edges (low width measurement) 11: Detection of rising and falling edges (high width measurement)

(3) Channel output mode

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used with this function.

(4) Simultaneous rewrite

The simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the TAUDnTTINm input signal width measurement function. Therefore, these registers should be set to 0.

Table 23.80 Simultaneous Rewrite Settings for TAUDnTTINm Input Signal Width Measurement Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

23.12.8.5 Operating Procedure for TAUDnTTINm Input Signal Width Measurement Function

Table 23.81 Operating Procedure for TAUDnTTINm Input Signal Width Measurement Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in Table 23.78, Contents of the TAUDnCMORm register for TAUDnTTINm Input Signal Width Measurement Function , and Table 23.79, Contents of the TAUDnCMURm register for TAUDnTTINm Input Signal Width Measurement Function . TAUDnCDRm register operates as a capture register.	Channel operation is stopped.
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and TAUDnCNTm waits for detection of the TAUDnTTINm start edge. When a TAUDnTTINm start edge is detected, TAUDnCNTm starts to count up.
During Operation	TAUDnCDRm, TAUDnCNTm, and TAUDnCSRm registers can be read at any time. TAUDnCSCm.TAUDnCLOV bit can be set to 1.	TAUDnCNTm starts to count up from 0000 _H . When TAUDnTTINm valid edge is detected: <ul style="list-style-type: none"> TAUDnCNTm transfers (captures) its value to TAUDnCDRm, and retains its value. INTTAUDnIm is then generated. Counting stops at the “value that transferred to TAUDnCDRm + 1” and TAUDnCNTm waits for detection of the TAUDnTTINm start edge. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and both it and TAUDnCSRm.TAUDnOVF retain their current values.

Restart

23.12.8.6 Specific Timing Diagrams: Overflow Operation

(1) TAUDnCMORm.TAUDnCOS[1:0] = 00_B

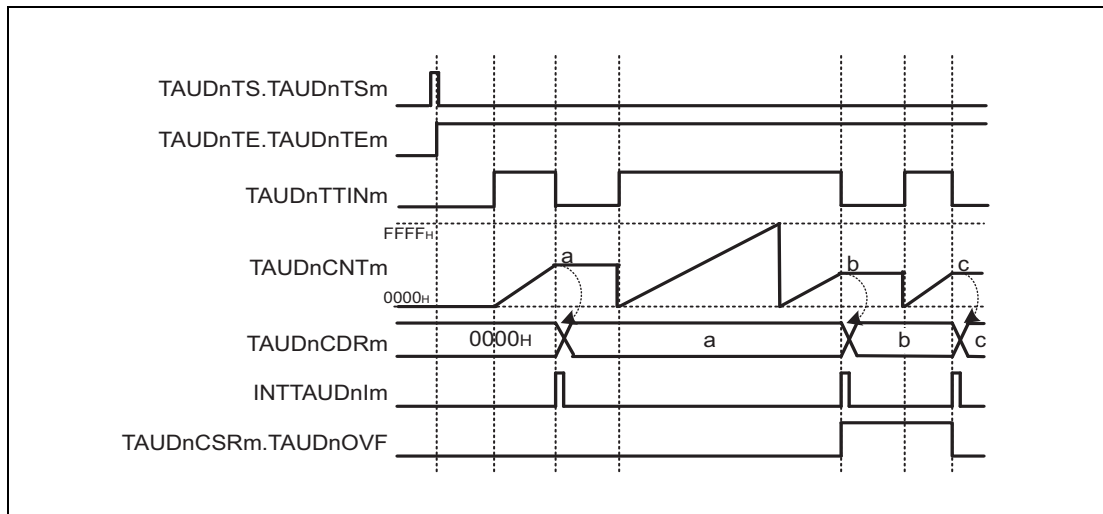

Figure 23.59 TAUDnCMORm.TAUDnCOS[1:0] = 00_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 11_B

- When an overflow occurs, the value of TAUDnCDRm remains unchanged and TAUDnCSRm.TAUDnOVF remains = 0.
- Upon detection of the next valid TAUDnTTINm input edge, the value of TAUDnCNTm is loaded into TAUDnCDRm and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge with no overflow occurring, TAUDnCSRm.TAUDnOVF is cleared to 0.

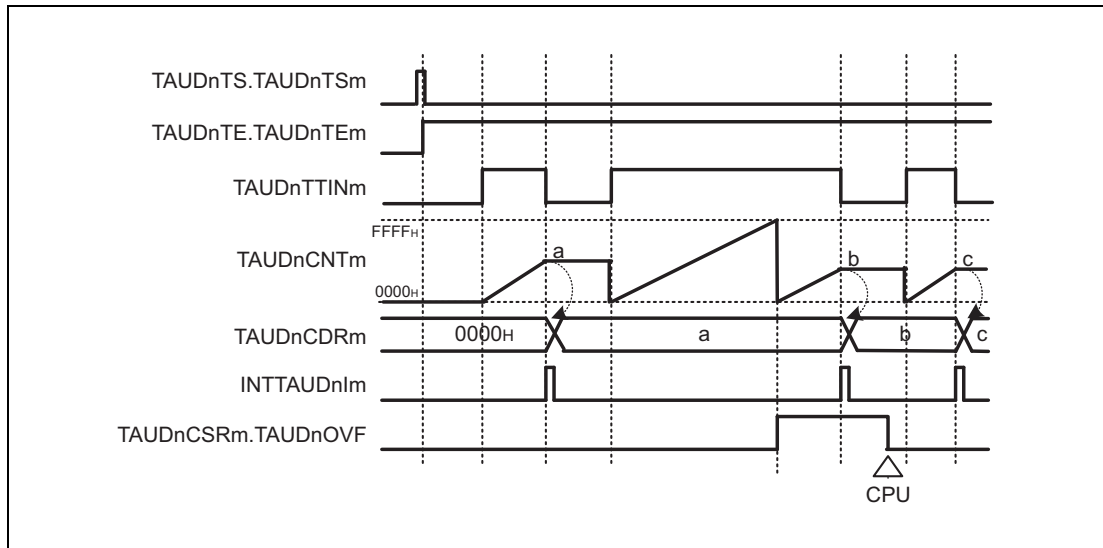

(2) TAUDnCMORm.TAUDnCOS[1:0] = 01_B

Figure 23.60 TAUDnCMORm.TAUDnCOS[1:0] = 01_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 11_B

- When an overflow occurs, the value of TAUDnCDRm remains unchanged and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge, the value of TAUDnCNTm is loaded into TAUDnCDRm.
- TAUDnCSRm.TAUDnOVF is only cleared by a CPU command. (by setting TAUDnCSCm.TAUDnCLOV bit to 1.)

(3) TAUDnCMORm.TAUDnCOS[1:0] = 10_B

Figure 23.61 TAUDnCMORm.TAUDnCOS[1:0] = 10_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 11_B

- When an overflow occurs, TAUDnCDRm is set to FFFF_H and TAUDnCSRm.TAUDnOVF remains = 0.
- Upon detection of the next valid TAUDnTTINm input edge, TAUDnCNTm stops, but TAUDnCDRm and TAUDnCSRm.TAUDnOVF remain unchanged.
- Thus, the next valid TAUDnTTINm input edge after the overflow is ignored.

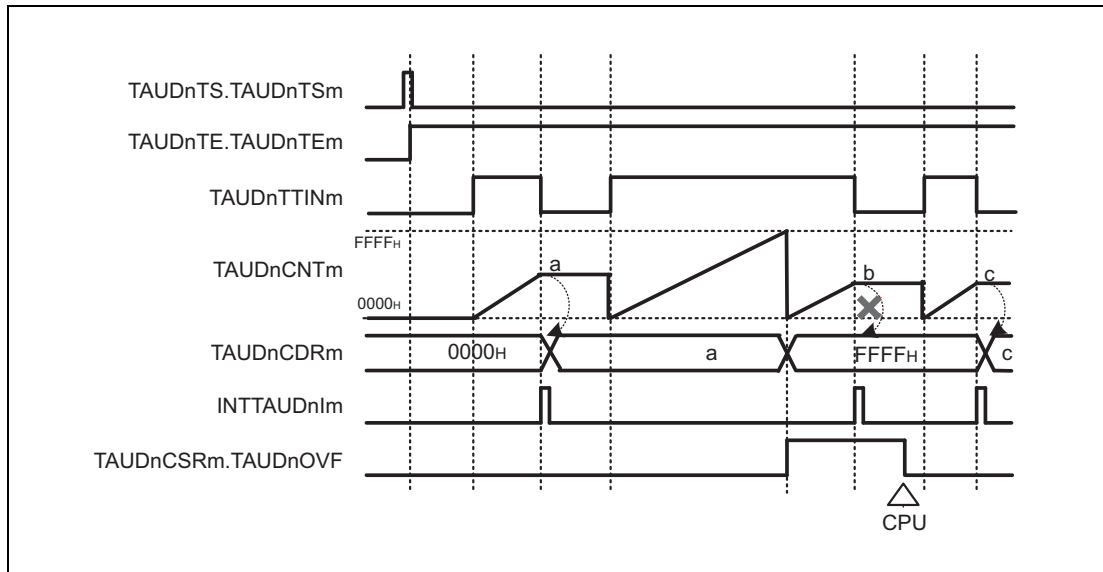

(4) TAUDnCMORm.TAUDnCOS[1:0] = 11_B

Figure 23.62 TAUDnCMORm.TAUDnCOS[1:0] = 11_B, TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 11_B

- When an overflow occurs, TAUDnCDRm is set to FFFF_H and TAUDnCSRm.TAUDnOVF is set to 1.
- Upon detection of the next valid TAUDnTTINm input edge, TAUDnCNTm stops, but TAUDnCDRm and TAUDnCSRm.TAUDnOVF remain unchanged.
- Thus, the next valid TAUDnTTINm input edge after the overflow is ignored.
- TAUDnCSRm.TAUDnOVF is cleared by setting TAUDnCSCm.TAUDnCLOV to 1.

23.12.9 TAUDnTTINm Input Position Detection Function

23.12.9.1 Overview

Summary

This function measures the input signal duration by capturing the count value at the valid edge of TAUDnTTINm.

Prerequisites

- The operating mode should be set to count capture mode. (See **Table 23.82, Contents of the TAUDnCMORm register for TAUDnTTINm Input Position Detection Function.**)
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The counter starts counting from 0000_H. When a valid TAUDnTTINm input edge is detected, the current value of TAUDnCNTm is loaded into TAUDnCDRm and an interrupt (INTTAUDnIm) is generated. The count operation continues.

When the counter reaches FFFF_H, the counter restarts to count from 0000_H.

NOTE

The TAUDTTINm input signal is sampled at the frequency of the operation clock specified by the TAUDnCMORm.TAUDnCKS[1:0] bits. As a result, the output cycle of the TAUDTTOUTm has an error of ±1 operation clock cycle.

Conditions

If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt does not occur at the beginning of operation or after restart. For details, see **Section 23.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts.**

23.12.9.2 Equations

Functional duration at a TAUDnTTINm input pulse =
 count clock cycle × (TAUDnCDRm capture value + 1)

23.12.9.3 Block Diagram and General Timing Diagram

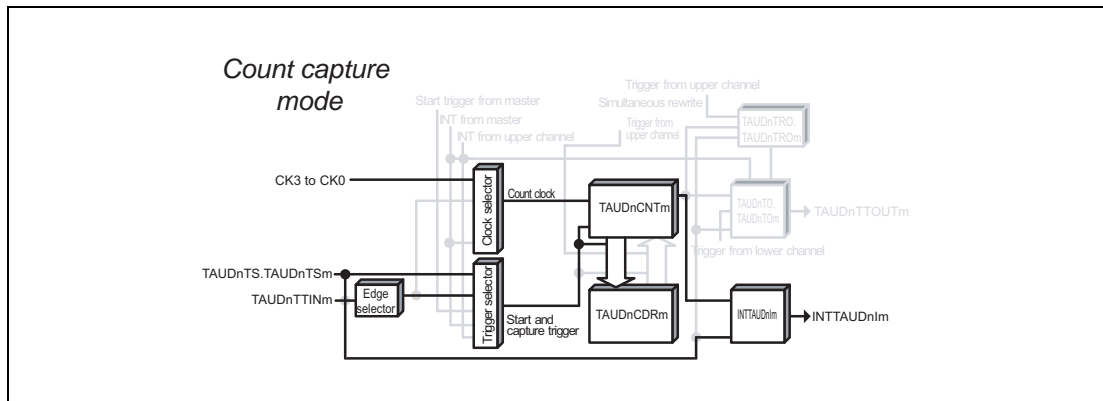

Figure 23.63 Block Diagram of TAUDnTTINm Input Position Detection Function

The following settings apply to the general timing diagram.

- INTTAUDnIm not generated at the beginning of operation. (TAUDnCMORM.TAUDnMD0 = 0)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

Figure 23.64 General Timing Diagram of TAUDnTTINm Input Position Detection Function

(3) Channel output mode

The channel output mode is not used by this function.

(4) Simultaneous rewrite

Simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with TAUDnTTINm input position detection function. Therefore, these registers should be set to 0.

Table 23.84 Simultaneous Rewrite Settings for TAUDnTTINm Input Position Detection Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

23.12.9.5 Operating Procedure for TAUDnTTINm Input Position Detection Function

Table 23.85 Operating Procedure for TAUDnTTINm Input Position Detection Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in Table 23.82, Contents of the TAUDnCMORm register for TAUDnTTINm Input Position Detection Function , and Table 23.83, Contents of the TAUDnCMURm register for TAUDnTTINm Input Position Detection Function . TAUDnCDRm register operates as a capture register.	Channel operation is stopped.
Restart	Set TAUDnTS.TAUDnTSM to 1. TAUDnTS.TAUDnTSM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is set to 1 and the counter starts. If TAUDnCMORm.TAUDnMD0 is 1, INTTAUDnIm occurs.
During Operation	The TAUDnCMURm.TAUDnTIS[1:0] bits can be changed at any time. The TAUDnCDRm and TAUDnCSRm registers can be read at any time.	TAUDnCNTm starts to count up from 0000 _H . When a valid TAUDnTTINm edge is detected: <ul style="list-style-type: none"> • TAUDnCNTm transfers (captures) its own value to TAUDnCDRm. • INTTAUDnIm occurs. • The counter is not cleared to 0000_H and TAUDnCNTm continues counting. Afterwards, this procedure is repeated. When TAUDnCNTm reaches FFFF _H , the counter restarts from 0000 _H .
Stop Operation	Set TAUDnTT.TAUDnTTM to 1. TAUDnTT.TAUDnTTM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is cleared to 0 and the counter stops. TAUDnCNTm stops. TAUDnCNTm retains its current value.

23.12.9.6 Specific Timing Diagrams

(1) Operation stop and restart

Figure 23.65 Operation Stop and Restart
(TAUDnCMORm.TAUDnMD0 = 0, TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

- The counter can stop operating by setting TAUDnTT.TAUDnTTM to 1. This sets TAUDnTE.TAUDnTEM to 0.
- TAUDnCNTm stops and retains its current value.
- If the counter stops operating, valid TAUDnTTINm input edges are ignored.
- The counter can be restarted by setting TAUDnTS.TAUDnTSM to 1. TAUDnCNTm restarts to count from 0000_H.

23.12.10 TAUDnTTINm Input Period Count Detection Function

23.12.10.1 Overview

Summary

This function measures the cumulative width of a TAUDnTTINm input signal.

Prerequisites

- The operating mode should be set to capture and gate count mode. (See **Table 23.86, Contents of the TAUDnCMORm register for TAUDnTTINm Input Period Count Detection Function.**)
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSM) to 1. This in turn sets TAUDnTE.TAUDnTEM = 1, enabling count operation. The counter awaits a valid TAUDnTTINm input edge.

When a valid TAUDnTTINm input start edge is detected, the counter starts to count from 0000_H.

When a valid TAUDnTTINm input stop edge is detected, the current TAUDnCNTm value is loaded into TAUDnCDRm and an interrupt (INTTAUDnIm) is generated. The counter stops and retains its value (TAUDnCDRm + 1) until the next valid TAUDnTTINm input start edge is detected.

When the next valid TAUDnTTINm input start edge is detected, the counter restarts to count from the value retained when stopped.

If the counter reaches FFFF_H, the counter restart to count from 0000_H.

NOTES

1. TAUDnTTINm input signal is sampled at the frequency of an operating clock set by the TAUDnCMORm.TAUDnCKS[1:0] bits.
2. As this function is to measure the TAUDnTTINm input signal width, setting TAUDnTS.TAUDnTSM to 1 is disabled while TAUDnTE.TAUDnTEM = 1.

Conditions

The valid start and stop edges are specified by the TAUDnCMURm.TAUDnTIS[1:0] bits:

- If TAUDnCMURm.TAUDnTIS[1:0] = 10_B, the TAUDnTTINm input low period is measured. The start trigger is a falling edge and the stop trigger is a rising edge.
- If TAUDnCMURm.TAUDnTIS[1:0] = 11_B, the TAUDnTTINm input high period is measured. The start trigger is a rising edge and the stop trigger is a falling edge.

23.12.10.2 Equations

Cumulative TAUDnTTINm input width = count clock cycle × (TAUDnCDRm capture value + 1)

23.12.10.3 Block Diagram and General Timing Diagram

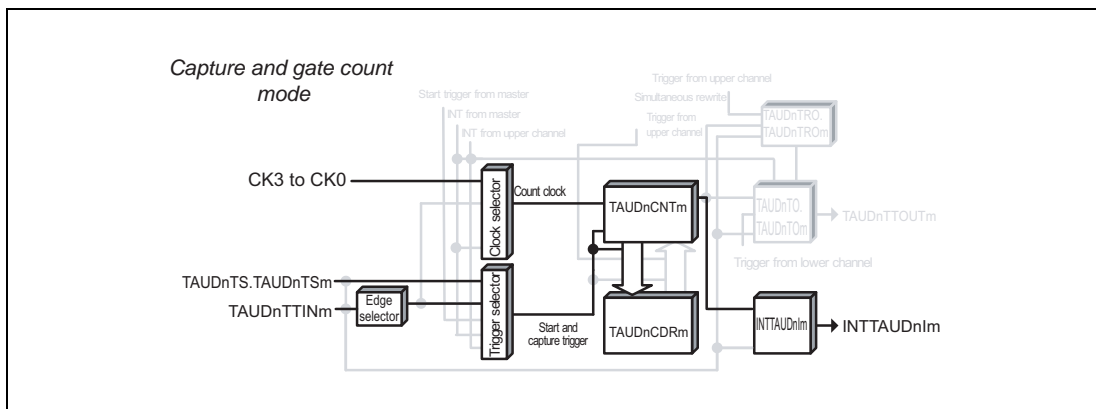

Figure 23.66 Block Diagram of TAUDnTTINm Input Period Count Detection Function

The following settings apply to the general timing diagram.

- Detection of rising and falling edges = high width measurement
(TAUDnCMURm.TAUDnTIS[1:0] = 11_B)

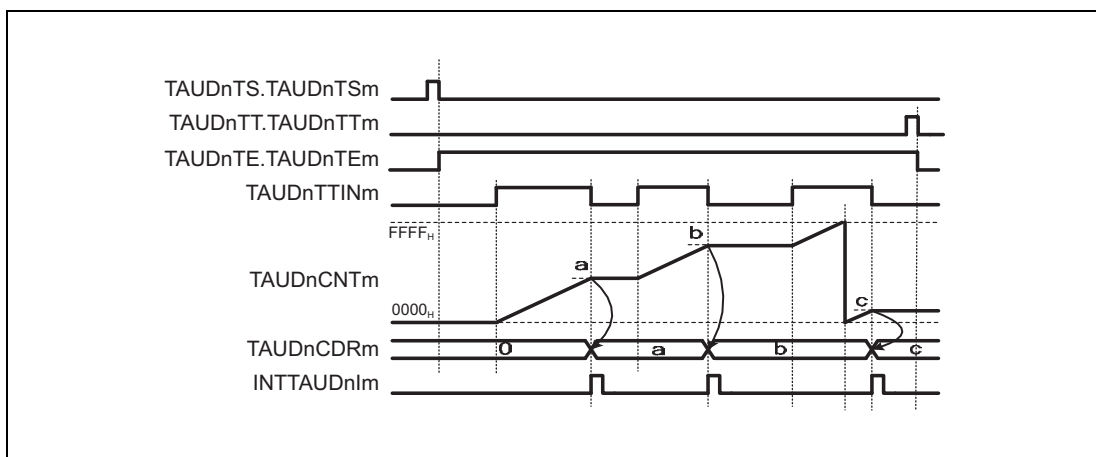

Figure 23.67 General Timing Diagram of TAUDnTTINm Input Period Count Detection Function

(3) Channel output mode

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used with this function.

(4) Simultaneous rewrite

Simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with TAUDnTTINm input period count detection. Therefore, these registers should be set to 0.

Table 23.88 Simultaneous Rewrite Settings for TAUDnTTINm Input Period Count Detection Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite
TAUDnRDS.TAUDnRDSm	0: When simultaneous rewrite is disabled (TAUDnRDE.TAUDnRDEm = 0), set these bits to 0
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

23.12.10.5 Operating Procedure for TAUDnTTINm Input Period Count Detection Function

Table 23.89 Operating Procedure for TAUDnTTINm Input Period Count Detection Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in Table 23.86, Contents of the TAUDnCMORm register for TAUDnTTINm Input Period Count Detection Function , and Table 23.87, Contents of the TAUDnCMURm register for TAUDnTTINm Input Period Count Detection Function .	Channel operation is stopped.
	TAUDnCDRm register operates as a capture register.	
Restart	Set TAUDnTS.TAUDnTSM to 1. TAUDnTS.TAUDnTSM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and TAUDnCNTm waits for detection of the TAUDnTTINm start edge.
	Detection of TAUDnTTINm edge The TAUDnCDRm, TAUDnCNTm, and TAUDnCSRm registers can be read at any time.	When a TAUDnTTINm start edge (rising edge for high width measurement, falling edge for low width measurement) is detected, TAUDnCNTm starts counting up from the stop value. When TAUDnCNTm detects a stop edge (falling edge for high width measurement, rising edge for low width measurement), it transfers the value to TAUDnCDRm and INTTAUDnIm is generated. Counting stops at the "value transferred to TAUDnCDRm + 1" and TAUDnCNTm waits for detection of the TAUDnTTINm start edge. When TAUDnCNTm reaches FFFF _H , the counter restarts to count from 0000 _H . Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops. TAUDnCNTm retains its current value.

23.12.10.6 Specific Timing Diagrams

(1) Operation stop and restart

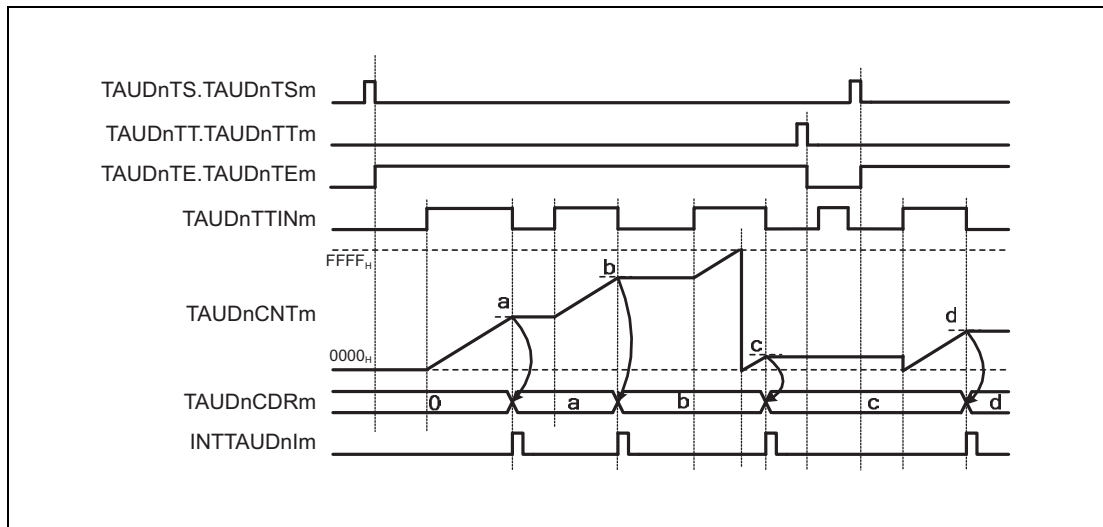

Figure 23.68 Operation Stop and Restart (TAUDnCMURm.TAUDnTIS[1:0] = 11_B)

- The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1. This sets TAUDnTE.TAUDnTEm to 0.
- TAUDnCNTm stops and retains its current value.
- If the counter is stopped, valid TAUDnTTINm input edges are ignored.
- The counter can be restarted by setting TAUDnTS.TAUDnTSM to 1. TAUDnCNTm restarts to count from 0000_H.

23.12.11 TAUDnTTINm Input Pulse Interval Judgment Function

23.12.11.1 Overview

Summary

This function outputs the result of a comparison between the count value (TAUDnCNTm) and the value in the channel data register (TAUDnCDRm) when a TAUDnTTINm input pulse occurs. An interrupt request signal INTTAUDnIm is generated if the result of the comparison is true.

Prerequisites

- The operating mode should be set to judge mode. See **Table 23.90, Contents of the TAUDnCMORm register for TAUDnTTINm Input Pulse Interval Judgment Function.**
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is started by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The current value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from this value.

When a TAUDnTTINm valid edge is detected or TAUDnTS.TAUDnTSm is set to 1, the function compares the current values of TAUDnCNTm and TAUDnCDRm. An interrupt request signal INTTAUDnIm is generated if the result of the comparison is true. TAUDnCNTm reloads the value of TAUDnCDRm and subsequently continues operation, regardless of the result of the comparison.

If the counter reaches 0000_H before a TAUDnTTINm valid edge is detected, TAUDnCNTm overflows and is set to FFFF_H. It then continues to count down.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

Conditions

The TAUDnCMORm.TAUDnMD0 bit specifies the type of comparison:

- If TAUDnCMORm.TAUDnMD0 = 0, INTTAUDnIm is generated when $TAUDnCNTm \leq TAUDnCDRm$.
- If TAUDnCMORm.TAUDnMD0 = 1, INTTAUDnIm is generated when $TAUDnCNTm > TAUDnCDRm$.

23.12.11.4 Operating Procedure for TAUDnTTINm Input Pulse Interval Judgment Function

Table 23.93 Operating Procedure for TAUDnTTINm Input Pulse Interval Judgment Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in Table 23.90, Contents of the TAUDnCMORm register for TAUDnTTINm Input Pulse Interval Judgment Function , and Table 23.91, Contents of the TAUDnCMURm register for TAUDnTTINm Input Pulse Interval Judgment Function .	Channel operation is stopped.
	Set the value of TAUDnCDRm register.	
Start Operation	Set TAUDnTS.TAUDnTSm to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCDRm value is loaded into TAUDnCNTm.
	The following register can be changed at any time: <ul style="list-style-type: none"> TAUDnCNTm register 	When TAUDnCMORm.TAUDnMD0 = 0 If TAUDnCNTm ≤ TAUDnCDRm when a TAUDnTTINm input edge is detected, INTTAUDnIm is generated. When TAUDnCMORm.TAUDnMD0 = 1 If TAUDnCNTm > TAUDnCDRm when a TAUDnTTINm input edge is detected, INTTAUDnIm is generated. If a TAUDnTTINm input edge is detected, then TAUDnCNTm starts to count down from the value of TAUDnCDRm. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

Restart

23.12.12 TAUDnTTINm Input Signal Width Judgment Function

23.12.12.1 Overview

Summary

This function compares the count value (TAUDnCNTm) for the high or low level width of a TAUDnTTINm input signal and the TAUDnCDRm value, and outputs the judgment result from the interrupt request signal INTTAUDnIm.

Prerequisites

- The operating mode should be set to judge and one-count mode. (See **Table 23.94, Contents of the TAUDnCMORm register for TAUDnTTINm Input Signal Width Judgment Function**)
- TAUDnTTOUTm is not used with this function.

Functional description

The counter is started by setting the channel trigger bit (TAUDnTS.TAUDnTSM) to 1. This in turn sets TAUDnTE.TAUDnTEM = 1, enabling count operation. When a valid TAUDnTTINm input start edge is detected, the current value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from this value.

When a TAUDnTTINm valid stop edge is detected, the function compares the current values of TAUDnCNTm and TAUDnCDRm. An interrupt request signal INTTAUDnIm is generated if the result of the comparison is true. The counter TAUDnCNTm retains its value until the next valid TAUDnTTINm start edge is detected, regardless of the result of the comparison.

If the counter reaches 0000_H before a valid TAUDnTTINm stop edge is detected, TAUDnCNTm overflows and is set to FFFF_H. The counter then continues to count down.

The value of TAUDnCDRm can be rewritten at any time, and the changed value of TAUDnCDRm is applied the next time the counter starts to count down.

Conditions

- The TAUDnCMORm.TAUDnMD0 bit specifies the type of comparison:
 - If TAUDnCMORm.TAUDnMD0 = 0, INTTAUDnIm is generated when $TAUDnCNTm \leq TAUDnCDRm$.
 - If TAUDnCMORm.TAUDnMD0 = 1, INTTAUDnIm is generated when $TAUDnCNTm > TAUDnCDRm$.
- The TAUDnCMURm.TAUDnTIS[1:0] bits specify a type of width measurement:
 - For high width measurement (TAUDnCMURm.TAUDnTIS[1:0] = 11_B), TAUDnTTINm rising edge is used as a start edge and TAUDnTTINm falling edge as a stop edge.
 - For low width measurement (TAUDnCMURm.TAUDnTIS[1:0] = 10_B), TAUDnTTINm falling edge is used as a start edge and TAUDnTTINm rising edge as a stop edge.
- This function cannot make a forced restart.

23.12.12.2 Block Diagram and General Timing Diagram

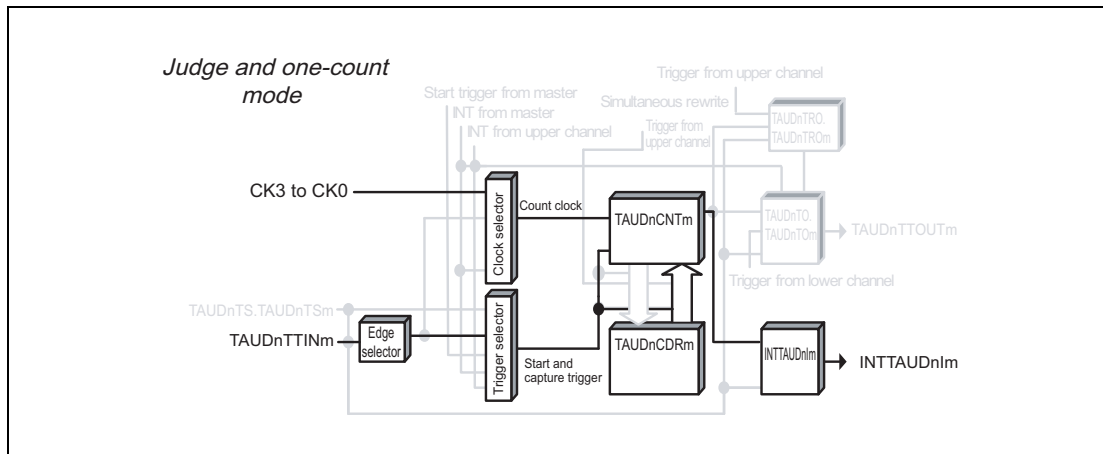

Figure 23.71 Block Diagram of TAUDnTTINm Input Signal Width Judgment Function

The following settings apply to the general timing diagram.

- INTTAUDnIm is generated when $TAUDnCNTm \leq TAUDnCDRm$ ($TAUDnCMORm.TAUDnMD0 = 0$)
- TAUDnTTINm valid start edge = rising edge, TAUDnTTINm valid stop edge = falling edge ($TAUDnCMURm.TAUDnTIS[1:0] = 11_B$)

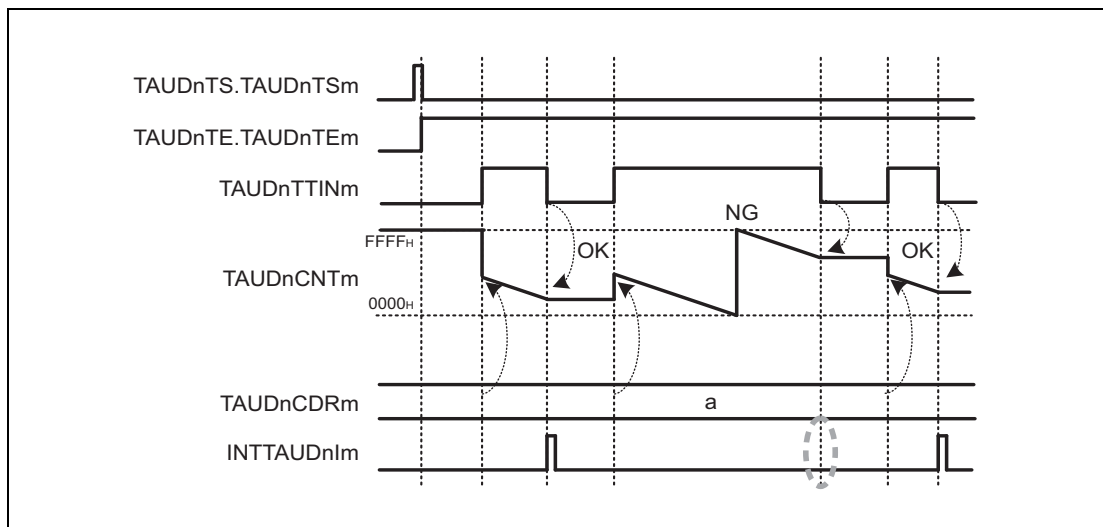

Figure 23.72 General Timing Diagram of TAUDnTTINm Input Signal Width Judgment Function

23.12.12.4 Operating Procedure for TAUDnTTINm Input Signal Width Judgment Function

Table 23.97 Operating Procedure for TAUDnTTINm Input Signal Width Judgment Function

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers as described in Table 23.94, Contents of the TAUDnCMORm register for TAUDnTTINm Input Signal Width Judgment Function , and Table 23.95, Contents of the TAUDnCMURm register for TAUDnTTINm Input Signal Width Judgment Function .	Channel operation is stopped.
	Set the value of TAUDnCDRm register.	
Start Operation	Set TAUDnTS.TAUDnTSM to 1. TAUDnTS.TAUDnTSM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is set to 1 and TAUDnCNTm waits for detection of the TAUDnTTINm start edge.
	The following register can be changed at any time: • TAUDnCDRm register	Upon detection of a TAUDnTTINm start edge, TAUDnCNTm starts count down from the value of TAUDnCDRm.
During Operation		When TAUDnCMORm.TAUDnMD0 = 0 If $TAUDnCNTm \leq TAUDnCDRm$ when a INTTAUDnIm input stop edge is detected, INTTAUDnIm is generated.
		When TAUDnCMORm.TAUDnMD0 = 1 If $TAUDnCNTm > TAUDnCDRm$ when a TAUDnTTINm input stop edge is detected, INTTAUDnIm is generated.
		Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTM to 1. TAUDnTT.TAUDnTTM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

23.12.13 One-Phase PWM Output Function

23.12.13.1 Overview

Summary

This function adds dead time to a TAUDnTTINm input signal. The resulting PWM signal is output via TAUDnTTOUTm of the channel and TAUDnTTOUTm of upper channels.

Prerequisites

- Each of two (or more) channels is enabled for dead time control (TAUDnTDE.TAUDnTDEm = 1).
- The operating mode for the lower channel should be set to one-count mode. (See **Table 23.99, Contents of the TAUDnCMORm register for the Lower Channel of the One-Phase PWM Output Function.**)
- Any operating mode can be set to upper channels.
- Channel output mode for upper and lower channels should be set to synchronous channel output mode 2 with one-phase PWN output. (See **Section 23.7, Channel Output Modes.**)

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSM) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation.

The counter starts when a valid TAUDnTTINm input start edge is detected. The value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from the TAUDnCDRm value.

When the counter reaches 0000_H, an interrupt occurs. The counter is reset to FFFF_H and waits for the next valid TAUDnTTINm input start edge.

Table 23.98 TAUDnTTOUTm to which Dead Time is Added and State of TAUDnTTINm

TAUDnCMURm. TAUDnTIS[1:0]	TAUDnTOL. TAUDnTOLm	TAUDnTTOUTm to which Dead Time is Added	TAUDnTDL. TAUDnTDLm	TAUDnTTINm State When Added
10	0	TAUDnTTOUTm low	0	High
			1	Low
	1	TAUDnTTOUTm high	0	High
			1	Low
11	0	TAUDnTTOUTm low	0	Low
			1	High
	1	TAUDnTTOUTm high	0	Low
			1	High

Conditions

- TAUDnCMURm.TAUDnTIS[1:0] bits specify the type of width measurement:
 - TAUDnCMURm.TAUDnTIS[1:0] = 10_B: Uses both edges as valid edges for detection (Low width measurement).
 - TAUDnCMURm.TAUDnTIS[1:0] = 11_B: Uses both edges as valid edges for detection (High width measurement).
- The TAUDnTDL.TAUDnTDLm bit specifies the operation of TAUDnTTOUTm for each channel when an interrupt or valid TAUDnTTINm edge is detected on the lower channel:
 - If TAUDnTDL.TAUDnTDLm = 0, dead time to the positive-phase width (normal) is added.
 - If TAUDnTDL.TAUDnTDLm = 1, dead time to the negative-phase width (inverted) is added.
- This function cannot make a forced restart.

23.12.13.2 Block Diagram and General Timing Diagram

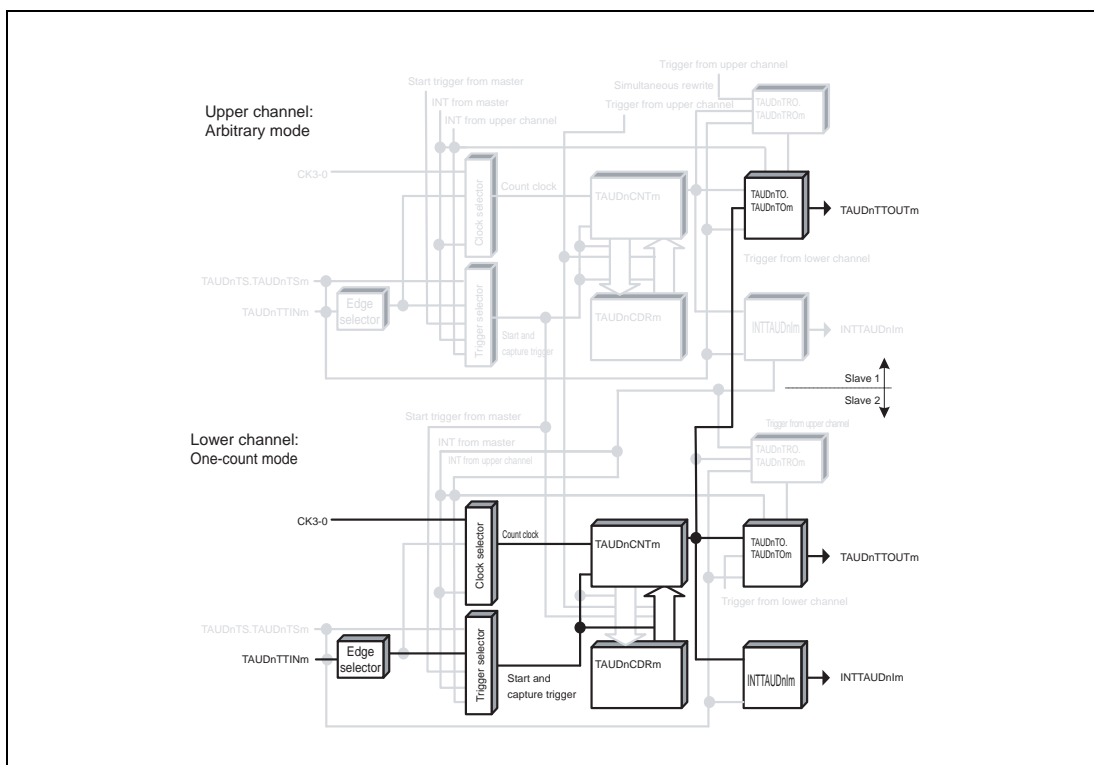

Figure 23.73 Block Diagram of One-Phase PWM Output Function

The following settings apply to the general timing diagram.

- Detection of rising and falling edges = high width measurement
(TAUDnCMURm.TAUDnTIS[1:0] = 11_B)

This setting considers a duty as a high active.

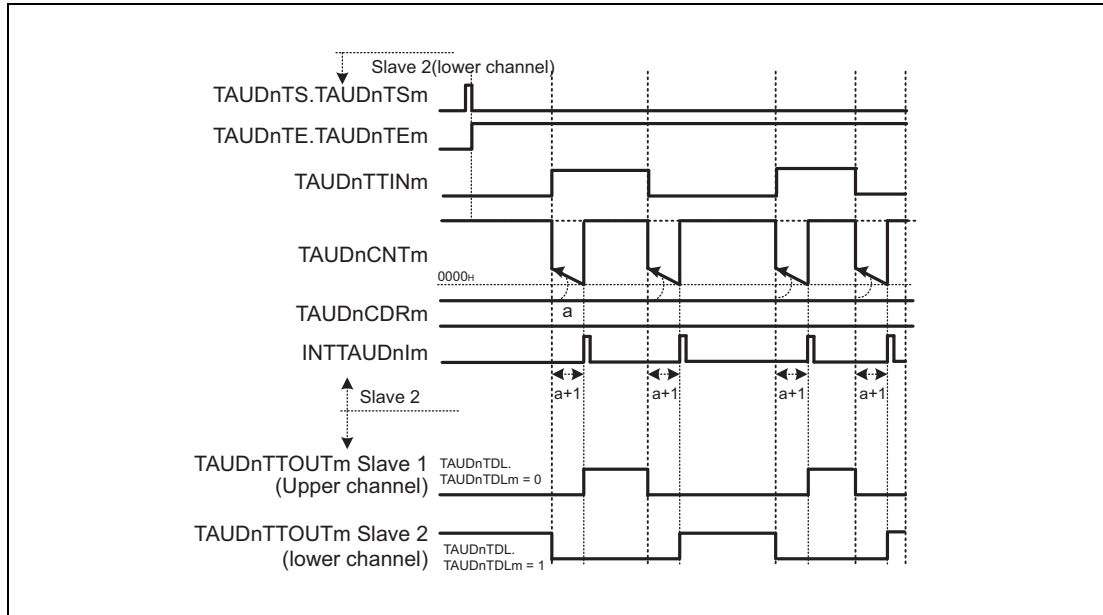

Figure 23.74 General Timing Diagram of One-Phase PWM Output Function

23.12.14 Real Time Output Function Type 1

23.12.14.1 Overview

Summary

This function outputs a value of the TAUDnTRO.TAUDnTROm bit from TAUDnTTOUTm when a specified channel generates an interrupt (INTTAUDnIm). In this function, the interrupt is generated at certain specified intervals.

The upper channel is a channel which generates a real-time output trigger (TAUDnTRC.TAUDnTRCm = 1), and the lower channel is a channel which makes a real-time output in response to the upper channel trigger (TAUDnTRC.TAUDnTRCm = 0).

Prerequisites

- Channels should use the TAUDnTTOUTm control of other channels.
- The operating mode for the upper channel should be set to interval timer mode. (See **Table 23.105, Contents of the TAUDnCMORM register for the Upper Channel of Real-Time Output Function Type 1.**)
- Any operating mode can be set for lower channels.
- The channel output mode for all the channels should be set to independent channel output mode 1 with real-time output. (See **Section 23.7, Channel Output Modes.**)
- Real-time output should be enabled for the upper channel (TAUDnTRE.TAUDnTREM = 1).

Functional description

The counter of the upper channel is started by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This in turn sets TAUDnTE.TAUDnTEm to 1, enabling count operation. The current value of the data register of the upper channel (TAUDnCDRm) is loaded into the counter (TAUDnCNTm) and the counter starts to count down from this value.

When the counter of the upper channel reaches 0000_H, INTTAUDnIm is generated and TAUDnTTOUTm outputs the current value of the real-time output bit (TAUDnTRO.TAUDnTROm) of every channel (only channels with TAUDnTRE.TAUDnTREM = 1). TAUDnCNTm then reloads the TAUDnCDRm value to continue operation subsequently.

The TAUDnTTOUTm signal changes only when an interrupt is generated, and when its value is different to current value of TAUDnTRO.TAUDnTROm at the moment that the interrupt is generated.

Conditions

- The channel which is monitored for INTTAUDnIm occurrence is specified by setting TAUDnTRC.TAUDnTRCm to 1 for the corresponding channel. The TAUDnTRC.TAUDnTRCm bit should be 0 for all other channels that do not generate a real-time output trigger.
- If real-time output of a lower channel is disabled (TAUDnTRE.TAUDnTREM = 0) or if the channel itself is used as a rewrite trigger (TAUDnTRC.TAUDnTRCm = 1), the value of that channel's TAUDnTRO.TAUDnTROm bit is output when INTTAUDnIm is generated in that channel.

- If real-time output of a lower channel is enabled ($TAUDnTRE.TAUDnTREM = 1$) and $TAUDnTRC.TAUDnTRCm = 0$, the value of that channel's $TAUDnTRO.TAUDnTROm$ bit is output when $INTTAUDnIm$ is generated in the upper channel.
- If the $TAUDnCMORm.TAUDnMD0$ bit is set to 0, the first interrupt after a start or restart is not output. For details, see **Section 23.9, $TAUDnTTOUTm$ Output and $INTTAUDnIm$ Generation when Counter Starts or Restarts.**

(2) TAUDnCMURm for lower channels

The TAUDnCMURm register for lower channels is available for any setting.

(3) Channel output mode for lower channels

Table 23.109 Control Bit Settings for the Lower Channels in Independent Channel Output Mode 1 with Real-Time Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: Setting is disabled (value after reset) in toggle mode.
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTRE.TAUDnTREM	1: Enables real-time output.
TAUDnTRO.TAUDnTROM	0: Real-time output is low. 1: Real-time output is high.
TAUDnTRC.TAUDnTRCm	0: Upper channel generates a real-time output trigger for channel m.
TAUDnTME.TAUDnTMEEm	0: Disables modulation

(4) Simultaneous rewrite for lower channels

Simultaneous rewrite registers for lower channels can be set arbitrarily.

23.12.14.6 Operating Procedure for Real-Time Output Function Type 1

Table 23.110 Operating Procedure for Real-Time Output Function Type 1

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers for upper channels as described in Table 23.105, Contents of the TAUDnCMORm register for the Upper Channel of Real-Time Output Function Type 1 , and Table 23.106, Contents of the TAUDnCMURm register for Upper Channel of Real-Time Output Function Type 1 .	Channel operation is stopped.
	Set TAUDnCMORm and TAUDnCMURm registers for lower channels as described in Section 23.12.14.5, Register Settings for Lower Channels .	
	Set the value of TAUDnCDRm register (only channels with TAUDnTRC.TAUDnTRCm = 1)	
	Set channel output mode by setting the control bits as described in Table 23.107, Control Bit Settings in Independent Channel Output Mode 1 with Real-Time Output .	
Start Operation	Set channel output mode by setting the control bits as described in Table 23.109, Control Bit Settings for the Lower Channels in Independent Channel Output Mode 1 with Real-Time Output .	
	Set TAUDnTS.TAUDnTSm = 1 on the channel with TAUDnTRC.TAUDnTRCm set to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	[Channel with TAUDnTRC.TAUDnTRCm set to 1] TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCDRm value is loaded into TAUDnCNTm. If TAUDnCMORm.TAUDnMD0 is 1, INTTAUDnIm occurs.
	TAUDnCDRm and TAUDnTRO.TAUDnTROm can be changed at any time. The TAUDnCNTm register can be read at any time.	TAUDnCNTm counts down. When the counter reaches 0000 _H : <ul style="list-style-type: none"> The TAUDnCDRm value is loaded in TAUDnCNTm again and count operation continues. INTTAUDnIm is generated. TAUDnTTOUTm outputs the current value of the real-time output bit TAUDnTRO.TAUDnTROm. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops. Both TAUDnCNTm and TAUDnTTOUTm retain their current values.

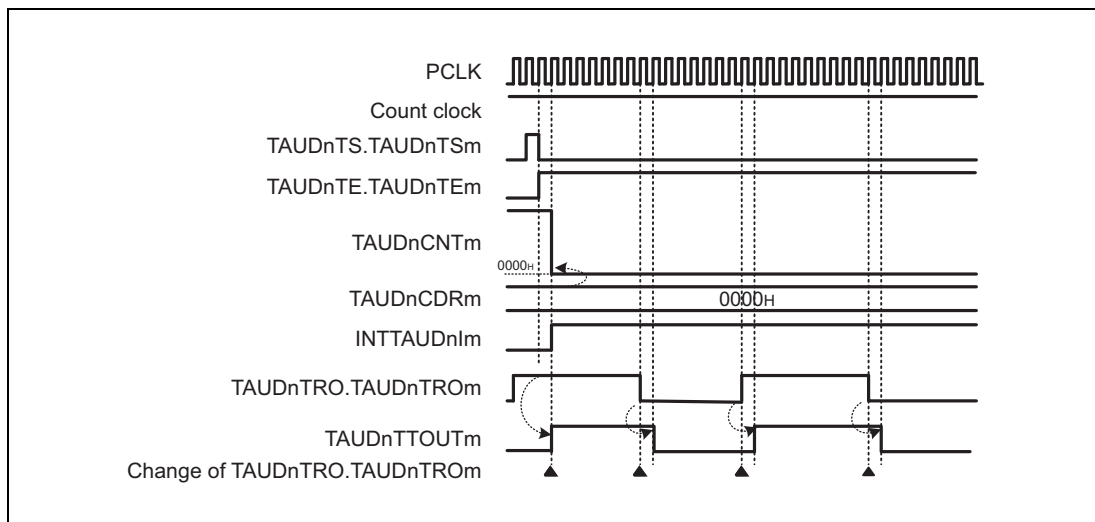

Figure 23.77 TAUDnCDRm = 0000H, TAUDnCMORm.TAUDnMD0 = 1

23.12.15 Real-Time Output Function Type 2

23.12.15.1 Overview

Summary

This function outputs the value of TAUDnTRO.TAUDnTROm bit from TAUDnTTOUTm when a specified channel generates an interrupt (INTTAUDnIm). In this function, the interrupt is generated when a valid TAUDnTTINm input edge is detected or the function starts.

The upper channel is a channel which generates a real-time output trigger (TAUDnTRC.TAUDnTRCm = 1), and the lower channel is a channel which makes a real-time output in response to the upper channel trigger (TAUDnTRC.TAUDnTRCm = 0).

Prerequisites

- Channels should use the TAUDnTTOUTm control of the other channels
- The operating mode for the upper channel should be set to capture mode. (See **Table 23.111, Contents of the TAUDnCMORm register for the Upper Channel of Real-Time Output Function Type 2.**)
- Any operating mode can be set for lower channels.
- The channel output mode for all the channels should be set to independent channel output mode 1 with real-time output. (See **Section 23.7, Channel Output Modes.**)
- Real-time output should be enabled for the upper channel (TAUDnTRE.TAUDnTREm = 1).

Functional description

The counter for upper channels is started by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm to 1, enabling count operation. The counter starts to count up.

When a valid TAUDnTTINm input edge is generated on one of upper channels, an interrupt occurs and TAUDnTTOUTm outputs the current value of the real-time output bit (TAUDnTRO.TAUDnTROm) of every channel (only channels with TAUDnTRE.TAUDnTREm = 1).

The TAUDnTTOUTm signal changes only when an interrupt is generated, and when TAUDnTTOUTm value is different to the current value of TAUDnTRO.TAUDnTROm during the occurrence of the interrupt.

Conditions

- The channel which is monitored for INTTAUDnIm occurrence is specified by setting TAUDnTRC.TAUDnTRCm to 1 for the corresponding channel. The TAUDnTRC.TAUDnTRCm bit should be 0 for all other channels that do not generate a real-time output trigger.
- If real-time output of a lower channel is disabled (TAUDnTRE.TAUDnTREm = 0) or if the channel itself is used as a rewrite trigger (TAUDnTRC.TAUDnTRCm = 1), the value of that channel's TAUDnTRO.TAUDnTROm bit is output when INTTAUDnIm is generated in that channel.
- If real-time output of a lower channel is enabled (TAUDnTRE.TAUDnTREm = 1) and TAUDnTRC.TAUDnTRCm = 0, the value of that channel's TAUDnTRO.TAUDnTROm bit is output when INTTAUDnIm is generated in the upper channel.

- If the $TAUDnCMORm.TAUDnMD0$ bit is set to 0, the first interrupt after a start or restart is not output. For details, see **Section 23.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts.**

(3) Channel output mode for lower channels

Table 23.115 Control Bit Settings for Lower Channels in Independent Channel Output Mode 1 with Real-Time Output

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode.
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: Setting is disabled (value after reset) in toggle mode.
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation.
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	1: Enables real-time output.
TAUDnTRO.TAUDnTROm	0: Real-time output is low. 1: Real-time output is high.
TAUDnTRC.TAUDnTRCm	0: Upper channel generates a real-time output trigger for channel m.
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous rewrite for lower channels

Simultaneous rewrite registers for lower channels can be set arbitrarily.

23.12.15.5 Operating Procedure for Real-Time Output Function Type 2

Table 23.116 Operating Procedure for Real-Time Output Function Type 2

	Operation	TAUDn Status	
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers for upper channels as described in Table 23.111, Contents of the TAUDnCMORm register for the Upper Channel of Real-Time Output Function Type 2 , and Table 23.112, Contents of the TAUDnCMURm register for the Upper Channel of Real-Time Output Function Type 2 .	Channel operation is stopped.	
	Set TAUDnCMORm and TAUDnCMURm registers for the lower channel as described in Section 23.12.15.4, Register Settings for Lower Channels .		
	The TAUDnCDRm register functions as a capture register (the channel of TAUDnTRC.TAUDnTRCm = 1).		
	Set channel output mode by setting the control bits as described in Table 23.113, Control Bit Settings in Independent Channel Output Mode 1 with Real-Time Output .		
Restart	Set channel output mode by setting the control bits as described in Table 23.115, Control Bit Settings for Lower Channels in Independent Channel Output Mode 1 with Real-Time Output .		
	Start Operation	Set TAUDnTS.TAUDnTSm = 1 on the channel with TAUDnTRC.TAUDnTRCm set to 1. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	[Channel with TAUDnTRC.TAUDnTRCm set to 1] TAUDnTE.TAUDnTEm is set to 1 and the counter starts. TAUDnCNTm is cleared to 0000 _H . If TAUDnCMORm.TAUDnMD0 is 1, INTTAUDnIm occurs.
	During Operation	TAUDnTRO.TAUDnTROm can be changed at any time.	TAUDnCNTm starts to count up from 0000 _H . When a valid TAUDnTTINm input edge is detected: <ul style="list-style-type: none"> • Capture the value of TAUDnCDRm in TAUDnCNTm to clear the counter to 0000_H. • INTTAUDnIm is generated. • When TAUDnTTINm input enable edge is detected, the TAUDnCSRm.TAUDnOVF bit is set to 1 if the detection is after an overflow, and is set to 0 if the detection is before an overflow. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops. TAUDnCNTm, TAUDnCSRm.TAUDnOVF, and TAUDnTTOUTm retain their current values.	

23.12.15.6 Specific Timing Diagrams

(1) Operation start and stop

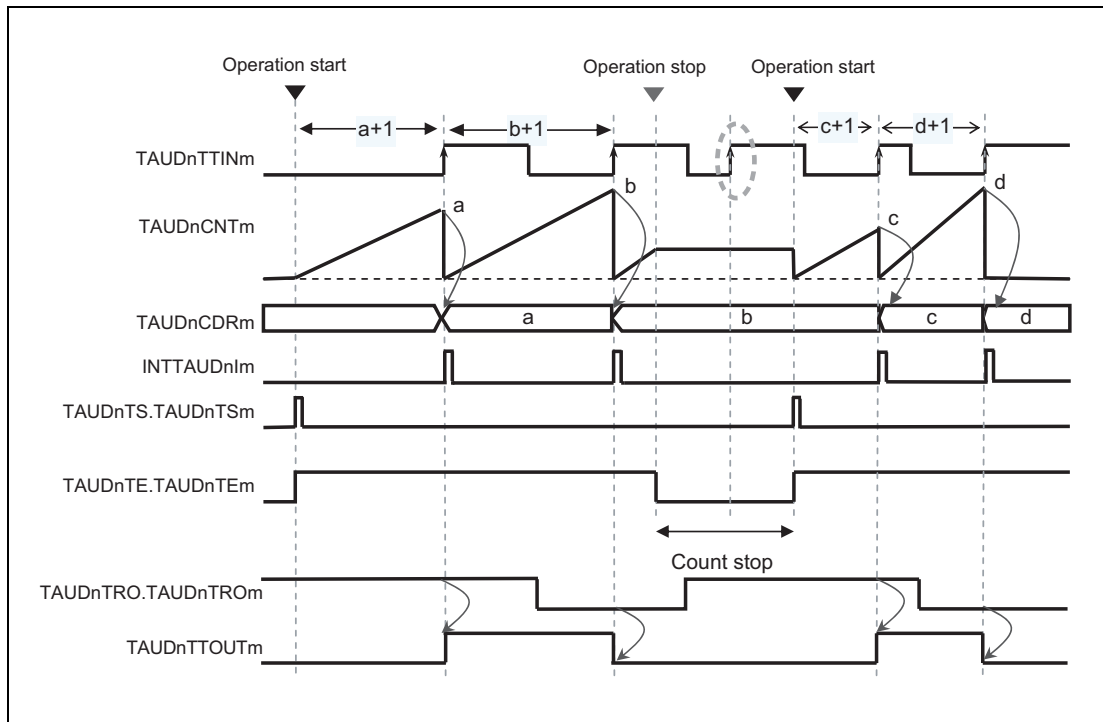

Figure 23.80 Operation Start and Stop (TAUDnCMORm.TAUDnMD0 = 0)

- When TAUDnTS.TAUDnTSm is set to 1, the counter starts counting up.
- When a valid input edge is detected, the current value of the counter is written to the data register (TAUDnCDRm) and an interrupt is generated.
- TAUDnTTOUTm outputs the current value of the real-time output bit (TAUDnTRO.TAUDnTROM) and the counter resets and starts to count up again.
- The TAUDnTTOUTm signal only changes when an interrupt is generated, and then only when its value is different to current value of TAUDnTRO.TAUDnTROM at the moment that the interrupt is generated.
- If the counter is stopped (TAUDnTE.TAUDnTEm is set to 0), valid input edges are ignored and no interrupt is generated.

23.12.16 Simultaneous Rewrite Trigger Generation Function Type 1

23.12.16.1 Overview

Summary

This function generates an interrupt on a specific channel that can be used by lower channels as a simultaneous rewrite trigger. The interrupt is generated at regular intervals.

The upper channel is a channel which generates a simultaneous rewrite trigger (TAUDnRDC.TAUDnRDCm = 1), and the lower channel is a channel which makes a simultaneous rewrite in response to the upper channel trigger (TAUDnRDC.TAUDnRDCm = 0).

Prerequisites

- Two or more channels lower than the channel used as upper channel are enabled for simultaneous rewrite (TAUDnRDE.TAUDnRDEm = 1).
- The operating mode for the upper channel should be set to interval timer mode. (See **Table 23.117, Contents of the TAUDnCMORm register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 1.**)
- For the operating mode that can be set for lower channels, see **Table 23.42, Channel Functions and the Methods They Use for Simultaneous Rewrite.**
- TAUDnTTOUTm is not used for any channel in this function.

Functional description

The counter operation is enabled by setting the channel trigger bits (TAUDnTS.TAUDnTSm) for upper and lower channels to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The current value of the data register buffer for upper channels (TAUDnCDRm buf) is loaded into the counter (TAUDnCNTm) and the counter starts to count down from this value. The counter for lower channels start to count according to the selected operating mode.

Once the counter reaches 0000_H, an interrupt occurs on the channel. The current value of the corresponding TAUDnCDRm buffer is loaded into TAUDnCNTm to continue operation subsequently.

If the channel where an interrupt occurs is specified as a trigger channel for simultaneous rewrite (TAUDnRDC.TAUDnRDCm = 1) and is an upper channel, simultaneous rewrite takes place on all lower channels in which simultaneous rewrite is currently possible (TAUDnRSF.TAUDnRSFm = 1).

The values of the data registers are copied to the corresponding data register buffers. Each time a counter starts to count down, it reads the value in the data register buffer and counts down from this value.

The value of a data register can be changed at any time, but it is only transferred to the corresponding data register buffer when simultaneous rewrite occurs.

Conditions

- The channel which is monitored for INTTAUDnIm occurrence is specified by setting TAUDnRDC.TAUDnRDCm = 1 for the corresponding channel. The TAUDnRDC.TAUDnRDCm bit should be set to 0 for all other channels in which simultaneous rewrite should take place.
- If the TAUDnCMORm.TAUDnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details, see **Section 23.9, TAUDnTTOUTm Output and INTTAUDnIm Generation when Counter Starts or Restarts.**

23.12.16.2 Equations

Simultaneous rewrite trigger generation cycle = count clock cycle \times (TAUDnCDRm + 1)

To control simultaneous rewrite, the following condition should be satisfied:

[PWM]

TAUDnCDRm = [(value of TAUDnCDRm of master channel subject to simultaneous rewrite + 1) \times number of interrupts] - 1

[Triangle PWM]

TAUDnCDRm = [(value of TAUDnCDRm of master channel subject to simultaneous rewrite + 1) \times 2 \times number of interrupts] - 1

That is, the ratio of TAUDnCDRm + 1 and TAUDnCDRm_master + 1 should be an integer. This integer corresponds to the number of interrupts.

For triangle PWM, remember that the cycle doubles.

23.12.16.3 Block Diagram and General Timing Diagram

Figure 23.81 Block Diagram of Simultaneous Rewrite Trigger Generation Function Type 1

The following settings apply to the general timing diagram.

- INTTAUDnIm generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)

Figure 23.82 General Timing Diagram of Simultaneous Rewrite Trigger Generation Function Type 1

23.12.16.4 Register Settings for Upper Channels

	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.118 Contents of the TAUDnCMURm register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 1

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for upper channels

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used with this function. However, this mode can be used in independent channel output mode controlled by software.

(4) Simultaneous rewrite for upper channels**Table 23.119 Simultaneous Rewrite Settings for Simultaneous Rewrite Trigger Generation Function Type 1**

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	1: Selects one of upper channels as simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Loads a simultaneous rewrite control signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	1: Monitors INTTAUDnIm signal which triggers a simultaneous rewrite on the channel.

23.12.16.5 Register Settings for Lower Channels**(1) TAUDnCMORm for lower channels**

TAUDnCMORm register for lower channels must follow the TAUDnCMORm register settings in the operating mode which can be set. (See **Table 23.42, Channel Functions and the Methods They Use for Simultaneous Rewrite.**)

(2) TAUDnCMURm for lower channels

TAUDnCMURm register for lower channels must follow the TAUDnCMURm register settings in the operating mode which can be set. (See **Table 23.42, Channel Functions and the Methods They Use for Simultaneous Rewrite.**)

(3) Channel output mode for lower channels

Output can be made according to the operating mode setting (master/slave) for lower channels. (For the functions for Simultaneous Rewrite Trigger Generation Function Type 1, see **Table 23.42, Channel Functions and the Methods They Use for Simultaneous Rewrite.**)

(4) Simultaneous rewrite for lower channels**Table 23.120 Simultaneous Rewrite Settings for Lower Channels in Simultaneous Rewrite Trigger Generation Function Type 1**

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	1: Selects one of upper channels as simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Follow the setting of the TAUDnRDM.TAUDnRDMm in the configurable operating mode.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

23.12.16.6 Operating Procedure for Simultaneous Rewrite Trigger Generation Function Type 1

Table 23.121 Operating Procedure for Simultaneous Rewrite Trigger Generation Function Type 1

	Operation	TAUDn Status
Initial Channel Setting	Set TAUDnCMORm and TAUDnCMURm registers for the upper channel as described in Table 23.117, Contents of the TAUDnCMORm register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 1 , and Table 23.118, Contents of the TAUDnCMURm register for the Upper Channel of Simultaneous Rewrite Trigger Generation Function Type 1 .	Channel operation is stopped.
	Set TAUDnCMORm and TAUDnCMURm registers for lower channels as described in Section 23.12.16.5, Register Settings for Lower Channels .	
	Set the value of TAUDnCDRm register.	
Restart	Start Operation Set TAUDnTS.TAUDnTSM to 1. TAUDnTS.TAUDnTSM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is set to 1 and the counter starts. TAUDnCDRm value is loaded into TAUDnCNTm. If TAUDnCMORm.TAUDnMD0 = 1, INTTAUDnIm occurs.
	During Operation TAUDnRDT.TAUDnRDTm and TAUDnCDR.TAUDnCDRm are changeable. TAUDnRSF.TAUDnRSFm can be always read.	TAUDnCNTm counts down. When the counter reaches 0000H: <ul style="list-style-type: none"> The TAUDnCDRm value is loaded in TAUDnCNTm again and count operation continues. INTTAUDnIm is generated. If INTAUDnIm occurs on the channel where TAUDnRDC.TAUDnRDCm is set to 1, simultaneous rewrite is controlled. Afterwards, this procedure is repeated.
Stop Operation	Set TAUDnTT.TAUDnTTm to 1. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is cleared to 0 and the counter stops. TAUDnCNTm stops and retains its current value.

23.13 Synchronous Channel Operation Functions

This section lists all the synchronous channel operation functions provided by the timer array unit D. For a general overview of synchronous channel operation, see **Section 23.2, Overview**

This section describes functions that generate PWM signals at regular intervals.

23.13.1 PWM Output Function

23.13.1.1 Overview

Summary

This function generates multiple PWM outputs by using a master and multiple slave channels. It enables the pulse cycle (frequency) and the duty cycle of the TAUDnTTOUTm to be set. The pulse cycle is set in the master channel. The duty cycle is set in the slave channel.

Prerequisites

- Two channels
- The operating mode for the master channel should be set to interval timer mode. (See **Table 23.122, Contents of the TAUDnCMORm register for the Master Channel of the PWM Output Function.**)
- The operating mode for the slave channels should be set to one count mode. (See **Table 23.125, Contents of the TAUDnCMORm register for the Slave Channel of the PWM Output Function.**)
- TAUDnTTOUTm is not used with the master channel of this function.
- The channel output mode for the slave channels should be set to Synchronous Channel Output Mode 1. (See **Section 23.7, Channel Output Modes.**)

Functional description

The counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The current value of TAUDnCDRm is loaded into TAUDnCNTm, and the counter starts counting down from the TAUDnCDRm value. If an INTTAUDnIm occurs on the master channel and TAUDnTTOUTm (slave) is set/reset, PWM output is made.

- Master channel:
When the master channel counter reaches 0000_H and the pulse cycle time has passed, INTTAUDnIm occurs. The counter loads TAUDnCDRm value into TAUDnCNTm and counts down.

- Slave channels:

When INTTAUDnIm occurs on the master channel, the counter operation of the slave channel is triggered. The current value of TAUDnCDRm (slave) is loaded into TAUDnCNTm (slave) and the counter starts counting down from the TAUDnCDRm value. TAUDnTTOUTm signal is set to the active level.

When the counter reaches to 0000_H (duty time has elapsed), INTTAUDnIm occurs and a TAUDnTTOUTm signal is set to an inactive level. The counter is reset to FFFF_H and waits for the next INTTAUDnIm (start of the next pulse cycle) of the master channel.

Counter operation can be stopped by setting the TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but their values are retained. The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1.

Conditions

Simultaneous rewrite can be used with this function. See **Section 23.6, Simultaneous Rewrite**.

23.13.1.2 Equations

Pulse cycle = (TAUDnCDRm (master) + 1) × count clock cycle

Duty cycle [%] = (TAUDnCDRm (slave) / (TAUDnCDRm (master) + 1)) × 100

– Duty cycle = 0%

TAUDnCDRm (slave) = 0000_H

– Duty cycle = 100%

TAUDnCDRm (slave) ≥ TAUDnCDRm (master) + 1

23.13.1.3 Block Diagram and General Timing Diagram

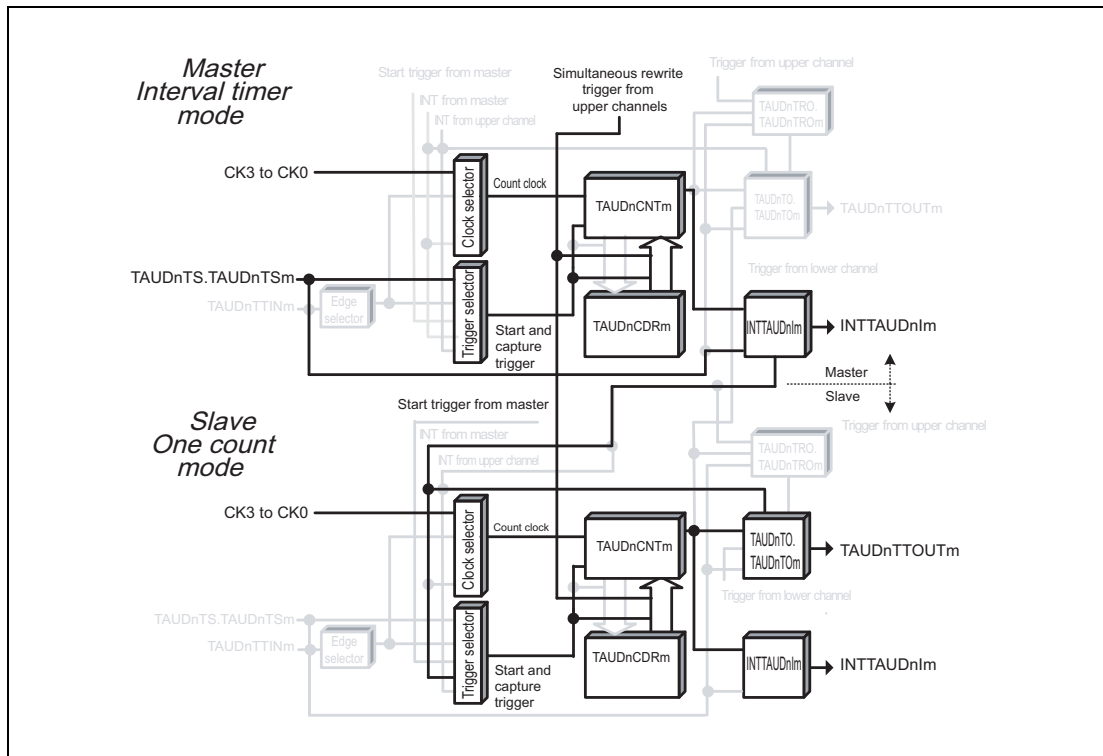

Figure 23.83 Block Diagram of PWM Output Function

The following settings apply to the general timing diagram.

- Slave channels: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

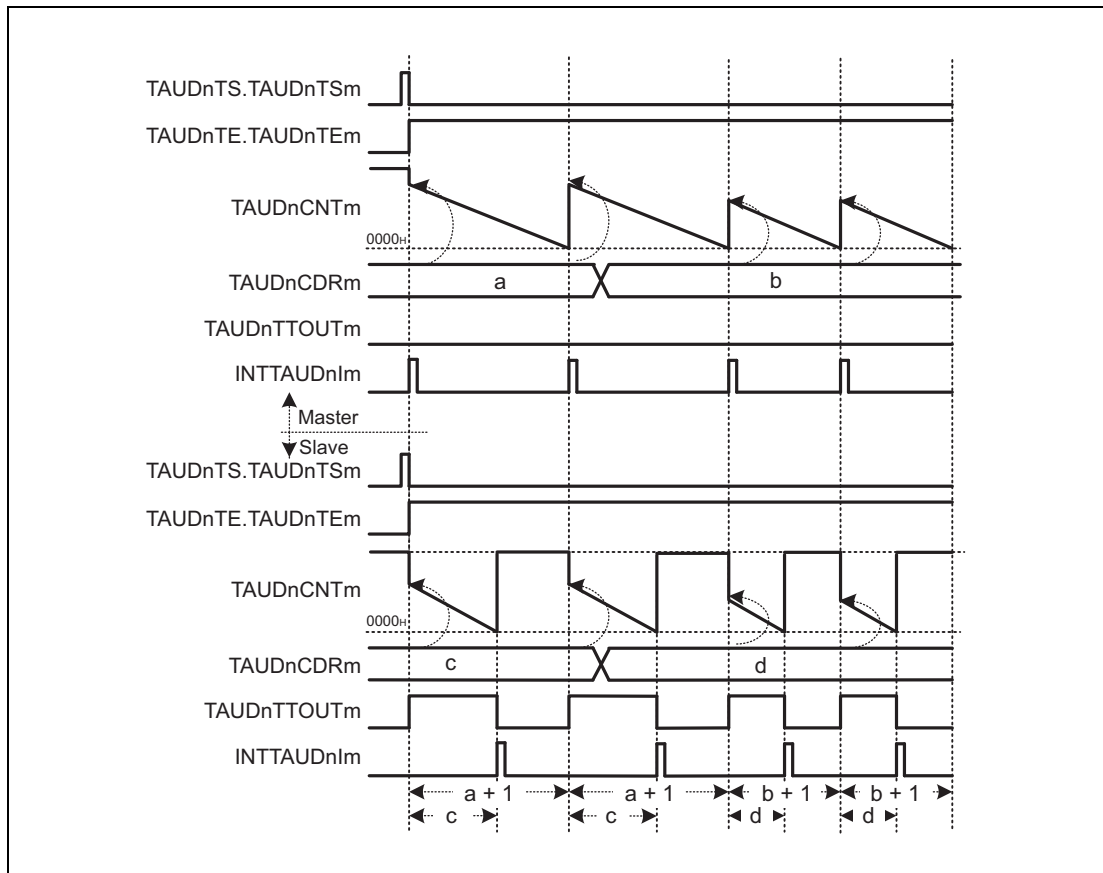

Figure 23.84 General Timing Diagram of PWM Output Function

NOTE

- The interval between the channel starting to count and an interrupt being generated is the value of corresponding TAUDnCDRm +1.
- The TAUDnTTOUTm signal from slave channel rises 1 cycle of the counter clock after the rising edge of INTTAUDnIm from the master channel.

23.13.1.4 Register Settings for the Master Channel

(1) TAUDnCMORm for the master channel

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 23.122 Contents of the TAUDnCMORm register for the Master Channel of the PWM Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	1: Channel is master channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	1: INTTAUDnIm generated at the beginning of operation.

(2) TAUDnCMURm for the master channel

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.123 Contents of the TAUDnCMURm register for the Master Channel of the PWM Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for the master channel

The channel output mode is not used with this function. However, this mode can be used with another function or in independent channel output mode controlled by software.

(4) Simultaneous rewrite for the master channel

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.124 Simultaneous Rewrite Settings for the Master Channel of the PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects master channel for simultaneous rewrite triggers. 1: Selects upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

NOTE

Use with TAUDnRDS.TAUDnRDSm bit = 1 requires a channel higher than the master channel that operates with the **Section 23.12.16, Simultaneous Rewrite Trigger Generation Function Type 1**.

Conduct operation settings under the following conditions:

- Simultaneous rewrite trigger output function type 1 setting channel:
TAUDnRDC.TAUDnRDCm=1, TAUDnRDS.TAUDnRDSm=1
TAUDnCDRm settings for this channel are as follows:
= ((TAUDnCDRm setting for the master channel targeted for simultaneous rewrite + 1) × interrupt count) - 1
- Master channels: TAUDnRDC.TAUDnRDCm=0, TAUDnRDS.TAUDnRDSm=1
- Slave channels: TAUDnRDC.TAUDnRDCm=0, TAUDnRDS.TAUDnRDSm=1

If TAUDnCDRm (slave) setting > TAUDnCDRm (master) setting + 1, the duty value (which exceeds 100%) is aggregated to be 100% output.

23.13.1.5 Register Settings for Slave Channels

(1) TAUDnCMORm for slave channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	100: INTTAUDnIm of master channel is a start trigger.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0100: One-count mode
0	TAUDnMD0	1: Start trigger during operation is valid.

(2) TAUDnCMURm for slave channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.126 Contents of the TAUDnCMURm register for the Slave Channel of the PWM Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for slave channels**Table 23.127 Control Bit Settings in Synchronous Channel Output Mode 1**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	0: Operating mode 1
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm TAUDnTDL.TAUDnTDLm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm TAUDnTRC.TAUDnTRCm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous rewrite for slave channels

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.128 Simultaneous Rewrite Settings for Slave Channels of PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects master channel for simultaneous rewrite triggers. 1: Selects upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

23.13.1.6 Operating Procedure for PWM Output Function

Table 23.129 Operating Procedure for PWM Output Function

	Operation	TAUDn Status
Initial Channel Setting	Master channels: Set TAUDnCMORM and TAUDnCMURm registers and the channel output mode as described in Section 23.13.1.4, Register Settings for the Master Channel.	Channel operation is stopped.
	Slave channels: Set TAUDnCMORM and TAUDnCMURm registers and the channel output mode as described in Section 23.13.1.5, Register Settings for Slave Channels.	
	Set the value of TAUDnCDRm register of every channel.	
Restart	Start Operation Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master and slave channels start. INTTAUDnIm is generated on the master channel and TAUDnTTOUTm (slave) is set.
	During operation TAUDnCDRm can be changed at any time. TAUDnTOL.TAUDnTOLm can be changed. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCNTm of master channel loads TAUDnCDRm value and counts down. When the counter reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUDnIm (master) occurs. • TAUDnCDRm value is loaded into TAUDnCNTm (master) to continue count operation. • TAUDnCDRm value is loaded into TAUDnCNTm (slave) to perform counting down. • TAUDnTTOUTm (slave) is set to the active level. If TAUDnCNTm (slave) reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUDnIm (slave) occurs. • TAUDnTTOUTm (slave) is set to an inactive level. Count operation of the slave channel stops.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

23.13.1.7 Specific Timing Diagrams

(1) Duty cycle = 0%

Figure 23.85 TAUDnCDRm (Slave) = 0000_H,
Positive Logic (TAUDnTOL.TAUDnTOLm (Slave) = 0)

- Every time the master channel generates an interrupt (INTTAUDnIm), 0000_H is loaded in to TAUDnCNTm (slave). Therefore, an interrupt (INTTAUDnIm) of the slave channel occurs simultaneously and TAUDnTTOUTm remains inactive.
- TAUDnCDRm value is loaded into TAUDnCNTm (slave) to generate an interrupt.

(2) Duty cycle = 100%

Figure 23.86 TAUDnCDRm (Slave) ≥ TAUDnCDRm (Master) + 1
Positive Logic (TAUDnTOL.TAUDnTOLm (Slave) = 0)

- If TAUDnCDRm (slave) value is greater than TAUDnCDRm (master) value, the slave channel counter does not reach 0000_H and consequently, no interrupt occurs. TAUDnTTOUTm remains active.

(3) Operation stop and restart

Figure 23.87 Operation Stop and Restart
Positive Logic (TAUDnTOL.TAUDnTOLm (Slave) = 0)

- The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0.
- TAUDnCNTm and TAUDnTTOUtm of all channels stop and the current values are retained. No interrupts are generated.
- The counter can be restarted by setting TAUDnTS.TAUDnTSm of master and slave channels to 1. TAUDnCDRm values of the master and slave channels are loaded to TAUDnCNTm and start to count down from these values.

23.13.2 One-Shot Pulse Output Function

23.13.2.1 Overview

Summary

This function outputs a signal pulse with a specific pulse width and delay time (both defined relative to an external input signal pulse or software trigger) by using a master and a slave channel. The delay time is specified using the master channel. The pulse width is specified using the slave channel.

Prerequisites

- Two channels
- The operating mode for the master channel should be set to one-count mode. (See **Table 23.130, Contents of the TAUDnCMORm register for the Master Channel of the One-Shot Pulse Output Function.**)
- The operating mode for slave channels should be set to pulse one-count mode. (See **Table 23.133, Contents of the TAUDnCMORm register for the Slave Channel of the One-Shot Pulse Output Function.**)
- TAUDnTTOUtm is not used with the master channel of this function.
- The channel output mode for the slave channel should be set to independent channel output mode 2. (See **Section 23.7, Channel Output Modes.**)
- TAUDnTTINm (master) has to be detected while TAUDnCNTm (master) and TAUDnCNTm (slave) await a trigger. Furthermore, the slave is only triggered by an interrupt from the master channel and not by TAUDnTTINm (slave).
- When using only the software trigger, do not select TAUDnTTINm with the alternative function of the pins.

Functional description

The counters are enabled by setting the channel trigger bits of the master channel and slave channel (TAUDnTS.TAUDnTSM) to 1. This sets TAUDnTE.TAUDnTEm to 1, enabling count operation.

- Master channel:
When the next valid TAUDnTTINm input edge or software trigger (when TAUDnTE.TAUDnTEm = 1, TAUDnTS.TAUDnTSM = 1 (m: master channel number)) is detected, the current value of TAUDnCDRm is loaded into TAUDnCNTm. The counter starts to count down from this value. If TAUDnCMORm.TAUDnMD0 = 0, a trigger (TAUDnTTINm) which is detected within the delay time is ignored.
When the counter of master channel reaches 0000_H, INTTAUDnIm is generated. The counter is reset to FFFF_H and waits for the next valid TAUDnTTINm input edge or software trigger (when TAUDnTE.TAUDnTEm = 1, TAUDnTS.TAUDnTSM = 1 (m: master channel number)).
- Slave channels:
INTTAUDnIm generated on master channel triggers the counter operation of slave channel. The current value of TAUDnCDRm (slave) is loaded into TAUDnCNTm (slave). The counter starts counting down from this value. An interrupt occurs and the TAUDnTTOUtm signal is set.
When the counter reaches 0001_H, INTTAUDnIm is generated and TAUDnTTOUtm signal is reset. The counter stops at 0000_H and waits for the next INTTAUDnIm of master channel.

The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but their values are retained. The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1.

Conditions

- If TAUDnCMORm.TAUDnMD0 of master channel is set to 0, TAUDnTTINm input edges detected during counting are ignored.
- Simultaneous rewrite can be used with this function. See **Section 23.6, Simultaneous Rewrite**.

23.13.2.2 Equations

Delay from trigger input to pulse output = (TAUDnCDRm (master) + 1) × count clock cycle

Pulse width = (TAUDnCDRm (slave)) × count clock cycle

23.13.2.3 Block Diagram and General Timing Diagram

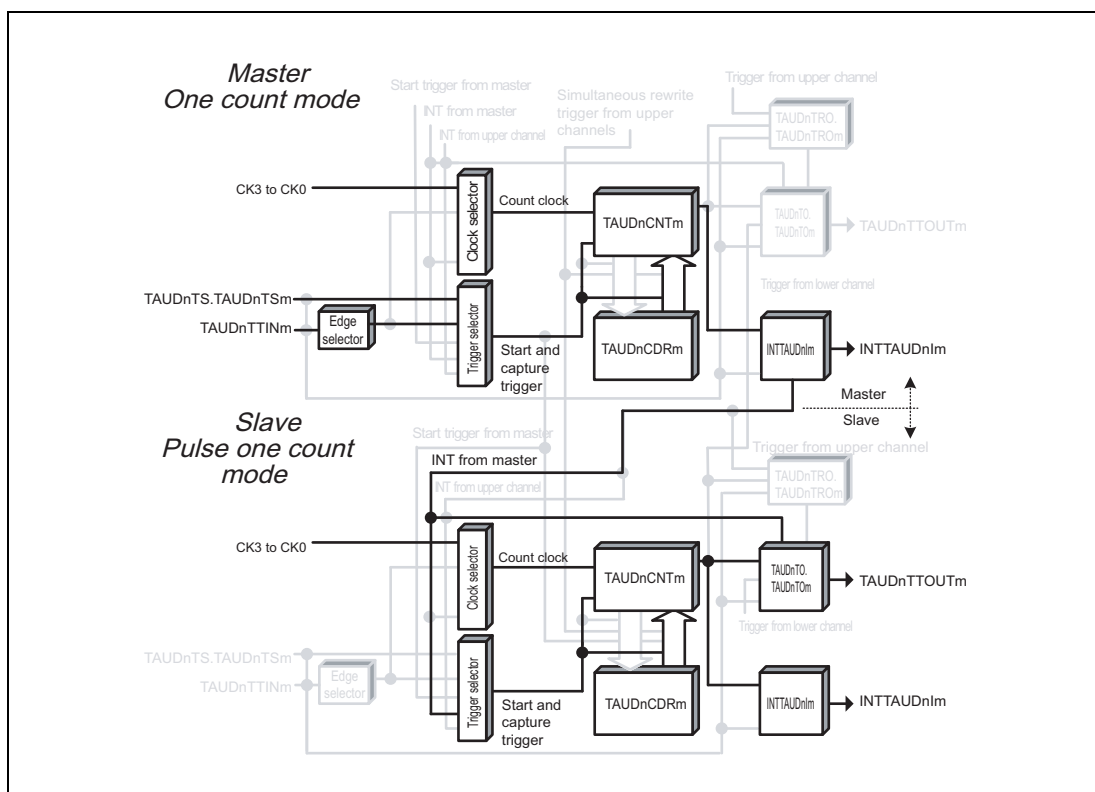

Figure 23.88 Block Diagram of One-Shot Pulse Output Function

The following settings apply to **Figure 23.89, General Timing Diagram of One-Shot Pulse Output Function (External Input Signal)** and **Figure 23.90, General Timing Diagram of One-Shot Pulse Output Function (Software Trigger)**.

- Start trigger detection is disabled during counting (TAUDnCMORm.TAUDnMD0 = 0)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

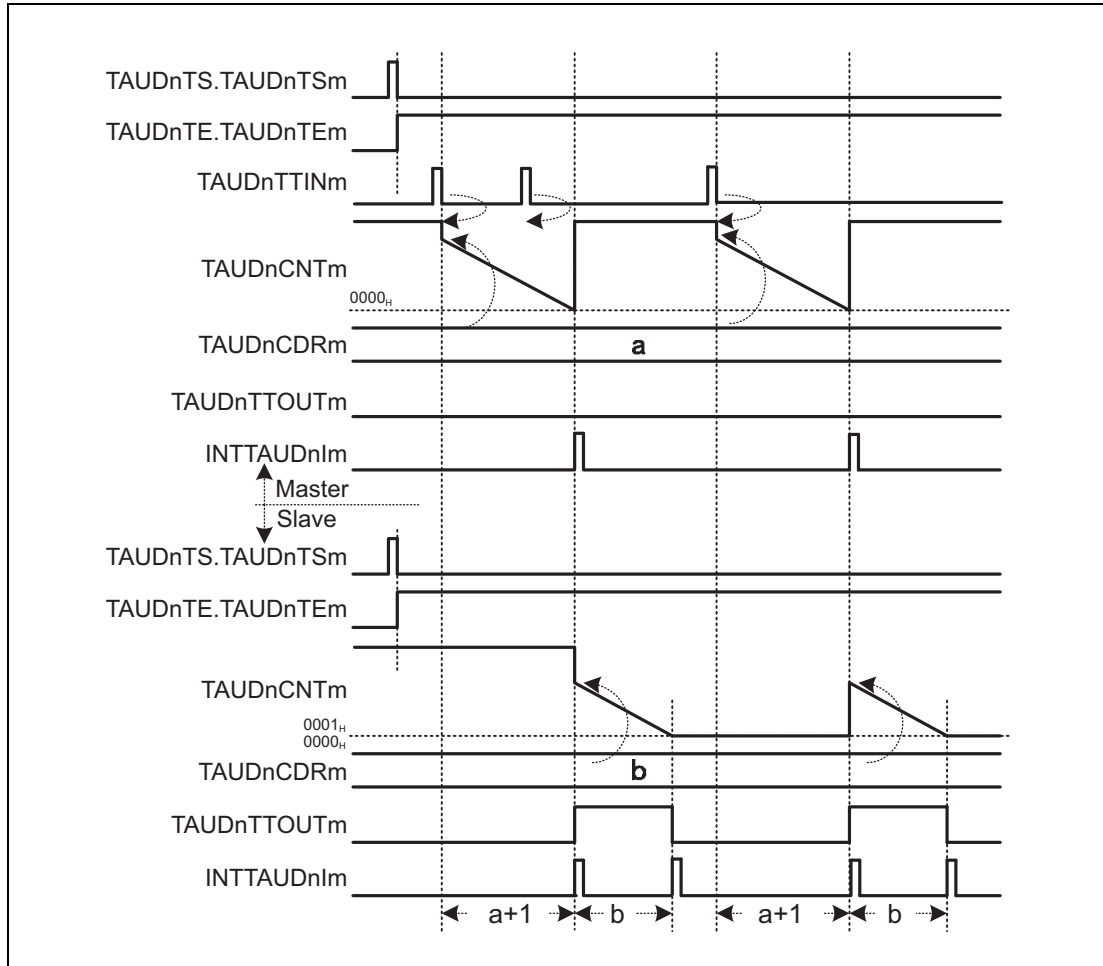

Figure 23.89 General Timing Diagram of One-Shot Pulse Output Function (External Input Signal)

15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	100: INTTAUDnIm of master channel is a start trigger.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	1010: Pulse one-count mode
0	TAUDnMD0	0: Disables detection of start trigger during count operation. 1: Enables start trigger detection while counting. MD0 bit of master and slave channels should have the same value.

(2) TAUDnCMURm for slave channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.134 Contents of the TAUDnCMURm register for the Slave Channel of the One-Shot Pulse Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for the slave channel**Table 23.135 Control Bit Settings in Independent Channel Output Mode 2**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	0: Operation as a real-time output trigger channel is prohibited.
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous rewrite for slave channels

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.136 Simultaneous Rewrite Settings for Slave Channels of One-Shot Pulse Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Master channel is simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

23.13.2.6 Operating Procedure for One-Shot Pulse Output Function

Table 23.137 Operating Procedure for One-Shot Pulse Output Function

	Operation	TAUDn Status
Initial Channel Setting	Master channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.2.4, Register Settings for the Master Channel.	Channel operation is stopped.
	Slave channels: Set TAUDnCMORm and TAUDnCMURm registers and channel output mode as described in Section 23.13.2.5, Register Settings for Slave Channels.	
	Set the value of TAUDnCDRm register of every channel.	
Restart	Start Operation Set TAUDnTS.TAUDnTSM of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the master channel awaits a TAUDnTTINm input.
During Operation	TAUDnCDRm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time.	When valid TAUDnTTINm input edge is detected, TAUDnCDRm value of master channel is loaded into TAUDnCNTm to start countdown. When the counter reaches 0000H: <ul style="list-style-type: none"> • INTTAUDnIm (master) occurs. • TAUDnCNTm (master) returns to FFFFH, and awaits for the next valid TAUDnTTINm input edge. • TAUDnCDRm value is reloaded into TAUDnCNTm (master) to start countdown. • TAUDnCDRm value is reloaded into TAUDnCNTm (slave) to start countdown. • INTTAUDnIm (slave) occurs. • TAUDnTTOUTm (slave) becomes active level. When TAUDnCNTm (slave) reaches 0001H: <ul style="list-style-type: none"> • INTTAUDnIm (slave) occurs. • TAUDnTTOUTm (slave) becomes inactive and count operation of the slave channel stops.
	TAUDnRDT.TAUDnRDTm can be changed during operation.	
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

23.13.2.7 Specific Timing Diagrams

(1) TAUDnCDRm (master) = 0000_H

The following settings apply to this diagram:

- Disables detection of start trigger during count operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

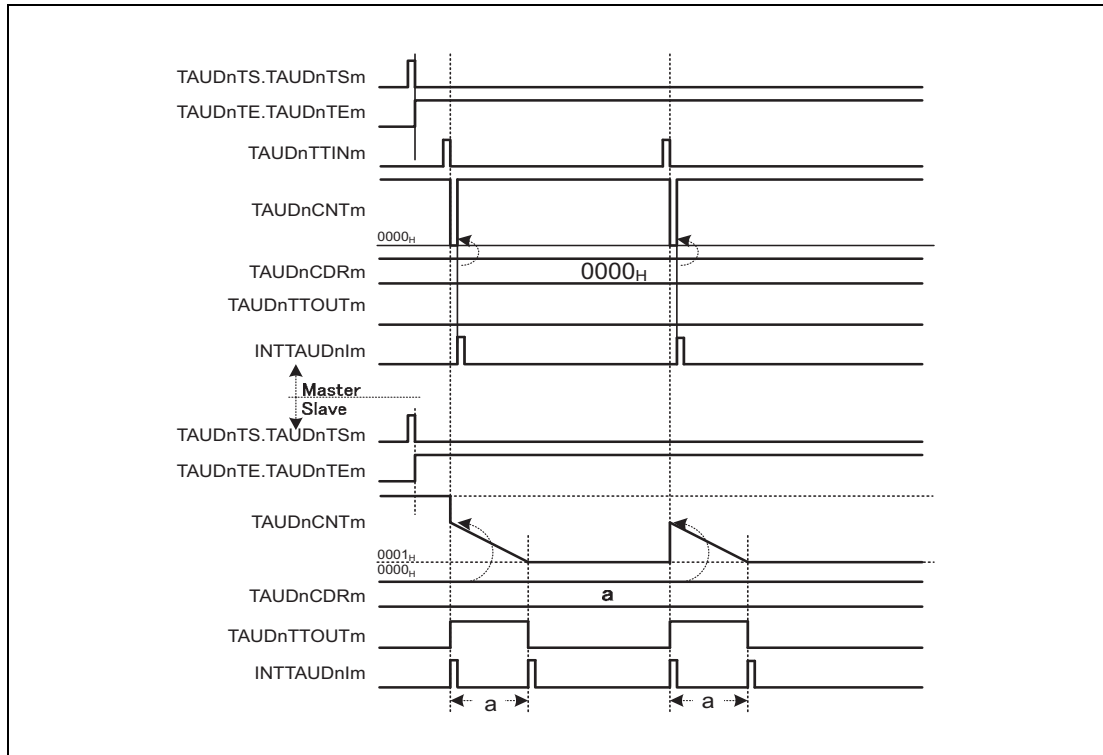

Figure 23.91 TAUDnCDRm (Master) = 0000_H

- When a valid TAUDnTTINm input edge is detected, the value 0000_H is written to TAUDnCNTm (master). The counter is set to 0000_H for one count and returns to FFFF_H. Thus the slave channel starts to count down one count clock later to TAUDnTTINm (master).

(2) TAUDnCDRm (slave) = 0000_H

The following settings apply to this diagram:

- Disables detection of start trigger during count operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

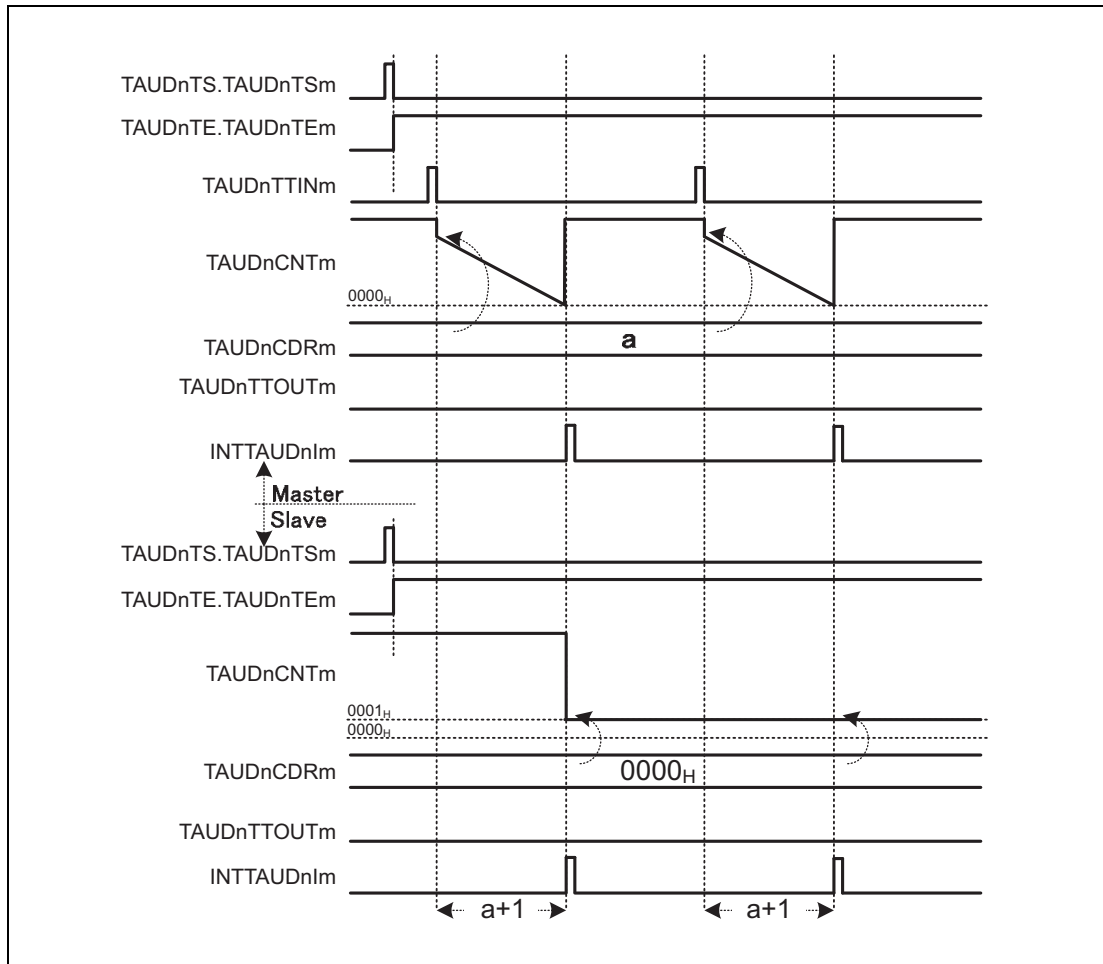

Figure 23.92 TAUDnCDRm (Slave) = 0000_H

- TAUDnTTOUTm remains at not active state, because the pulse width is zero.

(3) TAUDnCMORm.TAUDnMD0 = 1

The following settings apply to this diagram:

- Enables start trigger detection while counting. (TAUDnCMORm.TAUDnMD0 = 1)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

Figure 23.93 TAUDnCMORm.TAUDnMD0 = 1

- If a valid TAUDnTTINm input edge is detected while the counter of the master channel counts down, TAUDnCNTm reloads the value of TAUDnCDRm. The counter restarts to count down. This means the delay is extended by the value of TAUDnCNTm at the time a valid TAUDnTTINm input edge is detected.

(4) Restarting the master channel while the slave channel is counting

The following settings apply to this diagram:

- Disables detection of start trigger during count operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Detection of falling edge (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

Figure 23.94 Input Interval of TAUDnTTINm ≤ Delay Time + Pulse Width + 1

- If the master channel generates an interrupt before the counter of the slave channel has reached 0001_H or exactly when 0001_H is reached*¹, the interrupt (master) is ignored.
- If an interrupt of the master channel occurs when the counter of the slave channel awaits the next trigger, the value of TAUDnCDRm (slave) is reloaded. An interrupt is generated and TAUDnTTOUTm toggles. If TAUDnCNTm (master) has started to count down while the TAUDnCNTm (slave) is still counting*², TAUDnTTOUTm is not output with the expected delay time.
- To generate the correct one-shot pulse, the start trigger for the master channel must be detected while the master and slave channels are waiting for the start trigger, and not while they are counting.

23.13.3 Delay Pulse Output Function

23.13.3.1 Overview

Summary

This function outputs two signals. The pulse width and pulse cycle of the reference signal are defined using the master channel and slave channel 1. Slave channels 2 and 3 output the reference signal with a specified delay. The delay signal is identical to the reference signal, but delayed by the amount specified on slave channel 2.

The signal values are specified in the following way:

- The pulse cycle is specified using the master channel.
- The duty cycle of the reference signal is specified using slave channel 1. The duty cycle of the delay signal is specified using slave channel 3.
- The delay amount is specified on slave channel 2.

Prerequisites

- Four channels
- The operating mode for the master channel should be set to interval timer mode. (See **Table 23.138, Contents of the TAUDnCMORm register for the Master Channel of the Delay Pulse Output Function.**)
- The operating mode for slave channels 1 and 2 should be set to one-count mode. (See **Table 23.141, Contents of the TAUDnCMORm register for the Slave Channel 1 of the Delay Pulse Output Function, Table 23.145, Contents of the TAUDnCMORm register for the Slave Channel 2 of the Delay Pulse Output Function.**)
- The operating mode for slave channel 3 should be set to pulse one-count mode. (See **Table 23.148, Contents of the TAUDnCMORm register for the Slave Channel 3 of the Delay Pulse Output Function.**)
- TAUDnTTOUTm is not used with the master channel and slave channel 2.
- The channel output mode for slave channel 1 should be set to synchronous channel output mode 1. (See **Section 23.7, Channel Output Modes.**)
- The channel output mode for slave channel 3 should be set to independent channel output mode 2. (See **Section 23.7, Channel Output Modes.**)

Functional description

The counters of the channel group are started by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm to 1, enabling count operation.

- Master channel:
The current value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from this value. INTTAUDnIm is generated on the master channel.
When the counter value of master channel reaches 0000_H and pulse cycle time has elapsed, INTTAUDnIm is generated. The TAUDnCDRm value is reloaded into the counter to perform count down.

- Slave channels 1 and 2:

Slave channels 1 and 2 start to count down from the current TAUDnCDRm value when detecting an interrupt from the master channel. TAUDnTTOUTm signal (slave 1) is set.

 - Slave channel 1:

When the counter of slave channel 1 reaches 0000_H (duty time has elapsed), INTTAUDnIm is generated and TAUDnTTOUTm signal is reset. The counter is reset to FFFF_H and waits for the next INTTAUDnIm of master channel.
 - Slave channel 2:

When the counter of slave channel 2 reaches 0000_H and delay time has elapsed, INTTAUDnIm is generated. The counter is reset to FFFF_H and waits for the next INTTAUDnIm of master channel.

Generating INTTAUDnIm (slave channel 2) triggers the counter of slave channel 3.
- Slave channel 3:

When slave channel 3 detects an interrupt from slave channel 2, its counter starts counting down from the current value of TAUDnCDRm. INTTAUDnIm is generated and the TAUDnTTOUTm signal (slave channel 3) is set.

When the counter of slave channel 3 reaches 0001_H, INTTAUDnIm is generated and the TAUDnTTOUTm signal is reset.

The delayed PWM pulse is output from slave channel 3.

The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but their values are retained. The counter can be restarted by setting TAUDnTS.TAUDnTSm to 1.

Conditions

Simultaneous rewrite can be used with this function. See **Section 23.6, Simultaneous Rewrite**.

23.13.3.2 Equations

Pulse cycle = (TAUDnCDRm (master) + 1) × count clock cycle

Duty width 1 = (TAUDnCDRm (slave 1)) × count clock cycle

Delay width = (TAUDnCDRm (slave 2) + 1) × count clock cycle

Duty width 2 = (TAUDnCDRm (slave 3)) × count clock cycle

However, the delay width shall be set within the following range:

$0000_{\text{H}} \leq \text{TAUDnCDRm (slave 2)} < \text{TAUDnCDRm (master)}$

NOTES

1. The output waveform of TAUDnTTOUTm (slave 3) becomes the waveform made by delaying the output waveform of TAUDnTTOUTm (slave 1) by the quantity generated by slave 2. It is impossible to make a delay longer than the pulse cycle.
2. If INTTAUDnIm of slave 2 is generated while slave 3 is counting, slave 3 restarts operation. Therefore, the output waveform of TAUDnTTOUTm (slave 3) is retained on the active level. In this case, TOUTn (Slave-CH-3) cannot output the waveform generated by delaying the basic pulse of TOUTn (Slave-CH-1).

23.13.3.3 Block Diagram and General Timing Diagram

Figure 23.95 Block Diagram of Delay Pulse Output Function

The following settings apply to the general timing diagram.

- Slave channel 1: Positive logic (TAUDnTOL.TAUDnTOLm = 0)
- Slave channel 3: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

Figure 23.96 General Timing Diagram of Delay Pulse Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for the slave channel 1**Table 23.143 Control Bit Settings for the Slave Channel 1 in Synchronous Channel Output Mode 1**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	0: Operating mode 1
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	0: Operation as a real-time output trigger channel is prohibited.
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous rewrite for the slave channel 1

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.144 Simultaneous Rewrite Settings for the Slave Channel 1 of Delay Pulse Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Master channel is simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

23.13.3.6 Register Settings for Slave Channel 2

(1) TAUDnCMORm for slave channel 2

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for slave channel 3**Table 23.150 Control Bit Settings in Independent Channel Output Mode 2**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	0: Operation as a real-time output trigger channel is prohibited.
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous rewrite for slave channel 3

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.151 Simultaneous Rewrite Settings for Slave channel 3 of Delay Pulse Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Master channel is simultaneous rewrite control channel.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not use the channel to generate the simultaneous rewrite trigger.

23.13.3.8 Operating Procedure for Delay Pulse Output Function

Table 23.152 Operating Procedure for Delay Pulse Output Function (1/2)

	Operation	TAUDn Status
Initial Channel Setting	Master channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.3.4, Register Settings for the Master Channels.	Channel operation is stopped.
	Slave channel 1: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.3.5, Register Settings for the Slave Channel 1.	
	Slave channel 2: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.3.6, Register Settings for Slave Channel 2.	
	Slave channel 3: set the TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.3.7, Register Settings for Slave Channel 3.	
	Set the value of TAUDnCDRm register of every channel.	

Table 23.152 Operating Procedure for Delay Pulse Output Function (2/2)

	Operation	TAUDn Status
Restart	Start Operation Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master channel and slave channels 1 and 2 start. INTTAUDnIm is generated on the master channel and TAUDnTTOUTm (slave channel 1) is set.
	During Operation TAUDnCDRm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCNTm of master channel and slave channels 1 and 2 load TAUDnCDRm value and count down. When the counter of master channel reaches 0000H: <ul style="list-style-type: none"> • INTTAUDnIm (master) occurs. • TAUDnCDRm value is reloaded into TAUDnCNTm (master) to continue count operation. • TAUDnCDRm value is reloaded into TAUDnCNTm (slave 1/2) to start countdown. • TAUDnTTOUTm (slave 1) is set. When TAUDnCNTm (slave 1) reaches 0000H: <ul style="list-style-type: none"> • INTTAUDnIm (slave 1) occurs. • TAUDnTTOUTm (slave 1) is reset. When TAUDnCNTm (slave 2) reaches 0000H: <ul style="list-style-type: none"> • INTTAUDnIm (slave 2) occurs. • INTTAUDnIm (slave 3) occurs. • TAUDnTTOUTm (slave 3) is set. • TAUDnCDRm value is reloaded into TAUDnCNTm (slave 3) to start a countdown operation. When TAUDnCNTm (slave 3) reaches 0001H: <ul style="list-style-type: none"> • INTTAUDnIm (slave 3) occurs. • TAUDnTTOUTm (slave 3) is reset.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

23.13.3.9 Specific Timing Diagrams

(1) Duty cycle (slave 3) = 100%

The following values apply to **Figure 23.97**:

- TAUDnCDRm(master) = 000A_H
- TAUDnCDRm(slave 1) = 000B_H
- TAUDnCDRm(slave 2) = 0000_H
- TAUDnCDRm(slave 3) = 000B_H

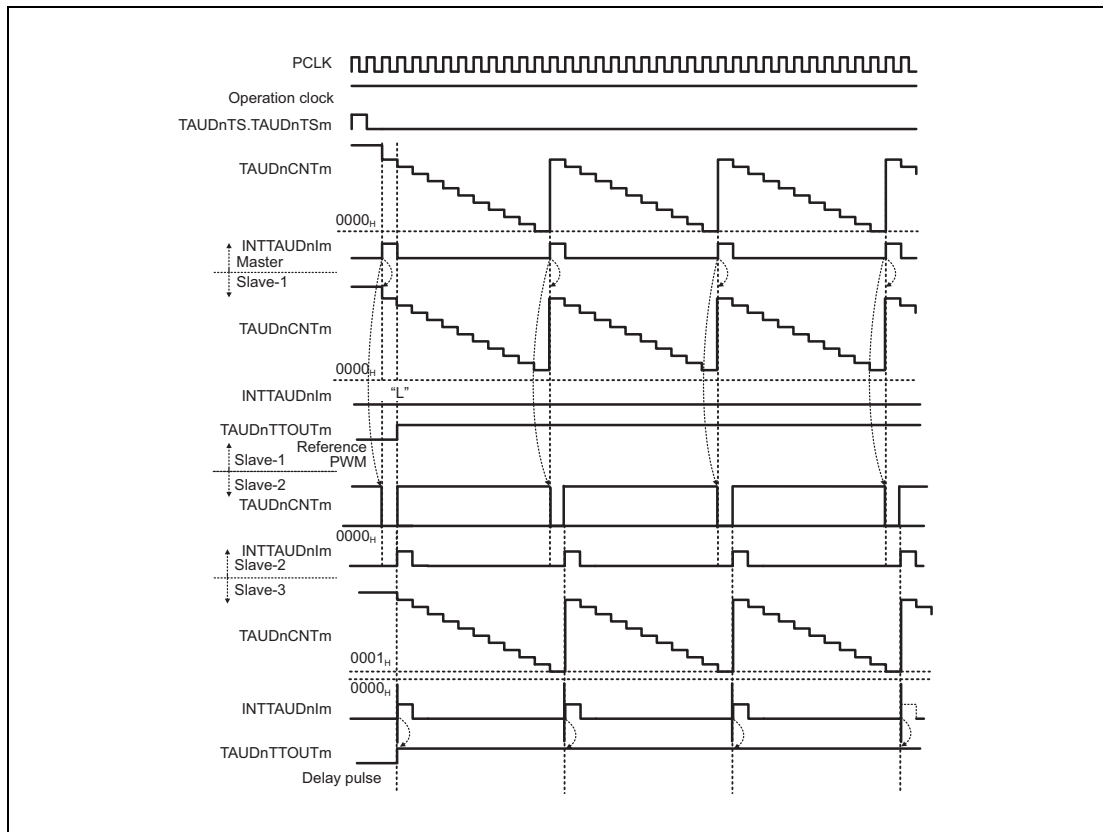

Figure 23.97 Duty Cycle (slave 3) = 100%

- If the value of TAUDnCDRm (slave 1 and 3) is higher than the value of TAUDnCDRm (master), the counter of slave channel 1 cannot reach 0000_H and cannot generate interrupts. TAUDnTTOUTm of channels 1 and 3 remain in the active state.

(2) TAUDnTTOUTm (slave 1)= TAUDnTTOUTm (slave 3)

The following values apply to **Figure 23.98**.

- TAUDnCDRm (master) = 000A_H
- TAUDnCDRm (slave 1) = 0005_H
- TAUDnCDRm (slave 2) = 0000_H
- TAUDnCDRm (slave 3) = 0005_H

Figure 23.98 TAUDnTTOUTm (Slave 1)= TAUDnTTOUTm (Slave 3)

- If TAUDnCDRm (slave 2) = 0000_H, the counter of slave channel 3 starts counting one count clock later than the counter of slave channel 1. The reference pulse and the delay pulse are output with a delay of one clock count.

23.13.4 Offset Trigger Output Function

23.13.4.1 Overview

Summary

This function generates triangle PWM outputs by using a master channel and slave channel. This sets the pulse cycle (frequency) of TAUDnTTOUTm.

The pulse cycle is set by detecting an effective input edge of the master channel. The pulse width is specified by the slave channel.

Prerequisites

- Two channels
- The operating mode for master channels should be set to capture mode. (See **Table 23.161, Contents of the TAUDnCMORm register for the Master Channel of the Triangle PWM Output Function.**)
- The operating mode for slave channels should be set one-count mode. (See **Table 23.165, Contents of the TAUDnCMORm register for the slave channel of the triangle PWM output function.**)
- The output mode for slave channels should be set to synchronous channel output mode 1. (See **Section 23.7, Channel Output Modes.**)
- TAUDTTOUTm is not used for master channels when this function is used.

Functional description

The counters are started by setting the channel trigger bit (TAUDnTS.TAUDnTSM) to 1. This in turn sets TAUDnTE.TAUDnTEM, enabling count operation. The counter of the master channel (TAUDnCNTm) starts to count up from 0000_H.

- Master channel:
When an effective TAUDTTINm input edge is detected, the current value of the counter (TAUDnCNTm) is loaded to the data register (TAUDnCDRm) of the master channel. INTTAUDnIm is generated and the counter restarts to count up from 0000_H.
- Slave channels:
When INTTAUDnIm is generated on the master channel, the TAUDTTOUTm (slave) signal is set and the counter of the slave channel is triggered. The current value of the TAUDnCDRm (slave) is loaded to TAUDnCNTm (slave) and the counter starts to count down from the TAUDnCDRm value.
When the counter reaches 0000_H (duty time is elapsed), INTTAUDnIm is generated and the INTTAUDnIm signal is reset. The counter is returned to FFFF_H and waits for the next INTTAUDnIm of the master channel.

Setting TAUDnTT.TAUDnTTm of the master/slave channel to 1 stops the counter operation. This sets TAUDnTE.TAUDnTEM to 0. TAUDnCNTm and TAUDTTOUTm of the master/slave channel stop, but retain their respective values. Setting TAUDnTS.TAUDnTSM to 1 restarts the count operation.

23.13.4.2 Equations

Pulse width = (TAUDnCDRm (slave)) × count clock cycle

Duty cycle [%] = [TAUDnCDRm (slave) / (TAUDnCDRm (master) + 1)] × 100

- Duty cycle = 0%
TAUDnCDRm (slave) = 0000_H
- Duty cycle = 100%
TAUDnCDRm (slave) ≥ TAUDnCDRm (master) + 1

23.13.4.3 Block Diagram and General Timing Diagram

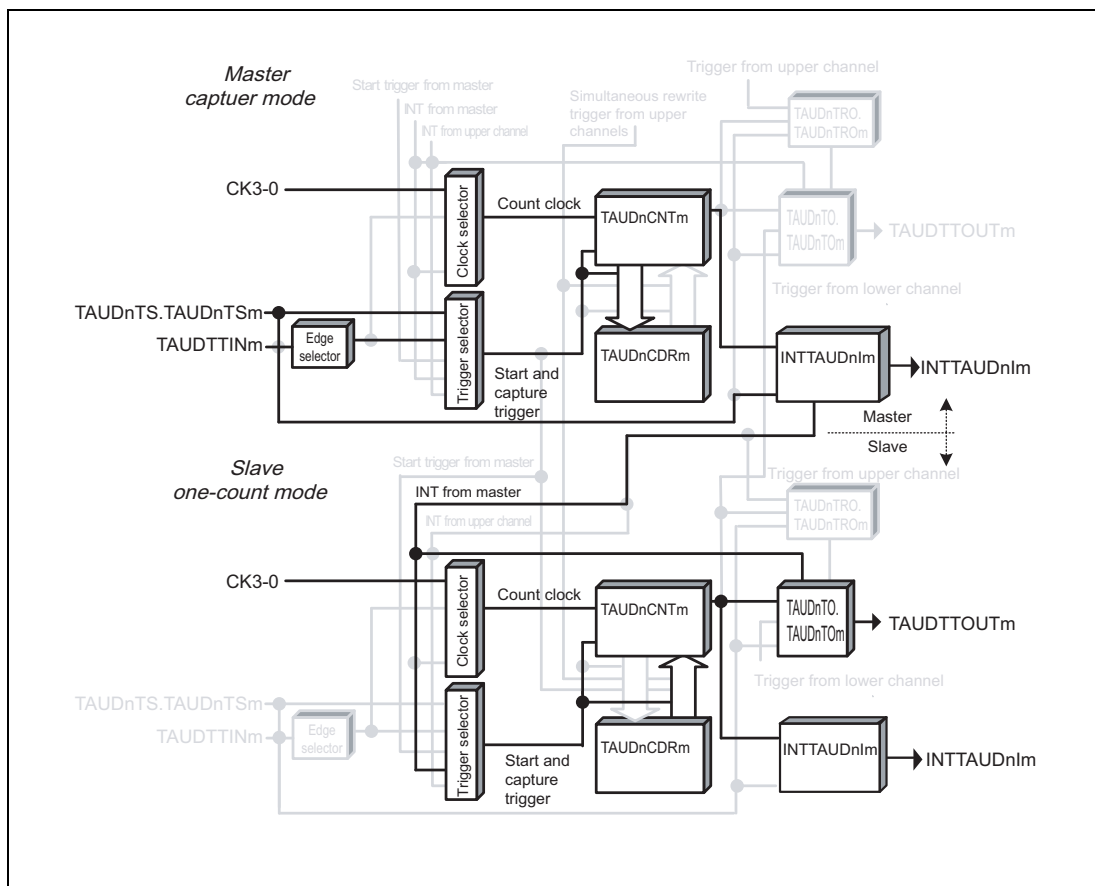

Figure 23.99 Block Diagram of Offset Trigger Output Function

The following settings apply to the general timing diagram.

- When a falling edge is detected (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

Figure 23.100 General Timing Diagram of Offset Trigger Output Function

NOTE

The TAUDTTOUTm signal from slave channel rises 1 cycle of the counter clock after the rising edge of INTTAUDnlm from the master channel.

23.13.4.4 Register Settings for Master Channels

(1) TAUDnCMORm for master channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 23.153 Contents of the TAUDnCMORm register for the Master Channel of the Offset Trigger Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS [1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	1: Channel is master channel
10 to 8	TAUDnSTS[2:0]	001: Uses an effective TAUDTTINm input edge signal as a start trigger
7, 6	TAUDnCOS[1:0]	11: Updates on detection of an effective TAUDTTINm input edge and occurrence of a counter overflow: <ul style="list-style-type: none"> – Detection of an effective TAUDTTINm input edge: A counter value is written to TAUDnCDRm. – Occurrence of an overflow; FFFF is written to TAUDnCDRm. The next effective TAUDTTINm input edge to be detected TAUDnCSRm.TAUDnOVF is set when a counter overflow occurs and cleared by the CPU instruction (TAUDnCSCm.TAUDnCLOV is set to 1).
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0010: Capture mode
0	TAUDnMD0	1: INTTAUDnIm is generated at the beginning of operation.

(2) TAUDnCMURm for master channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 23.154 Contents of the TAUDnCMURm register for the Master Channel of the Offset Trigger Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: A falling edge is detected. 01: A rising edge is detected. 10: Falling and rising edges are detected. 11: Setting prohibited

(3) Channel output mode for master channels

TAUDnTOE.TAUDnTOEm is set to 0 since channel output mode is not used in this function.

(4) Simultaneous rewrite for master channels

The simultaneous rewrite registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the offset trigger output function. Therefore, these registers must be set to 0.

Table 23.155 Simultaneous Rewrite Settings for Master Channels of Offset Trigger Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Disables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	When simultaneous rewrite is disabled, set this bit to 0 (TAUDnRDE.TAUDnRDEm = 0).
TAUDnRDM.TAUDnRDMm	
TAUDnRDC.TAUDnRDCm	

23.13.4.5 Register Settings for Slave Channels

(1) TAUDnCMORm for slave channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 23.156 Contents of TAUDnCMORm Register for Slave Channel of Offset Trigger Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bits of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	100: Up/down output trigger signal of master channel
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	1001: One-count mode
0	TAUDnMD0	1: Enables start trigger detection while counting.

(2) TAUDnCMURm for slave channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.157 Contents of the TAUDnCMURm Register for Slave Channel of Offset Trigger Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for slave channels**Table 23.158 Control Bit Settings in Synchronous Channel Output Mode 1**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	1: Operating mode 1
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm TAUDnTDL.TAUDnTDLm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set this bit to 0
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set this bit to 0
TAUDnTRC.TAUDnTRCm	0: Operation as a real-time output trigger channel is prohibited.
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous rewrite for slave channels

Simultaneous write registers (TAUDnRDE, TAUDnRDS, TAUDnRDM, and TAUDnRDC) cannot be used with the offset trigger output function. Therefore, these registers must be set to 0.

Table 23.159 Simultaneous Rewrite Settings for Slave Channels of Offset Trigger Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	0: Disables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm TAUDnRDM.TAUDnRDMm TAUDnRDC.TAUDnRDCm	When simultaneous rewrite is disabled, set this bit to 0 (TAUDnRDE.TAUDnRDEm = 0).

23.13.4.6 Operating Procedure for Offset Trigger Output Function

Table 23.160 Operating Procedure for Offset Trigger Output Function

	Operation	TAUDn Status
Initial Channel Setting	Master channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.4.4, Register Settings for Master Channels.	Channel operation is stopped.
	Slave channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.4.5, Register Settings for Slave Channels.	
	The TAUDnCDRm register of master channel operates as a capture register. Set the value of the TAUDnCDRm register of slave channel.	
Start Operation	Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master and slave channels start. <ul style="list-style-type: none"> TAUDnCNTm (master) starts to count up. The TAUDnCDRm value is loaded to TAUDnCNTm (slave) to perform counting down. INTTAUDnIm is generated on the master channel and TAUDnTTOUTm (slave) is set.
	TAUDnCDRm can be changed at any time. TAUDnCSCm.TAUDnCLOV can be set to 1. TAUDnCDRm of slave channel can be changed after INTTAUDnIm is generated. TAUDnCNT.TAUDnCNTm and TAUDnCSRm are readable at any time.	When the counter of master channel reaches 0000 _H : <ul style="list-style-type: none"> INTTAUDnIm (slave) occurs. TAUDnTTOUTm (slave) is reset and count operation stops on the slave channel. When a TAUDTTINm input edge is detected on the master channel: <ul style="list-style-type: none"> INTTAUDnIm (master) is generated. TAUDnCNTm (master) is reset to 0000_H and continues to count. TAUDnCDRm value is reloaded into TAUDnCNTm (slave) to perform counting down. TAUDTTOUTm (slave) is set.
During Operation		
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

23.13.4.7 Specific Timing Diagrams

(1) Duty cycle = 0%

The following settings apply to the specific timing diagram.

- When a falling edge is detected (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

Figure 23.101 TAUDnCDRm (Slave) = 0000_H

- When TAUDnCDRm (slave) is 0000_H, 0000_H is written to TAUDnCNTm every time master channel generates an interrupt (INTTAUDnIm). Thus TAUDnCNTm cannot start to count operation. TAUDTTOUTm remains inactive.
- TAUDnCNTm (slave) generates an interrupt every time the TAUDnCDRm value is reloaded. Slave and master channels generate interrupts in the same cycle.

(2) Duty cycle = 100%

The following settings apply to the specific timing diagram.

- When a falling edge is detected (TAUDnCMURm.TAUDnTIS[1:0] = 00_B)

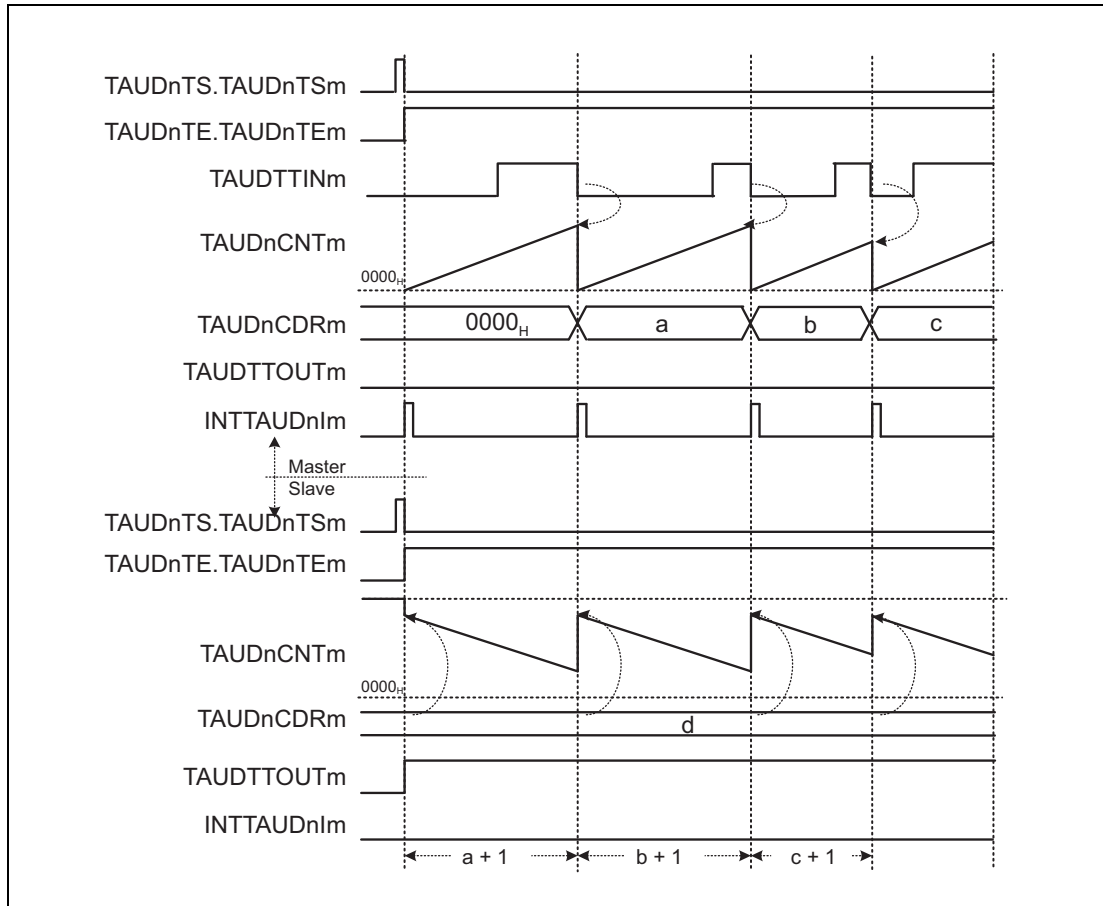

Figure 23.102 TAUDnCDRm (Slave) ≥ TAUDnCDRm (Master) + 1

- When TAUDnCDRm (slave) value exceeds the interval of an effective input edge, the counter of slave channel does not reach 0000H, and an interrupt is not generated. TAUDTTOUTm remains active.

23.13.5 A/D Conversion Trigger Output Function Type 1

23.13.5.1 Overview

Summary

This function is identical to **Section 23.13.1, PWM Output Function**, except that TAUDnTTOUTm is not output.

This function is enabled by setting the channel output mode for the slave to independent channel output mode controlled by software.

23.13.5.2 Block Diagram and General Timing Diagram

Figure 23.103 Block Diagram of A/D Conversion Trigger Output Function Type 1

23.13.5.3 General Timing Diagram

The following settings apply to the general timing diagram.

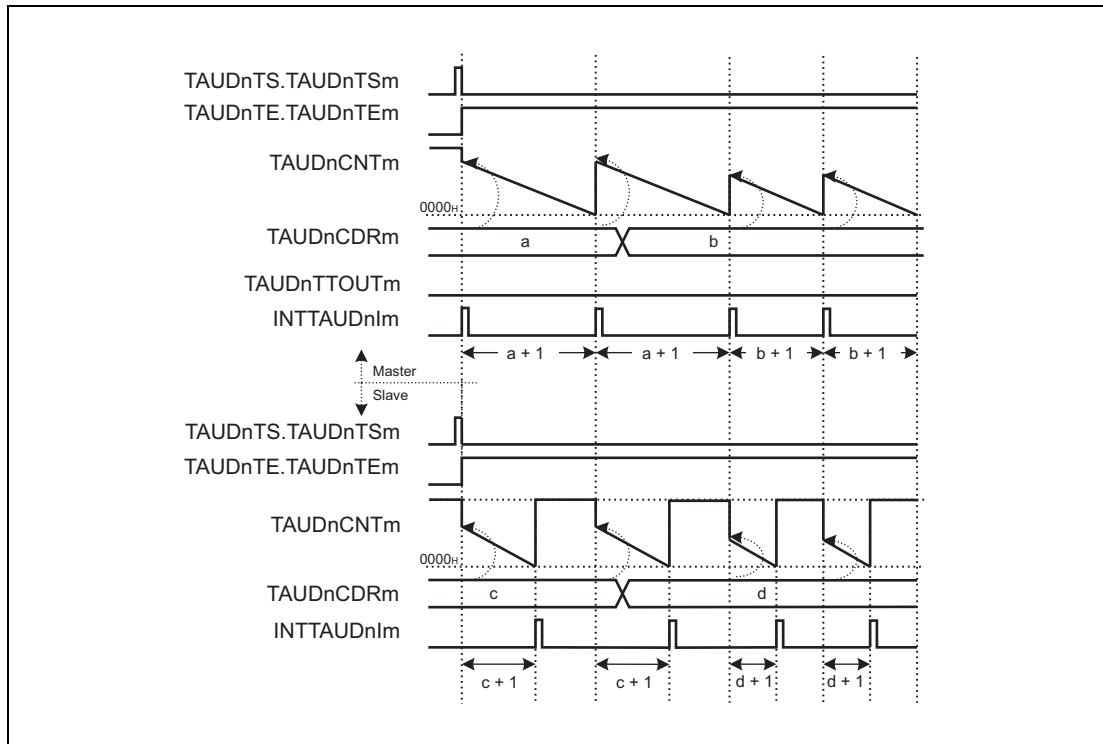

Figure 23.104 General Timing Diagram of A/D Conversion Trigger Output Function Type 1

23.13.6 Triangle PWM Output Function

23.13.6.1 Overview

Summary

This function generates multiple triangle PWM outputs by using a master and one or more slave channels. It enables the pulse cycle (frequency) and the duty cycle of TAUDnTTOUTm to be set using the master and slave channels respectively.

The master channel generates a carrier cycle. The first cycle of master channel controls the down status and the second cycle controls the up status of the slave counter.

Prerequisites

- Two channels
- The operating mode for master channels should be set to interval timer mode. (See **Table 23.161, Contents of the TAUDnCMORm register for the Master Channel of the Triangle PWM Output Function.**)
- The operating mode for slave channels should be set up/down count mode. (See **Table 23.165, Contents of the TAUDnCMORm register for the slave channel of the triangle PWM output function.**)
- The channel output mode for master channels should be set to independent channel output mode 1. (See **Section 23.7, Channel Output Modes.**)
- The channel output mode for slave channels should be set to synchronous channel output mode 2. (See **Section 23.7, Channel Output Modes.**)
- The following settings allow TAUDnTTOUTm signal to be at high level during the down status of a carrier cycle.
 - If TAUDnCMORm.TAUDnMD0 (master) bit is set to 0, TAUDnTO.TAUDnTOm should be set to 1 while TAUDnTOE.TAUDnTOEm is set to 0 (recommended setting).
 - If TAUDnCMORm.TAUDnMD0 (master) bit is set to 1, TAUDnTO.TAUDnTOm should be set to 0 while TAUDnTOE.TAUDnTOEm is set to 0.

Functional description

The counters are started by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1 for every channel. This in turn sets TAUDnTE.TAUDnTEm, enabling count operation.

The current values of TAUDnCDRm (master and slave) are loaded into TAUDnCNTm (master and slave) and the counters start counting down from these values. When the TAUDnCMORm.TAUDnMD0 bit of master channel is set to 1, an interrupt is generated and TAUDnTTOUTm signal of master toggles.

- Master channel:

When the counter of master channel reaches 0000_H (pulse cycle time has elapsed), INTTAUDnIm is generated and the TAUDnTTOUTm signal toggles. TAUDnCNTm then reloads the TAUDnCDRm value and counts down.

- Slave channels:

The INTTAUDnIm of master channel triggers the counter of the slave channel:

- If the slave counter is counting down, the count direction changes.
- If the slave counter is counting up, TAUDnCDRm value is reloaded and the counter starts to count down.

When the counter of the slave channel reaches 0001_H while counting up or down, INTTAUDnIm is generated and the TAUDnTTOUTm (slave) signal is set/reset.

The counter continues count-up/-down and waits for the next INTTAUDnIm of master channel.

Setting TAUDnTOL.TAUDnTOLm allows TAUDnTTOUTm signal switching between normal phase and reverse phase during operation.

The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm = 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but retain their values.

Conditions

This function enables simultaneous rewrite. See **Section 23.6, Simultaneous Rewrite**.

23.13.6.2 Equations

Pulse cycle = (TAUDnCDRm (master) + 1) × count clock cycle

0000_H ≤ TAUDnCDRm (master) < FFFF_H

Carrier cycle (down/up) = (TAUDnCDRm (master) + 1) × 2 × count clock cycle

Duty cycle [%] =

$(\text{TAUDnCDRm (master)} + 1 - \text{TAUDnCDRm (slave)}) / (\text{TAUDnCDRm (master)} + 1) \times 100$

- Duty cycle = 100%

TAUDnCDRm (slave) = 0000_H

- Duty cycle = 0%

TAUDnCDRm (slave) ≥ TAUDnCDRm (master) + 1

23.13.6.3 Block Diagram and General Timing Diagram

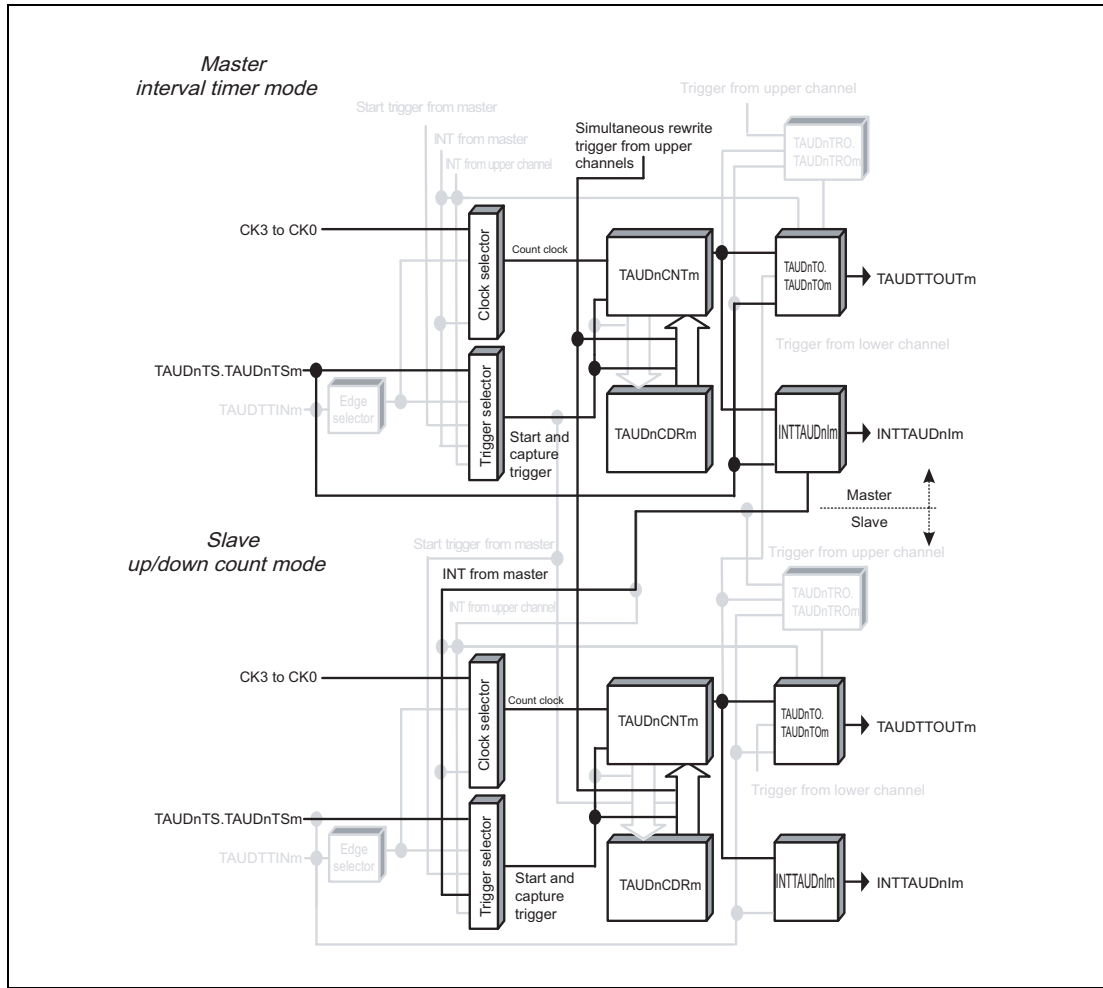

Figure 23.105 Block Diagram of Triangle PWM Output Function

The following settings apply to the general timing diagram.

- Master channel
 - INTTAUDnIm generated at the beginning of operation.
(TAUDnCMORm.TAUDnMD0 = 1)

7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for master channels**Table 23.163 Control Bit Settings in Independent Channel Output Mode 1**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode. (The value is the initial value after reset.)
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROM	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	0: Operation as a real-time output trigger channel is prohibited.
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous rewrite for master channels

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.164 Simultaneous Rewrite Settings for Master Channels of Triangle PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects master channel for simultaneous rewrite triggers. 1: Selects upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not use the channel to generate the simultaneous rewrite trigger.

NOTE

If TAUDnRDS.TAUDnRDSm = 1, it is necessary for an upper channel higher than a master channel to generate a simultaneous rewrite trigger signal.

23.13.6.5 Register Settings for Slave Channels

(1) TAUDnCMORm for slave channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for slave channels**Table 23.167 Control Bit Settings in Synchronous Channel Output Mode 2**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	0: Operation as a real-time output trigger channel is prohibited.
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous rewrite for slave channels

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.168 Simultaneous Rewrite Settings for Slave Channels of Triangle PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects master channel for simultaneous rewrite triggers. 1: Selects upper channel for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not use the channel to generate the simultaneous rewrite trigger.

23.13.6.6 Operating Procedure for Triangle PWM Output Function

Table 23.169 Operating Procedure for Triangle PWM Output Function

	Operation	TAUDn Status
Initial Channel Setting	Master channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.6.4, Register Settings for Master Channels.	Channel operation is stopped.
	Slave channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.6.5, Register Settings for Slave Channels.	
	Set the value of TAUDnCDRm register of every channel.	
Restart	Start Operation	<p>Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.</p> <p>TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master and slave channels start. INTTAUDnIm (master) is generated on the master channel if TAUDnCMORm.TAUDnMD0 is set to 1.</p>
During Operation	<p>TAUDnCDRm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnTOL.TAUDnTOLm can be changed.</p> <p>TAUDnRDT.TAUDnRDTm can be changed during operation.</p>	<p>TAUDnCDRm value of master and slave channels is loaded into TAUDnCNTm to perform counting down. 	Stop Operation	<p>Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.</p> <p>TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.</p>

23.13.6.7 Specific Timing Diagrams

(1) Duty cycle = 0%

The following settings apply to the general timing diagram.

- Master channel:
 - INTTAUDnIm generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)
 - TAUDnCDRm = a = 5_H
- Slave channels:
 - TAUDnCDRm = 6_H

Figure 23.107 TAUDnCDRm (Slave) ≥ TAUDnCDRm (Master) + 1

- If TAUDnCDRm (slave) value is greater than TAUDnCDRm (master) value + 1, INTTAUDnIm of the slave channel is not generated while counting down. TAUDnTTOUTm remains low because there is no set signal to be detected.

(2) Duty cycle = 100%

The following settings apply to the general timing diagram.

- Master channel:
 - INTTAUDnIm generated at the beginning of operation. ($\text{TAUDnCMORm.TAUDnMD0} = 1$)
 - $\text{TAUDnCDRm} = a = 5_{\text{H}}$
- Slave channels:
 - $\text{TAUDnCDRm} = 0_{\text{H}}$

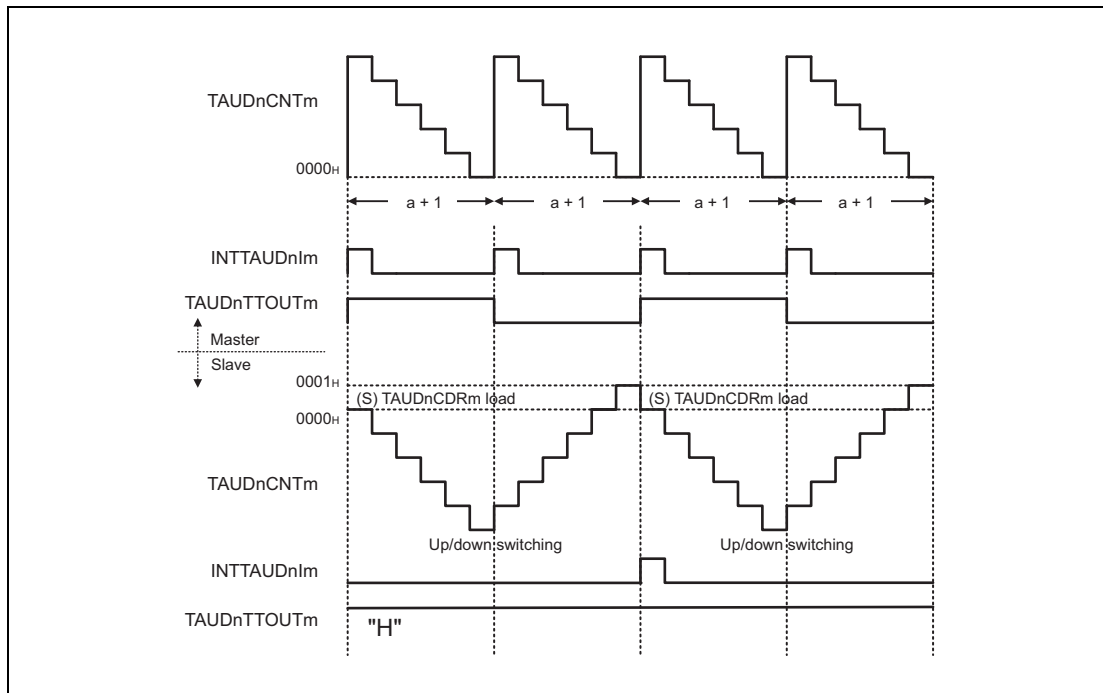

Figure 23.108 TAUDnCDRm (Slave) = 0000_H

- If $\text{TAUDnCDRm (slave)} = 0000_{\text{H}}$, INTTAUDnIm of slave channel is not generated while counting up. TAUDnTTOUTm remains high because there is no reset signal to be detected.

23.13.7 Triangle PWM Output Function with Dead Time

23.13.7.1 Overview

Summary

This function generates multiple triangle PWM outputs with a predefined dead time added by using a master and two or more slave channels. The resulting PWM signals with dead time are output via TAUDnTTOUTm of the slave channels 2 and 3, enabling the pulse cycle (frequency) and the duty cycle of TAUDnTTOUTm to be set using the master and slave channels.

Carrier cycles are generated on master channel. The first pulse controls the down status of slave counter and the second one controls the up status.

An interrupt on slave 2 causes TAUDnTTOUTm of slave channels to be set/reset. Depending on the settings of TAUDnTDL.TAUDnTDLm, delay time is added to positive or negative logic side of the signal (i.e., whether TAUDnTTOUTm is set/reset immediately or after dead time has elapsed). The duration of the dead time is specified by slave channel 3.

Prerequisites

- Three channels. For slave channels 2 and 3, select even-numbered channel CH (a) and odd-numbered channel CH (a + 1).
- The operating mode for master channels should be set to interval timer mode. (See **Table 23.171, Contents of the TAUDnCMORm register for the Master Channel of the Triangle PWM Output Function with dead time**)
- Slave channel 1 is not used for this function. This ensures that slave channel 2 is an even-numbered channel (a), and slave channel 3 is an odd-numbered channel (a + 1). Slave channel 1 can be used as a separate timer (independent function).
- The operating mode for slave channel 2 should be set to up/down count mode (See **Table 23.175, Contents of the TAUDnCMORm register for the Slave Channel 2 of the Triangle PWM Output Function with Dead Time**). Slave channel 2 should be an even-numbered channel.
- The operating mode for slave channel 3 should be set to one-count mode (See **Table 23.179, Contents of the TAUDnCMORm register for the Slave Channel 3 of the Triangle PWM Output Function with Dead Time**). Slave channel 3 should be an odd-numbered channel.
- The channel output mode for master channels should be set to independent channel output mode 1. (See **Section 23.7, Channel Output Modes**)
- The output mode for slave channels 2 and 3 should be set to synchronous channel output mode 2 with dead time output. (See **Section 23.7, Channel Output Modes**)

- The following settings make a TAUDnTTOUTm signal at high level during the down status of the carrier cycle:
 - If TAUDnCMORm.TAUDnMD0 (master) bit is set to 0, TAUDnTO.TAUDnTOm should be set to 1 while TAUDnTOE.TAUDnTOEm is set to 0. (recommended setting)
 - If TAUDnCMORm.TAUDnMD0 (master) bit is set to 1, TAUDnTO.TAUDnTOm should be set to 0 while TAUDnTOE.TAUDnTOEm is set to 0.

NOTE

The triangle PWM output function with dead time does not use slave channel 1. Slave channel 1 can be used as a separate timer (independent function).

Functional description

The counter starts by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This makes TAUDnTE.TAUDnTEm = 1, enabling count operation. The current value of TAUDnCDRm is loaded into TAUDnCNTm and the counter starts to count down from the TAUDnCDRm value. If TAUDnCMORm.TAUDnMD0 bit of master channel is set to 1, an interrupt is generated and the master's TAUDnTTOUTm signal is toggled.

- Master channel:
When the counter of master channel reaches 0000_H, an INTTAUDnIm is generated and the TAUDnTTOUTm signal is toggled. The TAUDnCDRm value is reloaded to continue countdown.
- Slave channel 2:
If INTTAUDnIm is generated on the master channel, the counter of slave channel 2 is triggered.
 - If the slave counter is counting down, the counting direction changes.
 - If the slave counter is counting up, the TAUDnCDRm value is reloaded and the counter starts to count down.

The counter continues to count down/up and waits for the next INTTAUDnIm of master channel. When the counter value of slave channel 2 reaches 0001_H, INTTAUDnIm is generated.

- Slave channel 3:
If INTTAUDnIm is generated on slave channel 2, the counter of slave channel 3 is triggered. The current value of TAUDnCDRm (slave 3) is loaded into TAUDnCNTm (slave 3) and the counter starts to count down from the TAUDnCDRm value.
When the counter reaches 0000_H, INTTAUDnIm occurs. The counter returns to FFFF_H and waits for the next INTTAUDnIm of slave channel 2.

As described in **Table 23.170, Operation of TAUDnTTOUTm upon Occurrence of an Interrupt on Slave Channel 2**, the set/reset timing (right after occurrence of an interrupt or after dead time has elapsed) depends on the TAUDnTDL.TAUDnTDLm setting of the corresponding channel.

The setting of TAUDnTOL.TAUDnTOLm also determines whether a high level signal (TAUDnTOL.TAUDnTOLm = 0) or a low level signal (TAUDnTOL.TAUDnTOLm = 1) is output from the corresponding channel.

The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but retain their values.

TAUDnTTOUTm can be 100% output by setting the TAUDnCDRm value of slave channel 2 to 0000_H.

Conditions

This function enables simultaneous rewrite. See **Section 23.6, Simultaneous Rewrite**.

TAUDnTOL.TAUDnTOLm and TAUDnTDL.TAUDnTDLm should be set before start of count operation. Slave channels 2 and 3 should have the opposite settings of TAUDnTOL.TAUDnTOLm or TAUDnTDL.TAUDnTDLm.

Table 23.170 Operation of TAUDnTTOUTm upon Occurrence of an Interrupt on Slave Channel 2

TAUDnTDL. TAUDnTDLm	Count Direction of Slave Channel 2 upon Occurrence of Interrupt	TAUDnTTOUTm Set/Reset Timing
0	Down	Set after elapse of dead time
	Up	Reset right after interrupt occurs
1	Down	Set right after interrupt occurs
	Up	Reset after elapse of dead time

23.13.7.2 Equations

Pulse cycle = (TAUDnCDRm (master) + 1) × count clock cycle

0000_H ≤ TAUDnCDRm (master) < FFFF_H

Carrier cycle (down/up) = (TAUDnCDRm (master) + 1) × 2 × count clock cycle

PWM signal width (normal phase) = [(TAUDnCDRm (master) + 1 – TAUDnCDRm (slave 2)) × 2 – (TAUDnCDRm (slave 3) + 1)] × count clock cycle

PWM signal width (reverse phase) = [(TAUDnCDRm (master) + 1 – TAUDnCDRm (slave 2)) × 2 + (TAUDnCDRm (slave 3) + 1)] × count clock cycle

23.13.7.3 Block Diagram and General Timing Diagram

Figure 23.109 Block Diagram of Triangle PWM Output Function with Dead Time

The following settings apply to the general timing diagram.

- Master channel:
 - INTTAUDnIm generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)
- Slave channel 2:
 - INTTAUDnIm not generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 0)
 - TAUDnTDL.TAUDnTDLm = 0
 - Positive logic (TAUDnTOL.TAUDnTOLm = 0)

- Slave channel 3:
 - Start trigger detection enabled during counting ($TAUDnCMORm.TAUDnMD0 = 1$)
 - $TAUDnTDL.TAUDnTDLm = 1$
 - Positive logic ($TAUDnTOL.TAUDnTOLm = 0$)

Figure 23.110 General Timing Diagram of Triangle PWM Output Function with Dead Time

23.13.7.4 Register Settings for Master Channels

(1) TAUDnCMORm for master channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKs[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 23.171 Contents of the TAUDnCMORm register for the Master Channel of the Triangle PWM Output Function with dead time

Bit Position	Bit Name	Function
15, 14	TAUDnCKs[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKs[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	1: Channel is master channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	0: INTTAUDnIm is not generated and TAUDnTTOUTm is not toggled at the beginning of operation. 1: INTTAUDnIm is generated and TAUDnTTOUTm is toggled at the beginning of operation.

(2) TAUDnCMURm for master channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.172 Contents of the TAUDnCMURm register for the Master Channel of the Triangle PWM Output Function with dead time

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for master channels**Table 23.173 Control Bit Settings in Independent Channel Output Mode 1**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: The setting is disabled in toggle mode (The value after reset).
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	0: Operation as a real-time output trigger channel is prohibited.
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous rewrite for master channels

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.174 Simultaneous Rewrite Setting for Master Channels of Triangle PWM Output Function with Dead Time

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects master channel for simultaneous rewrite triggers. 1: Selects upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

NOTE

If TAUDnRDS.TAUDnRDSm = 1, it is necessary for an upper channel higher than a master channel to generate a simultaneous rewrite trigger signal.

23.13.7.5 Register Settings for Slave Channel 2

(1) TAUDnCMORm for slave channel 2

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]		TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 23.175 Contents of the TAUDnCMORm register for the Slave Channel 2 of the Triangle PWM Output Function with Dead Time

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	111: Up/down output trigger signal of master channel
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	1001: Up/down count mode
0	TAUDnMD0	0: INTTAUDnIm not generated at the beginning of operation.

(2) TAUDnCMURm for slave channel 2

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.176 Contents of the TAUDnCMURm register for the Slave Channel 2 of the Triangle PWM Output Function with Dead Time

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for slave channel 2**Table 23.177 Control Bit Settings in Synchronous Channel Output Mode 2 with Dead Time Output**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	1: Enables dead time operation.
TAUDnTDM.TAUDnTDMm	0: Adds dead time if an interrupt is detected on an even-numbered upper channel and the conditions set by TAUDnTDL.TAUDnTDLm are satisfied.
TAUDnTDL.TAUDnTDLm	0: Adds dead time to normal phase. 1: Adds dead time to reverse phase.
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROM	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	0: Operation as a real-time output trigger channel is prohibited.
TAUDnTME.TAUDnTMEm	0: Disables modulation

CAUTION

Set TAUDnTDL.TAUDnTDLm exclusively from odd-numbered channels.

(4) Simultaneous rewrite for slave channel 2

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.178 Simultaneous Rewrite Settings for Slave Channel 2 of Triangle PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects master channel for simultaneous rewrite triggers. 1: Selects upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

23.13.7.6 Register Settings for Slave Channel 3

(1) TAUDnCMORm for slave channel 3

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]		TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 23.179 Contents of the TAUDnCMORm register for the Slave Channel 3 of the Triangle PWM Output Function with Dead Time

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	110: The up/down output trigger signal TAUDnUDCm of the master channel is the start trigger
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0100: One-count mode
0	TAUDnMD0	1: Enables start trigger detection while counting.

(2) TAUDnCMURm for slave channel 3

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.180 Contents of the TAUDnCMURm register for the Slave Channel 3 of the Triangle PWM Output Function with Dead Time

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for slave channel 3**Table 23.181 Control Bit Settings in Synchronous Channel Output Mode 2 with Dead Time Output**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel operation
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	1: Enables dead time operation.
TAUDnTDM.TAUDnTDMm	0: Adds dead time if an interrupt is detected on an even-numbered upper channel and the conditions set by TAUDnTDL.TAUDnTDLm are satisfied.
TAUDnTDL.TAUDnTDLm	0: Adds dead time to normal phase. 1: Adds dead time to reverse phase.
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROM	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	0: Operation as a real-time output trigger channel is prohibited.
TAUDnTME.TAUDnTMEm	0: Disables modulation

CAUTION

Set TAUDnTDL.TAUDnTDLm exclusively from even-numbered channels.

(4) Simultaneous rewrite for slave channel 3

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.182 Simultaneous Rewrite Settings for Slave Channel 3 of Triangle PWM Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects master channel for simultaneous rewrite triggers. 1: Selects upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

23.13.7.7 Operating Procedure for Triangle PWM Output Function with Dead Time

Table 23.183 Operating Procedure for Triangle PWM Output Function with Dead Time

	Operation	TAUDn Status
Initial Channel Setting	Master channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.7.4, Register Settings for Master Channels.	Channel operation is stopped.
	Slave channel 2: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.7.5, Register Settings for Slave Channel 2.	
	Slave channel 3: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.7.6, Register Settings for Slave Channel 3.	
	Set the value of TAUDnCDRm register of every channel.	
Start Operation	Set TAUDnTS.TAUDnTSM of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM (master and slave channels) is set to 1 and the counters of master and slave channels start. INTTAUDnIm (master) is generated on the master channel if TAUDnCMORm.TAUDnMD0 is set to 1.
	TAUDnCDRm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCDRm value of master channel and slave channel 2 is loaded into TAUDnCNTm to perform counting down. When the counter of master channel reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUDnIm (master) occurs. • TAUDnCDRm value is reloaded into TAUDnCNTm (master) to continue count operation. • TAUDnCDRm value is reloaded into TAUDnCNTm (slave 2) or counting is started in opposite direction. When TAUDnCNTm of slave channel 2 reaches 0001 _H : <ul style="list-style-type: none"> • IINTTAUDnIm (slave 2) is generated. • TAUDnCDRm value of slave channel 3 is loaded into TAUDnCNTm perform counting down. When TAUDnCNTm of slave channel 3 reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUDnIm is generated.
Stop Operation	Set TAUDnTT.TAUDnTTM of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

Restart

During Operation

Stop Operation

23.13.7.8 Specific Timing Diagrams

(1) Duty cycle = 0%

The following settings apply to the general timing diagram in **Figure 23.111**.

- Slave channel 2:
 - Positive logic (TAUDnTDL.TAUDnTDLm = 0)
- Slave channel 3:
 - Negative logic (TAUDnTDL.TAUDnTDLm = 1)

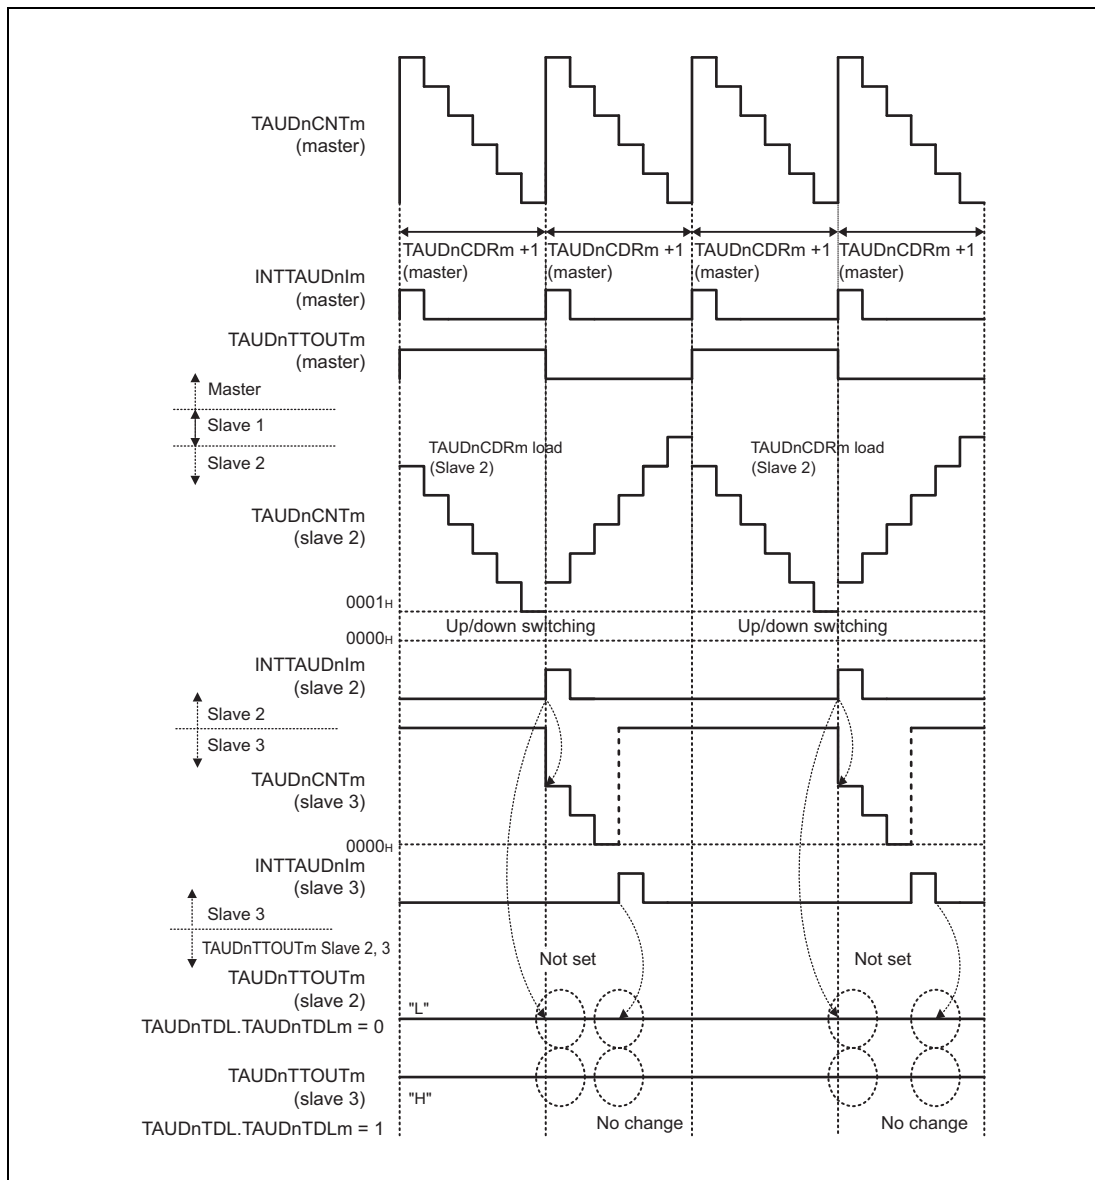

Figure 23.111 TAUDnCDRm (Slave 2) ≥ TAUDnCDRm (Master) + 1

- If TAUDnCDRm (slave 2) is greater than TAUDnCDRm (master), the counter of slave channel does not reach 0000_H while counting down. Therefore, TAUDnTTOUTm signal is not set/reset and remains initial. This signal becomes a reset signal because an interrupt occurs on slave channel 2 during count-up operation.

(2) Duty cycle = 100%

The following settings apply to the general timing diagram in **Figure 23.112**.

- Slave channel 2:
 - Positive logic (TAUDnTDL.TAUDnTDLm = 0)
- Slave channel 3:
 - Negative logic (TAUDnTDL.TAUDnTDLm = 1)

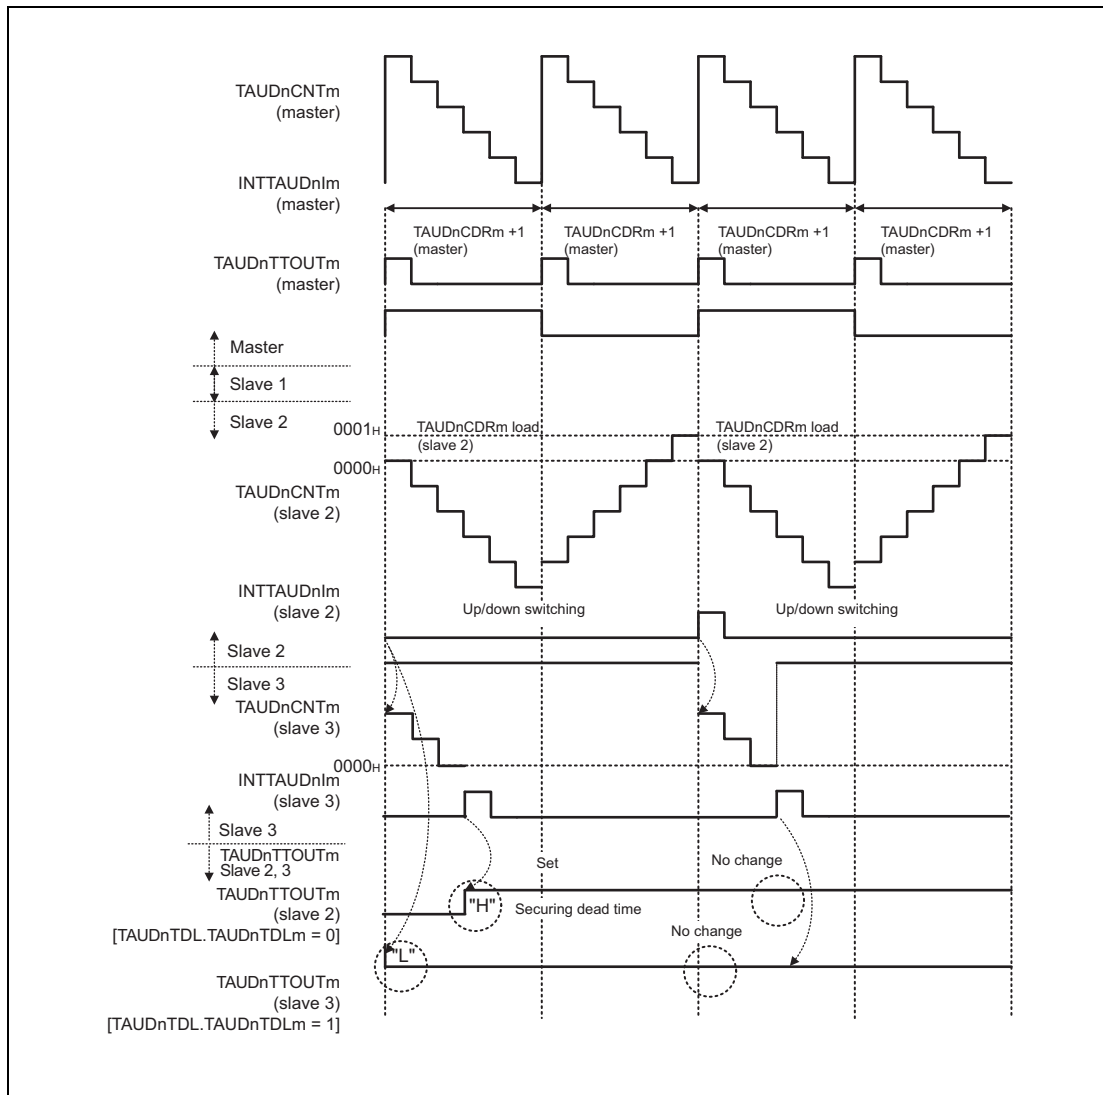

Figure 23.112 TAUDnCDRm (Slave) = 0000_H

- If TAUDnCDRm (slave 2) = 0000_H, the slave channel counter does not reach 0001_H while counting up. Therefore, no INTTAUDnIm occurs during count-up operation.
 - The set conditions for a channel with TAUDnTDL.TAUDnTDLm = 0 are met after elapse of dead time. TAUDnTTOUTm is left in a newly set state even if a set/reset is made because no reset conditions are satisfied on such a channel.
 - Slave channel 3 in the above diagram is set when the counter starts. However, TAUDnTTOUTm is left in an initial state on the slave channel with TAUDnTDL.TAUDnTDLm = 1 because no reset conditions are satisfied on that channel.

23.13.8 A/D Conversion Trigger Output Function Type 2

23.13.8.1 Overview

Summary

This function is identical to **Section 23.13.6, Triangle PWM Output Function**, except that TAUDnTTOUTm is not output.

This function is enabled by setting channel output mode for the slave to independent channel output mode controlled by software.

23.13.8.2 Block Diagram and General Timing Diagram

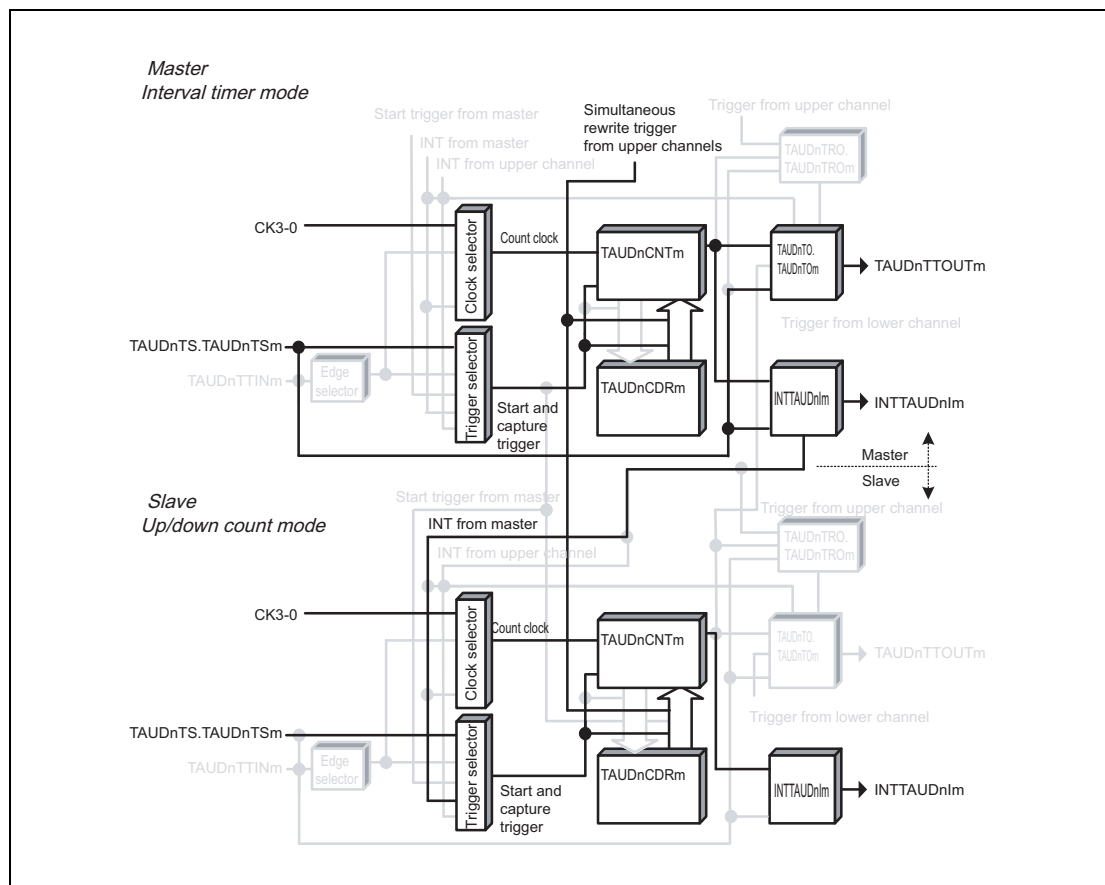

Figure 23.113 Block Diagram of A/D Conversion Trigger Output Function Type 2

The following settings apply to the general timing diagram.

- Master channel
 - INTTAUDnIm generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)

Figure 23.114 General Timing Diagram of A/D Conversion Trigger Output Function Type 2

23.13.9 Interrupt Request Signals Culling Function

23.13.9.1 Overview

Summary

This function divides the number of interrupts of the master channel by a specified value using a slave channel.

The interrupt request signals culling function is a sub function of the following functions:

- PWM Output Function (See **Section 23.13.1, PWM Output Function**)
- Triangle PWM Output Function (See **Section 23.13.6, Triangle PWM Output Function**)
- Triangle PWM Output Function with Dead Time
(See **Section 23.13.7, Triangle PWM Output Function with Dead Time**)

Prerequisites

- Two channels
- The operation mode of the master channel must be set to interval timer mode. (See **Table 23.184, Contents of the TAUDnCMORm register for the Master Channel of the Interrupt Request Signals Culling Function**)
- The operation mode of the slave channel must be set to Event Count Mode. (See **Table 23.187, Contents of the TAUDnCMORm register for the Slave Channel of the Interrupt Request Signals Culling Function**)
- TAUDnTTOUTm is not used for the master or slave channel of this function

Functional description

The counters (master and slave) are started by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1 for both channels. This in turn sets TAUDnTE.TAUDnTEm, enabling count operation. The current value of the data register of the master channel and slave channel (TAUDnCDRm) are written to the counter (TAUDnCNTm).

- Master channel:
When the counter of the master channel reaches 0000_H, INTTAUDnIm is generated and TAUDnCDRm value is reloaded to TAUDnCNTm.
- Slave channel:
Every time the master channel generates an INTTAUDnIm, the counter of the slave channel reduces by one. When the counter reaches 0000_H, it awaits the next interrupt from the master channel. This causes TAUDnCNTm (slave) to reload the value of TAUDnCDRm, and an INTTAUDnIm is generated.

Forced restart is not possible for this function. The counter can be stopped by setting TAUDnTT.TAUDnTTm to 1 for the master and slave channel, which in turn sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm of master and slave channel stop but retain their values.

Conditions

This function enables simultaneous rewrite. See **Section 23.6, Simultaneous Rewrite**.

23.13.9.2 Equations

Interrupt division operator = $TAUDnCDRm$ (slave channel)

- One $INTTAUDnIm$ is generated for the $INTTAUDnIm$ count of the master channel defined by $TAUDnCDRm$ (slave channel) + 1.

23.13.9.3 Block Diagram and General Timing Diagram

Figure 23.115 Block Diagram of Interrupt Request Signals Culling Function

The following settings apply to the general timing diagram.

Master channel:

- INTTAUDnIm generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 1)

Figure 23.116 General Timing Diagram of Interrupt Request Signals Culling Function

Table 23.185 Contents of the TAUDnCMURm register for the Master Channel of the Interrupt Request Signals Culling Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for the master channel

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used with this function.

(4) Simultaneous rewrite for the master channel

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.186 Simultaneous Rewrite Settings for the Master channel of Interrupt Request Signals Culling Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects master channel for simultaneous rewrite triggers. 1: Selects upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count. 1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

23.13.9.5 Register Settings for Slave Channels

(1) TAUDnCMORm for slave channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	11: INTTAUDnIm of the master channel is used as the count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0011: Event count mode
0	TAUDnMD0	0: INTTAUDnIm not generated at the beginning of operation.

(2) TAUDnCMURm for slave channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.188 Contents of the TAUDnCMURm register for the Slave Channel of the Interrupt Request Signals Culling Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for the slave channel

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used with this function.

(4) Simultaneous rewrite for slave channels

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.189 Simultaneous Rewrite Settings for Slave Channels of Interrupt Request Signals Culling Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Selects master channel for simultaneous rewrite triggers. 1: Selects upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count. 1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel.

23.13.9.6 Operating Procedure for Interrupt Request Signals Culling Function

Table 23.190 Operating Procedure for Interrupt Request Signals Culling Function

	Operation	TAUDn Status
Initial Channel Setting	Master channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.9.4, Register Settings for the Master Channel.	Channel operation is stopped.
	Slave channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.13.9.5, Register Settings for Slave Channels.	
	Set the value of TAUDnCDRm register of every channel.	
Restart	Start Operation Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm (master and slave channels) is set to 1 and the counters of master and slave channels start. INTTAUDnIm is generated on the master channel.
	During Operation TAUDnCDRm can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCNTm of master channel loads TAUDnCDRm value and counts down. When the counter reaches 0000 _H : <ul style="list-style-type: none"> INTTAUDnIm (master) occurs. TAUDnCNTm (master) loads TAUDnCDRm value and continues count operation. TAUDnCNTm of slave channels counts down each time INTTAUDnIm of master channel is detected. When TAUDnCNTm of the slave = 0000 _H : <ul style="list-style-type: none"> INTTAUDnIm (slave) occurs. TAUDnCNTm loads the TAUDnCDRm value and continues count operation.
Stop Operation	Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEm is cleared to 0 and the counter stops. TAUDnCNTm stops and retain their current values.

23.13.9.7 Specific Timing Diagram

(1) Interrupt count (master) = interrupt count (slave)

Figure 23.117 TAUDnCDRm (Slave) = 0000_H

- If TAUDnCDRm = 0000_H, TAUDnCDRm value of slave channels is loaded into TAUDnCNTm each time INTTAUDnIm of master channel is detected. In other words, TAUDnCNTm is always 0000_H.
- Therefore, an interrupt occurs on the master channel and simultaneously an interrupt occurs on slave channels.

23.14 Synchronous Non-Complementary and Complementary Modulation Output Functions

This section describes functions that generate 6-phase PWM output or triangle PWM output using a master channel and 7 slave channels.

23.14.1 Non-Complementary Modulation Output Function Type 1

23.14.1.1 Overview

Summary

This function outputs a PWM signal, a high-level signal, or a low-level signal from TAUDnTTOUTm depending on the values of the real-time output bits (TAUDnTRO.TAUDnTROm) and the modulation output enable bits (TAUDnTME.TAUDnTME m) of a pair of slave channels. Three pairs of channels are typically used.

Prerequisites

- One master channel and seven slave channels
- The operation mode of the master channel must be set to interval timer mode. (See **Table 23.192, Contents of the TAUDnCMORm register for the Master Channel of the Non-Complementary Modulation Output Function Type 1**)
- The operating mode for slave channels 1 to 7 should be set to one-count mode. (See **Table 23.195, Contents of the TAUDnCMORm register for the Slave Channel 1 of the Non-Complementary Modulation Output Function Type 1** and **Table 23.199, Contents of the TAUDnCMURm register for the Slave Channels 2 to 7 of the Non-Complementary Output Function Type 1**.)
- TAUDnTTOUTm is not used with the master channel of this function.
- TAUDnTTOUTm of slave channel 1 is not used with this function, but TAUDnTRC.TAUDnTRCm should be set to 1. (See **Section 23.7, Channel Output Modes**)
- The channel output mode for slave channels 2 to 7 should be set to synchronous channel output mode 1 with non-complementary modulation output. (See **Section 23.7, Channel Output Modes**)
- TAUDnCDRm of slave channel 1 should be set to 0000_H.

Functional description

The master/slave channel counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTE m = 1, enabling count operation. The value of data register (TAUDnCDRm) is loaded into the counter (TAUDnCNTm) and the counter starts to count down. When the counter reaches 0000_H, INTTAUDnIm occurs.

- Slave channel 1:
Slave channel 1 is set as a channel that triggers real-time output (TAUDnTRC.TAUDnTRCm = 1). If an interrupt occurs on slave channel 1 (TAUDnCDRm is fixed to 0000_H), the value of real-time output bit (TAUDnTRO.TAUDnTROm) of the channel that monitors the interrupt on slave channel 1 is reflected to TAUDTTOUTm respectively. After that, the counter returns to FFFF_H and waits for the next interrupt of master channel.

- Slave channel 2:
Slave channel 2 generates a PWM output. The master channel specifies a PWM output cycle and slave channel 2 specifies a duty cycle. After generating an interrupt, the counter returns to $FFFF_H$ and awaits the next interrupt from the master channel.

Slave channels 3 to 7 operate like slave channel 2.

As described in **Table 23.191, TAUDnTTOUTm Output from Slave Channels of Non-Complementary Modulation Output Function Type 1 (TAUDnTOL.TAUDnTOLm = 0)**, a signal output from TAUDnTTOUTm depends on the value of the real-time output bit (TAUDnTRO.TAUDnTROM) and modulation output bit (TAUDnTME.TAUDnTMEEm) of slave channel.

This function cannot use a forced restart. The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTEm to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but retain their values. The counters can be restarted by setting TAUDnTS.TAUDnTSM to 1.

Conditions

- If TAUDnTME.TAUDnTMEEm = 0 on slave channels 2 to 7 (TAUDnTOL.TAUDnTOLm = 0):
 - If the channel's TAUDnTRO.TAUDnTROM is set to 1, TAUDnTTOUTm outputs a high-level signal.
 - If the channel's TAUDnTRO.TAUDnTROM is set to 0, TAUDnTTOUTm outputs a low-level signal.
- If TAUDnTME.TAUDnTMEEm = 1 on slave channels 2 to 7 (TAUDnTOL.TAUDnTOLm = 0):
 - If the channel's TAUDnTRO.TAUDnTROM is set to 1, TAUDnTTOUTm outputs PWM corresponding to the channel (positive logic).
 - If the channel's TAUDnTRO.TAUDnTROM is set to 0, TAUDnTTOUTm outputs a low-level signal.
- If TAUDnTOL.TAUDnTOLm is set to 1, high-level and low-level signals output from TAUDnTTOUTm are inverted. PWM signals become negative logic. Only the initial setting of TAUDnTOL.TAUDnTOLm is permitted (cannot be changed during operation).

Table 23.191 TAUDnTTOUTm Output from Slave Channels of Non-Complementary Modulation Output Function Type 1 (TAUDnTOL.TAUDnTOLm = 0)

TAUDnTME.TAUDnTMEEm	TAUDnTRO.TAUDnTROM	TAUDnTTOUTm Output
0	0	Low level
	1	High level
1	0	Low level
	1	PWM (positive logic)

- This function enables simultaneous rewrite. See **Section 23.6, Simultaneous Rewrite**.
- TAUDnCDRm value of slave channel 1 should be set to 0000_H so that a real-time output is triggered at the same time as PWM generation on slave channels 2 to 7.
- If TAUDnTOL.TAUDnTOLm is set to 0 on slave channels 2 to 7, TAUDnTO.TAUDnTOM is set to 0 (low level) before TAUDnTE.TAUDnTEm is set to 0.
- If TAUDnTOL.TAUDnTOLm is set to 1 on slave channels 2 to 7, TAUDnTO.TAUDnTOM is set to 1 (high level) high before TAUDnTE.TAUDnTEm is set to 0.

23.14.1.2 Equations

Slave channels 2 to 7:

Pulse cycle = [TAUDnCDRm (master) + 1] × count clock cycle

Duty time = [TAUDnCDRm (slave)] × count clock cycle

23.14.1.3 Block Diagram and General Timing Diagram

Figure 23.118 Block Diagram of Non-Complementary Modulation Output Function Type 1

The following settings apply to the general timing diagram.

- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

Figure 23.119 General Timing Diagram of Non-Complementary Modulation Output Function Type 1

23.14.1.4 Register Settings for Master Channels

(1) TAUDnCMORm for master channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]			TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 23.192 Contents of the TAUDnCMORm register for the Master Channel of the Non-Complementary Modulation Output Function Type 1

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	1: Channel is master channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	1: INTTAUDnIm is generated at the beginning of operation or at a restart time.

(2) TAUDnCMURm for master channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.193 Contents of the TAUDnCMURm register for the Master Channel of the Non-Complementary Modulation Output Function Type 1

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for master channels

TAUDnTOE.TAUDnTOEm is set to 0 because channel output mode is not used with this function.

(4) Simultaneous rewrite for master channels

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.194 Simultaneous Rewrite Settings for Master Channels of Non-Complementary Modulation Output Function Type 1

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. When TAUDnRDS.TAUDnRDSm = 0, the master channel is monitored for simultaneous rewrite triggers regardless of the value of this bit.

NOTE

When the TAUDnRDS.TAUDnRDSm bit is 1, operation of a channel with a higher number than the master channel of the type described in Section 23.12.16, Simultaneous Rewrite Trigger Generation Function Type 1, is required. Also make the settings for operation described below.

- Setting the channel for simultaneous rewrite trigger output function type 1: TAUDnRDCm = 1, TAUDnRDSm = 1
The TAUDnCDRm setting for the given channel is derived from the formula below:
= (TAUDnCDRm setting value of master channel for simultaneous rewrite + 1) × interrupt count – 1
- Master channel: TAUDnRDCm = 0, TAUDnRDSm = 1
- Slave channel: TAUDnRDCm = 0, TAUDnRDSm = 1

23.14.1.5 Register Settings for Slave Channel 1

(1) TAUDnCMORm for slave channel 1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]		TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 23.195 Contents of the TAUDnCMORm register for the Slave Channel 1 of the Non-Complementary Modulation Output Function Type 1

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	100: INTTAUDnIm of master channel is a start trigger.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0100: One-count mode
0	TAUDnMD0	1: Enables the start trigger during operation

(2) TAUDnCMURm for slave channel 1

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.196 Contents of the TAUDnCMURm register for the Slave Channel 1 of the Non-Complementary Modulation Output Function Type 1

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used on slave channel 1 with this function. However, this mode can be used in independent channel output mode controlled by software.

CAUTION

TAUDnTRC.TAUDnTRCm should be set to 1 because slave channel 1 is used as a real-time output trigger channel.

(4) Simultaneous rewrite for slave channel 1

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.197 Simultaneous Rewrite Settings for Slave Channel 1 of Non-Complementary Modulation Output Function Type 1

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. When TAUDnRDS.TAUDnRDSm = 0, the master channel is monitored for simultaneous rewrite triggers regardless of the value of this bit.

23.14.1.6 Register Settings for Slave Channels 2 to 7

(1) TAUDnCMORm for slave channels 2 to 7

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	100: INTTAUDnIm of master channel is a start trigger.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0100: One-count mode
0	TAUDnMD0	1: Enables the start trigger during operation

(2) TAUDnCMURm for slave channels 2 to 7

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.199 Contents of the TAUDnCMURm register for the Slave Channels 2 to 7 of the Non-Complementary Output Function Type 1

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for slave channels 2 to 7**Table 23.200 Control Bit Settings in Synchronous Channel Output Mode 1 with Non-Complementary Modulation Output**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	1: Enables real-time output.
TAUDnTRO.TAUDnTROm	0: Real-time output is low. 1: Real-time output is high.
TAUDnTRC.TAUDnTRCm	0: Upper channel generates a real-time output trigger for channel m.
TAUDnTME.TAUDnTMEm	0: Disables modulation 1: Enables modulation

(4) Simultaneous rewrite of slave channels 2 to 7

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.201 Simultaneous Rewrite Settings for Slave Channels 2 to 7 of Non-Complementary Modulation Output Function Type 1

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	0: Generates a simultaneous rewrite trigger signal when the master channel starts to count.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. When TAUDnRDS.TAUDnRDSm = 0, the master channel is monitored for simultaneous rewrite triggers regardless of the value of this bit.

23.14.1.7 Operating Procedure for Non-Complementary Modulation Output Function Type 1

Table 23.202 Operating Procedure for Non-Complementary Modulation Output Function Type 1 (1/2)

	Operation	TAUDn Status
Initial Channel Setting	Master channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.14.1.4, Register Settings for Master Channels.	Channel operation is stopped.
	Slave channel 1: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.14.1.5, Register Settings for Slave Channel 1.	
	Slave channels 2 to 7: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.14.1.6, Register Settings for Slave Channels 2 to 7.	
	Set the value of TAUDnCDRm register of every channel. Set a pulse cycle with TAUDnCDRm of master channel, 0000 _H in TAUDnCDRm of slave channel 1, and duty width with TAUDnCDRm of slave channels 2 to 7.	
	Set TAUDnTRC.TAUDnTRCm to 1 on slave channel 1.	

Table 23.202 Operating Procedure for Non-Complementary Modulation Output Function Type 1 (2/2)

	Operation	TAUDn Status
Restart	Start Operation Set TAUDnTS.TAUDnTSM of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM of master and slave channels is set to 1 and the counter starts counting down.
	During Operation TAUDnCDRM, TAUDnTRO.TAUDnTROM, and TAUDnTME.TAUDnTME can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCDRM value of master channel, slave channel 1 and slave channels 2 to 7 is loaded into TAUDnCNTm to perform counting down. When the counter of master channel reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUDnIm is generated. • TAUDnCDRM value of master channel is reloaded into TAUDnCNTm to continue counting down. • PWM output signals of slave channels 2 to 7 are set/reset. • TAUDnCDRM value of slave channel 1 is reloaded into TAUDnCNTm to perform counting down. • TAUDnCDRM value of slave channels 2 to 7 is reloaded into TAUDnCNTm to perform counting down. • When the counter of slave channel 1 reaches 0000_H: <ul style="list-style-type: none"> – INTTAUDnIm is generated. – TAUDnTRO.TAUDnTROM value of slave channel 2 to 7 is reflected to the TAUDTTOUTm output. • When the counter of slave channels 2 to 7 reaches 0000_H: <ul style="list-style-type: none"> – INTTAUDnIm is generated. – PWM output signals of slave channels 2 to 7 are set. TAUDnTTOUTm of slave channels 2 to 7 outputs a PWM signal, a high-level signal or low-level signal depending on the values of real-time output bits (TAUDnTRO.TAUDnTROM) and modulation output bit (TAUDnTME.TAUDnTME) of a pair of slave channels.
	Stop Operation Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

23.14.1.8 Specific Timing Diagrams

The following settings apply to the specific timing diagram.

- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

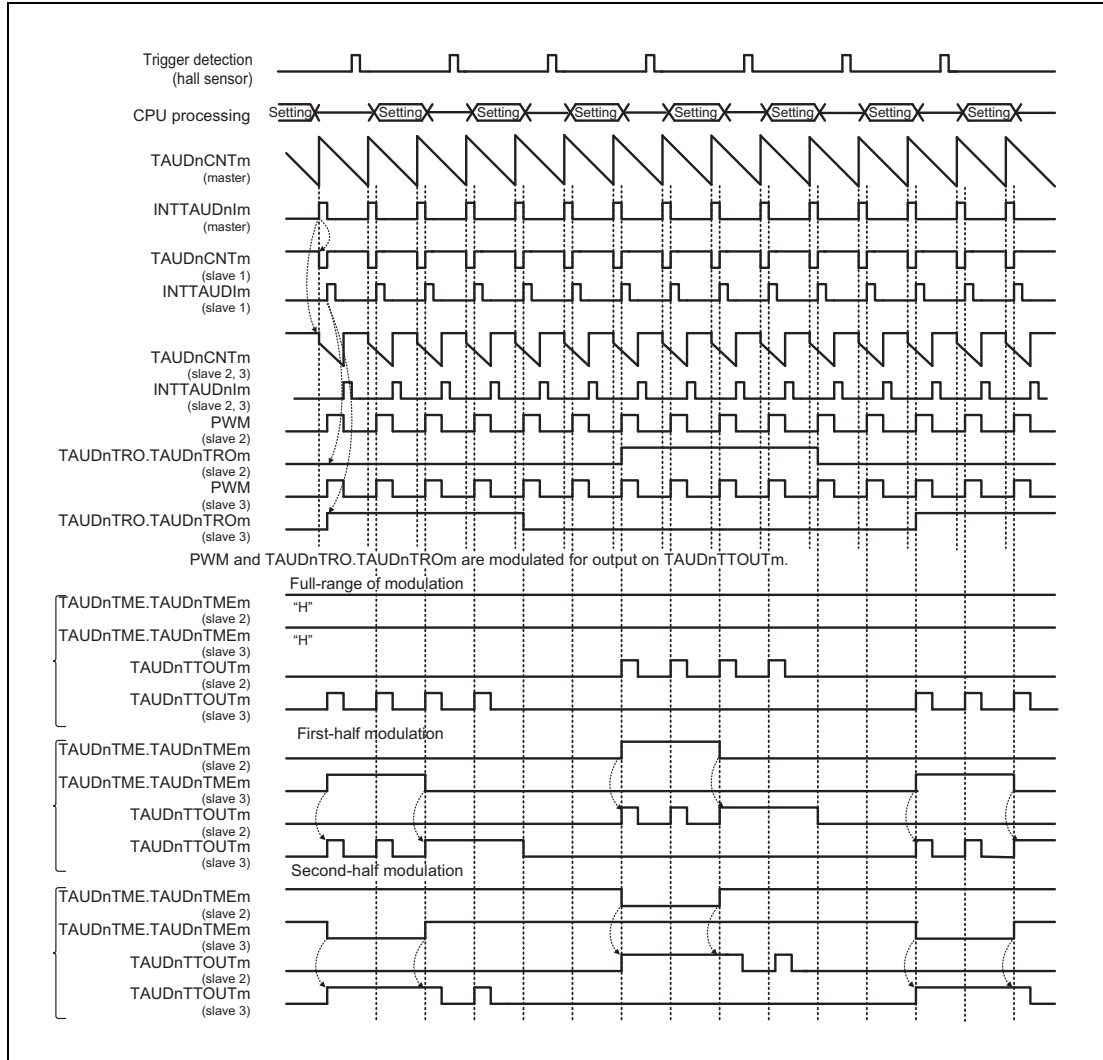

Figure 23.120 Specific Timing Diagram of Non-Complementary Modulation Output Function Type 1

The above timing diagram shows how full modulation, first-half modulation, and second-half modulation can be achieved by modifying the TAUDnTME.TAUDnTME bits of lower slave channels during operation.

The “Setting” symbol indicates a time period when the values of TAUDnCDRm, TAUDnTME.TAUDnTME, and TAUDnTRO.TAUDnTROm can be changed.

TAUDnTME.TAUDnTME setting is reflected by detecting the count start timing and master channel cycle. According to the modified setting, modulation waveforms are output from TAUDnTTOUTm.

TAUDnTRO.TAUDnTROm bit value is set by software, but a new setting is applied only when an interrupt occurs on slave channel 1.

23.14.2 Non-Complementary Modulation Output Function Type 2

23.14.2.1 Overview

Summary

This function outputs a triangular wave PWM output signal, a high-level signal, or low-level signal from TAUDnTTOUTm depending on the real-time output bit value (TAUDnTRO.TAUDnTROm) and the modulation output enable bit value (TAUDnTME.TAUDnTMEem) of a pair of slave channels. Three pairs of channels are typically used.

Prerequisites

- One master channel and seven slave channels
- The operation mode of the master channel must be set to interval timer mode. (See **Table 23.204, Contents of the TAUDnCMORm register for the Master Channel of the Non-Complementary Modulation Output Function Type 2**)
- The operating mode for slave channel 1 should be set to event count mode. (See **Table 23.208, Contents of the TAUDnCMORm register for the Slave Channel 1 of the Non-Complementary Modulation Output Function Type 2**)
- The operating mode for slave channels 2 to 7 should be set to up/down count mode. (See **Table 23.211, Contents of the TAUDnCMORm register for the Slave Channels 2 to 7 of the Non-Complementary Modulation Output Function Type 2**)
- Output mode of master channel should be set to channel single output mode 1. (See **Section 23.7, Channel Output Modes**)
- This function does not use TAUDnTTOUTm of slave channel 1 but TAUDnTRC.TAUDnTRCm should be set to 1. (See **Section 23.7, Channel Output Modes**)
- The channel output mode for slave channels 2 to 7 should be set to synchronous channel output mode 2 with non-complementary modulation output. (See **Section 23.7, Channel Output Modes**)

Functional description

The master/slave channel counter is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSM) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The value of data register (TAUDnCDRm) is loaded into the counter (TAUDnCNTm).

- Master channel:
The counter of master channel starts to count down. When the counter reaches 0000_H, INTTAUDnIm occurs.
- Slave channel 1:
When slave channel 1 detects an interrupt from the master channel, the TAUDnCNTm value is decremented by 1. When interrupt count from the master channel reaches TAUDnCDRm + 1, INTTAUDnIm is generated. Afterwards, it leads the TAUDnCDRm value to TAUDnCNTm and continues count operation.
When the counter reaches to 0000_H, slave channel 1 waits from the next interrupt from the master channel. And the TAUDnCDRm value is reloaded into TAUDnCNTm (slave 1) and INTTAUDnIm is generated.
Since slave channel 1 is set as a real-time output trigger channel

(TAUDnTRC.TAUDnTRCm = 1), the real-time output bit (TAUDnTRO.TAUDnTROm) of the channel which monitors an interrupt on the corresponding channel is reflected to respective TAUDTTOUTm output when an interrupt occurs on slave 1 channel.

- Slave channel 2:
Once an interrupt is detected from the master channel, TAUDnCNTm counts in the reverse direction. When an interrupt is detected during count-up operation, TAUDnCDRm value is reloaded and then the counter starts to count down.
If TAUDnCNTm = 0001_H, an interrupt occurs and a PWM output signal is set/reset.

The combined use of the master channel and slave channel 2 generates a PWM output signal. The master channel generates a PWM output cycle and slave channel 2 generate a duty cycle.

Slave channels 3 to 7 operates like slave channel 2.

A signal that is output from TAUDnTTOUTm depends on a real-time output bit value (TAUDnTRO.TAUDnTROm) and a modulation output bit value (TAUDnTME.TAUDnTME_m) of the slave channel, as described in **Table 23.203, TAUDnTTOUTm Output of Slave Channels in Non-Complementary Modulation Output Function Type 2 (TAUDnTOL.TAUDnTOLm = 0)**.

This function cannot make a forced restart. The counter can be stopped by setting TAUDnTT.TAUDnTTm of master and slave channels to 1. This sets TAUDnTE.TAUDnTE_m to 0. TAUDnCNTm and TAUDnTTOUTm of master and slave channels stop but retain their values. The counters can be restarted by setting TAUDnTS.TAUDnTSm to 1.

Conditions

- If TAUDnTME.TAUDnTME_m = 0 on slave channels 2 to 7 (TAUDnTOL.TAUDnTOLm = 0):
 - If the channel's TAUDnTRO.TAUDnTROm is set to 1, TAUDnTTOUTm outputs PWM corresponding to the channel (positive logic).
 - If the channel's TAUDnTRO.TAUDnTROm is set to 0, TAUDnTTOUTm outputs a low-level signal.
- If TAUDnTME.TAUDnTME_m = 1 on slave channels 2 to 7 (TAUDnTOL.TAUDnTOLm = 0):
 - If the channel's TAUDnTRO.TAUDnTROm is set to 1, TAUDnTTOUTm outputs a high-level signal.
 - If the channel's TAUDnTRO.TAUDnTROm is set to 0, TAUDnTTOUTm outputs a low-level signal.
- If TAUDnTOL.TAUDnTOLm is set to 1, high-level and low-level signals output from TAUDnTTOUTm are inverted. PWM signals become negative logic. Only the initial setting of TAUDnTOL.TAUDnTOLm is permitted (cannot be changed during operation).

Table 23.203 TAUDnTTOUTm Output of Slave Channels in Non-Complementary Modulation Output Function Type 2 (TAUDnTOL.TAUDnTOLm = 0)

TAUDnTME.TAUDnTME _m	TAUDnTRO.TAUDnTROm	TAUDnTTOUTm Output
0	0	Low level
	1	High level
1	0	Low level
	1	PWM (positive logic)

- This function enables simultaneous rewrite. See **Section 23.6, Simultaneous Rewrite**.
- If TAUDnTOL.TAUDnTOLm is set to 0 on slave channels 2 to 7, TAUDnTO.TAUDnTOm is set 0 (low level) before TAUDnTE.TAUDnTEm is set to 0.
- If TAUDnTOL.TAUDnTOLm is set to 1 on slave channels 2 to 7, TAUDnTO.TAUDnTOm is set 1 (high level) before TAUDnTE.TAUDnTEm is set to 0.

23.14.2.2 Equations

Slave channels 2 to 7:

Carrier cycle (down/up)

$$= [\text{TAUDnCDRm (master)} + 1] \times 2 \times \text{count clock cycle}$$

Duty time

$$= [\text{TAUDnCDRm (master)} + 1 - \text{TAUDnCDRm (slave)}] \times 2 \times \text{count clock cycle}$$

23.14.2.3 Block Diagram and General Timing Diagram

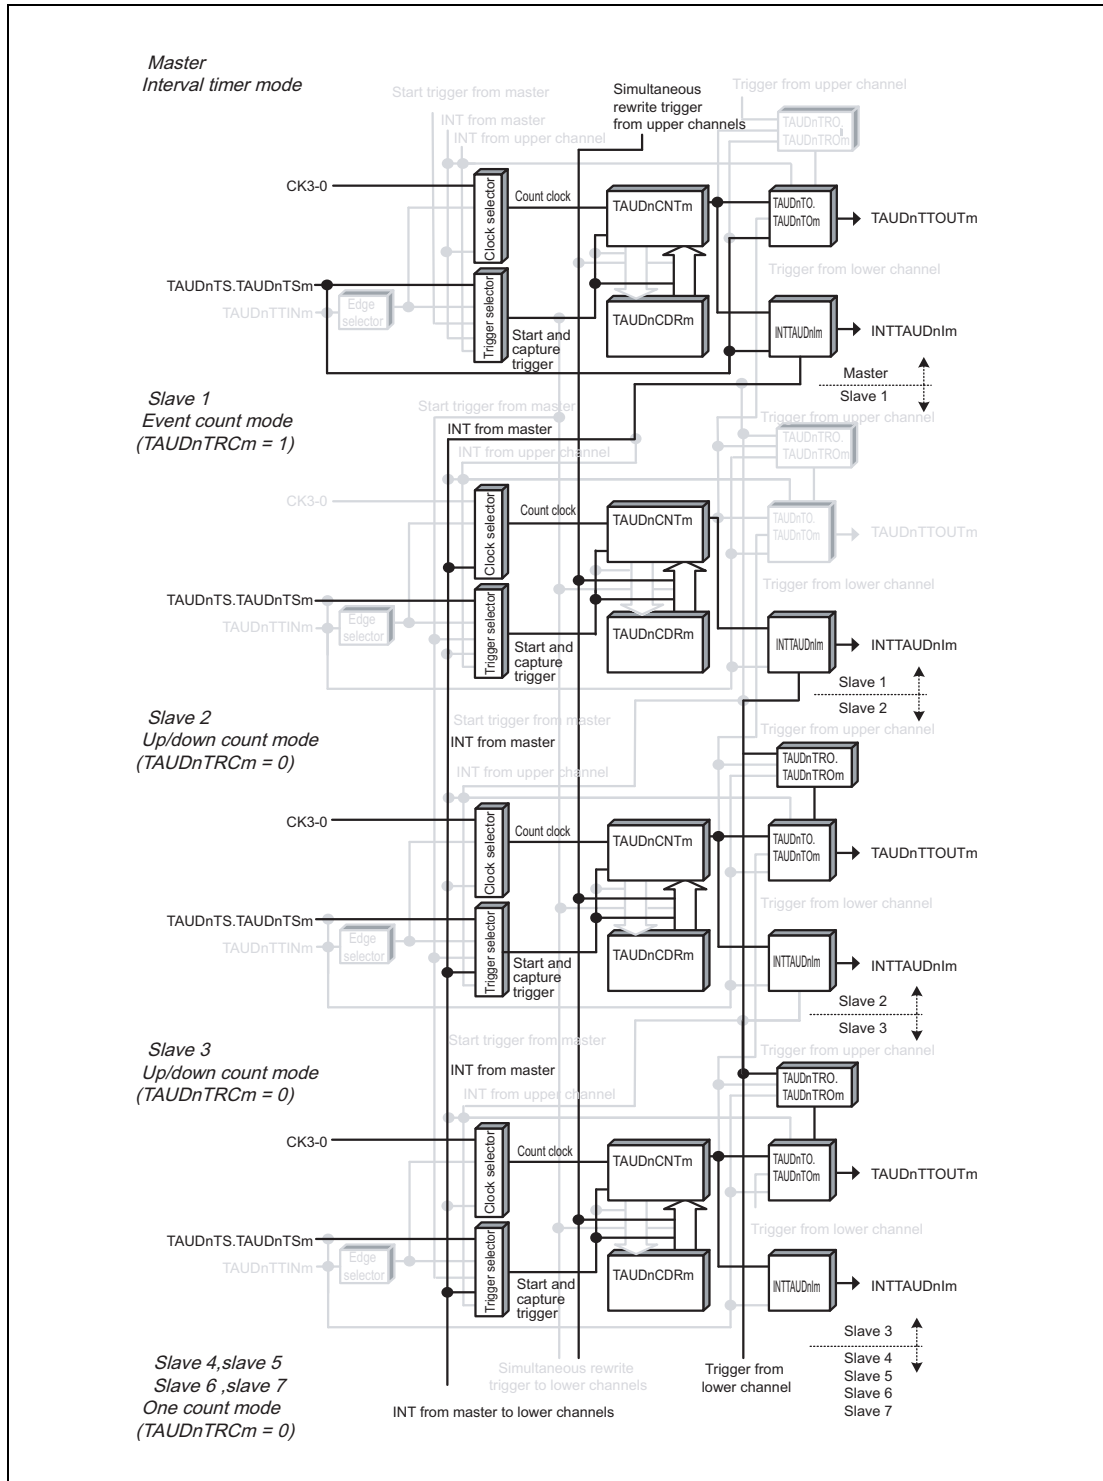

Figure 23.121 Block Diagram of Non-Complementary Modulation Output Function Type 2

The following settings apply to the general timing diagram.

- Master channel: INTTAUDnIm not generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

Figure 23.122 General Timing Diagram of Non-Complementary Modulation Output Function Type 2

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	1: Channel is master channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	0: INTTAUDnIm is not generated at the beginning of operation or at a restart time. 1: INTTAUDnIm is generated at the beginning of operation or at a restart time.

(2) TAUDnCMURm for master channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.205 Contents of the TAUDnCMURm register for the Master Channel of the Non-Complementary Modulation Output Function Type 2

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode for master channels**Table 23.206 Control Bit Settings for Master Channels in Non-Complementary Modulation Output Function Type 2**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (toggle mode with TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: Setting is disabled (value after reset) in toggle mode.
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: Set 0 while real-time output is prohibited (TAUDnTRE.TAUDnTREm = 0).
TAUDnTRC.TAUDnTRCm	0: Set 0 while real-time output is prohibited (TAUDnTRE.TAUDnTREm = 0).
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous rewrite for master channels

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.207 Simultaneous Rewrite Settings for Master Channels of Non-Complementary Modulation Output Function Type 2

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. TAUDnRDSm = 0, the master channel is monitored for simultaneous rewrite triggers regardless of the value of this bit.

NOTE

If TAUDnRDS.TAUDnRDSm = 1, it is necessary for an upper channel higher than a master channel to generate a simultaneous rewrite trigger signal.

23.14.2.5 Register Settings for Slave Channel 1

(1) TAUDnCMORm for slave channel 1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]		TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 23.208 Contents of the TAUDnCMORm register for the Slave Channel 1 of the Non-Complementary Modulation Output Function Type 2

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	11: INTTAUDnIm of the master channel is used as the count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software. 011: Triggers simultaneous rewrite.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0011: Event count mode
0	TAUDnMD0	0: INTTAUDnIm is not generated at the beginning of operation or at a restart time.

(2) TAUDnCMURm for slave channel 1

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R	R/W

Table 23.209 Contents of the TAUDnCMURm register for the Slave Channel 1 of the Non-Complementary Modulation Output Function Type 2

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used on slave channel 1 with this function. However, this mode can be used in independent channel output mode controlled by software.

CAUTION

TAUDnTRC.TAUDnTRCm should be set to 1 because slave channel 1 is used as a real-time output trigger channel.

(4) Simultaneous rewrite for slave channel 1

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.210 Simultaneous Rewrite Settings for Slave Channel 1 of Non-Complementary Modulation Output Function Type 2

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel counter is started and the corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. When TAUDnRDS.TAUDnRDSm = 0, the master channel is monitored for simultaneous rewrite triggers regardless of the value of this bit.

23.14.2.6 Register Settings for slave channels 2 to 7

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Output mode for slave channels 2 to 7**Table 23.213 Control Bit Settings in Synchronous Channel Output Mode 2 with Non-Complementary Modulation Output**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	1: Enables real-time output.
TAUDnTRO.TAUDnTROm	0: Real-time output is low. 1: Real-time output is high.
TAUDnTRC.TAUDnTRCm	0: The upper channel generates the real-time output trigger for channel m
TAUDnTME.TAUDnTMEm	0: Disables modulation 1: Enables modulation

(4) Simultaneous rewrite for slave channels 2 to 7

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.214 Simultaneous Rewrite Settings for Slave Channels 2 to 7 of Non-Complementary Modulation Output Function Type 2

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. When TAUDnRDS.TAUDnRDSm = 0, the master channel is monitored for simultaneous rewrite triggers regardless of the value of this bit.

23.14.2.7 Operating Procedure for Non-Complementary Modulation Output Function Type 2

Table 23.215 Operating Procedure for Non-Complementary Modulation Output Function Type 2 (1/2)

Operation	TAUDn Status
<p>Master channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.14.2.4, Register Settings for Master Channels.</p> <p>Slave channel 1: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.14.2.5, Register Settings for Slave Channel 1.</p> <p>Slave channels 2 to 7: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.14.2.6, Register Settings for slave channels 2 to 7.</p> <p>Set the value of TAUDnCDRm register of every channel. Set pulse cycle in TAUDnCDRm of master channel, and in TAUDnCDRm of slave channel 1, set the number of interrupts from master channel to be ignored before slave channel 1 generates a real-time output trigger. Set duty width in TAUDnCDRm of slave channels 2 to 7.</p> <p>Set TAUDnTRC.TAUDnTRCm to 1 on slave channel 1.</p>	Channel operation is stopped.

Initial Channel Setting

Table 23.215 Operating Procedure for Non-Complementary Modulation Output Function Type 2 (2/2)

	Operation	TAUDn Status
Restart	Start Operation Set TAUDnTS.TAUDnTSM of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSM is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM of master and slave channels is set to 1 and the counter starts counting down.
	During Operation TAUDnCDRm, TAUDnTRO.TAUDnTROM, and TAUDnTME.TAUDnTME can be changed at any time. TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time. TAUDnRDT.TAUDnRDTm can be changed during operation.	TAUDnCDRm value of master channel and slave channels 2 to 7 is loaded into TAUDnCNTm to perform count down. The TAUDnCDRm value of slave channel 1 is loaded and the counter waits for an interrupt from the master channel. When the counter of master channel reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUDnIm is generated. • TAUDnCDRm value is reloaded into TAUDnCNTm to continue counting down. • The TAUDnCNTm value of slave channel 1 decrements by 1 and the counter waits for a next interrupt from the master channel. • TAUDnCNTm of slave channels 2 to 7 reloads the TAUDnCDRm value or starts counting in opposite direction. • When the TAUDnCDRm value is loaded, the TAUDnTRO.TAUDnTROM value of slave channel 2 to 7 is reflected to the TAUDTTOUTm output. • When slave channel detects an interrupt of the master channel for TAUDnCDRm + 1 count. <ul style="list-style-type: none"> – INTTAUDnIm is generated. – The TAUDnTRO.TAUDnTROM value of slave channel 2 to 7 is reflected to the TAUDTTOUTm output. • When the counter of slave channel 1 reaches 0000_H, it waits for a next interrupt from the master channel. When an interrupt is detected: <ul style="list-style-type: none"> – INTTAUDnIm is generated. • When the counter of slave channels 2 to 7 reaches 0001_H: <ul style="list-style-type: none"> – INTTAUDnIm is generated. – PWM output signals of slave channels 2 to 7 are set/reset. TAUDnTTOUTm of slave channels 2 to 7 outputs a PWM signal, a high-level signal or low-level signal depending on the values of real-time output bits (TAUDnTRO.TAUDnTROM) and modulation output bit (TAUDnTME.TAUDnTME) of a pair of slave channels.
	Stop Operation Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously. TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.	TAUDnTE.TAUDnTEM is cleared to 0 and the counter stops. TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.

23.14.2.8 Specific Timing Diagrams

The following settings apply to the general timing diagram.

- Master channel: No INTTAUDnIm is generated at start of operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

Figure 23.123 Specific Timing Diagram of Non-Complementary Modulation Output Function Type 2

The above timing diagram shows how full modulation, first-half modulation, and second-half modulation can be achieved by modifying the TAUDnTME.TAUDnTMEm bits of lower slave channels during operation.

The “Setting” symbol indicates a time period when the values of TAUDnCDRm, TAUDnTME.TAUDnTMEm, and TAUDnTRO.TAUDnTROm can be changed.

TAUDnTME.TAUDnTMEm setting is reflected by detecting the count start timing and triangle PWM carrier cycle (peak interrupt timing).

TAUDnTRO.TAUDnTROm bit value is set by software, but a new setting is applied only when an interrupt occurs on slave channel 1.

23.14.3 Complementary Modulation Output Function

23.14.3.1 Overview

Summary

This function outputs a triangular PWM output signal, a high-level signal, or low-level signal from TAUDnTTOUTm adding dead time depending on the real-time output bit value (TAUDnTRO.TAUDnTROm), the modulation output bit value (TAUDnTME.TAUDnTME m), and the output level bit value (TAUDnTDL.TAUDnTDLm) of a pair of slave channels. Three pairs of channels are typically used.

Prerequisites

- One master channel and seven slave channels
- The operating mode of the master channel must be set to interval timer mode. (See **Table 23.217, Contents of the TAUDnCMORm register for the Master Channel of the Complementary Modulation Output Function**)
- The operating mode for slave channel 1 should be set to event count mode. (See **Table 23.221, Contents of the TAUDnCMORm register for the Slave Channel 1 of the Complementary Modulation Output Function**)
- The operating mode for slave channels 2, 4 and 6 should be set to up/down count mode. (See **Table 23.224, Contents of the TAUDnCMORm register for the Slave Channels 2, 4, and 6 of the Complementary Modulation Output Function**)
- The operating mode for slave channels 3, 5 and 7 should be set to one-count mode. (See **Table 23.228, Contents of the TAUDnCMORm register for the Slave Channels 3, 5, and 7 of the Complementary Modulation Output Function**). In addition, as the number of occurrences of an interrupt for slave channels 3, 5 and 7 within the carrier cycle is not uniquely determined, do not use the interrupt as an interrupt source.
- The output mode for master channels should be set to independent channel output mode 1. (See **23.7, Channel Output Modes**)
- This function does not use TAUDnTTOUTm of slave channel 1 but TAUDnTRC.TAUDnTRCm should be set to 1. (See **Section 23.7, Channel Output Modes**)
- The channel output mode for slave channels 2 to 7 should be set to synchronous channel output mode 2 with complementary modulation output. (See **Section 23.7, Channel Output Modes**)

Functional description

- Master channel:
The counter of master channel is enabled by setting the channel trigger bit (TAUDnTS.TAUDnTSm) to 1. This sets TAUDnTE.TAUDnTEm = 1, enabling count operation. The value of data register (TAUDnCDRm) of master channel is loaded into the counter (TAUDnCNTm) and the counter starts to count down from this value.
When the counter of master channel reaches 0000_H, INTTAUDnIm occurs. This decrements the counter value of slave channel 1 by 1 and the counter of slave channel 2 starts to count in the opposite direction.

- Slave channel 1:
When the counter reaches 0000_H , slave channel 1 waits for the next interrupt from the master channel. And the $TAUDnCDRm$ value is reloaded into $TAUDnCNTm$ (slave 1) and $INTTAUDnIm$ is generated.
Slave channel 1 is set as a real-time output trigger channel ($TAUDnTRC.TAUDnTRCm = 1$). The value of real-time output bit ($TAUDnTRO.TAUDnTROm$) of each channel is applied to the channel that detects the occurrence of an interrupt on slave channel 1 by an interrupt. The real-time output bit value can be changed in any timing by application software but a new value is not applied until an interrupt occurs on slave channel 1.
- Slave channel 2:
When the slave channel 2 counter reaches 0001_H , the slave channel 3 counter starts counting down. When the slave channel 3 counter reaches 0000_H , an interrupt occurs.
- Slave channels 2 and 3:
The combined use of the master channel and slave channels 2 and 3 generates a PWM output signal. The master channel generates a PWM output cycle, slave channel 2 generates a duty cycle, and slave channel 3 generates dead time.
- Slave channels 4 to 7:
Slave channels 4 and 6 operate like slave channel 2. Slave channels 5 and 7 operate like slave channel 3.

As in **Table 23.216, TAUDnTTOUTm Output ($TAUDnTOL.TAUDnTOLm = 0$) for a Pair of Slave Channels of Complementary Modulation Output Function**, a signal that is output from $TAUDnTTOUTm$ depends on a real-time output bit value ($TAUDnTRO.TAUDnTROm$), a modulation output bit value ($TAUDnTME.TAUDnTME m$), and an output level bit value ($TAUDnTDL.TAUDnTDLm$) of the slave channel.

It is, however, prohibited that a high-level signal is output from both channel 2 and channel 3 (in order to prevent a motor driver short circuit). This function cannot perform a forcible restart.

The counter can be stopped by setting $TAUDnTT.TAUDnTTm$ of master and slave channels to 1. This sets $TAUDnTE.TAUDnTE m$ to 0. $TAUDnCNTm$ and $TAUDnTTOUTm$ of master and slave channels stop but retain their values. The counters can be restarted by setting $TAUDnTS.TAUDnTSm$ to 1.

Conditions

- If TAUDnTME.TAUDnTMEm of a pair of channels is set to 1 (TAUDnTOL.TAUDnTOLm = 0):
 - If TAUDnTRO.TAUDnTROm of one channel is set to 1, TAUDnTTOUTm outputs the corresponding PWM of the channel.
 - If TAUDnTRO.TAUDnTROm of each channel is set to 0, a pair of TAUDnTTOUTm outputs a low-level signal.
- If TAUDnTME.TAUDnTMEm of a pair of channels is set to 0 (TAUDnTOL.TAUDnTOLm = 0):
 - If TAUDnTRO.TAUDnTROm is set to 1, TAUDnTTOUTm of the channel outputs a high-level signal.
 - If TAUDnTRO.TAUDnTROm is set to 0, TAUDnTTOUTm of the channel outputs a low-level signal.
- If TAUDnTOL.TAUDnTOLm is set to 1, high-level and low-level signals output from TAUDnTTOUTm are inverted. PWM signals become negative logic.

Table 23.216 TAUDnTTOUTm Output (TAUDnTOL.TAUDnTOLm = 0) for a Pair of Slave Channels of Complementary Modulation Output Function

TAUDnTME. TAUDnTME2	TAUDnTME. TAUDnTME3	TAUDnTRO. TAUDnTRO2	TAUDnTRO. TAUDnTRO3	TAUDnTDL. TAUDnTDL2	TAUDnTDL. TAUDnTDL3	TAUDnTTOUT2 Output	TAUDnTTOUT3 Output
0	0	0	0	X	X	Low level	Low level
		0	1	0	1	Low level	High level
		1	0	1	0	High level	Low level
		1	1	X	X	Setting prohibited	Setting prohibited
1	1	0	0	X	X	Low level	Low level
		0	1	0	1	~PWMm	PWMm
		1	0	1	0	PWMm	~PWMm
		1	1	X	X	Setting prohibited	Setting prohibited

NOTES

1. PWM in this Table indicates a normal PWM signal and ~PWM indicates an inverted PWM signal (positive logic). PWM and ~PWM are set by TAUDnTDL.TAUDnTDLm.
2. Any settings not listed above are prohibited.

- If TAUDnTME.TAUDnTMEm is continuously set to 1 while TAUDnTRO.TAUDnTROm of one of paired channels is set to 1, full modulation is applied.
- If TAUDnTME.TAUDnTMEm is set to 1 at the first half of the period while TAUDnTRO.TAUDnTROm of one of paired channels is set to 1, first-half modulation is applied.
- If TAUDnTME.TAUDnTMEm is set to 1 at the second half of the period while TAUDnTRO.TAUDnTROm of one of paired channels is set to 1, second-half modulation is applied.

- Whether dead time is added to a normal or inverted phase PWM signal when two channels become high-level signal outputs simultaneously depends on a TAUDnTDL.TAUDnTDLm bit value.
 - If TAUDnTDL.TAUDnTDLm = 0, dead time is added to a normal phase PWM signal.
 - If TAUDnTDL.TAUDnTDLm = 1, dead time is added to a reverse phase PWM signal.
 - The operation defined by a TAUDnTDL.TAUDnTDLm bit value should be conducted by application software during operation. To modify TAUDnTDL.TAUDnTDLm, rewrite it during the period when TAUDnTRO.TAUDnTROm is 00_B.
- The value of TAUDnCDRm of slave channel 1 should be set to the value that generates INTTAUDnIm on slave channel 1 at the peak of a carrier cycle.
- Set TAUDnCMORm.TAUDnMD0 of master channel to 0.
- This function enables simultaneous rewrite. See **Section 23.6, Simultaneous Rewrite**.
- When TAUDnTOL.TAUDnTOLm = 0 is set in slave channel 2 to 7:
 - If TAUDnTDL.TAUDnTDLm = 0, set TAUDnTO.TAUDnTOm to 0 (low level) before setting TAUDnTE.TAUDnTEm = 0.
 - If TAUDnTDL.TAUDnTDLm = 1, set TAUDnTO.TAUDnTOm to 1 (high level) before setting TAUDnTE.TAUDnTEm = 0.
- When TAUDnTOL.TAUDnTOLm = 1 is set in slave channel 2 to 7:
 - If TAUDnTDL.TAUDnTDLm = 0, set TAUDnTO.TAUDnTOm to 1 (high level) before setting TAUDnTE.TAUDnTEm = 0.
 - If TAUDnTDL.TAUDnTDLm = 1, set TAUDnTO.TAUDnTOm to 0 (low level) before setting TAUDnTE.TAUDnTEm = 0.

23.14.3.2 Equations

Pulse cycle = [TAUDnCDRm (master) + 1] × count clock cycle

$0000_H \leq \text{TAUDnCDRm (master)} < \text{FFFF}_H$

Carrier cycle (down/up) = [TAUDnCDRm (master) + 1] × 2 × count clock cycle

For slave channel 2 and 3:

PWM signal width (normal) = [(TAUDnCDRm (master) + 1 – TAUDnCDRm (slave 2)) × 2 – (TAUDnCDRm (slave 3) + 1)] × count clock cycle

PWM signal width (inverted) = [(TAUDnCDRm (master) + 1 – TAUDnCDRm (slave 2)) × 2 – (TAUDnCDRm (slave 3) + 1)] × count clock cycle

For slave channels 4 to 7:

Calculate slave channel 4 and 6 in the same way as slave channel 2 whereas calculate slave channel 5 and 7 in the same way as slave channel 3.

23.14.3.3 Block Diagram and General Timing Diagram

Figure 23.124 Block Diagram of Complementary Modulation Output Function

The following settings apply to the general timing diagram.

- Master channel: INTTAUDnIm not generated at the beginning of operation. (TAUDnCMORm.TAUDnMD0 = 0)
- Slave channels 1: TAUDnCDRm=0001_H

- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

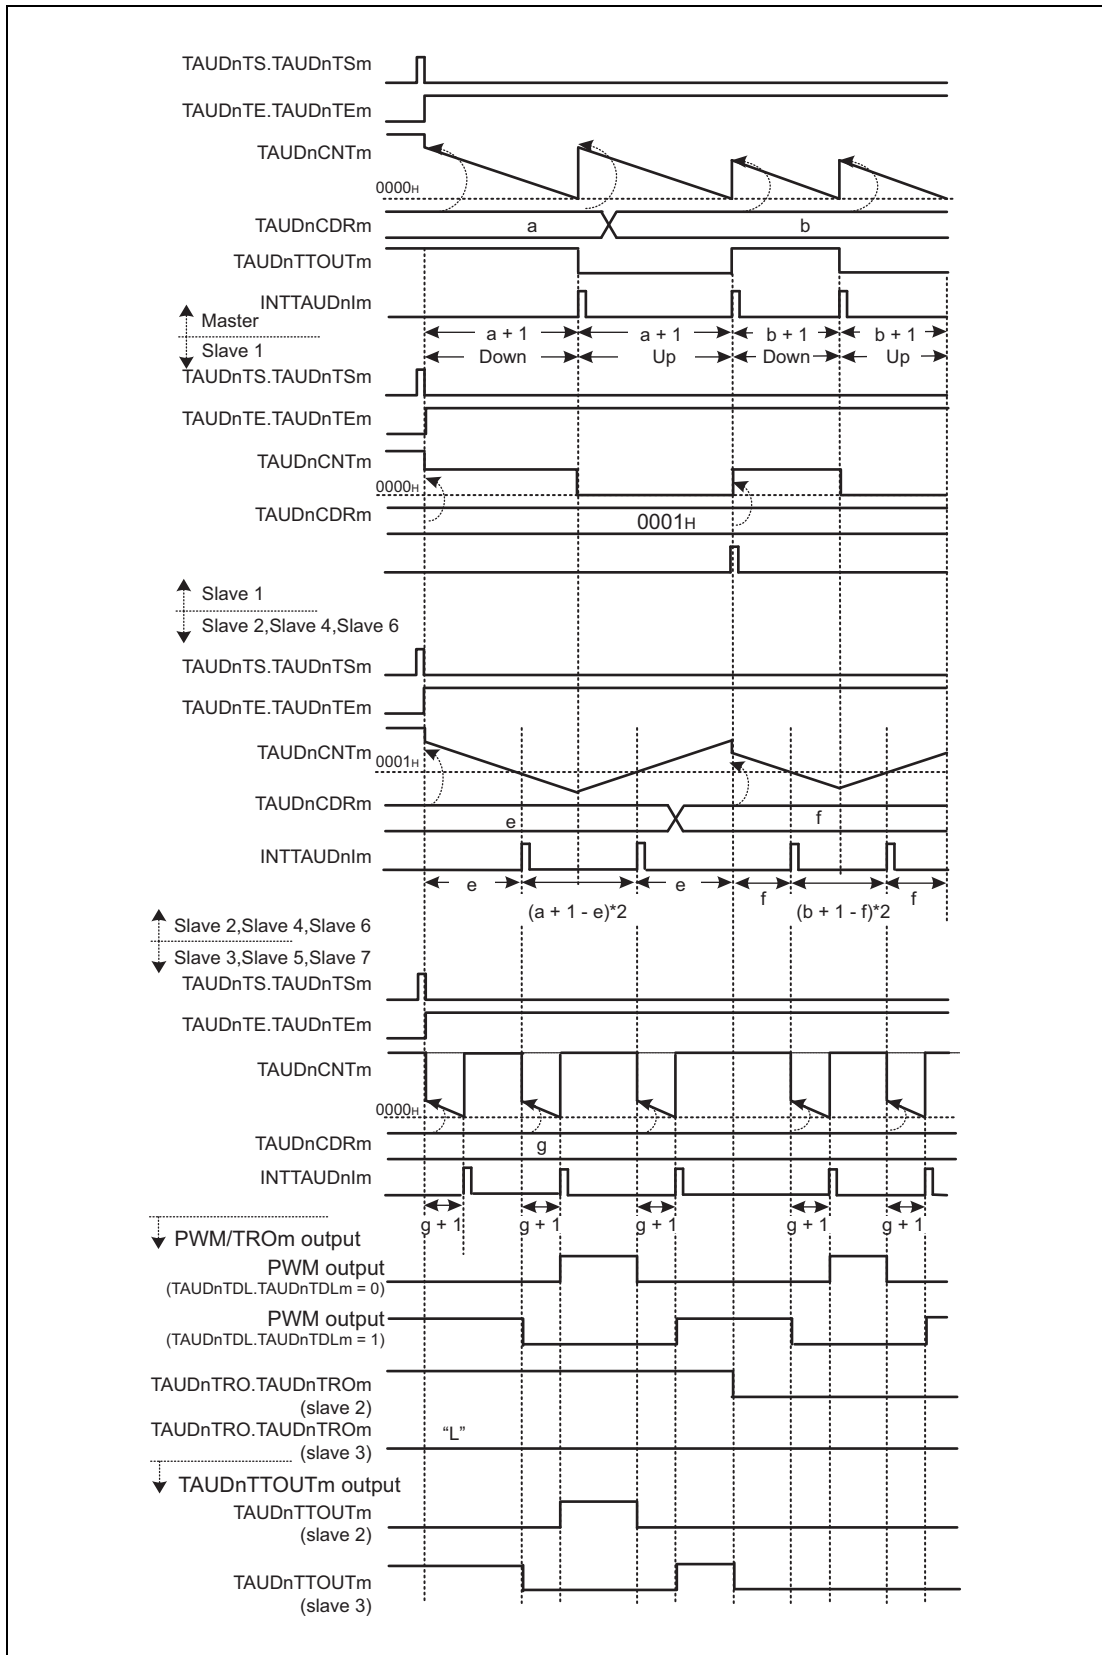

Figure 23.125 General Timing Diagram of Complementary Modulation Output Function

23.14.3.4 Register Settings for Master Channels

(1) TAUDnCMORm for master channels

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]		TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 23.217 Contents of the TAUDnCMORm register for the Master Channel of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	1: Channel is master channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0000: Interval timer mode
0	TAUDnMD0	0: INTTAUDnIm is not generated and TAUDnTTOUTm is not toggled at the beginning of operation or at a restart time. 1: INTTAUDnIm is generated to toggle TAUDnTTOUTm at the beginning of an operation.

(2) TAUDnCMURm for master channels

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.218 Contents of the TAUDnCMURm register for the Master Channel of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode of master channel**Table 23.219 Control Bit Settings in Independent Channel Output Mode 1**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	0: Independent channel output
TAUDnTOC.TAUDnTOCm	0: Operating mode 1 (Toggle mode if TAUDnTOM.TAUDnTOMm = 0)
TAUDnTOL.TAUDnTOLm	0: Setting is disabled (value after reset) in toggle mode.
TAUDnTDE.TAUDnTDEm	0: Disables dead time operation
TAUDnTDM.TAUDnTDMm	0: When dead time operation is disabled (TAUDnTDE.TAUDnTDEm = 0), set these bits to 0
TAUDnTDL.TAUDnTDLm	
TAUDnTRE.TAUDnTREm	0: Disables real-time output
TAUDnTRO.TAUDnTROm	0: When real-time output is disabled (TAUDnTRE.TAUDnTREm = 0), set these bits to 0
TAUDnTRC.TAUDnTRCm	
TAUDnTME.TAUDnTMEm	0: Disables modulation

(4) Simultaneous rewrite for master channels

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.220 Simultaneous Rewrite Settings for Master Channels of Complementary Modulation Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel counter is started and the corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. When TAUDnRDS.TAUDnRDSm = 0, the master channel is monitored for simultaneous rewrite triggers regardless of the value of this bit.

NOTE

If TAUDnRDS.TAUDnRDSm = 1, it is necessary for an upper channel higher than a master channel to generate a simultaneous rewrite trigger signal.

23.14.3.5 Register Settings for Slave Channel 1

(1) TAUDnCMORm for slave channel 1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]		TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 23.221 Contents of the TAUDnCMORm register for the Slave Channel 1 of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKS[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	11: INTTAUDnIm of the master channel is used as the count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	000: Trigger the counter using software. 011: Triggers simultaneous rewrite.
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0011: Event count mode
0	TAUDnMD0	0: INTTAUDnIm is not generated at the beginning of operation or at a restart time.

(2) TAUDnCMURm for slave channel 1

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.222 Contents of the TAUDnCMURm register for the Slave Channel 1 of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Channel output mode

TAUDnTOE.TAUDnTOEm is set to 0 because the channel output mode is not used on slave channel 1 with this function. However, this mode can be used in independent channel output mode controlled by software.

CAUTION

TAUDnTRC.TAUDnTRCm should be set to 1 because slave channel 1 is used as a real-time output trigger channel.

(4) Simultaneous rewrite for slave channel 1

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.223 Simultaneous Rewrite Settings for Slave Channel 1 of Complementary Modulation Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel counter is started and the corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. When TAUDnRDS.TAUDnRDSm = 0, the master channel is monitored for simultaneous rewrite triggers regardless of the value of this bit.

23.14.3.6 Register Settings for slave channels 2, 4, and 6

(1) TAUDnCMORm for slave channels 2, 4, and 6

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKs[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]		TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 23.224 Contents of the TAUDnCMORm register for the Slave Channels 2, 4, and 6 of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
15, 14	TAUDnCKs[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUDnCKs[1:0] bit of the master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	111: Up/down output trigger signal of master channel
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	1001: Up/down count mode
0	TAUDnMD0	0: INTTAUDnIm is not generated at the beginning of operation or at a restart time.

(2) TAUDnCMURm for slave channels 2, 4, and 6

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.225 Contents of the TAUDnCMURm register for the Slave Channels 2, 4, and 6 of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Output mode for slave channels 2, 4, and 6**Table 23.226 Control Bit Settings in Synchronous Channel Output Mode 2 with Complementary Modulation Output**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	1: Enables dead time operation.
TAUDnTDM.TAUDnTDMm	0: Adds dead time upon detection of a duty cycle on an even-numbered upper channel and when the condition set in TAUDnTDL.TAUDnTDLm is met.
TAUDnTDL.TAUDnTDLm	0: Adds dead time to normal phase. 1: Adds dead time to reverse phase.
TAUDnTRE.TAUDnTREM	1: Enables real-time output.
TAUDnTRO.TAUDnTROM	0: Real-time output is low. 1: Real-time output is high.
TAUDnTRC.TAUDnTRCm	0: Upper channel generates a real-time output trigger for channel m.
TAUDnTME.TAUDnTMEm	0: Disables modulation 1: Enables modulation

CAUTION

Set TAUDnTDL.TAUDnTDLm exclusively from odd-numbered channels during PWM output.

(4) Simultaneous rewrite for slave channels 2, 4, and 6

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.227 Simultaneous Rewrite Settings for Slave Channels 2, 4, and 6 of Complementary Modulation Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel starts to count and the corresponding slave channel is at the peak of a triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. When TAUDnRDS.TAUDnRDSm = 0, the master channel is monitored for simultaneous rewrite triggers regardless of the value of this bit.

23.14.3.7 Register Settings for slave channels 3, 5, and 7

(1) TAUDnCMORM for slave channels 3, 5, and 7

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUDnCKS[1:0]		TAUDnCCS[1:0]		TAUDnMAS	TAUDnSTS[2:0]		TAUDnCOS[1:0]		—	TAUDnMD[4:1]				TAUDnMD0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Bit Position	Bit Name	Function
15, 14	TAUDnCKS[1:0]	Operating Clock Selection 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The TAUDnCKS[1:0] values of master and slave channels must be identical.
13, 12	TAUDnCCS[1:0]	00: Uses an operating clock as a count clock
11	TAUDnMAS	0: Slave channel
10 to 8	TAUDnSTS[2:0]	110: Dead time trigger
7, 6	TAUDnCOS[1:0]	00: Unused. Set to 00.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUDnMD[4:1]	0100: One-count mode
0	TAUDnMD0	1: Enables start trigger detection while counting.

(2) TAUDnCMURM for slave channels 3, 5, and 7

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUDnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 23.229 Contents of the TAUDnCMURM register for the Slave Channels 3, 5, and 7 of the Complementary Modulation Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUDnTIS[1:0]	00: Unused. Set to 00.

(3) Output mode for slave channels 3, 5, and 7**Table 23.230 Control Bit Settings in Synchronous Channel Output Mode 2 with Complementary Modulation Output**

Bit Name	Setting
TAUDnTOE.TAUDnTOEm	1: Enables independent channel output mode
TAUDnTOM.TAUDnTOMm	1: Synchronous channel output
TAUDnTOC.TAUDnTOCm	1: Operating mode 2
TAUDnTOL.TAUDnTOLm	0: Positive logic 1: Negative logic
TAUDnTDE.TAUDnTDEm	1: Enables dead time operation.
TAUDnTDM.TAUDnTDMm	0: Adds dead time upon detection of a duty cycle on an even-numbered upper channel and when the condition set in TAUDnTDL.TAUDnTDLm is met.
TAUDnTDL.TAUDnTDLm	0: Adds dead time to normal phase. 1: Adds dead time to reverse phase.
TAUDnTRE.TAUDnTREM	1: Enables real-time output.
TAUDnTRO.TAUDnTROM	0: Real-time output is low. 1: Real-time output is high.
TAUDnTRC.TAUDnTRCm	0: Upper channel generates a real-time output trigger for channel m.
TAUDnTME.TAUDnTMEm	0: Disables modulation 1: Enables modulation

CAUTION

Set TAUDnTDL.TAUDnTDLm exclusively from even-numbered channels during PWM output.

(4) Simultaneous rewrite for slave channels 3, 5, and 7

Both master and slave channels should have the same simultaneous rewrite settings.

Table 23.231 Simultaneous Rewrite Settings for Slave Channels 3, 5, and 7 of Complementary Modulation Output Function

Bit Name	Setting
TAUDnRDE.TAUDnRDEm	1: Enables simultaneous rewrite.
TAUDnRDS.TAUDnRDSm	0: Monitors master channel for simultaneous rewrite triggers. 1: Monitors upper channel other than the channel group for simultaneous rewrite triggers.
TAUDnRDM.TAUDnRDMm	1: A simultaneous rewrite trigger signal is generated when master channel counter is started and the corresponding slave channel is at the peak of triangular wave.
TAUDnRDC.TAUDnRDCm	0: Does not operate as a simultaneous rewrite trigger generation channel. When TAUDnRDS.TAUDnRDSm = 0, the master channel is monitored for simultaneous rewrite triggers regardless of the value of this bit.

23.14.3.8 Operating Procedure for Complementary Modulation Output Function

Table 23.232 Operating Procedure for Complementary Modulation Output Function (1/2)

Operation	TAUDn Status
<p>Master channels: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.14.3.4, Register Settings for Master Channels.</p> <p>Slave channel 1: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.14.3.5, Register Settings for Slave Channel 1.</p> <p>Slave channels 2, 4, and 6: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.14.3.6, Register Settings for slave channels 2, 4, and 6.</p> <p>Slave channels 3, 5, and 7: Set TAUDnCMORm and TAUDnCMURm registers and the channel output mode as described in Section 23.14.3.7, Register Settings for slave channels 3, 5, and 7.</p> <p>Set the value of TAUDnCDRm register of every channel. Set a pulse cycle using TAUDnCDRm of master channel, and an interrupt count of master channel ignored using TAUDnCDRm of slave channel 1. Also set a duty width in TAUDnCDRm of slave channels 2, 4, and 6, and a dead time delay on slave channels 3, 5, and 7.</p> <p>Set TAUDnTRC.TAUDnTRCm to 1 on slave channel 1.</p>	<p>Channel operation is stopped.</p>
<p>Set TAUDnTS.TAUDnTSm of master and slave channels to 1 simultaneously. TAUDnTS.TAUDnTSm is a trigger bit, which is automatically cleared to 0.</p>	<p>TAUDnTE.TAUDnTEm of master and slave channels is set to 1 and the counter starts counting down.</p>

Initial Channel Setting

Restart

Table 23.232 Operating Procedure for Complementary Modulation Output Function (2/2)

	Operation	TAUDn Status
Restart	<p>TAUDnCDRm, TAUDnTRO.TAUDnTROm, TAUDnTME.TAUDnTMEEm, and TAUDnTDL.TAUDnTDLm can be changed at any time.</p> <p>TAUDnCNTm and TAUDnRSF.TAUDnRSFm can be read at any time.</p> <p>TAUDnRDT.TAUDnRDTm can be changed during operation.</p>	<p>TAUDnCDRm value of master channel and slave channels 2 to 7 is loaded into TAUDnCNTm to perform count down. TAUDnCDRm value of slave channel 1 is loaded and the counter waits for a master channel interrupt. When the counter of master channel reaches 0000_H:</p> <ul style="list-style-type: none"> • INTTAUDnIm is generated. • TAUDnCDRm value is reloaded into TAUDnCNTm to continue counting down. • TAUDnCNTm value of slave channel 1 decreases by 1 and the counter waits for the next master channel interrupt. • TAUDnCNTm of slave channels 2, 4, and 6 reloads the TAUDnCDRm value or performs counting in the reverse direction. • When the TAUDnCDRm values of slave channel 2, 4, and 6 are loaded, the TAUDnTME.TAUDnTMEEm of slave 2 to 7 are reflected to the TAUDTTOUTm output. • The counter of slave channel 1 waits for the next interrupt from the master channel when reaching 0000_H. When the interrupt is detected: <ul style="list-style-type: none"> – TAUDnCDRm value is reloaded into TAUDnCNTm and the counter waits for the next master channel interrupt. – INTTAUDnIm is generated. – TAUDnTRO.TAUDnTROm is changeable. • When the counter of slave channels 2, 4, and 6 reaches 0001_H: <ul style="list-style-type: none"> – INTTAUDnIm is generated. – PWM output of slave channel m is set/ reset (when the specified condition of channel output mode is met). – TAUDnCDRm value of slave channels 3, 5, and 7 is loaded into TAUDnCNTm to perform count down. • When the counter of slave channels 3, 5, and 7 reaches 0000_H: <ul style="list-style-type: none"> – INTTAUDnIm is generated. – PWM output of slave channel m is set/ reset (when the specified condition of channel output mode is met). <p>TAUDnTTOUTm of slave channels 2 to 7 outputs a PWM signal, a high-level signal or low-level signal depending on the values of real-time output bit (TAUDnTRO.TAUDnTROm), modulation output bit (TAUDnTME.TAUDnTMEEm), and output level bit (TAUDnTDL.TAUDnTDLm) of a pair of slave channels.</p>
During Operation		
Stop Operation	<p>Set TAUDnTT.TAUDnTTm of master and slave channels to 1 simultaneously.</p> <p>TAUDnTT.TAUDnTTm is a trigger bit, which is automatically cleared to 0.</p>	<p>TAUDnTE.TAUDnTEEm is cleared to 0 and the counter stops.</p> <p>TAUDnCNTm and TAUDnTTOUTm stop and retain their current values.</p>

23.14.3.9 Specific Timing Diagrams

The following settings apply to the timing diagram.

- Master channel: INTTAUDnIm is not generated at startup (TAUDnCMORm.TAUDnMD0 = 0).
- Slave channel 1: TAUDnCDRm=0001_H
- Slave channels 2 to 7: Positive logic (TAUDnTOL.TAUDnTOLm = 0)

Figure 23.126 Specific Timing Diagram of Complementary Modulation Output Function

The above timing diagram shows how full modulation, first-half modulation, and second-half modulation can be achieved by modifying the TAUDnTME.TAUDnTMEm bits of lower slave channels during operation.

A modulated PWM output signal and TAUDnTRO.TAUDnTROm bit value are output from slave channels 2 and 3. Therefore, a type (normal/reverse phase) of PWM signal to be output from each channel depends on this bit value. Setting values of TAUDnTME.TAUDnTMEm and TAUDnTDL.TAUDnTDLm are reflected at count start timing and upon a carrier period (peak) of a triangular wave PWM.

TAUDnTRO.TAUDnTROm bit value is specified by software, but a new setting is applied only when an interrupt occurs on slave channel 1.

NOTE

Dead time is added to suppress simultaneous change of PWM edges of normal and reverse phases.

The “Setting” symbol indicates a time period when the values of TAUDnCDRm, TAUDnTME.TAUDnTME_m, TAUDnTRO.TAUDnTRO_m, and TAUDnTDL.TAUDnTDL_m can be changed.

Section 24 Timer Array Unit J (TAUJ)

The Timer Array Unit J (TAUJ) is multifunction timer unit with several 32-bit timers (32-bit timer array unit). TAUJ is implemented 3 units with the channel interface of 4 per one unit.

24.1 Features of RH850/P1M-E TAUJ

24.1.1 Units and Channels

This microcontroller has the following number of TAUJ units.

Table 24.1 Number of Units

Product	RH850/P1M-E 100 pins	RH850/P1M-E 144 pins
Number of Units	3	3
Name	TAUJn (n = 0 to 2)	TAUJn (n = 0 to 2)

TAUJn has the following number of channels of timers.

Table 24.2 TAUJn Unit Configurations and Channels

Unit Name (Channel Name) TAUJn	Channels per Unit	RH850/P1M-E 100 pins (12 ch)	RH850/P1M-E 144 pins (12 ch)
TAUJ0	4	√	√
TAUJ1	4	√	√
TAUJ2	4	√	√

Table 24.3 Index

Index	Description
n	Throughout this section, the individual TAUJ units are identified by the index "n" (n = 0 to 2); for example, TAUJnTOM is the TAUJn channel output mode register.
m	The TAUJ has 4 channels. Throughout this section, the individual channels are identified by the index "m" (m = 0 to 3), thus a certain channel is denoted as CHm. The even numbered channels (m = 0, 2) are denoted as CHm_even. The odd numbered channels (m = 1, 3) are denoted as CHm_odd.

24.1.2 Register Base Address

TAUJn base addresses are listed in the following table.

TAUJn register addresses are given as offsets from the base addresses throughout the section.

Table 24.4 Register Base Addresses

Base Address Name	Base Address
<TAUJ0_base>	FFE5 0000 _H
<TAUJ1_base>	FFE5 1000 _H
<TAUJ2_base>	FFE5 2000 _H

24.1.3 Clock Supply

Clock supply by and to TAUJn is listed in the following table.

Table 24.5 Clock Supply

Unit Name	Clock Unit Name	Supply Clock Name
TAUJn	PCLK	High-speed peripheral clock CLK_HSB

24.1.4 Interrupt Requests

TAUJn interrupt requests are listed in the following table.

Table 24.6 Interrupt Requests

Unit Interrupt Name	Description	Interrupt Number	DMA/DTS Trigger Number
TAUJ0			
INTTAUJ010	Channel 0 interrupt	133	1
INTTAUJ011	Channel 1 interrupt	134	2
INTTAUJ012	Channel 2 interrupt	135	3
INTTAUJ013	Channel 3 interrupt	136	4
TAUJ1			
INTTAUJ110	Channel 0 interrupt	137	5
INTTAUJ111	Channel 1 interrupt	138	6
INTTAUJ112	Channel 2 interrupt	139	7
INTTAUJ113	Channel 3 interrupt	140	8
TAUJ2			
INTTAUJ210	Channel 0 interrupt	256	9
INTTAUJ211	Channel 1 interrupt	257	10
INTTAUJ212	Channel 2 interrupt	258	11
INTTAUJ213	Channel 3 interrupt	259	12

24.1.5 Reset Sources

Please refer to **Section 8, Reset Controller**.

24.1.6 External Input/Output Signals

External input/output signals of TAUJn are listed below.

Table 24.7 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
TAUJ0			
TAUJ0TTIN0 to TAUJ0TTIN3*2	I	Inputs for channel 0 to 3	TAUJ0I0 to TAUJ0I3
TAUJ0TTOUT0 to TAUJ0TTOUT3	O	Outputs for channel 0 to 3	TAUJ0O0 to TAUJ0O3
TAUJ1			
TAUJ1TTIN0 to TAUJ1TTIN3*2	I	Inputs for channel 0 to 3	TAUJ1I0 to TAUJ1I3
TAUJ1TTOUT0 to TAUJ1TTOUT3	O	Outputs for channel 0 to 3	TAUJ1O0 to TAUJ1O3
TAUJ2			
TAUJ2TTIN0 to TAUJ2TTIN3*1*2	I	Inputs for channel 0 to 3	TAUJ0I0 to TAUJ0I3 TAUJ1I0 to TAUJ1I3 TAUJ2I0 to TAUJ2I3
TAUJ2TTOUT0 to TAUJ2TTOUT3	O	Outputs for channel 0 to 3	TAUJ2O0 to TAUJ2O3

Note 1. The input signal is switched by PIC. For details, see **Section 29.2.2.28, PIMONSEL — Port Input Monitor Select Register** and **Section 29.2.3.14, Timer Input Monitor Function**.

Note 2. Setting of the noise filter for the port is required when the channel input pin is used. For details, see **Section 2.6, Noise Filter and Edge Level Detection Circuit**.

24.1.7 Internal Input/Output Signals

The internal input/output signals of TAUJn are listed below.

Table 24.8 Internal Input/Output Signals

Unit Signal Name	Description	Connected to
TAUJnTSSTm*1	Simultaneous channel start trigger input	PIC

Note 1. n = 0, 1 only. TAUJ2TSSTm is not connected to PIC.

24.2 Overview

24.2.1 Functional Overview

The TAUJ has the following functions:

- Independent channel operation function (operated using a single channel)
- Synchronous channel operation function (operated using a master channel and multiple slave channels)

The timer array unit J is used to perform various count or timer operations and to output a signal which depends on the result of the operation. It contains one prescaler block for count clock generation and 4 channels, each equipped with a 32-bit counter TAUJnCNTm and a 32-bit data register TAUJnCDRm to hold the count start value or compare value.

It also contains several control and status registers.

Independent and synchronous operation

Every channel can operate in two operating modes, either independently or in combination with other channels (synchronously). When one master channel and one or more slave channels operate in combination, the slave channels depend on the master channel.

When a channel is operated independently, it can be operated independent of all other channels.

The synchronous operation function is implemented using a combination of channel groups (consisted of master and slave channels).

Several rules apply to the settings of channels.

24.2.2 Terms

In this section, the following terms are used.

Independent channel operation function / synchronous operation channel operation function

TAUJ has 4 channels, and provides an independent channel operation function that individual channels operate independently and a synchronous channel operation function that is implemented using a combination of channels.

- The independent channel operation function can be used any channel independently of all other channels.
- The synchronous channel operation function is implemented using a combination of channel groups (comprised of master and slave channels).

Several rules apply to the settings of channels.

Channel group

In the synchronous channel operation function, all channels that depend on each other are referred to as a “channel group”.

A channel group has one master channel and one or more slave channels.

Upper/lower channel

Based on the channel number m , a channel with a smaller channel number or higher channel number can be referred to as “upper” or “lower” channel:

- Upper channel: Channel with a smaller channel number
- Lower channel: Channel with a larger channel number

For instance, as to channel 2, channel 1 is an upper channel and channel 3 is a lower channel. Channel 0 is the highest channel and channel 3 is the lowest channel.

24.2.3 Timer Operation Functions

This timer provides the following functions by operating individual channels independently or a combination of channels.

Table 24.9 TAUJ Operation Functions

Operation Function	Example
Independent Channel Operation Functions	Section 24.12
Interval timer function	Section 24.12.1
TAUJnTTINm input interval timer function	Section 24.12.2
TAUJnTTINm input pulse interval measurement function	Section 24.12.3
TAUJnTTINm input signal width measurement function	Section 24.12.4
TAUJnTTINm input position detection function	Section 24.12.5
TAUJnTTINm input period count detection function	Section 24.12.6
Synchronous Channel Operation Functions	Section 24.13
PWM output function	Section 24.13.1

24.2.4 TAUJ I/O and Interrupt Request Signals

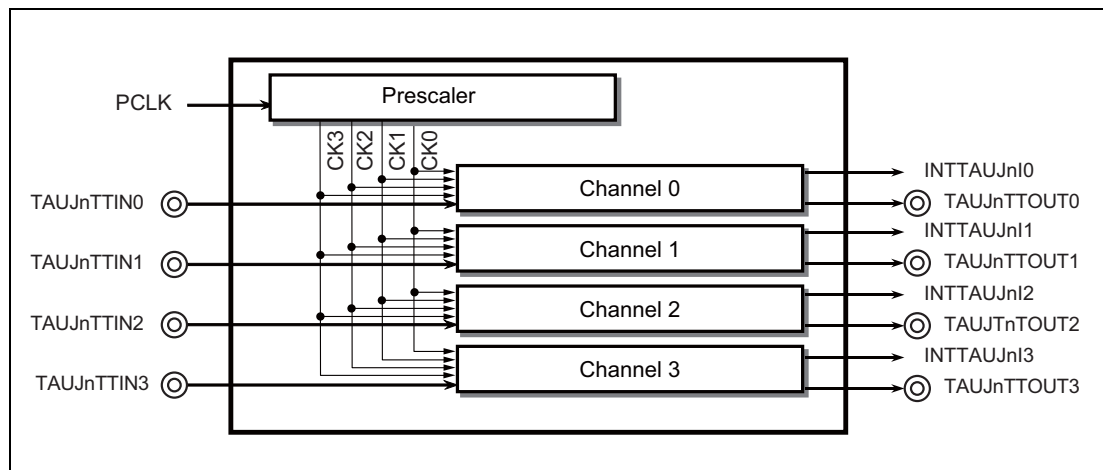

Figure 24.1 TAUJ I/O and Interrupt Request Signals

24.2.5 Block Diagram

The following figure shows the main components of the TAUJ:

Figure 24.2 Block Diagram of the TAUJ

The prefix “TAUJn” has been omitted from the register names for the sake of clarity in the above figure.

24.2.6 Description of Blocks

The description of blocks is the followings;

Prescaler

The prescaler provides up to 4 clock signals (CK0 to CK3) that can be used as count clocks for all channels.

Prescaler outputs CK0 to CK2 are derived by dividing PCLK in the prescaler by a division factors of 2^0 to 2^{15} . The fourth count clock, CK3, is derived by dividing PCLK by a division factor that is not a power of 2 by using the baud rate generator.

Clock and count clock selection

For every channel, the count clock selector selects which of the following is used as the clock source.

- One of the clock outputs CK0 to CK3 (selected by the clock selector)

Controller

The controller controls the main operations of the counter.

- Operating mode
(selected by the TAUJnCMORm.TAUJnMD[4:0] bits)
- Counter start enable (TAUJnTS.TAUJnTSm) and counter stop (TAUJnTT.TAUJnTTm)

When counter start is enabled, status flag TAUJnTE.TAUJnTEm is set.

Trigger selector

The counter starts automatically when it is enabled (TAUJnTE.TAUJnTEm = 1), or it waits for an external start trigger signal. Any of the following signals can be used as the start trigger.

- Synchronous channel start trigger input TAUJnTSSTm
- Valid edge of TAUJnTTINm input
- INTTAUJnIm from the master channel

Simultaneous rewrite controller

Simultaneous rewrite control is a special function that can be enabled in synchronous operating modes. The data registers of all channels in a channel group (TAUJnCDRm) can be rewritten at any time. The simultaneous rewrite controller ensures that new data register values of all channels become effective at the same time.

TAUJnTO controller

The output control of every channel enables the generation of various output signals such as PWM signals.

24.3 Registers

24.3.1 List of Registers

TAUJ registers are listed in the following table.

For details about <TAUJn_base>, see **Section 24.1.2, Register Base Address**.

Table 24.10 Registers

Module	Register	Symbol	Address
TAUJn prescaler registers			
TAUJn	TAUJn prescaler clock select register	TAUJnTPS	<TAUJn_base> + 90 _H
TAUJn	TAUJn prescaler baud rate setting register	TAUJnBRS	<TAUJn_base> + 94 _H
TAUJn control registers			
TAUJn	TAUJn channel data register m	TAUJnCDRm	<TAUJn_base> + m × 4 _H
TAUJn	TAUJn channel counter register m	TAUJnCNTm	<TAUJn_base> + 10 _H + m × 4 _H
TAUJn	TAUJn channel mode OS register m	TAUJnCMORm	<TAUJn_base> + 80 _H + m × 4 _H
TAUJn	TAUJn channel mode user register m	TAUJnCMURm	<TAUJn_base> + 20 _H + m × 4 _H
TAUJn	TAUJn channel status register m	TAUJnCSRm	<TAUJn_base> + 30 _H + m × 4 _H
TAUJn	TAUJn channel status clear register m	TAUJnCSCm	<TAUJn_base> + 40 _H + m × 4 _H
TAUJn	TAUJn channel start trigger register	TAUJnTS	<TAUJn_base> + 54 _H
TAUJn	TAUJn channel enable status register	TAUJnTE	<TAUJn_base> + 50 _H
TAUJn	TAUJn channel stop trigger register	TAUJnTT	<TAUJn_base> + 58 _H
TAUJn output registers			
TAUJn	TAUJn channel output enable register	TAUJnTOE	<TAUJn_base> + 60 _H
TAUJn	TAUJn channel output register	TAUJnTO	<TAUJn_base> + 5C _H
TAUJn	TAUJn channel output mode register	TAUJnTOM	<TAUJn_base> + 98 _H
TAUJn	TAUJn channel output configuration register	TAUJnTOC	<TAUJn_base> + 9C _H
TAUJn	TAUJn channel output active level register	TAUJnTOL	<TAUJn_base> + 64 _H
TAUJn reload data registers			
TAUJn	TAUJn channel reload data enable register	TAUJnRDE	<TAUJn_base> + A0 _H
TAUJn	TAUJn channel reload data mode register	TAUJnRDM	<TAUJn_base> + A4 _H
TAUJn	TAUJn channel reload data trigger register	TAUJnRDT	<TAUJn_base> + 68 _H
TAUJn	TAUJn channel reload status register	TAUJnRSF	<TAUJn_base> + 6C _H

24.3.2 Details of TAUJn Prescaler Registers

24.3.2.1 TAUJnTPS — TAUJn Prescaler Clock Select Register

This register specifies clocks CK0, CK1, CK2, and CK3_PRE for all channels of the PCLK prescalers. CK3 is generated by dividing CK3_PRE by the factor specified in TAUJnBRS.

Access: Readable/writable in 16-bit units.

Address: <TAUJn_base> + 90_H

Value after reset: FFFF_H This register is initialized by various types of reset.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUJnPRS3[3:0]				TAUJnPRS2[3:0]				TAUJnPRS1[3:0]				TAUJnPRS0[3:0]			
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.11 TAUJnTPS Register Contents (1/3)

Bit Position	Bit Name	Function
15 to 12	TAUJnPRS3 [3:0]	Specify a CK3_PRE clock. The CK3_PRE clock is the input clock signal for the BRG unit, which supplies prescaler output CK3 to all channels.
	TAUJnPRS3[3:0]	CK3_PRE clock
	0000 _B	PCLK/2 ⁰
	0001 _B	PCLK/2 ¹
	0010 _B	PCLK/2 ²
	0011 _B	PCLK/2 ³
	0100 _B	PCLK/2 ⁴
	0101 _B	PCLK/2 ⁵
	0110 _B	PCLK/2 ⁶
	0111 _B	PCLK/2 ⁷
	1000 _B	PCLK/2 ⁸
	1001 _B	PCLK/2 ⁹
	1010 _B	PCLK/2 ¹⁰
	1011 _B	PCLK/2 ¹¹
	1100 _B	PCLK/2 ¹²
	1101 _B	PCLK/2 ¹³
	1110 _B	PCLK/2 ¹⁴
	1111 _B	PCLK/2 ¹⁵

The above bits are rewritable only when all the counters using CK3 are stopped (TAUJnTE.TAUJnTEm = 0).

The above bits are rewritable only when all the counters using CK0 are stopped (TAUJnTE.TAUJnTEm = 0).

NOTE

TAUJn clock input PCLK is defined in the first part of this section, **Section 24.1.3, Clock Supply**.

24.3.2.2 TAUJnBRS — TAUJn Prescaler Baud Rate Setting Register

This register specifies the division factor of prescaler clock CK3.

CK3 is generated by dividing CK3_PRE by the factor specified in this register plus one. The PCLK prescaler for CK3_PRE is specified in TAUJnTPS. TAUJnPRS3[3:0].

Access: Readable/writable in 8-bit units.

Address: <TAUJn_base> + 94_H

Value after reset: 00_H This register is initialized by various types of reset.

24.3.3 Details of TAUJn Control Registers

24.3.3.1 TAUJnCDRm — TAUJn Channel Data Register

This register functions either as a compare register or as a capture register, depending on the operating mode specified in TAUJnCMORm.TAUJnMD[4:1].

- Access:** Readable/writable in 32-bit units.
- When this register functions as a capture register, only reading is possible. Any write operation is ignored.
 - When this register functions as a compare register, reading and writing is possible.

Address: <TAUJn_base> + 0_H + m × 4_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TAUJnCDR[31:16]

Bit Position	Bit Name	Function
31 to 0	TAUJnCDR [31:0]	Data register for capture/compare values

24.3.3.2 TAUJnCNTm — TAUJn Channel Counter Register

This is a channel m counter register.

Access: Only readable in 32-bit units.

Address: <TAUJn_base> + 10_H + m × 4_H

Value after reset: FFFF FFFF_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.14 TAUJnCNTm Register Contents

Bit Position	Bit Name	Function
31 to 0	TAUJnCNT [31:0]	32-bit counter value

The read value depends on a counter, an operating mode change, or TAUJnTS.TAUJnTSm/TAUJnTT.TAUJnTTm bit value.

The initial counter read value depends on the operating mode and how the counter is stopped.

- By a reset
- By a counter stop trigger (TAUJnTT.TAUJnTTm = 1)

The following table lists the initial counter read values after the counter is stopped (TAUJnTE.TAUJnTEm = 0) and re-enabled (TAUJnTS.TAUJnTSm = 1).

The table also contains the counter read value one count after the counter is enabled (TAUJnTS.TAUJnTSm = 1) with the counter waiting for a start trigger.

Table 24.15 TAUJnCNTm Read Values after Re-Enabling Counter

Mode Name	Count Method (Up/Down)	TAUJnCNTm		
		Start Value ^{*1}	After Stop Trigger	After One Count
Interval timer mode	Count down	FFFF FFFF _H	Stop value	—
Capture mode	Count up	0000 0000 _H	Stop value	—
One-count mode	Count down	FFFF FFFF _H	Stop value	Stop value
Capture and one-count mode	Count up	0000 0000 _H	Stop value	Capture value + 1 (TAUJnCDRm)
Count capture mode	Count up	0000 0000 _H	Stop value	—
Capture and gate count mode	Count up	0000 0000 _H	Stop value	Stop value

Note 1. The value set in the TAUJnCNTm when operation modes are changed after reset release.

24.3.3.3 TAUJnCMORm — TAUJn Channel Mode OS Register

This register controls channel m operation.

Access: Readable/writable in 16-bit units. Writable only when the counter is stopped (TAUJnTE.TAUJnTE_m = 0).

Address: <TAUJn_base> + 80_H + m × 4_H

Value after reset: 0000_H This register is initialized by various types of reset.

24.3.3.4 TAUJnCMURm — TAUJn Channel Mode User Register

This register specifies a type of valid edge detection used for TAUJnTTINm input.

Access: Readable/writable in 8-bit units.

Address: <TAUJn_base> + 20_H + m × 4_H

Value after reset: 00_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUJnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 24.17 TAUJnCMURm Register Contents

Bit Position	Bit Name	Function															
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.															
1, 0	TAUJnTIS[1:0]	Specify a valid edge of TAUJnTTINm input signal.															
		<table border="1"> <thead> <tr> <th>TAUJn TIS1</th> <th>TAUJn TIS0</th> <th>Functional Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Detection of falling and rising edges (selection of low width measurement) Start trigger: Falling edge Stop trigger (capture): Rising edge</td> </tr> <tr> <td>1</td> <td>1</td> <td>Detection of falling and rising edges (selection of high width measurement) Start trigger: Rising edge Stop trigger (capture): Falling edge</td> </tr> </tbody> </table>	TAUJn TIS1	TAUJn TIS0	Functional Description	0	0	Falling edge	0	1	Rising edge	1	0	Detection of falling and rising edges (selection of low width measurement) Start trigger: Falling edge Stop trigger (capture): Rising edge	1	1	Detection of falling and rising edges (selection of high width measurement) Start trigger: Rising edge Stop trigger (capture): Falling edge
TAUJn TIS1	TAUJn TIS0	Functional Description															
0	0	Falling edge															
0	1	Rising edge															
1	0	Detection of falling and rising edges (selection of low width measurement) Start trigger: Falling edge Stop trigger (capture): Rising edge															
1	1	Detection of falling and rising edges (selection of high width measurement) Start trigger: Rising edge Stop trigger (capture): Falling edge															

Edge detection of TAUJnTTINm input signal is based on the operating clock selected by TAUJnCMORm.TAUJnCKS[1:0].

24.3.3.5 TAUJnCSRm — TAUJn Channel Status Register

This register indicates the overflow status of channel m.

Access: Only readable in 8-bit units.

Address: <TAUJn_base> + 30_H + m × 4_H

Value after reset: 0X_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAUJnOVF
Value after reset	0	0	0	0	0	0	—	0
R/W	R	R	R	R	R	R	R	R

Table 24.18 TAUJnCSRm Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read.
1	Reserved	When read, an undefined value is read.
0	TAUJnOVF	Indicates the counter overflow status: 0: No overflow occurs 1: Overflow occurs This bit is used only in the following modes: <ul style="list-style-type: none"> • Capture mode • Capture and one-count mode The function of this bit depends on the setting of control bits TAUJnCMORm.TAUJnCOSC[1:0].

24.3.3.6 TAUJnCSCm — TAUJn Channel Status Clear Trigger Register

This register is a trigger register for clearing the overflow flag TAUJnCSRm.TAUJnOVF of channel m.

Access: Only writable in 8-bit units. The read value is always 00_H.

Address: <TAUJn_base> + 40_H + m × 4_H

Value after reset: 00_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAUJnCLOV
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 24.19 TAUJnCSCm Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAUJnCLOV	0: No effect (Setting 0 does not affect the overflow flag TAUJnCSRm.TAUJnOVF bit.) 1: Clears the overflow flag TAUJnCSRm.TAUJnOVF

24.3.3.7 TAUJnTS — TAUJn Channel Start Trigger Register

This register enables the counter operation for each channel.

Access: Only writable in 8-bit units. The read value is always 00_H.

Address: <TAUJn_base> + 54_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0

Table 24.20 TAUJnTS Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When writing, write the value after reset.
3 to 0	TAUJnTSm	Enables the counter operation for channel m: 0: No effect (Setting 0 does not enable the counter operation of channel m.) 1: Enables the counter operation and sets TAUJnTE.TAUJnTEm = 1
<p>Only the counter operation is enabled even if TAUJnTE.TAUJnTEm = 1. Whether the counter is started or not depends on the selected of operating mode.</p>		

24.3.3.8 TAUJnTE — TAUJn Channel Enable Status Register

This register enables/disables a counter operation.

Access: Only readable in 8-bit units.

Address: <TAUJn_base> + 50_H

Value after reset: 00_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTE03	TAUJnTE02	TAUJnTE01	TAUJnTE00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 24.21 TAUJnTE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read.
3 to 0	TAUJnTEm	Enables/disables channel m's counter operation. 0: Disables the counter operation 1: Enables the counter operation
<p>These bits are set to 1 when trigger input of TAUJnTSSTm (synchronous channel start trigger signal) is detected or when TAUJnTS.TAUJnTSm is set to 1. These bits are set to 0 when TAUJnTT.TAUJnTTm is set to 1.</p>		

24.3.3.9 TAUJnTT — TAUJn Channel Stop Trigger Register

This register stops the counter operation of each channel.

Access: Only writable in 8-bit units. The read value is always 00_H.

Address: <TAUJn_base> + 58_H

Value after reset: 00_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTT03	TAUJnTT02	TAUJnTT01	TAUJnTT00
Value after reset	0	0	0	0	0	0	0	0

Table 24.22 TAUJnTT Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When writing, write the value after reset.
3 to 0	TAUJnTTm	Stops channel m's counter operation. 0: No effect (Setting 0 does not enable the counter operation of channel m.) 1: Stops the counter operation and resets TAUJnTE.TAUJnTEm TAUJnCNTm, TAUJnTO.TAUJnTOM, and TAUJnTTOUTm retain the values provided before the counter is stopped.

24.3.4 TAUJn Simultaneous Rewrite Register Details

24.3.4.1 TAUJnRDE — TAUJn Channel Reload Data Enable Register

This register enables and disables simultaneous rewrite of the data register TAUJnCDRm. It also enables and disables simultaneous rewrite of the data register TAUJnTOL.TAUJnTOLm for the PWM output function.

Access: This register can be read/written in 8-bit units. It can only be written when the counter is stopped (TAUJnTE.TAUJnTEm = 0).

Address: <TAUJn_base> + A0_H

Value after reset: 00_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnRDE03	TAUJnRDE02	TAUJnRDE01	TAUJnRDE00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 24.23 TAUJnRDE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	TAUJnRDEm	Enables/disables simultaneous rewrite of the data register of channel m: 0: Disables simultaneous rewrite 1: Enabled simultaneous rewrite

24.3.4.2 TAUJnRDM — TAUJn Channel Reload Data Mode Register

This register selects when the signal that controls simultaneous rewrite is generated.

Access: This register can be read/written in 8-bit units. It can only be written when the counter is stopped (TAUJnTE.TAUJnTEm = 0).

Address: <TAUJn_base> + A4_H

Value after reset: 00_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnRDM03	TAUJnRDM02	TAUJnRDM01	TAUJnRDM00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 24.24 TAUJnRDM Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	TAUJnRDMm	Specify when the signal that triggers simultaneous rewrite is generated: 0: When the master channel counter starts counting 1: Setting prohibited

These bits only apply when TAUJnRDE.TAUJnRDEm = 1.

24.3.4.3 TAUJnRDT — TAUJn Channel Reload Data Trigger Register

This register triggers the simultaneous rewrite enable state.

Access: This register can only be written in 8-bit unit. It is always read as 00_H.

Address: <TAUJn_base> + 68_H

Value after reset: 00_H This register is initialized by any reset source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnRDT03	TAUJnRDT02	TAUJnRDT01	TAUJnRDT00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	W	W	W	W

Table 24.25 TAUJnRDT Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When writing, write the value after reset.
3 to 0	TAUJnRDTm	Triggers the simultaneous rewrite enable state: 0: No effect (Setting 0 does not trigger the simultaneous rewrite enable state.) 1: Simultaneous rewrite enable state is triggered. The simultaneous rewrite enable flag (TAUJnRSF.TAUJnRSFm) is set to 1. The system waits for the simultaneous rewrite trigger. These bits only apply when TAUJnRDE.TAUJnRDEm = 1.

24.3.4.4 TAUJnRSF — TAUJn Channel Reload Status Register

This flag register indicates the simultaneous rewrite status.

Access: This register can only be read in 8-bit units.

Address: <TAUJn_base> + 6C_H

Value after reset: 00_H This register is initialized by any reset source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnRSF03	TAUJnRSF02	TAUJnRSF01	TAUJnRSF00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 24.26 TAUJnRSF Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read.
3 to 0	TAUJnRSFm	Indicates the simultaneous rewrite status: 0: Indicates that the simultaneous rewrite is complete by the generation of the simultaneous rewrite trigger. 1: Indicates a trigger waiting state in the simultaneous rewrite enable state (TAUJnRDT.TAUJnRDTm = 1).

24.3.5 TAUJn Output Registers Details

24.3.5.1 TAUJnTOE — TAUJn Channel Output Enable Register

This register enables and disables Independent Channel Output Mode Controlled by Software.

Access: This register can be read/written in 8-bit units.

Address: <TAUJn_base> + 60_H

Value after reset: 00_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTOE03	TAUJnTOE02	TAUJnTOE01	TAUJnTOE00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 24.27 TAUJnTOE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	TAUJnTOEm	Enables/disables Independent Channel Output Mode: 0: Disables Independent Timer Output Function (by software) 1: Enables Independent Timer Output Function

24.3.5.2 TAUJnTO — TAUJn Channel Output Register

This register specifies and reads the level of TAUJnTTOUTm.

Access: This register can be read/written in 8-bit units.

Address: <TAUJn_base> + 5C_H

Value after reset: 00_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTO03	TAUJnTO02	TAUJnTO01	TAUJnTO00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 24.28 TAUJnTO Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	TAUJnTOm	Specifies/reads the level of TAUJnTTOUTm: 0: Low 1: High Only TAUJnTO.TAUJnTOm bits for which the independent channel output function is disabled (TAUJnTOE.TAUJnTOEm = 0) can be written.

24.3.5.3 TAUJnTOM — TAUJn Channel Output Mode Register

This register specifies the output mode of each channel.

Access: This register can be read/written in 8-bit units. It can only be written when the counter is stopped (TAUJnTE.TAUJnTEm = 0).

Address: <TAUJn_base> + 98_H

Value after reset: 00_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTOM03	TAUJnTOM02	TAUJnTOM01	TAUJnTOM00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 24.29 TAUJnTOM Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	TAUJnTOMm	Specify the output mode: 0: Independent channel output mode 1: Synchronous channel output mode The output mode depends on several channel output control bit TAUJnTOE.TAUJnTOEm setting.

24.3.5.4 TAUJnTOC — TAUJn Channel Output Configuration Register

This register specifies the output mode of each channel in combination with TAUJnTOM.TAUJnTOMm.

Access: This register can be read/written in 8-bit units. It can only be written when the counter is stopped (TAUJnTE.TAUJnTEm = 0).

Address: <TAUJn_base> + 9C_H

Value after reset: 00_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTOC03	TAUJnTOC02	TAUJnTOC01	TAUJnTOC00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 24.30 TAUJnTOC Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	TAUJnTOCm	Specify the output mode: 0: Operation mode 1 (= Toggle mode) 1: Setting prohibited

These bits must always be set 0 in all output modes except the independent channel output mode controlled by software. The output mode depends on the setting of TAUJnTOM.TAUJnTOMm as shown in the table below.

TAUJn TOMm	TAUJn TOCm	Function
0	0	Toggle mode: Toggling proceeds when INTTAUJnIm is generated.
0	1	Setting prohibited
1	0	Synchronous channel operation mode: set when INT is generated on the master channel and reset when INT is generated on the slave channel.
1	1	Setting prohibited

24.3.5.5 TAUJnTOL — TAUJn Channel Output Active Level Register

This register specifies the output logic of the channel output bit (TAUJnTO.TAUJnTOm).

Access: This register can be read/written in 8-bit units.

Address: <TAUJn_base> + 64_H

Value after reset: 00_H This register is initialized by various types of reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAUJnTOL03	TAUJnTOL02	TAUJnTOL01	TAUJnTOL00
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 24.31 TAUJnTOL Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	TAUJnTOLm	Specify the output logic of the channel m output bit (TAUJnTO.TAUJnTOm): 0: Positive logic (active high) 1: Negative logic (active low)

24.4 Operating Procedure

The following lists the general operation procedure for the TAUJn:

After reset release, the operation of each channel is stopped. Clock supply is started and writing to each register is enabled. All circuits and registers of all channels are initialized. The control register of TAUJnTTOUTm is also initialized and outputs a low level.

1. Set the TAUJnTPS and TAUJnBRS registers to specify the clock frequency of CK0 to CK3.
2. Configure the desired TAUJn function:
 - Set the operation mode
 - Set the channel output mode
 - Set any other control bits
3. Enable the counter by setting the TAUJnTS.TAUJnTSM bit to 1.
The counter starts to count immediately, or when an appropriate trigger is detected, depending on the bit settings.
4. If desired, and if possible for the configured function, stop the counter or perform a forced restart operation during count operation. The counter can be stopped by setting the TAUJnTT.TAUJnTTm bit to 1. The counter can be forcibly restarted by setting the TAUJnTS.TAUJnTSM bit to 1.
5. Stop the function by setting the TAUJnTT.TAUJnTTm bit to 1.

NOTES

1. A detailed description of the required control bits and the operation of the individual functions is given in the following sections:
 - **Section 24.12, Independent Channel Operation Functions**
 - **Section 24.13, Synchronous Channel Operation Functions**
2. Modify the function while the counter is stopped (TAUJnTE.TAUJnTEm = 0).

24.5 Concepts of Synchronous Channel Operation

The synchronous channel operation depends on multiple channels and is affected by other channels. Therefore, several rules apply to the synchronous channel operation.

These rules are detailed in **Section 24.5.1, Rules of Synchronous Channel Operation**.

Two special features for the synchronous channel operation function are detailed in the following sections:

- **Section 24.5.2, Simultaneous Start and Stop of Synchronous Channel Counters**
- **Section 24.6, Simultaneous Rewrite**

24.5.1 Rules of Synchronous Channel Operation

Number of master and slave channels

- Only even channels (CH0, CH2) can be set as master channels. Any channel apart from CH0 can be set as a slave channel.
- Only channels lower than the master channel can be set as slave channels, and multiple slave channels can be set for one master channel.
Example: If CH2 is a master channel, CH3 can be set as slave channel.
- If two master channels are used, slave channels cannot cross the master.
Example: If CH0 and CH2 are master channels, CH1 can be set as slave channels for CH0, but CH3 cannot.

Operating clock

- The same operating clock should be set for the master channel and the synchronized slave channel. This is achieved by setting the same value in the TAUJnCMORm.TAUJnCKS[1:0] bits of the master and slave channels.

The basic concepts of master/slave usage and operating clocks are illustrated in **Figure 24.3**.

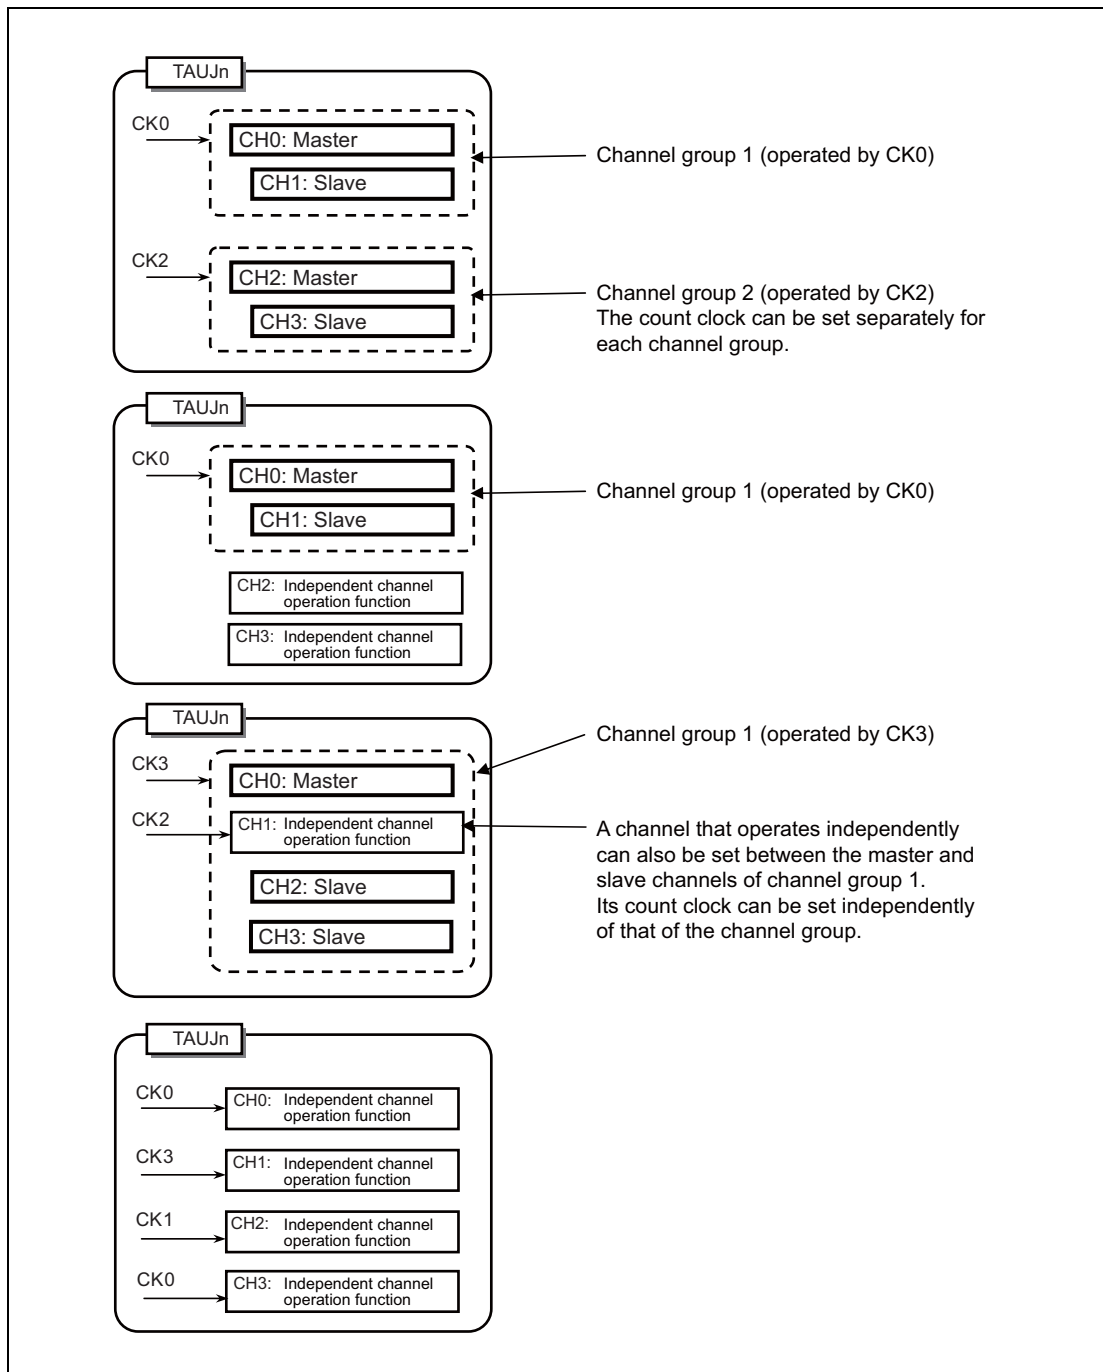

Figure 24.3 Grouping of Channels and Assignment of Count Clocks

24.5.2 Simultaneous Start and Stop of Synchronous Channel Counters

Channels that are operated synchronously can be started and stopped simultaneously, both within a TAUJ unit and between TAUJ units.

24.5.2.1 Simultaneous Start and Stop within a TAUJ Unit

- To simultaneously start synchronized channels, the TAUJnTS.TAUJnTSM bits of the channels should be set at the same time.
- To simultaneously stop synchronized channels, the TAUJnTT.TAUJnTTM bits of the channels should be set at the same time.

Setting 1 in the TAUJnTS.TAUJnTSM bits sets the corresponding TAUJnTE.TAUJnTEM bits to 1, enabling counting. The count start timing of the counter depends on the operating mode.

24.5.2.2 Simultaneous Start between TAUJ Units

Counters in different TAUJ units can also be started simultaneously if the corresponding counters are enabled before receiving the simultaneous trigger signal.

24.6 Simultaneous Rewrite

24.6.1 Functional Overview

Simultaneous rewrite describes the ability to change the compare/start value and the output logic of multiple channels at the same time.

The corresponding data and control registers (TAUJnCDRm and TAUJnTOL) can nevertheless be written at any time. The new value does not affect the counter operation or the output signal until simultaneous rewrite is triggered.

Simultaneous rewrite can be triggered when the counter on the master channel reaching a certain value.

Table 24.32 lists the simultaneous rewrite method (TAUJnRDM.TAUJnRDMm = 0).

Table 24.32 Simultaneous Rewrite Method

Method	Simultaneous Rewrite Triggered Timing	TAUJnRDE.TAUJnRDEm
—	No simultaneous rewrite	0
A	The master channel (re)starts counting	1

24.6.2 How to Control Simultaneous Rewrite

The following figure shows the general procedure for simultaneous rewrite. The three main blocks (Initial settings, Start counter & count operation, and Simultaneous rewrite) are explained afterwards.

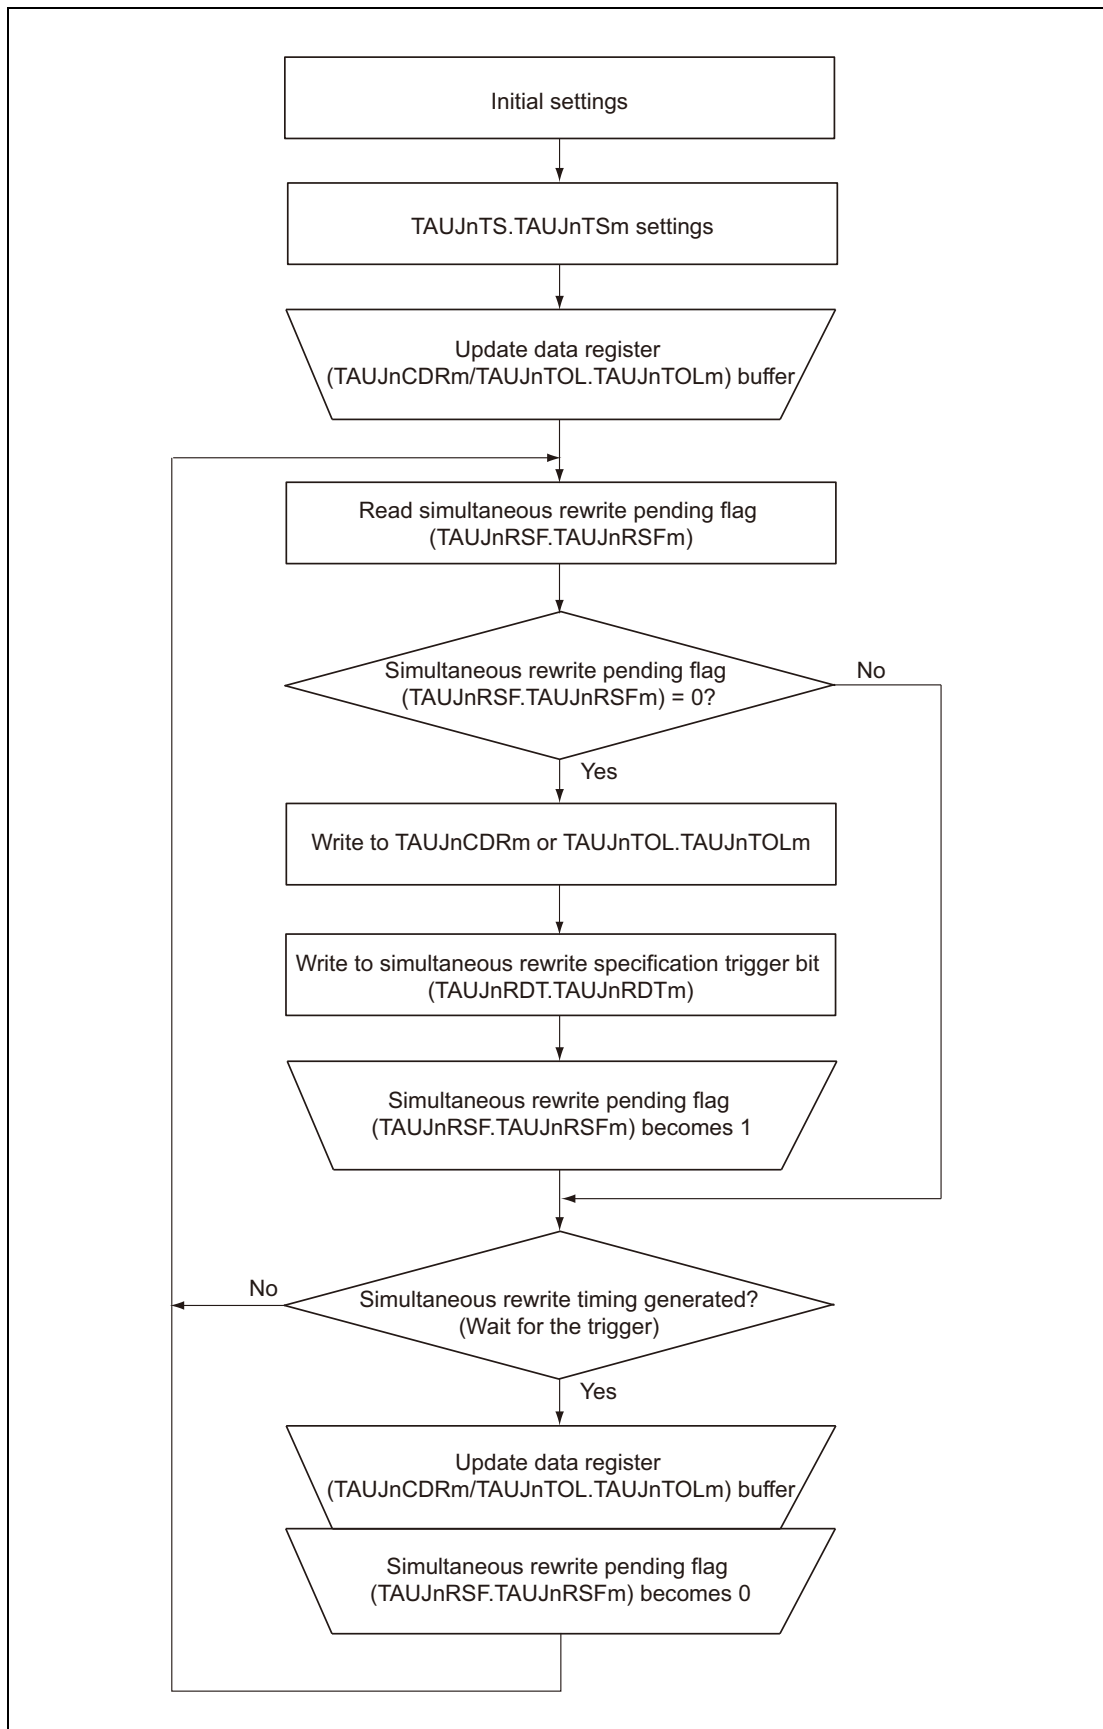

Figure 24.4 General Procedure for Simultaneous Rewrite

24.6.2.1 Initial Settings

- To enable simultaneous rewrite in channel m, set TAUJnRDE.TAUJnRDEm = 1

24.6.2.2 Start Counter and Count Operation

- To start all the TAUJnCnTm counters in the channel group, set the corresponding TAUJnTS.TAUJnTSM bits to 1. TAUJnTOL.TAUJnTOLm and the values in the data registers (TAUJnCDRm) are loaded into the corresponding TAUJnTOL.TAUJnTOLm buffer (TAUJnTOL.TAUJnTOLm buf) and data buffer registers (TAUJnCDRm buf) and the counters start.
- Setting the reload data trigger bit (TAUJnRDT.TAUJnRDTm) to 1 sets the reload flag (TAUJnRSF.TAUJnRSFm) to 1, enabling simultaneous rewrite. TAUJnRSF.TAUJnRSFm remains set to 1 until simultaneous rewrite is completed.
- When a specified trigger for simultaneous rewrite is detected, the TAUJnRSF.TAUJnRSFm bit is checked to see if simultaneous rewrite is enabled (TAUJnRSF.TAUJnRSFm = 1). If enabled, simultaneous rewrite is carried out. Otherwise simultaneous rewrite is not carried out and the system waits for detection of the next simultaneous rewrite trigger.

24.6.2.3 Simultaneous Rewrite

- When the simultaneous rewrite trigger is detected and simultaneous rewrite is enabled (TAUJnRSF.TAUJnRSFm = 1), the current values of the data registers are copied to their buffers. These values are then loaded into the corresponding counters and the values are applied the next time the counter starts or restarts.
- When the simultaneous rewrite is completed, the TAUJnRSF.TAUJnRSFm bit is set to 0, and the system awaits the next simultaneous rewrite trigger.

24.6.3 Other General Rules for Simultaneous Rewrite

The following rules also apply.

- TAUJnRDE.TAUJnRDEm and TAUJnRDM.TAUJnRDMm cannot be changed while the counter is in operation (TAUJnTE.TAUJnTEm = 1).
- TAUJnTOL.TAUJnTOLm can be rewritten only during operation using the PWM output function. For all other functions, TAUJnTOL.TAUJnTOLm should be written before the counter starts. If it is rewritten while any other function is used, TAUJnTTOUTm outputs an invalid wave.

24.6.4 Simultaneous Rewrite Procedure

The simultaneous rewrite procedure in PWM output mode is described in the following figure.

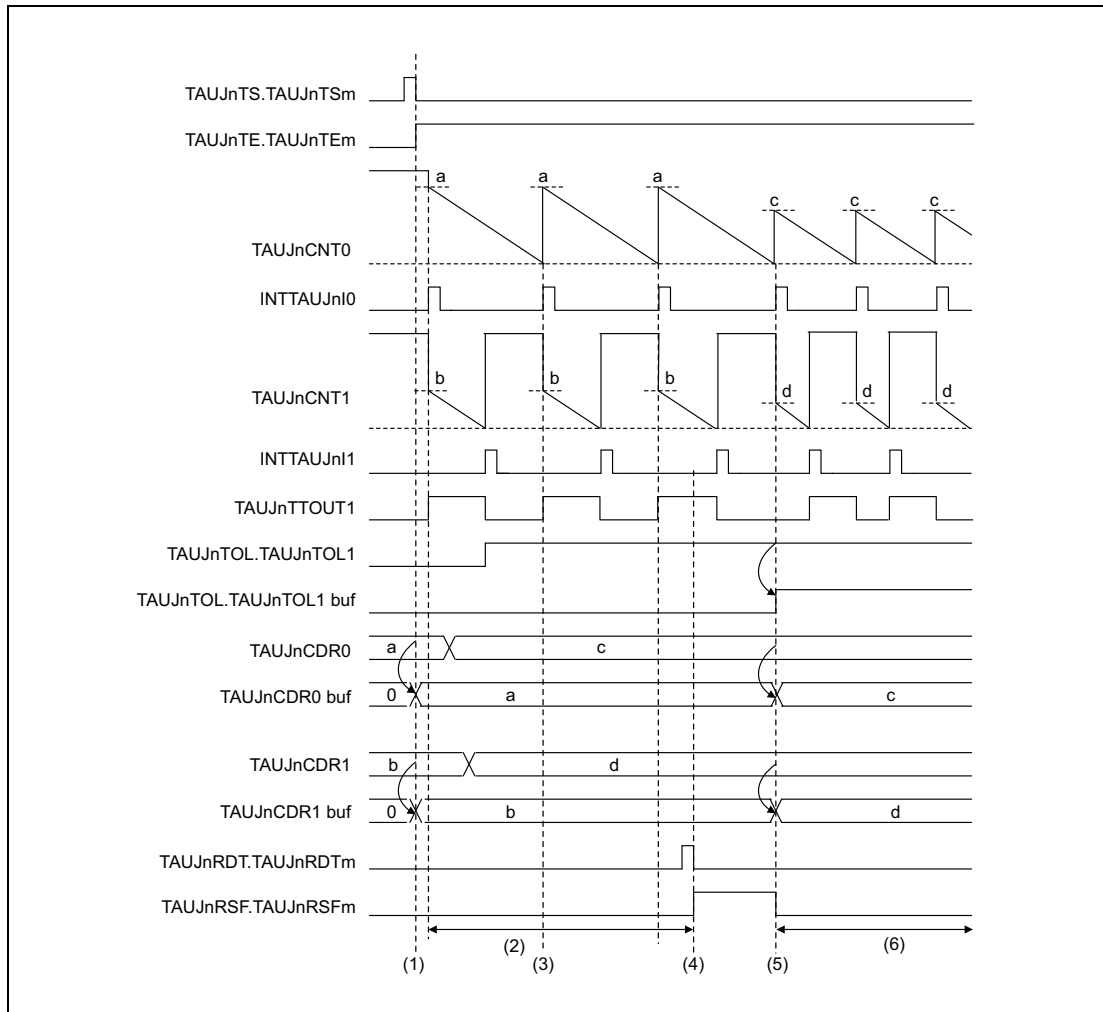

Figure 24.5 Simultaneous Rewrite in PWM Output Mode

Setting

CH0 is a master channel in PWM output mode, and CH1 represents an slave channel in PWM output mode. Simultaneous rewrite is applied when the master channel starts counting.

Description:

- (1) When $\text{TAUJnTS.TAUJnTSM} = 1$ is set, the value of TAUJnCDRm is copied to the TAUJnCDRm buffer and the value of $\text{TAUJnTOL.TAUJnTOLm}$ is copied to the $\text{TAUJnTOL.TAUJnTOLm}$ buffer.
- (2) The TAUJnCDRm and $\text{TAUJnTOL.TAUJnTOLm}$ registers can be written at any time.
- (3) CH0 restarts counting, but simultaneous rewrite does not occur because it is disabled ($\text{TAUJnRSF.TAUJnRSFm} = 0$).
- (4) The reload data trigger bit ($\text{TAUJnRDT.TAUJnRDTm}$) is set to 1 which sets the status flag ($\text{TAUJnRSF.TAUJnRSFm} = 1$), enabling simultaneous rewrite.
- (5) Simultaneous rewrite is triggered when CH0 restarts counting, because simultaneous rewrite is enabled. The TAUJnCDRm value is loaded into the TAUJnCDRm buffer and the $\text{TAUJnTOL.TAUJnTOLm}$ value is loaded into the $\text{TAUJnTOL.TAUJnTOLm}$ buffer.
- (6) The counter counts down and awaits the next simultaneous rewrite trigger. The values of TAUJnCDRm and $\text{TAUJnTOL.TAUJnTOLm}$ can be changed again.

24.7 Channel Output Modes

The output of the TAUJnTTOUTm pin can be controlled in two ways, the latter of which can be further split into individual modes.

- By software (TAUJnTOE.TAUJnTOEm = 0)
When controlled by software, the value written in the output register bit (TAUJnTO.TAUJnTOM) is sent out of the output pin (TAUJnTTOUTm).
- By TAUJ signals (TAUJnTOE.TAUJnTOEm = 1)
When controlled by TAUJ signals, the output level of TAUJnTTOUTm is set or reset or toggled by internal signals. The value of TAUJnTO.TAUJnTOM is updated accordingly to reflect the value of TAUJnTTOUTm.
 - Independently (TAUJnTOM.TAUJnTOMm = 0)
In case of independent operation, the output of the TAUJnTTOUTm pin is only affected by settings of channel m. Therefore, independent channel operation should be selected (TAUJnTOM.TAUJnTOMm = 0).
 - Synchronously (TAUJnTOM.TAUJnTOMm = 1)
In case of synchronous operation, the output of the TAUJnTTOUTm pin is affected by settings of channel m and those of other channels. Therefore, synchronous channel operation should be selected for all synchronized channels (TAUJnTOM.TAUJnTOMm = 1).

The TAUJnTO.TAUJnTOM bit can always be read to determine the current value of TAUJnTTOUTm, regardless of whether the pin is controlled by software, operated independently, or operated synchronously.

(1) Control bits

The settings of the control bits required to select a specific channel output mode are listed in **Table 24.33, Channel Output Modes**.

The channel output modes are described in details below.

- **Section 24.7.2, Channel Output Modes Controlled Independently by TAUJn Signals**
- **Section 24.7.3, Channel Output Modes Controlled Synchronously by TAUJn Signals**

(2) Batch operation of TAUJnTOM bit

Whether a set value is reflected to the TAUJnTO.TAUJnTOM bit or not is controlled by the TAUJnTOE.TAUJnTOEm bit.

The TAUJnTO.TAUJnTOM setting is written only to the bit (channel) set with TAUJnTOE.TAUJnTOEm bit = 0 when a write to the TAUJnTO register is attempted.

No TAUJnTO.TAUJnTOM setting is reflected to the bit (channel) set with TAUJnTOE.TAUJnTOEm bit = 1.

NOTE

TAUJnTO.TAUJnTOM bit is placed so that its bit number corresponds to a channel number.

(3) Output logic

Positive logic or negative logic of the output is specified by control bit TAUJnTOL.TAUJnTOLm.

The value of TAUJnTOL.TAUJnTOLm bit should be set before the counter is started. It can only be changed during operation with PWM output function. Otherwise, changes to TAUJnTOL.TAUJnTOLm result in an undefined TAUJnTTOUTm signal output.

See **Section 24.6, Simultaneous Rewrite**.

The various channel output modes and the channel output control bits are listed in the following table (TAUJnTOC.TAUJnTOCm = 0).

Table 24.33 Channel Output Modes

Channel Output Mode	TAUJnTOE. TAUJnTOEm	TAUJnTOM. TAUJnTOMm
By software		
Independent channel output mode controlled by software	0	x
By TAUJ signals, independently		
Independent channel output mode 1	1	0
By TAUJ signals, synchronously		
Synchronous channel output mode 1	1	1

- Any combination not in the list is prohibited.
- Any value can be set in the bit indicated as “x”.

NOTE

Do not modify the bits listed below during counting operation (TAUJnTE.TAUJnTEm = 1).

- TAUJnTOM.TAUJnTOMm
- TAUJnTOC.TAUJnTOCm

24.7.1 General Procedures for Specifying a Channel Output Mode

This section describes the general procedures for specifying a TAUJnTTOUTm channel output mode. The prerequisite is that timer output operation is disabled (TAUJnTOE.TAUJnTOEm = 0).

- (1) Set TAUJnTO.TAUJnTOm to specify the initial level of the TAUJnTTOUTm output.
- (2) Set channel output mode according to Table 24.33, Channel Output Modes, and the output logic using the TAUJnTOL.TAUJnTOLm bit.
- (3) Start the counter (TAUJnTS.TAUJnTSm = 1).

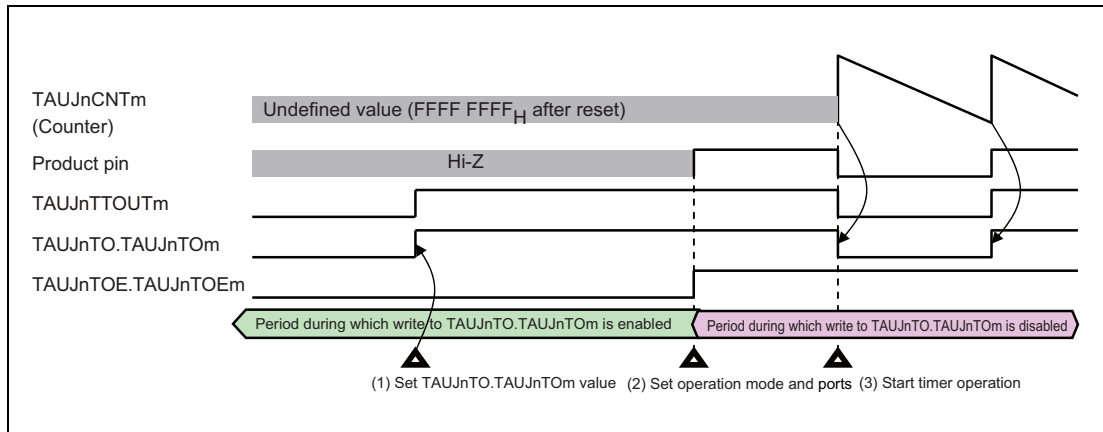

Figure 24.6 General Procedure for Specifying a TAUJnTTOUTm Channel Output Mode

24.7.2 Channel Output Modes Controlled Independently by TAUJn Signals

This section lists the channel output modes that are controlled independently by TAUJn signals. The control bits used to specify a mode are listed in Table 24.33, Channel Output Modes.

(1) Independent channel output mode 1

Set/reset conditions

In this output mode, TAUJnTTOUTm toggles when INTTAUJnIm is detected.

The value of TAUJnTOL.TAUJnTOLm is ignored.

Prerequisites

There are no prerequisites other than those shown in Table 24.33, Channel Output Modes.

24.7.3 Channel Output Modes Controlled Synchronously by TAUJn Signals

This section lists the channel output modes that are controlled synchronously by TAUJn signals. The control bits used to specify a mode are listed in **Table 24.33, Channel Output Modes**.

(1) Synchronous channel output mode 1

Set/reset conditions

In this output mode, INTTAUJnIm of master channel serves as a set signal and INTTAUJnIm of the slave channel as a reset signal. If INTTAUJnIm of the master channel and INTTAUJnIm of the slave channel are generated at the same time, INTTAUJnIm of the slave channel (reset signal) has priority over INTTAUJnIm (set signal) of the master channel, i.e., the master channel is ignored.

Prerequisites

There are no prerequisites other than those shown in **Table 24.33, Channel Output Modes**.

24.8 Start Timing in Each Operating Modes

This section describes the timing at which the counter starts after TAUJnTS.TAUJnTSM is set to 1 in each operating mode.

The value of data register (TAUJnCDRm register) and whether or not an interrupt occurs depends on mode and register settings.

CAUTION

The count start timing described in this section is for your reference. Actually, the count start timing depends on the count clock timing.

24.8.1 Interval Timer Mode, Capture Mode, and Count Capture Mode

The counter starts operating with the next count clock cycle after TAUJnTS.TAUJnTSM is set to 1. The value of data register is also loaded when the counter starts.

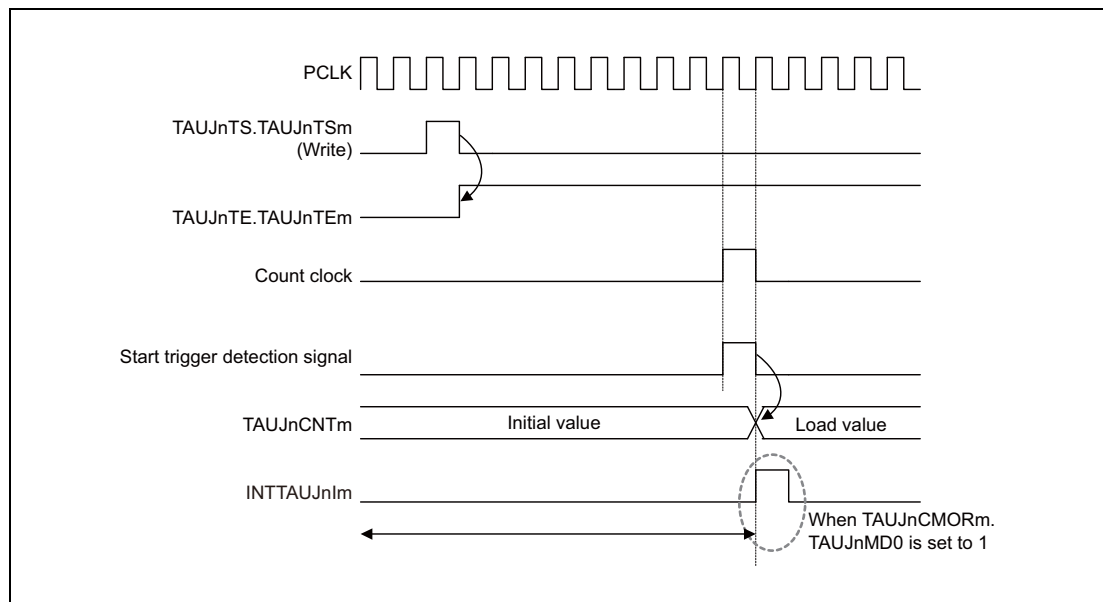

Figure 24.7 Start Timing in Interval Timer Mode, Capture Mode, and Count Capture Mode

24.8.2 Other Operating Modes

In other operating modes, count clock cycle is irrelevant to start of counter operation. The counter is triggered only by TAUJnTTINm valid edge detection. As the counter starts, the value of the data register is also loaded. The cycle of the counter clock is irrelevant to the start of counter operation but does determine the frequency with which all operations take place.

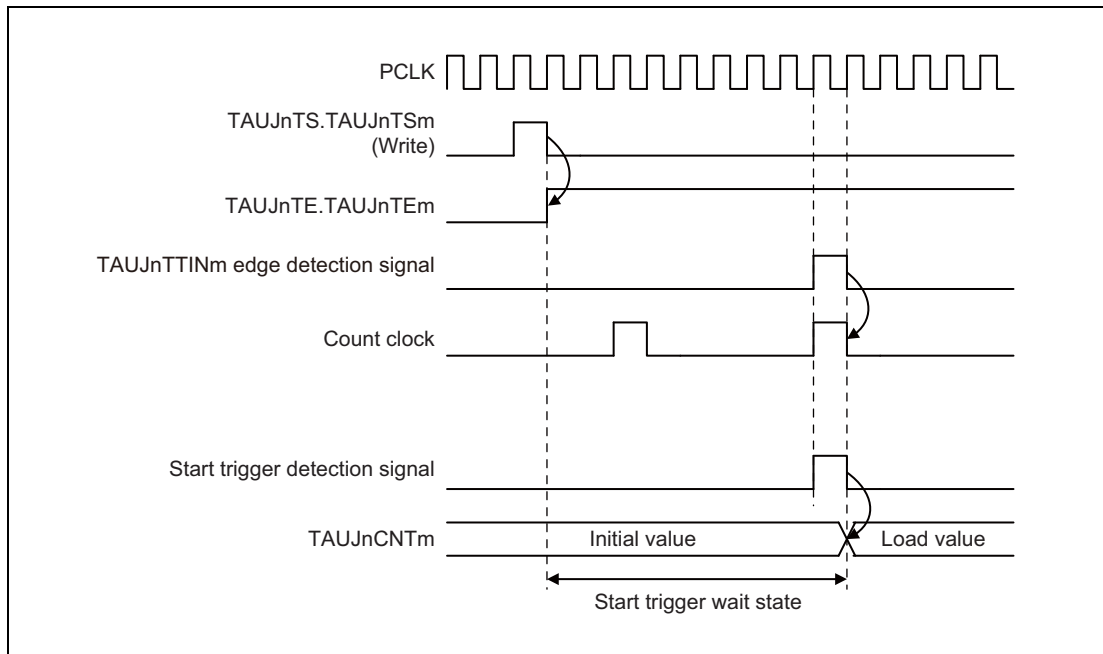

Figure 24.8 Count Start Timing in Other Operating Modes

24.9 TAUJnTTOUTm Output and INTTAUJnIm Generation when Counter Starts or Restarts

The TAUJnCMORm.TAUJnMD0 bits are used to specify whether the corresponding INTTAUJnIm interrupts are generated when the counter starts. The effect of the TAUJnCMORm.TAUJnMD0 bits on INTTAUJnIm generation when counting starts and on TAUJnTTOUTm depends on the selected mode. For details, see the descriptions of TAUJnCMORm.TAUJnMD0 in sections on the related modules.

Figure 24.9 INTTAUJnIm Generation Timing (TAUJnCMORm.TAUJnMD0 = 0)

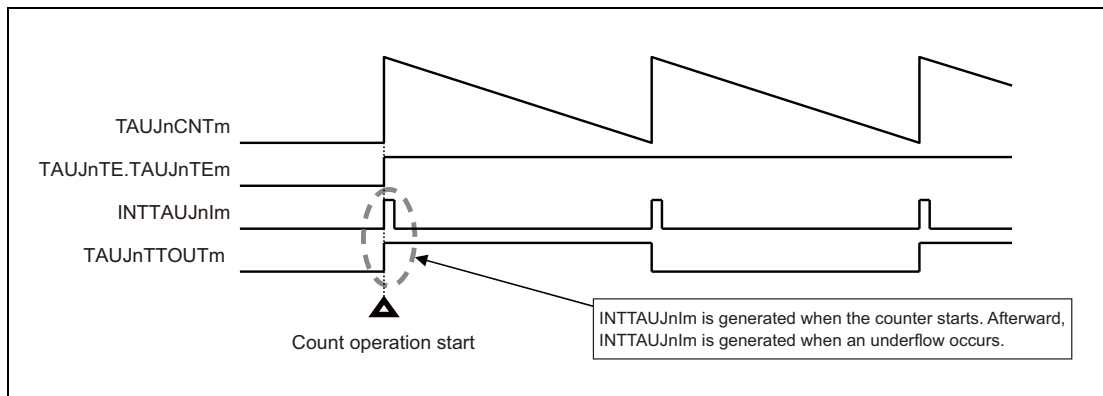

Figure 24.10 INTTAUJnIm Generation Timing (TAUJnCMORm.TAUJnMD0 = 1)

24.10 Interrupt Generation upon Overflow

In certain independent functions, an interrupt is not generated when the counter value reaches FFFF FFFF_H and an overflow occurs during count-up. This section describes how to generate an interrupt by combining channel operations in a mode that counts up and in a mode that counts down.

The appropriate operation mode for the second channel depends on the operation mode of the first channel. Nevertheless, the principle is the same for all combinations:

- Find an operation mode for the second channel that counts down in such a manner, that it reaches 0000 0000_H at the same time as the first channel overflows (TAUJnCNTm = FFFF FFFF_H).
- Set TAUJnCDRm of the second channel to FFFF FFFF_H.
- The two channels must count at the same speed (i.e. they must have the same count clock).

Result:

The down-counter of the second channel reaches 0000 0000_H at exactly the same time as the up-counter of the first channel overflows (TAUJnCNTm = FFFF FFFF_H). Thus the second channel generates the desired interrupt.

The following sections list the operating modes that count down that are required to match specific operating modes that count up, as well as example timing diagrams.

24.10.1 Combination of the TAUJnTTINm Input Position Detection Function and the Interval Timer Function

When the counters of both channels are started simultaneously, INTTAUJnIm of the interval timer function can detect the overflow when TAUJnCNTm of the TAUJnTTINm input position detection function exceeds FFFF FFFF_H.

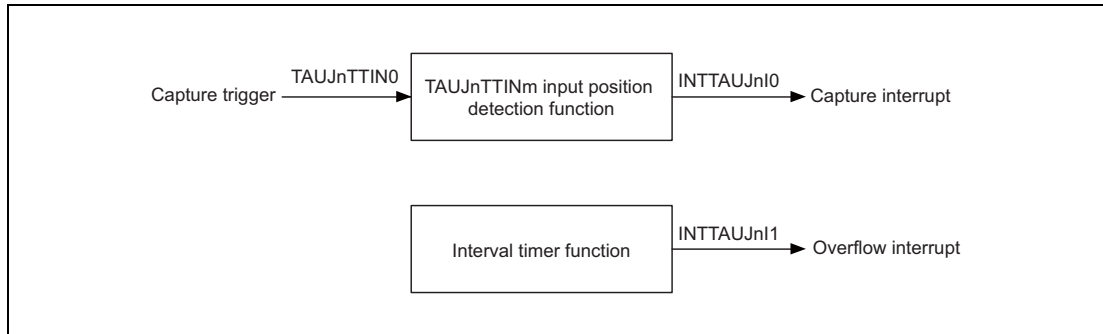

Figure 24.11 Example of Combination of the TAUJnTTINm Input Position Detection Function and the Interval Timer Function (Ch0, Ch1)

Timing diagram

Figure 24.12 Example of Interrupt Generation via Combination of the TAUJnTTINm Input Position Detection Function and the Interval Timer Function (Ch0, Ch1)

24.11 TAUJnTTINm Edge Detection

Edge detection is based on the operating clock. This means that an edge can only be detected at the next rising edge of the operating clock. This can lead to a maximum delay of one operating clock cycle.

The following figure shows when edge detection takes place.

Figure 24.13 Basic Edge Detection Timing

Figure 24.13 shows an image of operation timing. In the actual operation, delay time occurs due to noise filter and synchronization circuit between the TAUJnIm pin and TAUJn.

- Delay time by a noise filter + delay time for edge detection (maximum one sampling clock cycle)

24.12 Independent Channel Operation Functions

The following sections list the independent channel operation functions provided by the TAUJ. For a general overview of independent channel operation functions, see **Section 24.2, Overview**.

24.12.1 Interval Timer Function

24.12.1.1 Overview

Summary

This function is used as a reference timer for generating timer interrupts (INTTAUJnIm) at regular intervals. When an interrupt is generated, the TAUJnTTOUTm signal toggles, resulting in a square wave.

Prerequisites

- The operation mode must be set to Interval Timer Mode, refer to **Table 24.34, Contents of the TAUJnCMORm register for the Interval Timer Function**.
- The channel output mode must be set to Independent Channel Output Mode 1, refer to **Section 24.7, Channel Output Modes**.

Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSM) to 1. This in turn sets TAUJnTE.TAUJnTEM = 1, enabling count operation. The current value of TAUJnCDRm is written to TAUJnCNTm and the counter starts to count down from this value.

When the counter reaches 0000 0000_H, INTTAUJnIm is generated and the TAUJnTTOUTm signal toggles. TAUJnCNTm then loads the TAUJnCDRm value and subsequently continues operation.

The value of TAUJnCDRm can be rewritten at any time, and the changed value of TAUJnCDRm is applied the next time the counter starts to count down.

The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1, which in turn sets TAUJnTE.TAUJnTEM to 0. TAUJnCNTm and TAUJnTTOUTm stop but retain their values. The counter can be restarted by setting TAUJnTS.TAUJnTSM to 1. The counter can also be forcibly restarted (without stopping it first) by setting TAUJnTS.TAUJnTSM to 1 during operation.

Conditions

If the TAUJnCMORm.TAUJnMD0 bit is set to 0, the first interrupt after a start or restart is not generated, and therefore TAUJnTTOUTm does not toggle. This results in an inverted TAUJnTTOUTm signal compared to when TAUJnCMORm.TAUJnMD0 is set to 1. For details refer to **Section 24.9, TAUJnTTOUTm Output and INTTAUJnIm Generation when Counter Starts or Restarts**.

24.12.1.2 Equations

$$\text{INTTAUJnIm cycle} = \text{count clock cycle} \times (\text{TAUJnCDRm} + 1)$$

$$\text{TAUJnTTOUTm square wave cycle} = \text{count clock cycle} \times (\text{TAUJnCDRm} + 1) \times 2$$

24.12.1.3 Block Diagram and General Timing Diagram

Figure 24.14 Block Diagram for Interval Timer Function

The following settings apply to the general timing diagram:

- INTTAUJnIm is generated at operation start (TAUJnCMORm.TAUJnMD0 = 1)

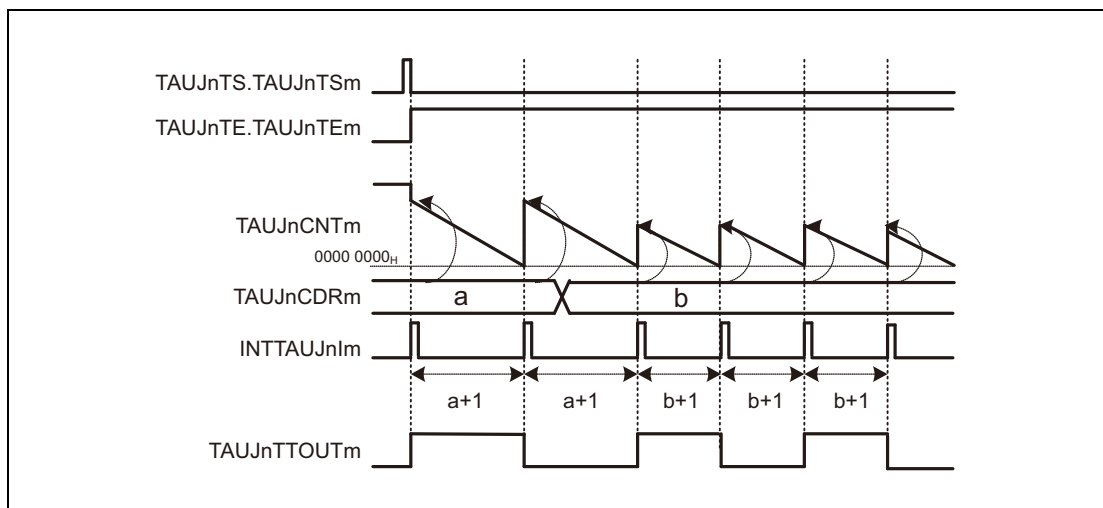

Figure 24.15 General Timing Diagram for Interval Timer Function

24.12.1.4 Register Settings

1, 0	TAUJnTIS[1:0]	00: Not used, so set to 00

(3) Channel output mode**Table 24.36 Control Bit Settings for Independent Channel Output Mode 1**

Bit name	Setting
TAUJnTOE.TAUJnTOEm	Write 1 _B .
TAUJnTOM.TAUJnTOMm	Write 0 _B .
TAUJnTOC.TAUJnTOCm	Write 0 _B .
TAUJnTOL.TAUJnTOLm	Write 0 _B .

NOTE

The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUJnTOE.TAUJnTOEm = 0. TAUJnTOUTm can then be controlled independently of the interrupts. For details refer to **Section 24.7, Channel Output Modes**.

(4) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the Interval Timer Function. Therefore, these registers must be set to 0.

Table 24.37 Simultaneous Rewrite Settings for Interval Timer Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

24.12.1.5 Operating Procedure for Interval Timer Function

Table 24.38 Operating Procedure for Interval Timer Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in Table 24.34, Contents of the TAUJnCMORm register for the Interval Timer Function and Table 24.35, Contents of the TAUJnCMURm register for the Interval Timer Function .	Channel operation is stopped.
	Set the value of the TAUJnCDRm register.	
	Set the channel output mode by setting the control bits as described in Table 24.36, Control Bit Settings for Independent Channel Output Mode 1 .	
Restart	Start operation Set TAUJnTS.TAUJnTSM to 1. TAUJnTS.TAUJnTSM is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEM is set to 1 and the counter starts. TAUJnCNTm loads the TAUJnCDRm value. When TAUJnCMORm.TAUJnMD0 = 1, INTTAUJnIm is generated and TAUJnTTOUTm toggles.
	During operation The TAUJnCDRm register value can be changed at any time. The TAUJnCNTm register can be read at all times.	TAUJnCNTm counts down. When the counter reaches 0000 0000 _H : <ul style="list-style-type: none"> TAUJnCNTm reloads the TAUJnCDRm value and continues count operation INTTAUJnIm is generated and TAUJnTTOUTm toggles.
Stop operation	Set TAUJnTT.TAUJnTTM to 1. TAUJnTT.TAUJnTTM is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEM is cleared to 0 and the counter stops. TAUJnCNTm and TAUJnTTOUTm stop and retain their current values.

24.12.1.6 Specific Timing Diagrams

(1) TAUJnCDRm = 0000 0000_H, count clock = PCLK/2

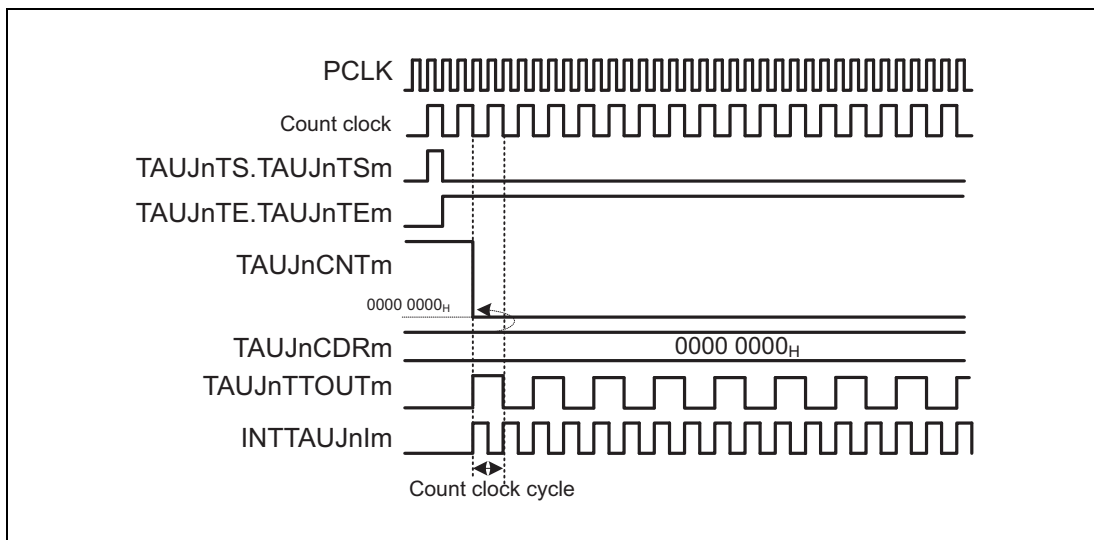

Figure 24.16 TAUJnCDRm = 0000 0000_H, Count Clock = PCLK/2

- If TAUJnCDRm = 0000 0000_H and the count clock = PCLK/2, the TAUJnCDRm value is written to TAUJnCNTm every count clock, meaning that TAUJnCNTm is always 0000 0000_H.
- INTTAUJnIm is generated every count clock, resulting in TAUJnTTOUTm toggling every count clock.

(2) TAUJnCDRm = 0000 0000_H, count clock = PCLK

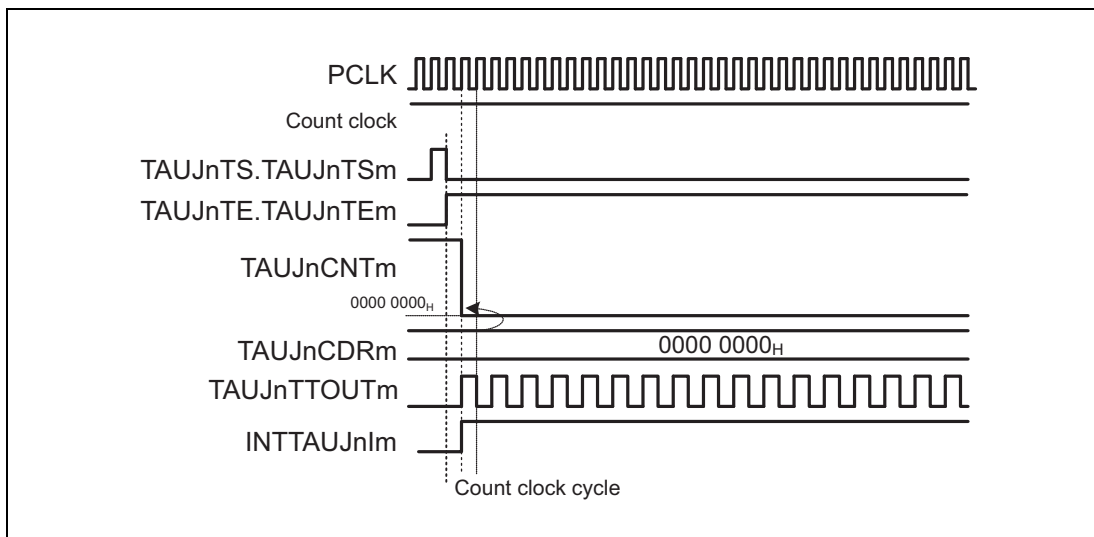

Figure 24.17 TAUJnCDRm = 0000 0000_H, Count Clock = PCLK

- If TAUJnCDRm = 0000 0000_H and the count clock = PCLK, the TAUJnCDRm value is written to TAUJnCNTm every PCLK clock, meaning that TAUJnCNTm is always 0000 0000_H.
- INTTAUJnIm is fixed to the high level. Though the first interrupt is generated, subsequent interrupts are not generated. TAUJnTTOUTm is toggled every PCLK clock.

(3) Operation stop and restart

Figure 24.18 Operation Stop and Restart, TAUJnCMORm.TAUJnMD0 = 1

- The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1, which in turn sets TAUJnTE.TAUJnTEm to 0.
- TAUJnCnTm and TAUJnTTOUtm stop but retain their values.
- The counter can be restarted by setting TAUJnTS.TAUJnTsm to 1.

(4) Forced restart

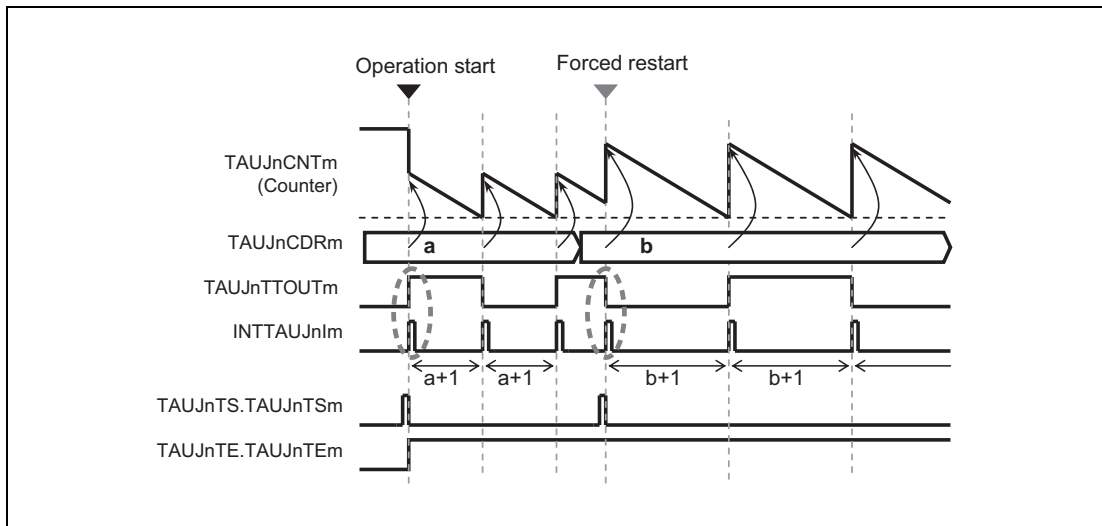

Figure 24.19 Forced Restart Operation, TAUJnCMORm.TAUJnMD0 = 1

- The counter can be forcibly restarted (without stopping it first) by setting TAUJnTS.TAUJnTsm to 1 during operation.
- If the TAUJnCMORm.TAUJnMD0 bit is set to 1, the first interrupt after a start or restart is generated.
- At the time of a forced restart, the value of TAUJnCDRm is reflected to TAUJnCnTm and counting starts. Perform a forced restart to reflect the modified value of TAUJnCDRm immediately.

24.12.2 TAUJnTTINm Input Interval Timer Function

24.12.2.1 Overview

Summary

This function is used as a reference timer for generating timer interrupts (INTTAUJnIm) at regular intervals or when a valid TAUJnTTINm input edge is detected. When an interrupt is generated, the TAUJnTTOUTm signal toggles, resulting in a square wave.

Prerequisites

- The operation mode must be set to Interval Timer Mode, refer to **Table 24.39, Contents of the TAUJnCMORm register for TAUJnTTINm Input Interval Timer Function**.
- The channel output mode must be set to Independent Channel Output Mode 1, refer to **Section 24.7, Channel Output Modes**.

Description

This function operates in an identical manner to the Interval Timer Function (see **Section 24.12.1, Interval Timer Function**), except that this function is restarted by a valid TAUJnTTINm input edge. The type of edge used as the trigger is specified using the TAUJnCMURm.TAUJnTIS[1:0] bits. Either rising edge, falling edge, or rising and falling edge can be selected.

24.12.2.2 Equations

$$\text{INTTAUJnIm cycle} = \text{count clock cycle} \times (\text{TAUJnCDRm} + 1)$$

$$\text{TAUJnTTOUTm square wave cycle} = \text{count clock cycle} \times (\text{TAUJnCDRm} + 1) \times 2$$

24.12.2.3 Block Diagram and General Timing Diagram

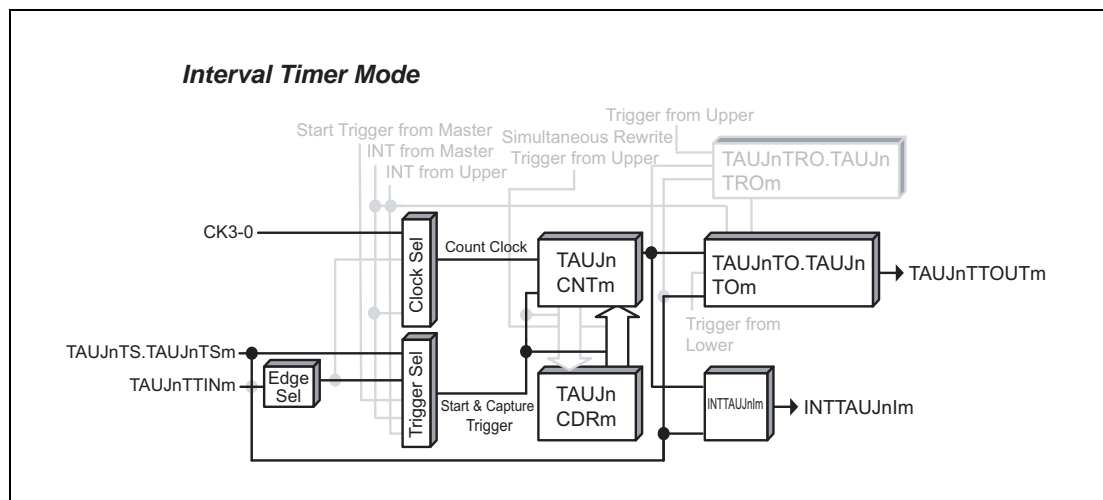

Figure 24.20 Block Diagram for TAUJnTTINm Input Interval Timer Function

The following settings apply to the general timing diagram:

- INTTAUJnIm is generated at operation start (TAUJnCMORm.TAUJnMD0 = 1).
- Rising edge detection (TAUJnCMURm.TAUJnTIS[1:0] = 01_B)

Figure 24.21 General Timing Diagram for TAUJnTTINm Input Interval Timer Function

NOTE

The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUJnTOE.TAUJnTOEm = 0. TAUJnTOUTm can then be controlled independently of the interrupts. For details refer to **Section 24.7, Channel Output Modes**.

(4) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm Input Interval Timer Function. Therefore, these registers must be set to 0.

Table 24.42 Simultaneous Rewrite Settings for TAUJnTTINm Input Interval Timer Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

Afterwards, this procedure is repeated.</p>
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCnTm and TAUJnTTOUTm stop and retain their current values.

Restart

During operation

Stop operation

24.12.2.6 Specific Timing Diagrams

The timing diagrams in **Section 24.12.1, Interval Timer Function** also apply, and in addition, the counter can also be restarted by a valid TAUJnTTINm input edge.

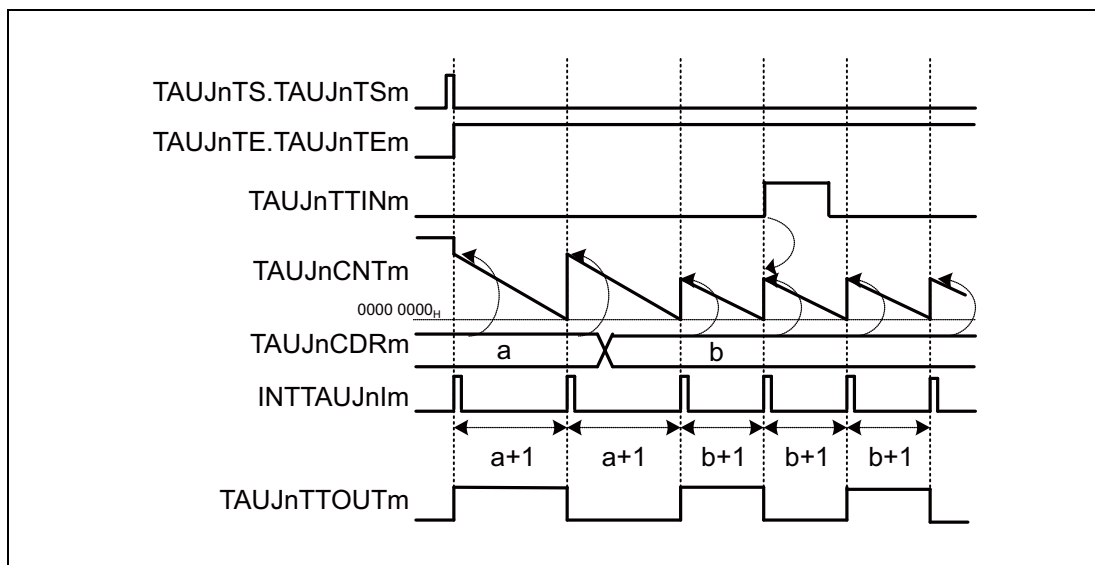

Figure 24.22 Counter Triggered by Rising TAUJnTTINm Input Edge
 (TAUJnCMURm.TAUJnTIS[1:0] = 01_B), TAUJnCMORM.TAUJnMD0 = 1

If an effective TAUJnTTINm input edge is detected, an interrupt is generated which causes TAUJnTTOUTm to toggle. In this example, the effective edge is a rising edge (TAUJnCMURm.TAUJnTIS[1:0] = 01_B).

24.12.3 TAUJnTTINm Input Pulse Interval Measurement Function

24.12.3.1 Overview

Summary

This function captures the count value and uses this value and the overflow bit TAUJnCSRm.TAUJnOVF to measure the interval of the TAUJnTTINm input signals.

Prerequisites

- The operation mode must be set to capture mode, refer to **Table 24.45, Contents of the TAUJnCMORm register for TAUJnTTINm Input Pulse Interval Measurement Function**.
- TAUJnTTOUTm is not used for this function.

Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The counter TAUJnCNTm starts counting up from 0000 0000_H. When a valid TAUJnTTINm edge is detected, the value of TAUJnCNTm is captured, transferred to TAUJnCDRm, and an interrupt INTTAUJnIm is generated. The counter resets to 0000 0000_H and subsequently continues operation.

If the counter reaches FFFF FFFF_H before a valid TAUJnTTINm edge is detected, it overflows. The counter is reset to 0000 0000_H and subsequently continues operation. The values transferred to TAUJnCDRm and TAUJnCSRm.TAUJnOVF respectively depend on the values of bits TAUJnCMORm.TAUJnCOS[1:0]:

Table 24.44 Effects of an Overflow

TAUJnCMORm. TAUJnCOS[1:0]	When overflow occurs		When a valid TAUJnTTINm input is then detected	
	TAUJnCDRm	TAUJnCSRm. TAUJnOVF	TAUJnCDRm and TAUJnCNTm	TAUJnCSRm. TAUJnOVF
00	Unchanged	0	TAUJnCNTm written to TAUJnCDRm	1
01		1		
10	Set to FFFF FFFF _H	0	TAUJnCNTm set to 0, TAUJnCDRm unchanged	Unchanged
11		1		

If an overflow is set (TAUJnCSRm.TAUJnOVF = 1) when TAUJnCMORm.TAUJnCOS[0] = 1, it can only be cleared by setting TAUJnCSCm.TAUJnCLOV = 1.

The combination of the value of TAUJnCDRm and TAUJnCSRm.TAUJnOVF can be used to deduce the interval of the TAUJnTTINm signal. However, if an overflow occurs multiple times before a valid TAUJnTTINm input is detected, the overflow bit TAUJnCSRm.TAUJnOVF cannot indicate this.

The function can be stopped by setting TAUJnTT.TAUJnTTm = 1, which in turn sets TAUJnTE.TAUJnTEm = 0. TAUJnCNTm stops but retains its value. While the function is stopped, TAUJnTTINm input valid edge detection and TAUJnCNTm capture are not performed.

Conditions

If the TAUJnCMORm.TAUJnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details refer to **Section 24.9, TAUJnTTOUTm Output and INTTAUJnIm Generation when Counter Starts or Restarts.**

NOTE

When TAUJnCMORm.TAUJnCOS[1] = 1, the value of TAUJnCNTm is not written to TAUJnCDRm when the first valid TAUJnTTINm input edge occurs after an overflow. However, an interrupt is generated.

24.12.3.2 Equations

$$\text{TAUJnTTINm input pulse interval} = \text{count clock cycle} \times [(\text{TAUJnCSRm.TAUJnOVF} \times (\text{FFFF FFFF}_H + 1)) + \text{TAUJnCDRm capture value} + 1]$$

24.12.3.3 Block Diagram and General Timing Diagram

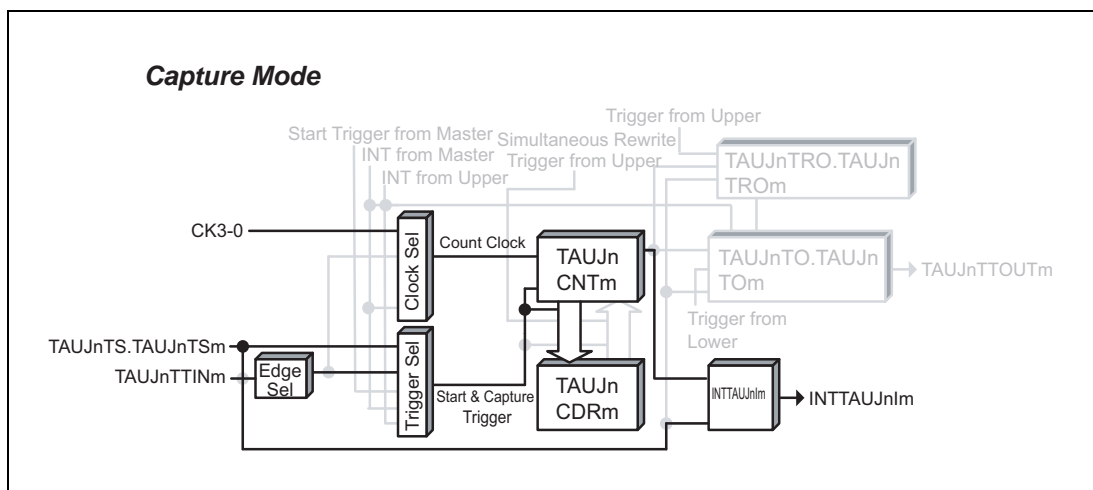

Figure 24.23 Block Diagram for TAUJnTTINm Input Pulse Interval Measurement Function

The following settings apply to the general timing diagram:

- INTTAUJnIm not generated at operation start (TAUJnCMORm.TAUJnMD0 = 0)
- Falling edge detection (TAUJnCMURm.TAUJnTIS[1:0] = 00_B)
- When a valid TAUJnTTINm input is detected after an overflow, TAUJnCDRm is changed and TAUJnCSRm.TAUJnOVF is set to 1 (TAUJnCMORm.TAUJnCOS[1:0] = 00_B)

(3) Channel output mode

TAUJnTOE.TAUJnTOEm is set to 0 because the channel output mode is not used by this function.

(4) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm Input Pulse Interval Measurement Function. Therefore, these registers must be set to 0.

Table 24.47 Simultaneous Rewrite Settings for TAUJnTTINm Input Pulse Interval Measurement Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

24.12.3.5 Operating Procedure for TAUJnTTINm Input Pulse Interval Measurement Function

Table 24.48 Operating Procedure for TAUJnTTINm Input Pulse Interval Measurement Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in Table 24.45, Contents of the TAUJnCMORm register for TAUJnTTINm Input Pulse Interval Measurement Function and Table 24.46, Contents of the TAUJnCMURm register for TAUJnTTINm Input Pulse Interval Measurement Function .	Channel operation is stopped.
	The TAUJnCDRm register operates as a capture register.	
Restart	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and the counter starts. TAUJnCnTm is cleared to 0000 0000 _H . INTTAUJnIm is generated when TAUJnCMORm.TAUJnMD0 is set to 1.
	Detection of TAUJnTTINm edges. The TAUJnCMURm.TAUJnTIS[1:0] bits can be changed at any time. The TAUJnCDRm and TAUJnCSRm registers can be read at any time. TAUJnCSCm.TAUJnCLOV bit can be written to 1. (TAUJnCSRm.TAUJnOVF bit is cleared to 0.)	TAUJnCnTm starts to count up from 0000 0000 _H . When a TAUJnTTINm valid edge is detected: <ul style="list-style-type: none"> TAUJnCnTm transfers (captures) its value to TAUJnCDRm, and returns to 0000 0000_H INTTAUJnIm is then generated. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCnTm stops and both it and TAUJnCSRm.TAUJnOVF retain their current values.

24.12.3.6 Specific Timing Diagrams: Overflow Behavior

(1) TAUJnCMORm.TAUJnCOS[1:0] = 00_B

Figure 24.25 TAUJnCMORm.TAUJnCOS[1:0] = 00_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and TAUJnCSRm.TAUJnOVF remains = 0.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is written to TAUJnCDRm and TAUJnCSRm.TAUJnOVF is set to 1.
- If the next valid TAUJnTTINm input edge is detected when no overflow occurs, TAUJnCSRm.TAUJnOVF is cleared to 0.

(2) TAUJnCMORm.TAUJnCOS[1:0] = 01_B

Figure 24.26 TAUJnCMORm.TAUJnCOS[1:0] = 01_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and TAUJnCSRm.TAUJnOVF is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is written to TAUJnCDRm.
- TAUJnCSRm.TAUJnOVF is only cleared by a CPU command (by setting the TAUJnCSCm.TAUJnCLOV bit to 1).

(3) TAUJnCMORm.TAUJnCOS[1:0] = 10_B

Figure 24.27 TAUJnCMORm.TAUJnCOS[1:0] = 10_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 00_B

- When an overflow occurs, TAUJnCDRm is set to FFFF FFFF_H and TAUJnCSRm.TAUJnOVF remains = 0.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm is reset to 0, but TAUJnCDRm and TAUJnCSRm.TAUJnOVF remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.

(4) $\text{TAUJnCMORm.TAUJnCOS}[1:0] = 11_{\text{B}}$ 

Figure 24.28 $\text{TAUJnCMORm.TAUJnCOS}[1:0] = 11_{\text{B}}$, $\text{TAUJnCMORm.TAUJnMD0} = 0$,
 $\text{TAUJnCMURm.TAUJnTIS}[1:0] = 00_{\text{B}}$

- When an overflow occurs, TAUJnCDRm is set to $\text{FFFF FFFF}_{\text{H}}$, and $\text{TAUJnCSRm.TAUJnOVF}$ is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm is reset to 0, but TAUJnCDRm and $\text{TAUJnCSRm.TAUJnOVF}$ remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.
- $\text{TAUJnCSRm.TAUJnOVF}$ is cleared by setting the $\text{TAUJnCSCm.TAUJnCLOV}$ bit to 1.

24.12.4 TAUJnTTINm Input Signal Width Measurement Function

24.12.4.1 Overview

Summary

This function measures the width of a TAUJnTTINm signal by starting counting on one edge of the TAUJnTTINm signal and capturing the counter value on the opposite edge.

Prerequisites

- The operation mode must be set to capture and one-count mode, refer to **Table 24.50, Contents of the TAUJnCMORm register for TAUJnTTINm Input Signal Width Measurement Function**.
- TAUJnTTOUTm is not used for this function
- TAUJnCMORm.TAUJnMD should be set to 0.

Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. When a valid TAUJnTTINm start edge is detected, the counter TAUJnCNTm starts counting up from 0000 0000_H. When a valid TAUJnTTINm stop edge is detected, the value of TAUJnCNTm is captured, transferred to TAUJnCDRm, and an interrupt INTTAUJnIm is generated. The counter retains its value and awaits the next valid TAUJnTTINm input start edge.

If the counter reaches FFFF FFFF_H before a valid TAUJnTTINm stop edge is detected, it overflows. The counter is reset to 0000 0000_H and subsequently continues operation. The values transferred to TAUJnCDRm and TAUJnCSRm.TAUJnOVF respectively depend on the values of bits TAUJnCMORm.TAUJnCOS[1:0]:

Table 24.49 Effects of an overflow

TAUJnCMORm. TAUJnCOS[1:0]	When overflow occurs		When a valid TAUJnTTINm input stop edge is detected	
	TAUJnCDRm	TAUJnCSRm. TAUJnOVF	TAUJnCDRm and TAUJnCNTm	TAUJnCSRm. TAUJnOVF
00	Unchanged	0	TAUJnCNTm written to TAUJnCDRm	1
01		1		
10	Set to FFFF FFFF _H	0	TAUJnCNTm stops counting TAUJnCDRm unchanged	Unchanged
11		1		

If an overflow is set (TAUJnCSRm.TAUJnOVF = 1) when TAUJnCMORm.TAUJnCOS[0] = 1, it can only be cleared by setting TAUJnCSCm.TAUJnCLOV = 1.

The combination of the value of TAUJnCDRm and TAUJnCSRm.TAUJnOVF can be used to deduce the width of the TAUJnTTINm signal. However, if an overflow occurs multiple times before a valid TAUJnTTINm input is detected, the overflow bit TAUJnCSRm.TAUJnOVF cannot indicate this.

This function cannot be forcibly restarted.

This function is not supported by forced restarting

NOTE

When $\text{TAUJnCMORm.TAUJnCOS}[1] = 1$, the value of TAUJnCNTm is not written to TAUJnCDRm when the first valid TAUJnTTINm input edge occurs after an overflow. However, an interrupt is generated.

24.12.4.2 Equations

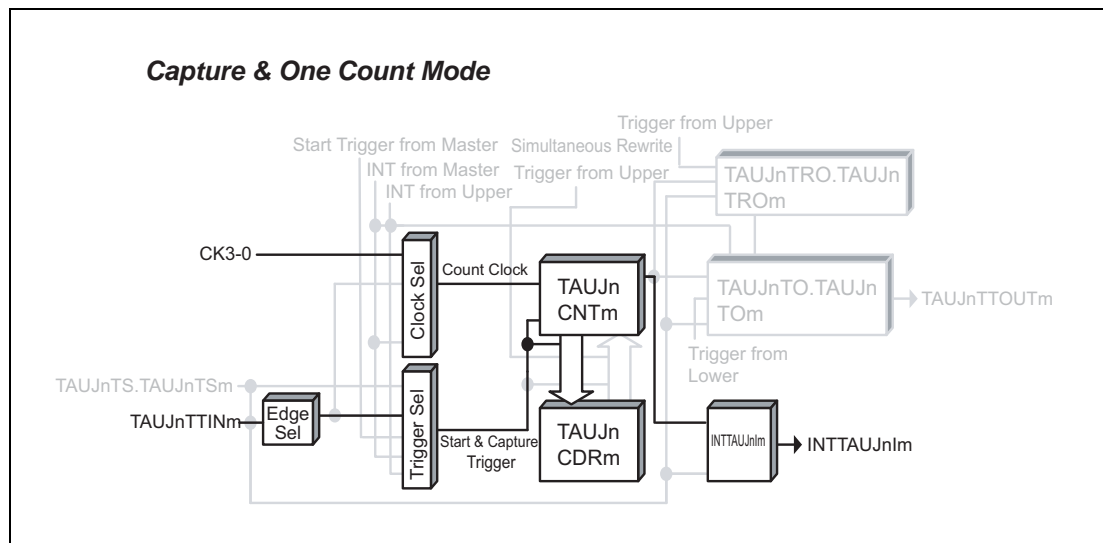

$$\text{TAUJnTTINm input signal width} = \text{count clock cycle} \times [(\text{TAUJnCSRm.TAUJnOVF} \times (\text{FFFF FFFF}_H + 1)) + \text{TAUJnCDRm capture value} + 1]$$
24.12.4.3 Block Diagram and General Timing Diagram

Figure 24.29 Block diagram for TAUJnTTINm Input Signal Width Measurement Function

The following settings apply to the general timing diagram:

- Rising and falling edge detection = high width measurement ($\text{TAUJnCMURm.TAUJnTIS}[1:0] = 11_B$)
- When a valid TAUJnTTINm input is detected after an overflow, TAUJnCDRm is changed and $\text{TAUJnCSRm.TAUJnOVF}$ is set to 1 ($\text{TAUJnCMORm.TAUJnCOS}[1:0] = 00_B$)

1, 0	TAUJnTIS[1:0]	10: Rising and falling edge detection (low width measurement) 11: Rising and falling edge detection (high width measurement)

(3) Channel output mode

TAUJnTOE.TAUJnTOEm is set to 0 because the channel output mode is not used with this function.

(4) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm Input Signal Width Measurement Function. Therefore, these registers must be set to 0.

Table 24.52 Simultaneous Rewrite Settings for TAUJnTTINm Input Signal Width Measurement Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm=0), set these bits to 0

24.12.4.5 Operating Procedure for TAUJnTTINm Input Signal Width Measurement Function

Table 24.53 Operating Procedure for TAUJnTTINm Input Signal Width Measurement Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in Table 24.50, Contents of the TAUJnCMORm register for TAUJnTTINm Input Signal Width Measurement Function and Table 24.51, Contents of the TAUJnCMURm register for TAUJnTTINm Input Signal Width Measurement Function . The TAUJnCDRm register operates as a capture register.	Channel operation is stopped.
Restart	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and TAUJnCnTm waits for detection of the TAUJnTTINm start edge. When a TAUJnTTINm start edge is detected, TAUJnCnTm starts to count up.
During operation	The TAUJnCDRm, TAUJnCnTm, and TAUJnCSRm registers can be read at any time. The TAUJnCSCm.TAUJnCLOV bit can be set to 1.	TAUJnCnTm starts to count up from 0000 0000 _H . When a TAUJnTTINm valid edge is detected: <ul style="list-style-type: none"> • TAUJnCnTm transfers (captures) its value to TAUJnCDRm, and retains its value • INTTAUJnIm is then generated. • Counting stops at the “value transferred to TAUJnCDRm + 1” and TAUJnCnTm waits for detection of the TAUJnTTINm start edge. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCnTm stops and both it and TAUJnCSRm.TAUJnOVF retain their current values.

24.12.4.6 Specific Timing Diagrams: Overflow Behavior

(1) TAUJnCMORm.TAUJnCOS[1:0] = 00_B

Figure 24.31 TAUJnCMORm.TAUJnCOS[1:0] = 00_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 11_B

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and TAUJnCSRm.TAUJnOVF remains = 0.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is written to TAUJnCDRm and TAUJnCSRm.TAUJnOVF is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge with no overflow occurring, TAUJnCSRm.TAUJnOVF is cleared to 0.

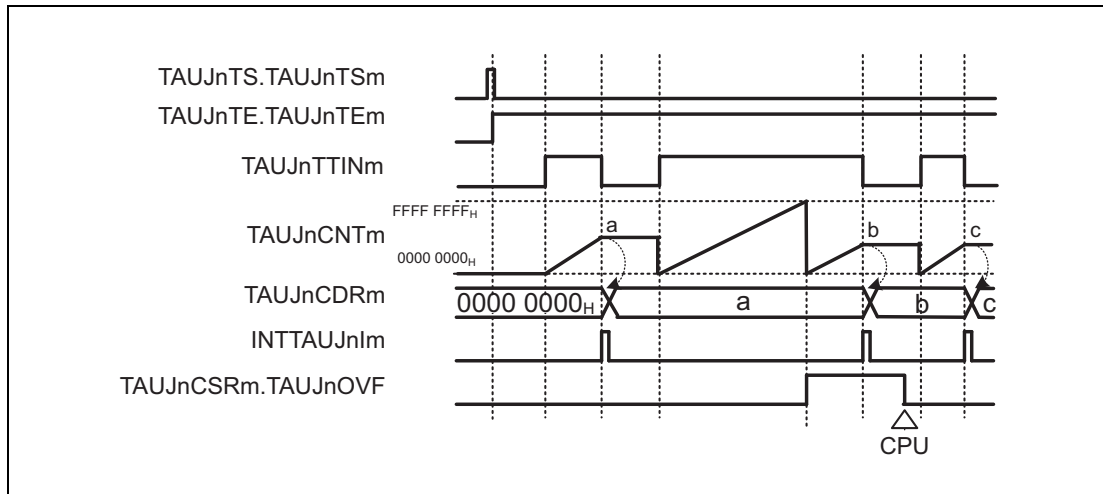

(2) $\text{TAUJnCMORm.TAUJnCOS}[1:0] = 01_{\text{B}}$ 

Figure 24.32 $\text{TAUJnCMORm.TAUJnCOS}[1:0] = 01_{\text{B}}$, $\text{TAUJnCMORm.TAUJnMD0} = 0$,
 $\text{TAUJnCMURm.TAUJnTIS}[1:0] = 11_{\text{B}}$

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and $\text{TAUJnCSRm.TAUJnOVF}$ is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is written to TAUJnCDRm .
- $\text{TAUJnCSRm.TAUJnOVF}$ is only cleared by a CPU command (by setting $\text{TAUJnCScm.TAUJnCLOV}$ bit = 1).

(3) $\text{TAUJnCMORm.TAUJnCOS}[1:0] = 10_{\text{B}}$ 

Figure 24.33 $\text{TAUJnCMORm.TAUJnCOS}[1:0] = 10_{\text{B}}$, $\text{TAUJnCMORm.TAUJnMD0} = 0$,
 $\text{TAUJnCMURm.TAUJnTIS}[1:0] = 11_{\text{B}}$

- When an overflow occurs, TAUJnCDRm is set to $\text{FFFF FFFF}_{\text{H}}$ and $\text{TAUJnCSRm.TAUJnOVF}$ remains = 0.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm stops counting, but TAUJnCDRm and $\text{TAUJnCSRm.TAUJnOVF}$ remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.

(4) TAUJnCMORm.TAUJnCOS[1:0] = 11_B

Figure 24.34 TAUJnCMORm.TAUJnCOS[1:0] = 11_B, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 11_B

- When an overflow occurs, TAUJnCDRm is set to FFFF FFFF_H, and TAUJnCSRm.TAUJnOVF is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm stops counting, but TAUJnCDRm and TAUJnCSRm.TAUJnOVF remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.
- TAUJnCSRm.TAUJnOVF is cleared by setting the TAUJnCSCm.TAUJnCLOV bit to 1.

24.12.5 TAUJnTTINm Input Position Detection Function

24.12.5.1 Overview

Summary

This function measures the interval of input signals by capturing the counter value on a valid edge of the TAUJnTTINm signal.

Prerequisites

- The operation mode must be set to count capture mode, refer to **Table 24.54, Contents of the TAUJnCMORm register for TAUJnTTINm Input Position Detection Function**.
- TAUJnTTOUTm is not used for this function

Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The counter starts to count from 0000 0000_H. When a valid TAUJnTTINm input edge is detected, the current TAUJnCNTm value is written to TAUJnCDRm and an interrupt (INTTAUJnIm) is generated. The counter continues to count.

When the counter reaches FFFF FFFF_H, it restarts from 0000 0000_H.

NOTE

The TAUJnTTINm input signal is sampled at the frequency of the operation clock specified by the TAUJnCMORm.TAUJnCKS[1:0] bits. As a result, the output cycle of the TAUJnTTOUTm has an error of ±1 operation clock cycle.

Conditions

If the TAUJnCMORm.TAUJnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For the detail, see **Section 24.9, TAUJnTTOUTm Output and INTTAUJnIm Generation when Counter Starts or Restarts**.

24.12.5.2 Equations

Function duration at a TAUJnTTINm input pulse =
count clock cycle × (TAUJnCDRm capture value + 1)

24.12.5.3 Block Diagram and General Timing Diagram

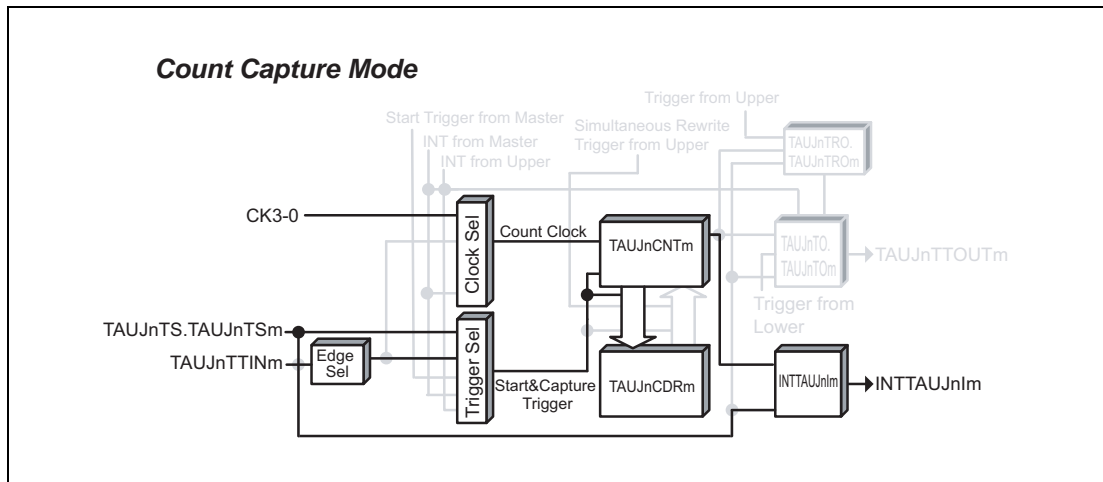

Figure 24.35 Block Diagram of TAUJnTTINm Input Position Detection Function

The following settings apply to the general timing diagram:

- INTTAUJnIm not generated at operation start (TAUJnCMORm.TAUJnMD0 = 0)
- Falling edge detection (TAUJnCMURm.TAUJnTIS[1:0] = 00_B)

(3) Channel output mode

The channel output mode is not used by this function.

(4) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm Input Position Detection Function. Therefore, these registers must be set to 0.

Table 24.56 Simultaneous Rewrite Settings for TAUJnTTINm Input Period Count Detection Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm=0), set these bits to 0

24.12.5.5 Operating Procedure for TAUJnTTINm Input Position Detection Function

Table 24.57 Operating Procedure for TAUJnTTINm Input Position Detection Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in Table 24.54, Contents of the TAUJnCMORm register for TAUJnTTINm Input Position Detection Function and Table 24.55, Contents of the TAUJnCMURm register for TAUJnTTINm Input Position Detection Function . The TAUJnCDRm register operates as a capture register.	Channel operation is stopped.
Restart	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and the counter starts. INTTAUJnIm is generated when TAUJnCMORm.TAUJnMD0 is set to 1.
During operation	The TAUJnCMURm.TAUJnTIS[1:0] bits can be changed at any time. The TAUJnCDRm and TAUJnCSRm registers can be read at any time.	TAUJnCNTm starts to count up from 0000 0000 _H . When a TAUJnTTINm valid edge is detected: <ul style="list-style-type: none"> • TAUJnCNTm transfers (captures) its value to TAUJnCDRm • INTTAUJnIm is output. • The counter value is not cleared to 0000 0000_H and TAUJnCNTm continues count operation. Afterwards, this procedure is repeated. If the TAUJnCNTm reaches FFFF FFFF _H , it restarts counting from 0000 0000 _H .
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and retains its current value.

24.12.5.6 Specific Timing Diagrams

(1) Operation stop and restart

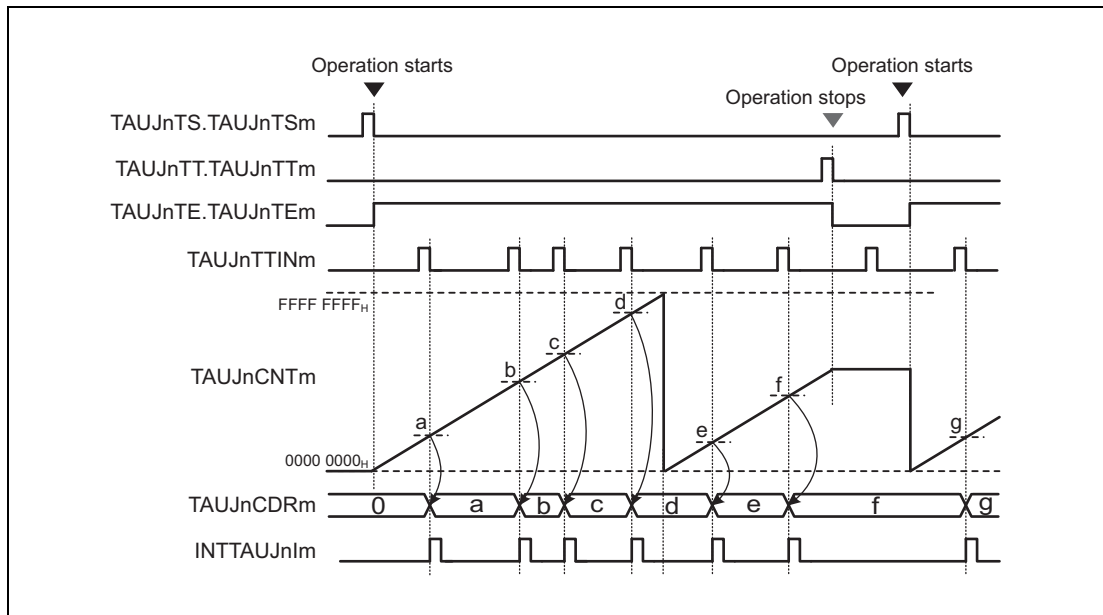

Figure 24.37 Operation Stop and Restart, TAUJnCMORm.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 00_B

- The counter can be stopped by setting TAUJnTT.TAUJnTTM to 1, which in turn sets TAUJnTE.TAUJnTEM to 0.
- TAUJnCNTm stops and the current value is retained.
- If the counter is stopped, valid TAUJnTTINm input edges are ignored.
- The counter can be restarted by setting TAUJnTS.TAUJnTSM to 1. TAUJnCNTm restarts to count from 0000 0000_H.

24.12.6 TAUJnTTINm Input Period Count Detection Function

24.12.6.1 Overview

Summary

This function measures the cumulative width of a TAUJnTTINm input signal.

Prerequisites

- The operation mode must be set to capture and gate count mode, refer to **Table 24.58, Contents of the TAUJnCMORm Register for TAUJnTTINm Input Period Count Detection Function**.
- TAUJnTTOUTm is not used for this function.

Description

The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The counter awaits a valid TAUJnTTINm input edge.

When a valid TAUJnTTINm input start edge is detected, the counter starts to count from 0000 0000_H.

When a valid TAUJnTTINm input stop edge is detected, the current TAUJnCNTm value is written to TAUJnCDRm and an interrupt (INTTAUJnIm) is generated. The counter stops and retains its value until the next valid TAUJnTTINm input start edge is detected.

When the next valid TAUJnTTINm input start edge is detected, the counter restarts counting from the stop value.

If the counter reaches FFFF FFFF_H the counter restarts from 0000 0000_H.

In this function, a forced restart cannot be performed.

NOTE

The TAUJnTTINm input signal is sampled at the frequency of the operating clock, specified by the TAUJnCMORm.TAUJnCKS[1:0] bits.

Conditions

The valid start and stop edges are specified by the TAUJnCMURm.TAUJnTIS[1:0] bits:

- If TAUJnCMURm.TAUJnTIS[1:0] = 10_B, the TAUJnTTINm input low period is counted. The start trigger is a falling edge and the stop trigger is a rising edge.
- If TAUJnCMURm.TIS[1:0] = 11_B, the TAUJnTTINm input high period is counted. The start trigger is a rising edge and the stop trigger is a falling edge.

24.12.6.2 Equations

Cumulative TAUJnTTINm input width =
count clock cycle × (TAUJnCDRm capture value + 1)

24.12.6.3 Block Diagram and General Timing Diagram

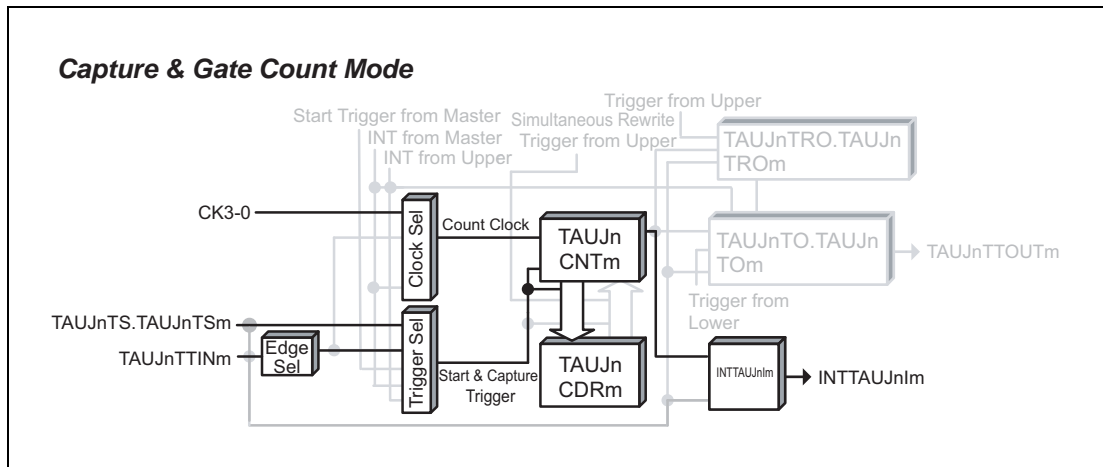

Figure 24.38 Block diagram for TAUJnTTINm Input Period Count Detection Function

The following settings apply to the general timing diagram:

- Rising and falling edge detection = high width measurement
(TAUJnCMURm.TAUJnTIS[1:0] = 11_B)

Figure 24.39 General Timing Diagram for TAUJnTTINm Input Period Count Detection Function

24.12.6.4 Register Settings

(1) TAUJnCMORM

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUJnCKS[1:0]		TAUJnCCS[1:0]		TAUJnMAS	TAUJnSTS[2:0]			TAUJnCOS[1:0]		—	TAUJnMD[4:1]				TAUJnMD0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 24.58 Contents of the TAUJnCMORM Register for TAUJnTTINm Input Period Count Detection Function

Bit Position	Bit Name	Function
15, 14	TAUJnCKS[1:0]	Selects an operating clock. 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3
13, 12	TAUJnCCS[1:0]	Write 00 _B .
11	TAUJnMAS	Write 0 _B .
10 to 8	TAUJnSTS[2:0]	Write 010 _B .
7, 6	TAUJnCOS[1:0]	Write 01 _B .
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUJnMD[4:1]	Write 1101 _B .
0	TAUJnMD0	Write 0 _B .

(2) TAUJnCMURm

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUJnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 24.59 Contents of the TAUJnCMURm Register for TAUJnTTINm Input Period Count Detection Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUJnTIS[1:0]	10: Rising and falling edge detection (Low width measurement) 11: Rising and falling edge detection (High width measurement)

(3) Channel output mode

TAUJnTOE.TAUJnTOEm is set to 0 because the channel output mode is not used with this function.

(4) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm Input Period Count Detection Function. Therefore, these registers must be set to 0.

Table 24.60 Simultaneous Rewrite Settings for TAUJnTTINm Input Period Count Detection Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm=0), set these bits to 0

24.12.6.5 Operating Procedure for TAUJnTTINm Input Period Count Detection Function

Table 24.61 Operating Procedure for TAUJnTTINm Input Period Count Detection Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in Table 24.58, Contents of the TAUJnCMORm Register for TAUJnTTINm Input Period Count Detection Function and Table 24.59, Contents of the TAUJnCMURm Register for TAUJnTTINm Input Period Count Detection Function .	Channel operation is stopped.
	The TAUJnCDRm register operates as a capture register.	
Restart	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and TAUJnCNTm waits for detection of the TAUJnTTINm start edge.
During operation	TAUJnTTINm edge detection The TAUJnCDRm, TAUJnCNTm, and TAUJnCSRm registers can be read at any time.	When a TAUJnTTINm start edge (rising edge for high width measurement, falling edge for low width measurement) is detected, TAUJnCNTm starts to count up from the stop value. When TAUJnCNTm detects a stop edge (falling edge for high width measurement, rising edge for low width measurement), it transfers the value to TAUJnCDRm and INTTAUJnIm is generated. Counting stops at the "value transferred to TAUJnCDRm + 1" and TAUJnCNTm waits for detection of the TAUJnTTINm start edge. If the TAUJnCNTm reaches FFFF FFFF _H , it restarts counting from 0000 0000 _H . Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and retains its current value.

24.12.6.6 Specific Timing Diagrams

(1) Operation stop and restart

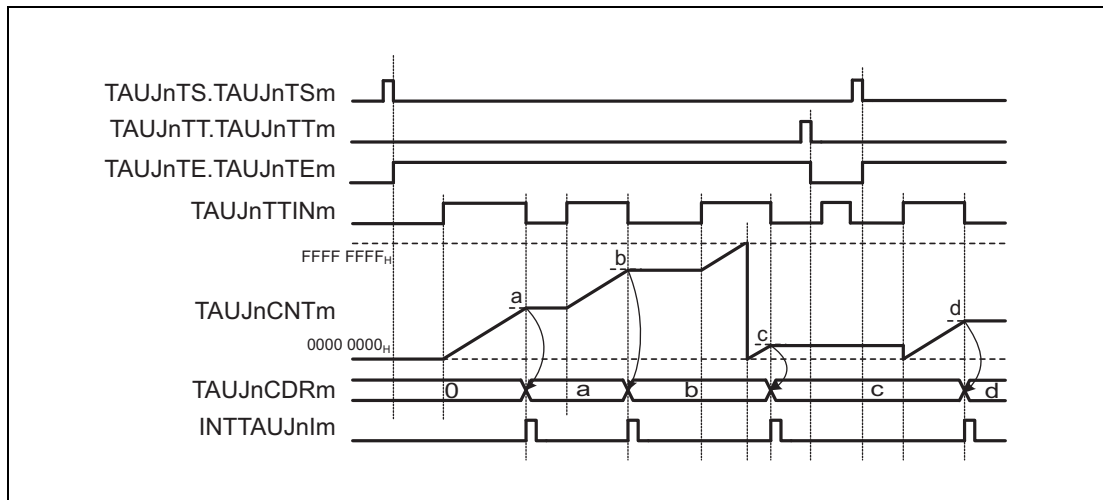

Figure 24.40 Operation Stop and Restart, TAUJnCMURm.TAUJnTIS[1:0] = 11_B

- The counter can be stopped by setting TAUJnTT.TAUJnTTM to 1, which in turn sets TAUJnTE.TAUJnTEM to 0.
- TAUJnCNTm stops and the current value is retained.
- If the counter is stopped, valid TAUJnTTINm input edges are ignored.
- The counter can be restarted by setting TAUJnTS.TAUJnTSM to 1. TAUJnCNTm restarts to count from 0000 0000_H.

24.13 Synchronous Channel Operation Functions

This section lists all the synchronous channel operation functions provided by the TAUJ. For a general overview of synchronous channel operation, see **Section 24.2, Overview**.

24.13.1 PWM output function

24.13.1.1 Overview

Summary

This function generates multiple PWM outputs by using a master and multiple slave channels. It enables the pulse cycle (frequency) and the duty of the TAUJnTTOUTm to be set. The pulse cycle is set in the master channel. The duty is set in the slave channel.

Prerequisites

- Two channels
- The operating mode for the master channel should be set to interval timer mode, refer to **Table 24.62, Contents of the TAUJnCMORm register for the Master Channel of the PWM Output Function**.
- The operating mode for the slave channels should be set to one count mode, refer to **Table 24.65, Contents of the TAUJnCMORm register for the Slave Channel of the PWM Output Function**.
- TAUJnTTOUTm is not used for this function
- The channel output mode for the slave channels should be set to Synchronous Channel Output Mode 1, refer to **Section 24.7, Channel Output Modes**.

Description

The counters are enabled by setting the channel trigger bits (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The current value of TAUJnCDRm is written to TAUJnCNTm and the counters start to count down from these values. INTTAUJnIm is generated on the master channel and TAUJnTTOUTm (slave) is set or reset to realize the PWM output.

- Master channel:

When the counter of the master channel reaches 0000 0000_H, pulse cycle time has elapsed and INTTAUJnIm is generated. The TAUJnCDRm value is written to TAUJnCNTm, and the counter counts down.

- Slave channel(s):

INTTAUJnIm generated on the master channel triggers the counter of the slave channel(s). The current value of TAUJnCDRm (slave) is written to TAUJnCNTm (slave) and the counter starts to count down from this value. The TAUJnTTOUTm signal is set to the active level.

When the counter reaches 0000 0000_H, i.e. duty time has elapsed, INTTAUJnIm is generated and the TAUJnTTOUTm signal is set to the inactive level. The counter returns to FFFF FFFF_H and awaits the next INTTAUJnIm of the master channel, and thus the start of the next pulse cycle.

The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1 for the master and slave channel(s), which in turn sets TAUJnTE.TAUJnTEm to 0. TAUJnCNTm and TAUJnTTOUTm of master and slave

channel(s) stop but retain their values. The counters can be restarted by setting TAUJnTS.TAUJnTSM to 1.

Conditions

Simultaneous rewrite can be used with this function. Please refer to **Section 24.6, Simultaneous Rewrite**.

24.13.1.2 Equations

Pulse cycle = (TAUJnCDRm (master) + 1) × count clock cycle

Duty cycle [%] = (TAUJnCDRm (slave)/(TAUJnCDRm (master) + 1)) × 100

- Duty cycle = 0%
TAUJnCDRm (slave) = 0000 0000_H
- Duty cycle = 100%
TAUJnCDRm (slave) ≥ TAUJnCDRm (master) + 1

24.13.1.3 Block Diagram and General Timing Diagram

Figure 24.41 Block diagram for PWM Output Function

The following settings apply to the general timing diagram:

- Slave channel: Positive logic (TAUJnTOL.TAUJnTOLm = 0)

Figure 24.42 General Timing Diagram for PWM Output Function

NOTE

- The interval between the channel starting to count and an interrupt being generated is the value of corresponding TAUJnCDRm + 1.
- The TAUJnTTOUTm signal from slave channel rises 1 cycle of the counter clock after the rising edge of INTTAUJnIm from the master channel.

24.13.1.4 Register Settings for the Master Channel

(1) TAUJnCMORm for the master channel

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUJnCKS[1:0]		TAUJnCCS[1:0]		TAUJnMAS	TAUJnSTS[2:0]		TAUJnCOS[1:0]		—	TAUJnMD[4:1]				TAUJnMD0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 24.62 Contents of the TAUJnCMORm register for the Master Channel of the PWM Output Function

Bit Position	Bit Name	Function
15, 14	TAUJnCKS[1:0]	Selects an operating clock. 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUJnCKS[1:0] bit of the master and slave channel(s) must be identical.
13, 12	TAUJnCCS[1:0]	Write 00 _B .
11	TAUJnMAS	Write 1 _B .
10 to 8	TAUJnSTS[2:0]	Write 000 _B .
7, 6	TAUJnCOS[1:0]	Write 00 _B .
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUJnMD[4:1]	Write 0000 _B .
0	TAUJnMD0	Write 1 _B .

(2) TAUJnCMURm for the master channel

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUJnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 24.63 Contents of the TAUJnCMURm register for the Master Channel of the PWM Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUJnTIS[1:0]	00: Not used so set to 00

(3) Channel output mode for the master channel

The channel output mode is not used by this function.

(4) Simultaneous rewrite for the master channel

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 24.64 Simultaneous Rewrite Settings for the Master Channel of the PWM Output Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	1: Enables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting

24.13.1.5 Register Settings for the Slave Channel(s)

(1) TAUJnCMORm for the slave channel(s)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAUJnCKS[1:0]		TAUJnCCS[1:0]		TAUJnMAS	TAUJnSTS[2:0]		TAUJnCOS[1:0]		—	TAUJnMD[4:1]				TAUJnMD0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Table 24.65 Contents of the TAUJnCMORm register for the Slave Channel of the PWM Output Function

Bit Position	Bit Name	Function
15, 14	TAUJnCKS[1:0]	Selects an operating clock. 00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUJnCKS[1:0] bit of the master and slave channel(s) must be identical.
13, 12	TAUJnCCS[1:0]	Write 00 _B .
11	TAUJnMAS	Write 0 _B .
10 to 8	TAUJnSTS[2:0]	Write 100 _B .
7, 6	TAUJnCOS[1:0]	Write 00 _B .
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 1	TAUJnMD[4:1]	Write 0100 _B .
0	TAUJnMD0	Write 1 _B .

(2) TAUJnCMURm for the slave channel(s)

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TAUJnTIS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R/W	R/W

Table 24.66 Contents of the TAUJnCMURm register for the Slave Channel of the PWM Output Function

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TAUJnTIS[1:0]	00: Not used so set to 00

(3) Channel output mode for the slave channel(s)**Table 24.67 Control Bit Settings for Synchronous Channel Output Mode 1**

Bit Name	Setting
TAUJnTOE.TAUJnTOEm	Write 1 _B .
TAUJnTOM.TAUJnTOMm	Write 1 _B .
TAUJnTOC.TAUJnTOCm	Write 0 _B .
TAUJnTOL.TAUJnTOLm	0: Positive logic 1: Negative logic

(4) Simultaneous rewrite for the slave channel(s)

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 24.68 Simultaneous Rewrite Settings for the Slave Channel of the PWM Output Function

Bit Name	Setting
TAUJnRDE.TAUJnRDEm	1: Enables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting

24.13.1.6 Operating Procedure for PWM Output Function

Table 24.69 Operating Procedure for PWM Output Function

	Operation	Status of TAUJn
Initial channel setting	Master channel: set the TAUJnCMORm and TAUJnCMURm registers and the channel output mode as described in Section 24.13.1.4, Register Settings for the Master Channel.	Channel operation is stopped.
	Slave channel: set the TAUJnCMORm and TAUJnCMURm registers and the channel output mode as described in Section 24.13.1.5, Register Settings for the Slave Channel(s).	
	Set the values of the TAUJnCDRm registers of all channels	
Restart	Start operation Set TAUJnTS.TAUJnTSm of the master and slave channels to 1 simultaneously. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm (master and slave channels) is set to 1 and the counters of the master and slave channels start. INTTAUJnIm is generated on the master channel and TAUJnTTOUTm (slave) is set.
	During operation TAUJnCDRm can be changed at any time. TAUJnCNTm and TAUJnRSF.TAUJnRSFm can be read at any time. TAUJnRDT.TAUJnRDTm can be changed during operation.	TAUJnCNTm of the master channel loads TAUJnCDRm and counts down. When the counter reaches 0000 0000 _H : <ul style="list-style-type: none"> • INTTAUJnIm (master) is generated • TAUJnCNTm (master) loads the TAUJnCDRm value and continues count operation • TAUJnCNTm (slave) loads the TAUJnCDRm value and counts down • TAUJnTTOUTm (slave) is set to the active level. When TAUJnCNTm (slave) reaches 0000 0000 _H : <ul style="list-style-type: none"> • INTTAUJnIm (slave) is generated • TAUJnTTOUTm (slave) is set to the inactive level.
Stop operation	Set TAUJnTT.TAUJnTTm of the master and slave channels to 1 simultaneously. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm and TAUJnTTOUTm stop and retain their current values.

24.13.1.7 Specific Timing Diagrams

(1) Duty cycle = 0%

Figure 24.43 TAUJnCDRm (Slave) = 0000 0000_H, Positive Logic
(TAUJnTOL.TAUJnTOLm (Slave) = 0)

- Every time the master channel generates an interrupt (INTTAUJnIm), 0000 0000_H is written to TAUJnCNTm (slave). Therefore, an interrupt (INTTAUJnIm) is simultaneously generated at the slave channel and TAUJnTTOUTm remains at not active state.
- The value of TAUJnCDRm is loaded into TAUJnCNTm (slave) to generate an interrupt.

(2) Duty cycle = 100%

Figure 24.44 TAUJnCDRm (Slave) ≥ TAUJnCDRm (Master) + 1, Positive Logic (TAUJnTOL.TAUJnTOLm (Slave) = 0)

If the TAUJnCDRm (slave) value is greater than the TAUJnCDRm (master) value, no interrupt occurs because the counter of the slave channel does not reach 0000 0000_H. TAUJnTTOUTm remains active.

(3) Operation stop and restart

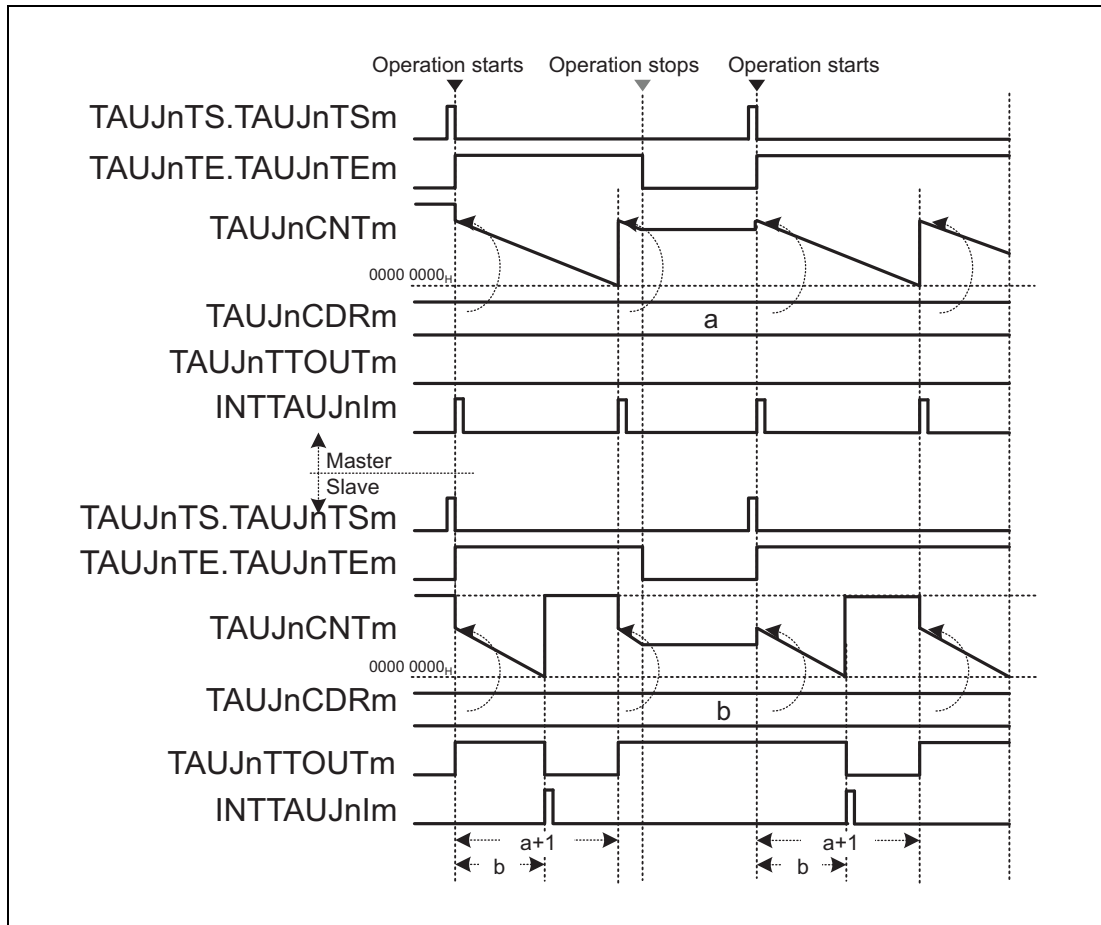

Figure 24.45 Operation Stop and Restart, Positive Logic (TAUJnTOL.TAUJnTOLm (Slave) = 0)

- The counter can be stopped by setting TAUJnTT.TAUJnTTm of master and slave channels to 1. This sets TAUJnTE.TAUJnTEm to 0.
- TAUJnCNTm and TAUJnTTOUTm of every channel stop and retain their current values. No interrupt occurs.
- The counter can be restarted by setting TAUJnTS.TAUJnTSM of master and slave channels to 1. TAUJnCDRm value of master and slave channels is loaded into TAUJnCNTm. The counter starts to count down from this value.

Section 25 Motor Control Timer (TSG3)

The Motor Control Timer (TSG3) is 18-bit counter which can generate the output corresponding to various motor control systems. TSG3 is implemented 2 units.

25.1 Features of RH850/P1M-E TSG3

25.1.1 Number of Units

This microcontroller has the following number of units of TSG3 units.

Table 25.1 Number of Units

Product	RH850/P1M-E 100 pins	RH850/P1M-E 144 pins
Number of Units	2	2
Name	TSG3n (n = 0, 1)	TSG3n (n = 0, 1)

Table 25.2 Index

Index	Description
n	Throughout this section, the individual TSG3 units are identified by the index “n” (n = 0, 1), for example, TSG3nCTL0 refers to the TSG3n control register 0.
m, k	Throughout this section, the variables used for description are indicated by the index “m” or “k”, for example, TSG3nCMPmE refers to a specific compare register.

25.1.2 Register Base Address

TSG3 base addresses are listed in the following table.

TSG3 register addresses are given as offsets from the base addresses.

Table 25.3 Register Base Address

Base Address Name	Base Address
<TSG30_base>	FFE7 0000 _H
<TSG31_base>	FFE7 1000 _H

25.1.3 Clock Supply

Clock supply by and to TSG3 is listed in the following table.

Table 25.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
TSG3n	PCLK	High-speed peripheral clock CLK_HSB

25.1.4 Interrupt Requests

TSG3 interrupt requests are listed in the following table.

Table 25.5 Interrupt Requests

Unit Interrupt Name	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number
TSG30				
INTTSG30I0	TSG30 compare match interrupt 0/ TSG30 period interrupt (in HT-PWM mode only)	40	—	—
INTTSG30I1	TSG30 compare match interrupt 1	41	—	—
INTTSG30I2	TSG30 compare match interrupt 2	42	—	—
INTTSG30I3	TSG30 compare match interrupt 3	43	—	—
INTTSG30I4	TSG30 compare match interrupt 4	44	—	—

INTTSG30IWN	TSG30 warning interrupt	56	—	—
TSG31				
INTTSG31I0	TSG31 compare match interrupt 0/ TSG31 period interrupt (in HT-PWM mode only)	57	—	—
INTTSG31I1	TSG31 compare match interrupt 1	58	—	—
INTTSG31I2	TSG31 compare match interrupt 2	59	—	—
INTTSG31I3	TSG31 compare match interrupt 3	60	—	—
INTTSG31I4	TSG31 compare match interrupt 4	61	—	—
INTTSG31I5	TSG31 compare match interrupt 5	62	—	—
INTTSG31I6	TSG31 compare match interrupt 6	63	—	—
INTTSG31I7	TSG31 compare match interrupt 7	64	—	—
INTTSG31I8	TSG31 compare match interrupt 8	65	—	—
INTTSG31I9	TSG31 compare match interrupt 9	66	—	—
INTTSG31I10	TSG31 compare match interrupt 10	67	—	—
INTTSG31I11	TSG31 compare match interrupt 11	68	103	103
INTTSG31I12	TSG31 compare match interrupt 12	69	104	104
INTTSG31IPEK	TSG31 peak interrupt	70	105	105
INTTSG31IVLY	TSG31 valley interrupt	71	106	106
INTTSG31IER	TSG31 error interrupt	72	—	—
INTTSG31IWN	TSG31 warning interrupt	73	—	—

25.1.5 Reset Sources

Please refer to **Section 8, Reset Controller**.

25.1.6 External Input/Output Signals

External input/output signals of TSG3 are listed in the following table.

Table 25.6 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
TSG30			
TSG30CLKI	I	Clock enable input	TSG30CLKI
TSG30PTSI0 to TSG30PTSI2	I	External pattern input	ENCA0E0, ENCA0E1, ENCA0EC ^{*1}
TSG30O0 to TSG30O7	O	Timer output	TSG30O0 to TSG30O7
TSG31			
TSG31CLKI	I	Clock enable input	TSG31CLKI
TSG31PTSI0 to TSG31PTSI2	I	External pattern input	ENCA1E0, ENCA1E1, ENCA1EC ^{*1}
TSG31O0 to TSG31O7	O	Timer output	TSG31O0 to TSG31O7

Note 1. External pattern input is shared with ENCA_n input.

25.2 Overview

25.2.1 Functional Overview

The TSG3n is an 18-bit timer counter with various motor control functions.

- Count clock resolution: Minimum 12.5 ns (count clock = 80 MHz)
- Operating mode corresponding to various motor control methods
- Compare registers with reload buffer
- 10-bit dead time counter
 - Dead time counter with reload buffer
 - Independent dead time can be set for positive to negative phase change and negative to positive phase change.
- A/D conversion trigger signal generation
 - Three A/D conversion trigger signals can be generated by the compare registers TSG3nDCMP0E, TSG3nDCMP1E, and TSG3nDCMP2E.
 - Skipping function of A/D conversion trigger signals TSG3nADTRG0 and TSG3nADTRG1 can be set independently. The skipping ratio can be selected among 1/1, 1/2, 1/4, and 1/8.
 - The dedicated pin (TSG3nO7) can be used to output the toggle or diagnostic signal set by the TSG3nADTRG0 signal and reset by the TSG3nADTRG1 signal.
- Interrupt skipping
 - Skipping rate: 1/1 to 1/32
- Forced output stop function
 - Using the timer option (TAPA) function allows high-impedance control of the TSG3nO1 to TSG3nO6 pin outputs.
- Compare value setting
 - Reload (simultaneous rewrite) or anytime rewrite can be selected.
- Reload mode
 - Writing to TSG3nCMP1E (setting the reload request flag (TSG3nRSF)) enables reload, and allows simultaneous transfer of values for multiple registers.
 - Data can be transferred at peak/valley/peak or valley reload timing
 - Reload request flag (TSG3nRSF)
 - Register address assignment allowing DMA transfer
 - Reload skipping
- HT-PWM mode
 - 0 to 100% PWM duty cycle output is possible (with possible dead time reduction).
 - The LSB in the compare register can be used to append an additional pulse to the PWM output during count up, thus improving the output resolution without extra load on software.

- 120-DC control
 - Semi-automatic drive function (trigger signal can be generated by an offset in conjunction with two-phase encoder, three-phase encoder, or ENCA).
- Three-phase encoder function (hall sensor signals can be input).
- Active level of the output pins TSG3nO1 to TSG3nO6 can be set individually.
- Fail-safe function (warning interrupt or error interrupt can be generated)
 - Simultaneous active output detect function for positive and inverse phases.
 - Abnormal input detection function of the three-phase encoder

NOTE

In this section, active level is indicated as high level.

25.2.2 Block Diagram

Figure 25.1 TSG3n Block Diagram

- TSG3nTSST: Simultaneous start trigger (input from PIC1A)

25.3 Registers

25.3.1 List of Registers

TSG3n registers are listed in the following table.

For <TSG3n_base>, see **Section 25.1.2, Register Base Address**

Table 25.7 List of Registers (1/3)

Module Name	Register Name	Symbol	Address	Reload
TSG3n	TSG3n control register0	TSG3nCTL0	<TSG3n_base> + 208 _H	Disabled
TSG3n	TSG3n control register1	TSG3nCTL1	<TSG3n_base> + 20C _H	Disabled
TSG3n	TSG3n control register2	TSG3nCTL2	<TSG3n_base> + 78C _H	Enabled
TSG3n	TSG3n control register 3	TSG3nCTL3	<TSG3n_base> + 004 _H	Disabled
TSG3n	TSG3n control register 4	TSG3nCTL4	<TSG3n_base> + 07C _H	Enabled
TSG3n	TSG3n control register 5	TSG3nCTL5	<TSG3n_base> + 008 _H	Disabled
TSG3n	TSG3n control register 6	TSG3nCTL6	<TSG3n_base> + 00C _H	Disabled
TSG3n	TSG3n control register 7	TSG3nCTL7	<TSG3n_base> + 218 _H	Disabled
TSG3n	TSG3n control register 8	TSG3nCTL8	<TSG3n_base> + 21C _H	Disabled
TSG3n	TSG3n I/O control register 0	TSG3nIOC0	<TSG3n_base> + 200 _H	Disabled
TSG3n	TSG3n I/O control register 1	TSG3nIOC1	<TSG3n_base> + 204 _H	Disabled
TSG3n	TSG3n I/O control register 2	TSG3nIOC2	<TSG3n_base> + 000 _H	Disabled
TSG3n	TSG3n I/O control register 3	TSG3nIOC3	<TSG3n_base> + 074 _H	Enabled
TSG3n	TSG3n status register 0	TSG3nSTR0	<TSG3n_base> + 010 _H	Disabled
TSG3n	TSG3n status register 1	TSG3nSTR1	<TSG3n_base> + 014 _H	Disabled
TSG3n	TSG3n status register 2	TSG3nSTR2	<TSG3n_base> + 018 _H	Disabled
TSG3n	TSG3n status clear trigger register	TSG3nSTC	<TSG3n_base> + 01C _H	Disabled
TSG3n	TSG3n option register 0	TSG3nOPT0	<TSG3n_base> + 020 _H	Disabled
TSG3n	TSG3n option register 1	TSG3nOPT1	<TSG3n_base> + 024 _H	Disabled
TSG3n	TSG3n trigger register 0	TSG3nTRG0	<TSG3n_base> + 030 _H	Disabled
TSG3n	TSG3n trigger register 1	TSG3nTRG1	<TSG3n_base> + 034 _H	Disabled
TSG3n	TSG3n trigger register 2	TSG3nTRG2	<TSG3n_base> + 038 _H	Disabled
TSG3n	TSG3n counter read buffer register	TSG3nCNT	<TSG3n_base> + 028 _H	Disabled
TSG3n	TSG3n bit extended counter read buffer register	TSG3nCNTB	<TSG3n_base> + 1A0 _H	Disabled
TSG3n	TSG3n sub-counter read buffer register	TSG3nSBC	<TSG3n_base> + 02C _H	Disabled
TSG3n	TSG3n bit extended sub-counter read buffer register	TSG3nSBCB	<TSG3n_base> + 1A4 _H	Disabled
TSG3n	TSG3n compare register 0	TSG3nCMP0	<TSG3n_base> + 058 _H	Enabled
TSG3n	TSG3n bit extended compare register 0	TSG3nCMP0B	<TSG3n_base> + 14C _H	Enabled
TSG3n	TSG3n compare register 1, 2	TSG3nCMP1W	<TSG3n_base> + 040 _H	Enabled
TSG3n	TSG3n compare register 5, 6	TSG3nCMP5W	<TSG3n_base> + 044 _H	Enabled
TSG3n	TSG3n compare register 9, 10	TSG3nCMP9W	<TSG3n_base> + 048 _H	Enabled
TSG3n	TSG3n compare register 3, 4	TSG3nCMP3W	<TSG3n_base> + 04C _H	Enabled
TSG3n	TSG3n compare register 7, 8	TSG3nCMP7W	<TSG3n_base> + 050 _H	Enabled
TSG3n	TSG3n compare register 11, 12	TSG3nCMP11W	<TSG3n_base> + 054 _H	Enabled
TSG3n	TSG3n compare register 1	TSG3nCMP1	<TSG3n_base> + 080 _H	Enabled
TSG3n	TSG3n compare register 2	TSG3nCMP2	<TSG3n_base> + 084 _H	Enabled
TSG3n	TSG3n compare register 3	TSG3nCMP3	<TSG3n_base> + 098 _H	Enabled
TSG3n	TSG3n compare register 4	TSG3nCMP4	<TSG3n_base> + 09C _H	Enabled

Table 25.7 List of Registers (2/3)

Module Name	Register Name	Symbol	Address	Reload
TSG3n	TSG3n compare register 5	TSG3nCMP5	<TSG3n_base> + 088 _H	Enabled
TSG3n	TSG3n compare register 6	TSG3nCMP6	<TSG3n_base> + 08C _H	Enabled
TSG3n	TSG3n compare register 7	TSG3nCMP7	<TSG3n_base> + 0A0 _H	Enabled
TSG3n	TSG3n compare register 8	TSG3nCMP8	<TSG3n_base> + 0A4 _H	Enabled
TSG3n	TSG3n compare register 9	TSG3nCMP9	<TSG3n_base> + 090 _H	Enabled
TSG3n	TSG3n compare register 10	TSG3nCMP10	<TSG3n_base> + 094 _H	Enabled
TSG3n	TSG3n compare register 11	TSG3nCMP11	<TSG3n_base> + 0A8 _H	Enabled
TSG3n	TSG3n compare register 12	TSG3nCMP12	<TSG3n_base> + 0AC _H	Enabled
TSG3n	TSG3n bit extended compare register 1	TSG3nCMP1E	<TSG3n_base> + 17C _H	Enabled
TSG3n	TSG3n bit extended compare register 2	TSG3nCMP2E	<TSG3n_base> + 178 _H	Enabled
TSG3n	TSG3n bit extended compare register 3	TSG3nCMP3E	<TSG3n_base> + 164 _H	Enabled
TSG3n	TSG3n bit extended compare register 4	TSG3nCMP4E	<TSG3n_base> + 160 _H	Enabled
TSG3n	TSG3n bit extended compare register 5	TSG3nCMP5E	<TSG3n_base> + 174 _H	Enabled
TSG3n	TSG3n bit extended compare register 6	TSG3nCMP6E	<TSG3n_base> + 170 _H	Enabled
TSG3n	TSG3n bit extended compare register 7	TSG3nCMP7E	<TSG3n_base> + 15C _H	Enabled
TSG3n	TSG3n bit extended compare register 8	TSG3nCMP8E	<TSG3n_base> + 158 _H	Enabled
TSG3n	TSG3n bit extended compare register 9	TSG3nCMP9E	<TSG3n_base> + 16C _H	Enabled
TSG3n	TSG3n bit extended compare register 10	TSG3nCMP10E	<TSG3n_base> + 168 _H	Enabled
TSG3n	TSG3n bit extended compare register 11	TSG3nCMP11E	<TSG3n_base> + 154 _H	Enabled
TSG3n	TSG3n bit extended compare register 12	TSG3nCMP12E	<TSG3n_base> + 150 _H	Enabled
TSG3n	TSG3n diagnostic output compare register 0, 1	TSG3nDCMP0W	<TSG3n_base> + 05C _H	Enabled
TSG3n	TSG3n diagnostic output compare register 2	TSG3nDCMP2	<TSG3n_base> + 060 _H	Enabled
TSG3n	TSG3n bit extended diagnostic output compare register 0	TSG3nDCMP0E	<TSG3n_base> + 148 _H	Enabled
TSG3n	TSG3n bit extended diagnostic output compare register 1	TSG3nDCMP1E	<TSG3n_base> + 144 _H	Enabled
TSG3n	TSG3n bit extended diagnostic output compare register 2	TSG3nDCMP2E	<TSG3n_base> + 140 _H	Enabled
TSG3n	TSG3n pattern register 0	TSG3nPAT0W	<TSG3n_base> + 064 _H	Enabled
TSG3n	TSG3n pattern register 1	TSG3nPAT1W	<TSG3n_base> + 068 _H	Enabled
TSG3n	TSG3n dead time control register 0	TSG3nDTC0W	<TSG3n_base> + 06C _H	Enabled
TSG3n	TSG3n dead time control register 1	TSG3nDTC1W	<TSG3n_base> + 070 _H	Enabled
TSG3n	TSG3n HT-PWM U phase compare register	TSG3nCMPU	<TSG3n_base> + 0B0 _H	Enabled
TSG3n	TSG3n HT-PWM V phase compare register	TSG3nCMPV	<TSG3n_base> + 0B4 _H	Enabled
TSG3n	TSG3n HT-PWM W phase compare register	TSG3nCMPW	<TSG3n_base> + 0B8 _H	Enabled
TSG3n	TSG3n bit extended HT-PWM U phase compare register	TSG3nCMPUE	<TSG3n_base> + 188 _H	Enabled
TSG3n	TSG3n bit extended HT-PWM V phase compare register	TSG3nCMPVE	<TSG3n_base> + 184 _H	Enabled
TSG3n	TSG3n bit extended HT-PWM W phase compare register	TSG3nCMPWE	<TSG3n_base> + 180 _H	Enabled
TSG3n	TSG3n SP-PWM U phase active width register	TSG3nUPW	<TSG3n_base> + 0BC _H	Enabled
TSG3n	TSG3n SP-PWM V phase active width register	TSG3nVPW	<TSG3n_base> + 0C0 _H	Enabled
TSG3n	TSG3n SP-PWM W phase active width register	TSG3nWPW	<TSG3n_base> + 0C4 _H	Enabled
TSG3n	TSG3n bit extended SP-PWM U phase active width register	TSG3nUPWE	<TSG3n_base> + 198 _H	Enabled
TSG3n	TSG3n bit extended SP-PWM V phase active width register	TSG3nVPWE	<TSG3n_base> + 194 _H	Enabled
TSG3n	TSG3n bit extended SP-PWM W phase active width register	TSG3nWPWE	<TSG3n_base> + 190 _H	Enabled
TSG3n	TSG3n HSP-PWM W phase shift register	TSG3nHSPSHWE	<TSG3n_base> + 120 _H	Enabled

Table 25.7 List of Registers (3/3)

Module Name	Register Name	Symbol	Address	Reload
TSG3n	TSG3n HSP-PWM V phase shift register	TSG3nHSPSHVE	<TSG3n_base> + 124 _H	Enabled
TSG3n	TSG3n HSP-PWM U phase shift register	TSG3nHSPSHUE	<TSG3n_base> + 128 _H	Enabled
TSG3n	TSG3n HSP-PWM W phase compare register	TSG3nHSPCMWE	<TSG3n_base> + 12C _H	Enabled
TSG3n	TSG3n HSP-PWM V phase compare register	TSG3nHSPCMVE	<TSG3n_base> + 130 _H	Enabled
TSG3n	TSG3n HSP-PWM U phase compare register	TSG3nHSPCMUE	<TSG3n_base> + 134 _H	Enabled
TSG3n	TSG3n dead time protection register	TSG3nDTPR	<TSG3n_base> + 210 _H	Disabled

25.3.2 TSG3nCTL0 — TSG3n Control Register 0

This register specifies the pulse width for the diagnostic output and operating mode of the TSG3n.

Access: This register can be read/written in 8-bit units.

Address: <TSG3n_base> + 208_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	TSG3nDWD	—	TSG3nMD[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R/W	R/W	R/W

Table 25.8 TSG3nCTL0 Register Contents

Bit Position	Bit Name	Function																												
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.																												
4	TSG3nDWD	<p>Selects the pulse width for the diagnostic output.</p> <p>0: The output pulse width is set to 8 clocks.</p> <p>1: The output pulse width is set to 16 clocks.</p> <p>The setting of this bit is valid when diagnostic output is enabled (TSG3nIOC1.TSG3nTGS = 1).</p>																												
3	Reserved	When read, the value after reset is read. When writing, write the value after reset.																												
2 to 0	TSG3nMD[2:0]	<p>Selects timer mode</p> <table border="1"> <thead> <tr> <th>TSG3n MD2</th> <th>TSG3n MD1</th> <th>TSG3n MD0</th> <th>Timer Mode</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>PWM mode</td> </tr> <tr> <td>0</td> <td>0</td> <td>1</td> <td>HT-PWM mode (HT-PWM)</td> </tr> <tr> <td>0</td> <td>1</td> <td>0</td> <td>Shift pulse PWM mode (SP-PWM)</td> </tr> <tr> <td>0</td> <td>1</td> <td>1</td> <td>120-DC mode</td> </tr> <tr> <td>1</td> <td>0</td> <td>0</td> <td>High-accuracy shift pulse PWM mode (HSP-PWM)</td> </tr> <tr> <td colspan="3">Other than above</td> <td>Setting prohibited</td> </tr> </tbody> </table>	TSG3n MD2	TSG3n MD1	TSG3n MD0	Timer Mode	0	0	0	PWM mode	0	0	1	HT-PWM mode (HT-PWM)	0	1	0	Shift pulse PWM mode (SP-PWM)	0	1	1	120-DC mode	1	0	0	High-accuracy shift pulse PWM mode (HSP-PWM)	Other than above			Setting prohibited
TSG3n MD2	TSG3n MD1	TSG3n MD0	Timer Mode																											
0	0	0	PWM mode																											
0	0	1	HT-PWM mode (HT-PWM)																											
0	1	0	Shift pulse PWM mode (SP-PWM)																											
0	1	1	120-DC mode																											
1	0	0	High-accuracy shift pulse PWM mode (HSP-PWM)																											
Other than above			Setting prohibited																											

CAUTION

This register should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0). Only the same value can be written during timer operation (TSG3nSTR0.TSG3nTE = 1). If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed. If this register is erroneously rewritten, set this register again after stopping the timer

25.3.3 TSG3nCTL1 — TSG3n Control Register 1

This register controls the flags of TSG3n.

Access: This register can be read/written in 16-bit units.

Address: <TSG3n_base> + 20C_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG3nTBA2	TSG3nTBA1	TSG3nTBA0	TSG3nPPC	TSG3nPEC	TSG3nTDC	TSG3nNDC	TSG3nPRC	TSG3nPTC	TSG3nPTC [1:0]
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.9 TSG3nCTL1 Register Contents (1/2)

Bit Position	Bit Name	Function
15 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	TSG3nTBA2	<p>Enables or disables detection of the simultaneous active states of the TSG3nO5 and TSG3nO6 pins.</p> <p>0: Disables detection of simultaneous active states of the TSG3nO5 and TSG3nO6 pins.</p> <p>1: Enables detection of simultaneous active states of the TSG3nO5 and TSG3nO6 pins.</p> <p>If the simultaneous active state is detected when the TSG3nIOC1.TSG3nEOC and TSG3nTBA2 bits are 1, the positive phase and inverse phase simultaneous active state detection flag 2 (TSG3nTBF2) is set to 1, and an error interrupt (INTTSG3nIER) is generated.</p>
8	TSG3nTBA1	<p>Enables or disables detection of the simultaneous active states of the TSG3nO3 and TSG3nO4 pins.</p> <p>0: Disables detection of simultaneous active states of the TSG3nO3 and TSG3nO4 pins.</p> <p>1: Enables detection of simultaneous active states of the TSG3nO3 and TSG3nO4 pins.</p> <p>If the simultaneous active state is detected when the TSG3nIOC1.TSG3nEOC and TSG3nTBA1 bits are 1, the positive phase and inverse phase simultaneous active state detection flag 1 (TSG3nTBF1) is set to 1, and an error interrupt (INTTSG3nIER) is generated.</p>
7	TSG3nTBA0	<p>Enables or disables detection of the simultaneous active states of the TSG3nO1 and TSG3nO2 pins.</p> <p>0: Disables detection of simultaneous active states of the TSG3nO1 and TSG3nO2 pins.</p> <p>1: Enables detection of simultaneous active states of the TSG3nO1 and TSG3nO2 pins.</p> <p>If the simultaneous active state is detected when the TSG3nIOC1.TSG3nEOC and TSG3nTBA0 bits are 1, the positive phase and inverse phase simultaneous active state detection flag 0 (TSG3nTBF0) is set to 1, and an error interrupt (INTTSG3nIER) is generated.</p>
6	TSG3nPPC	<p>Enables or disables detection of the pattern phase difference (TSG3nSTR2.TSG3nPPF) between the TSG3nPTSI2-0 and TSG3nOPF2-0.</p> <p>0: Disables detection of I/O pattern difference.</p> <p>1: Enables detection of I/O pattern difference</p>
5	TSG3nPEC	<p>Enables or disables detection of the pattern error (TSG3nSTR2.TSG3nPEF) of the TSG3nPTSI2-0 pins.</p> <p>0: Disables detection of the pattern error of the TSG3nPTSI2-0 pins.</p> <p>1: Enables detection of the pattern error of the TSG3nPTSI2-0 pins.</p>

Table 25.9 TSG3nCTL1 Register Contents (2/2)

Bit Position	Bit Name	Function															
4	TSG3nTDC	Enables or disables detection of the simultaneous trigger (TSG3nSTR2.TSG3nTDF) of the TSG3nOPCI0 and TSG3nOPCI1. 0: Disables detection of the simultaneous trigger of the TSG3nOPCI0 and TSG3nOPCI1. 1: Enables detection of the simultaneous trigger of the TSG3nOPCI0 and TSG3nOPCI1.															
3	TSG3nNDC	Enables or disables detection of the noise generation (two or more pins change simultaneously) (TSG3nSTR2.TSG3nNDF) on the TSG3nPTSI2-0 pins. 0: Disables detection of the noise generation on the TSG3nPTSI2-0 pins. 1: Enables detection of the noise generation on the TSG3nPTSI2-0 pins.															
2	TSG3nPRC	Enables or disables detection of the reversal of the pattern (TSG3nSTR2.TSG3nPRF) of the TSG3nPTSI2-0 pins. 0: Disables detection of the reversal of the pattern of the TSG3nPTSI2-0 pins. 1: Enables detection of the reversal of the pattern of the TSG3nPTSI2-0 pins.															
1, 0	TSG3nPTC[1:0]	Enables or disables detection of an abnormal toggle (TSG3nSTR2.TSG3nPTF) of the TSG3nPTSI2-0 pins between TSG3nOPCI1 and TSG3nOPCI0 triggers <table border="1" data-bbox="678 788 1417 1079"> <thead> <tr> <th>TSG3n PTC1</th> <th>TSG3n PTC0</th> <th>Function</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Disables detection of an abnormal toggle of the TSG3nPTSI2-0 pins.</td> </tr> <tr> <td>0</td> <td>1</td> <td></td> </tr> <tr> <td>1</td> <td>0</td> <td>Enables detection of an abnormal toggle of the TSG3nPTSI2-0 pins.</td> </tr> <tr> <td>1</td> <td>1</td> <td>Enables detection of an abnormal toggle of the TSG3nPTSI2-0 pins. When an abnormal toggle is detected, the pattern output switch trigger is automatically switched from trigger switch to pattern switch (TSG3nPOT is switched from 1 to 0.)</td> </tr> </tbody> </table>	TSG3n PTC1	TSG3n PTC0	Function	0	0	Disables detection of an abnormal toggle of the TSG3nPTSI2-0 pins.	0	1		1	0	Enables detection of an abnormal toggle of the TSG3nPTSI2-0 pins.	1	1	Enables detection of an abnormal toggle of the TSG3nPTSI2-0 pins. When an abnormal toggle is detected, the pattern output switch trigger is automatically switched from trigger switch to pattern switch (TSG3nPOT is switched from 1 to 0.)
TSG3n PTC1	TSG3n PTC0	Function															
0	0	Disables detection of an abnormal toggle of the TSG3nPTSI2-0 pins.															
0	1																
1	0	Enables detection of an abnormal toggle of the TSG3nPTSI2-0 pins.															
1	1	Enables detection of an abnormal toggle of the TSG3nPTSI2-0 pins. When an abnormal toggle is detected, the pattern output switch trigger is automatically switched from trigger switch to pattern switch (TSG3nPOT is switched from 1 to 0.)															

CAUTIONS

1. If TSG3nDTC0 or TSG3nDTC1 is set to 0000_H (without dead time), the TSG3nTBA2-0 bits should be set to 0.
2. This register should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0). Only the same value can be written during timer operation (TSG3nSTR0.TSG3nTE = 1). If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed. If this register is erroneously rewritten, set this register again after stopping the timer

25.3.4 TSG3nCTL2 — TSG3n Control Register 2

This register selects a count clock for TSG3n.

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 078_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSG3n CKS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 25.10 TSG3nCTL2 Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TSG3nCKS	Selects a count clock 0: Selects PCLK as a count clock. 1: Counted by PCLK when clock enable input (TSG3nCLKI) is high level.

CAUTION

Set the TSG3nCTL2.TSG3nCKS bit to 0 in HT-PWM mode and HSP-PWM mode.

25.3.5 TSG3nCTL3 — TSG3n Control Register 3

This register selects the rewrite method of the compare registers.

Access: This register can be read/written in 8-bit units.

Address: <TSG3n_base> + 004_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG3nRIA	TSG3nRMC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 25.11 TSG3nCTL3 Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	TSG3nRIA	<p>Selects the reload timing of the compare register values.</p> <p>0: The reload timing is set to peak reload timing (set by TSG3nCTL4.TSG3nPRE) and valley reload timing (set by TSG3nCTL4.TSG3nVRE).</p> <p>1: The reload timing is set to peak interrupt timing and valley interrupt timing.</p> <p>The setting of this bit is valid in reload mode (TSG3nRMC = 0).</p>
0	TSG3nRMC	<p>Selects the transfer timing of the compare register values.</p> <p>0: Reload mode (simultaneous rewrite) Writing to registers to be reloaded enables reloading and the register values are rewritten simultaneously at the next reload timing. Writing to any register other than registers to be reloaded does not enable reloading. For the register to be reloaded, see Section 25.3.1, List of Registers.</p> <p>1: Anytime rewrite mode The compare registers are rewritten independently. Whenever a value is written to the compare register, the written value is reflected immediately. TSG3nRSF is cleared. Do not set TSG3nRMC to 1 when operated in 120-DC mode or in HSP-PWM mode.</p>

25.3.6 TSG3nCTL4 — TSG3n Control Register 4

This register enables or disables generation of a peak interrupt and a valley interrupt, and the reload timing.

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 07C_H

Value after reset: 0000 0000_H

0	TSG3nAT10	<p>Specifies generation of A/D conversion trigger (TSG3nADTRG1) at the timing (valley interrupt) when the 18-bit counter switches from incrementing to decrementing.</p> <p>0: Disables generation of the A/D conversion trigger at the timing of a valley interrupt (INTTSG3nIVLY) after being skipped.</p> <p>1: Enables generation of the A/D conversion trigger at the timing of a valley interrupt (INTTSG3nIVLY) after being skipped.</p> <p>This bit can be set to 1 only in HT-PWM mode. In other modes, this bit must be set to 0.</p>

25.3.9 TSG3nCTL7 — TSG3n Control Register 7

This register sets the level of PWM output from the TSG3O1 to TSG3O6 pins at operation start (TSG3nTE is changed from 0 to 1) and at operation restart in SP-PWM mode.

This register can be written only when SP-PWM mode is selected (TSG3nMD2 to TSG3nMD0 = 010) and the timer is stopped (TSG3nTE = 0). Do not rewrite this register in other modes (PWM mode, HT-PWM mode, 120-DC mode, HSP-PWM mode) or while the timer is operating (TSG3nTE = 1).

Access: This register can be read/written in 8-bit units.

Address: <TSG3n_base> + 218_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	TSG3n SPSTL2	TSG3n SPSTL1	TSG3n SPSTL0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 25.15 TSG3nCTL7 Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	TSG3nSPSTL2	SP-PWM Mode Start Level Control Bit 2 0: TSG3nO5 (W phase) is cleared and TSG3nO6 (WB phase) is set at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode. 1: TSG3nO5 (W phase) is set and TSG3nO6 (WB phase) is cleared at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode.
1	TSG3nSPSTL1	SP-PWM Mode Start Level Control Bit 1 0: TSG3nO3 (V phase) is cleared and TSG3nO4 (VB phase) is set at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode. 1: TSG3nO3 (V phase) is set and TSG3nO4 (VB phase) is cleared at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode.
0	TSG3nSPSTL0	SP-PWM Mode Start Level Control Bit 0 0: TSG3nO1 (U phase) is cleared and TSG3nO2 (UB phase) is set at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode. 1: TSG3nO3 (U phase) is set and TSG3nO1 (UB phase) is cleared at operation start (TSG3nTE changed from 0 to 1) or restart in SP-PWM mode.

NOTE

The settings of bits TSG3nSPSTL2 to TSG3nSPSTL0 affect output on the TSG3nO1 to TSG3nO6 pins when operation starts or is restarted. The set dead time is always inserted at these times.

25.3.10 TSG3nCTL8 — TSG3n Control Register 8

This register specifies timer output timing when input patterns are changed in 120-DC mode.

This register can be written only when 120-DC mode is selected (TSG3nMD2-0 = 011) and the timer is stopped (TSG3nTE = 0).

Do not rewrite this register in other modes (PWM mode, SP-PMW mode, HT-PWM mode, HSP-PWM mode) or while the timer is operating (TSG3nTE = 1).

Access: This register can be read/written in 8-bit units.

Address: <TSG3n_base> +21C_H

Table 25.16 TSG3nCTL8 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TSG3n S120DCO	120-DC Mode Control Bit 0 0: When the input patterns are changed while 120-DC mode is selected, the main counter (TSG3nCnTE) is cleared and the change of input patterns is immediately reflected to timer output. 1: When the input patterns are changed while 120-DC mode is selected, the change of input patterns is reflected to timer output after a match of the main counter (TSG3nCnTE) with TSG3nCMP0E (from the next timer period).

CAUTION

When TSG3nS120DCO is set to 1 in 120DC mode, set the TSG3nOPT0.TSG3nSOC.

The settings of the TSG3nOPT0.TSG3nSTE and TSG3nOPT0.TSG3nPOT bits must not be changed while the timer is operating (TSG3nSTR0.TSG3nTE = 1).

25.3.11 TSG3nIOC0 — TSG3n I/O Control Register0

This register controls the timer output pins (TSG3nO1 to TSG3nO6).

Access: This register can be read/written in 8-bit units.

Address: <TSG3n_base> +200_H

Value after reset: 7E_H

Bit	7	6	5	4	3	2	1	0
	—	TSG3nTOE6	TSG3nTOE5	TSG3nTOE4	TSG3nTOE3	TSG3nTOE2	TSG3nTOE1	—
Value after reset	0	1	1	1	1	1	1	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 25.17 TSG3nIOC0 Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 1	TSG3nTOE6 to TSG3nTOE1	Enables or disables controlling of TSG3nO6 to TSG3nO1 by TSG3nIOC2. When these bits are 1, rewriting of TSG3nIOC2 is ignored. 0: Controlling is enabled. 1: Controlling is disabled.
0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

CAUTION

This register should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0). Only the same value can be written during timer operation (TSG3nSTR0.TSG3nTE = 1). If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed. If this register is erroneously rewritten, set this register again after stopping the timer.

25.3.12 TSG3nIOC1 — TSG3n I/O Control Register1

This register controls the timer output pins (TSG3nO1 to TSG3nO6).

Access: This register can be read/written in 8-bit units.

Address: <TSG3n_base> + 204_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	TSG3nPTS	TSG3nEOC	TSG3nWOC	TSG3nTGS	TSG3nTOS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 25.18 TSG3nIOC1 Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	TSG3nPTS	Enables or disables output of the edge detection signal (TSG3nPTE) of TSG3nPTSI0 to TSG3nPTSI2 and two-phase encoder count signal (TSG3nPEC). 0: Disables output of the toggle signal by edge detection of TSG3nPTSI0 to TSG3nPTSI2. 1: Enables output of the toggle signal by edge detection of TSG3nPTSI0 to TSG3nPTSI2.
3	TSG3nEOC	Enables or disables detection of the error condition at the motor control. 0: Disables generation of an error interrupt (INTTSG3nIER). 1: Enables generation of an error interrupt (INTTSG3nIER). For details on controlling the error interrupt, see Section 25.4.6.1, Error Interrupt Function .
2	TSG3nWOC	Enables or disables detection of the warning condition at the motor control. 0: Disables generation of a warning interrupt (INTTSG3nIWN). 1: Enables generation of a warning interrupt (INTTSG3nIWN). For details on the controlling generation of warning interrupt, see Section 25.4.6.2, Warning Interrupt Function .
1	TSG3nTGS	Selects the A/D conversion trigger diagnostic output (TSG3nO7) signal. 0: Selects A/D conversion trigger output. 1: Selects diagnostic output.
0	TSG3nTOS	Selects the timer counter increment/decrement status output (TSG3nO0) signal. 0: Outputs the up/down count flag of the 18-bit counter. 1: Outputs the up/down count flag of the 18-bit sub-counter. <ul style="list-style-type: none"> • When TSG3nTOS is 0, the status of TSG3nSTR0.TSG3nCUF is output to TSG3nO0. When TSG3nTOS is 1, the status of TSG3nSTR0.TSG3nSUF is output to TSG3nO0. • The setting of this bit is valid only in HT-PWM mode.

CAUTION

This register should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0). Only the same value can be written during timer operation (TSG3nSTR0.TSG3nTE = 1). If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed. If this register is erroneously rewritten, set this register again after stopping the timer.

25.3.13 TSG3nIOC2 — TSG3n I/O Control Register2

This register controls the timer output pins (TSG3nO1 to TSG3nO6).

Access: This register can be read/written in 16-bit units.

Address: <TSG3n_base> + 000_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	TSG3nOL6	TSG3nOL5	TSG3nOL4	TSG3nOL3	TSG3nOL2	TSG3nOL1	—	—	TSG3nTO6	TSG3nTO5	TSG3nTO4	TSG3nTO3	TSG3nTO2	TSG3nTO1	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 25.19 TSG3nIOC2 Register Contents

Bit Position	Bit Name	Function
15	Reserved	When read, the value after reset is read. When writing, write the value after reset.
14 to 9	TSG3nOL6 to TSG3nOL1	Specifies the active level of TSG3nO6 to TSG3nO1 outputs. 0: Active level is high level 1: Active level is low level
8 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 1	TSG3nTO6 to TSG3nTO1	Specifies the latch level of the output buffer of the TSG3nO6 to TSG3nO1. 0: Latch level of output buffer is low level 1: Latch level of output buffer is high level
0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

CAUTION

When the counting is stopped (TSG3nSTR0.TSG3nTE = 0), the TSG3nO1-6 pins maintain their previous output states. The output level should be changed by setting the TSG3nIOC0.TSG3nTOEm bit to 0, using the TSG3nTOm bit. This register can be rewritten when TSG3nIOC0.TSG3nTOEm = 0 (m = 1 to 6).

NOTE

While the timer is stopped (TSG3nSTR0.TSG3nTE = 0) and control of TSG3nOm by rewriting TSG3nIOC2 is enabled (TSG3nIOC0.TSG3nTOEm = 0), TSG3nOLm and TSG3nTOm of TSG3nIOC2 select the output level for the corresponding TSG3nOm output as listed in the table below.

TSG3nOLm	TSG3nTOm	Output level of TSG3nOm
0	0	Low level
0	1	High level
1	0	High level
1	1	Low level

25.3.14 TSG3nIOC3 — TSG3n I/O Control Register3

This register controls timer output pins (TSG3nO1 to TSG3nO6).

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 074_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.20 TSG3nIOC3 Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 1	TSG3nTOL6 to TSG3nTOL1	Controls the set/clear level of output. 0: Outputs the normal level. 1: Outputs the reversed level. Setting of this bit is reflected at the start of output. The change of the output level is reflected at the next compare match timing after the change.
0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

CAUTION

TSG3nTOL6 to TSG3nTOL1 should be set to 0 in HT-PWM mode and HSP-PWM mode.

25.3.15 TSG3nSTR0 — TSG3n Status Register 0

This register controls the flags.

Access: This register can be read only in 8-bit units.

Address: <TSG3n_base> + 010_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TSG3nCUF	TSG3nSUF	TSG3nRSF	TSG3nTE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 25.21 TSG3nSTR0 Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read.
3	TSG3nCUF	<p>Indicates the count direction of the 18-bit counter.</p> <p>0: The 18-bit counter is incremented. 1: The 18-bit counter is decremented.</p> <p>TSG3nCUF is valid only in HT-PWM mode. In other modes, it is invalid (TSG3nCUF = 0).</p>
2	TSG3nSUF	<p>Indicates the count direction of the 18-bit sub-counter.</p> <p>0: The 18-bit sub-counter is incremented. 1: The 18-bit sub-counter is decremented.</p> <ul style="list-style-type: none"> TSG3nSUF detects counting of the 18-bit sub-counter from 0000_H to (TSG3nCMP0E value - 0002_H) as up-counting, and counting from the TSG3nCMP0E value to 0002_H as down-counting. This bit is valid only in HT-PWM mode.
1	TSG3nRSF	<p>Indicates whether there is a reload request.</p> <p>0: No reload request or reload has completed. 1: There is a reload request.</p> <ul style="list-style-type: none"> This bit is valid only in TSG3nRMC = 0. This bit indicates that the data to be transferred next is held. This bit is set to 1 by writing to registers to be reloaded, and cleared to 0 when reload has completed. When TSG3nRMC is changed from 0 to 1 in HT-PWM mode, TSG3nRSF is cleared to 0. <p>For registers to be reloaded, see Section 25.3.1, List of Registers.</p>
0	TSG3nTE	<p>Indicates the TSG3n operation status.</p> <p>0: TSG3n is stopped. 1: TSG3n is operating.</p> <p>This bit is set when TSG3nTRG0.TSG3nTS = 1, and cleared when TSG3nTRG1.TSG3nTT = 1.</p>

25.3.16 TSG3nSTR1 — TSG3n Status Register 1

This register controls the flags.

Access: This register can be read only in 8-bit units.

Address: <TSG3n_base> + 014_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0

9	TSG3nTBR2	<p>This is a trigger bit that clears TSG3nSTR2.TSG3nTBF2.</p> <p>0: Does not clear TSG3nTBF2. 1: Clears TSG3nTBF2.</p> <p>When TSG3nTBR2 writing and TSG3nSTR2.TSG3nTBF2 setting occur simultaneously, TSG3nSTR2.TSG3nTBF2 setting has a priority, and the flag is not cleared.</p>
8	TSG3nTBR1	<p>This is a trigger bit that clears TSG3nSTR2.TSG3nTBF1.</p> <p>0: Does not clear TSG3nTBF1. 1: Clears TSG3nTBF1.</p> <p>When TSG3nTBR1 writing and TSG3nSTR2.TSG3nTBF1 setting occur simultaneously, TSG3nSTR2.TSG3nTBF1 setting has a priority, and the flag is not cleared.</p>
7	TSG3nTBR0	<p>This is a trigger bit that clears TSG3nSTR2.TSG3nTBF0.</p> <p>0: Does not clear TSG3nTBF0. 1: Clears TSG3nTBF0.</p> <p>When TSG3nTBR0 writing and TSG3nSTR2.TSG3nTBF0 setting occur simultaneously, TSG3nSTR2.TSG3nTBF0 setting has a priority, and the flag is not cleared.</p>
6	TSG3nPPR	<p>This is a trigger bit that clears TSG3nSTR2.TSG3nPPF.</p> <p>0: Does not clear TSG3nPPF. 1: Clears TSG3nPPF.</p> <p>When TSG3nPPR writing and TSG3nSTR2.TSG3nPPF setting occur simultaneously, TSG3nSTR2.TSG3nPPF setting has a priority, and the flag is not cleared.</p>
5	TSG3nPER	<p>This is a trigger bit that clears TSG3nSTR2.TSG3nPEF.</p> <p>0: Does not clear TSG3nPEF. 1: Clears TSG3nPEF.</p> <p>When TSG3nPER writing and TSG3nSTR2.TSG3nPEF setting occur simultaneously, TSG3nSTR2.TSG3nPEF setting has a priority, and the flag is not cleared.</p>
4	TSG3nTDR	<p>This is a trigger bit that clears TSG3nSTR2.TSG3nTDF.</p> <p>0: Does not clear TSG3nTDF. 1: Clears TSG3nTDF.</p> <p>When TSG3nTDR writing and TSG3nSTR2.TSG3nTDF setting occur simultaneously, TSG3nSTR2.TSG3nTDF setting has a priority, and the flag is not cleared.</p>

Table 25.24 TSG3nSTC Register Contents (2/2)

Bit Position	Bit Name	Function
3	TSG3nNDR	<p>This is a trigger bit that clears TSG3nSTR2.TSG3nNDF. 0: Does not clear TSG3nNDF. 1: Clears TSG3nNDF.</p> <p>When TSG3nNDR writing and TSG3nSTR2.TSG3nNDF setting occur simultaneously, TSG3nSTR2.TSG3nNDF setting has a priority, and the flag is not cleared.</p>
2	TSG3nPRR	<p>This is a trigger bit that clears TSG3nSTR2.TSG3nPRF. 0: Does not clear TSG3nPRF. 1: Clears TSG3nPRF.</p> <p>When TSG3nPRR writing and TSG3nSTR2.TSG3nPRF setting occur simultaneously, TSG3nSTR2.TSG3nPRF setting has a priority, and the flag is not cleared.</p>
1	TSG3nPTR	<p>This is a trigger bit that clears TSG3nSTR2.TSG3nPTF. 0: Does not clear TSG3nPTF. 1: Clears TSG3nPTF.</p> <p>When TSG3nPTR writing and TSG3nSTR2.TSG3nPTF setting occur simultaneously, TSG3nSTR2.TSG3nPTF setting has a priority, and the flag is not cleared.</p>
0	Reserved	When writing, write the value after reset.

25.3.19 TSG3nOPT0 — TSG3n Option Register 0

This register sets the optional functions.

Access: This register can be read/written in 8-bit units.

Address: <TSG3n_base> + 020_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	TSG3nSOC	TSG3nSTE	TSG3nPOT	TSG3nPSS	TSG3nIDC	TSG3nPSC	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 25.25 TSG3nOPT0 Register Contents (1/2)

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	TSG3nSOC	<p>Enables or disables control of the timer output (TSG3nO1 to TSG3nO6 pins) by software.</p> <p>0: Disables control by software. 1: Enables control by software.</p> <p>When TSG3nSOC is set to 1, timer output is switched to the software control/trigger control output pattern specified by TSG3nSPC2 to TSG3nSPC0. The dead time is secured by the dead time counter.</p>
5	TSG3nSTE	<p>Enables or disables control by the pattern output trigger.</p> <p>0: Disables the TSG3nPTSI0 to TSG3nPTSI2 and TSG3nOPCI0, and TSG3nOPCI1 inputs. 1: Enables TSG3nPTSI0 to TSG3nPTSI2 and TSG3nOPCI0, and TSG3nOPCI1 inputs.</p> <ul style="list-style-type: none"> The pattern output trigger is selected by TSG3nPOT. TSG3nSTE is valid in 120-DC mode and when software output control function is enabled.
4	TSG3nPOT	<p>Selects the pattern output trigger.</p> <p>0: Switches the output pattern by the external pattern input pins (TSG3nPTSI0 to TSG3nPTSI2) (pattern switch method). 1: Switches the output pattern by the rising edge of the TSG3nOPCI0 and TSG3nOPCI1 (trigger switch method).</p>
3	TSG3nPSS	<p>Selects the pattern output order switch factor.</p> <p>0: The pattern output order is not switched by TSG3nPSC. 1: The pattern output order is switched by TSG3nPSC.</p>
2	TSG3nIDC	<p>Determines the output pattern from the TSG3nO1 to TSG3nO6 pins in combination with the TSG3nIDC and TSG3nSTR1.TSG3nTSF and TSG3nPSC signals.</p> <p>For the timer output order and patterns to be output, see Figure 25.80 to Figure 25.83, Example of Operation in 120-DC Mode, in Section 25.4.7.4 (5), Operation in 120-DC Mode.</p>

Table 25.25 TSG3nOPT0 Register Contents (2/2)

Bit Position	Bit Name	Function
1	TSG3nPSC	<p>Selects the pattern output order when the semi-automatic cruise function is enabled.</p> <p>0: Switches the timer output (TSG3nO1 to TSG3nO6) in the normal rotation. 1: Switches the timer output (TSG3nO1 to TSG3nO6) in the reverse rotation.</p> <ul style="list-style-type: none"> • TSG3nPSC specifies the timer output pattern order assuming the output pattern specified by TSG3nSPC2 to TSG3nSPC0 as the initial pattern. TSG3nPSC is valid when TSG3nPOT = 1 and TSG3nPSS = 1. • It is recommended to rewrite TSG3nPSC when TSG3nSTR0.TSG3nTE = 0 or TSG3nPOT = 0. If TSG3nPSC is rewritten when TSG3nPOT = 1, unexpected timer output pattern might be caused. • If the signal input to TSG3nPTSI0 to TSG3nPTSI2 changes with TSG3n operation being stopped (TSG3nSTR0.TSG3nTE = 0), the TSG3nTRG0.TSG3nTS bit should be set to 1 after matching the input signal change logic with the TSG3nPSC order. • For output order in normal or reverse rotation, see Section 25.4.7.4, 120-DC Mode. Here, normal rotation and reverse rotation refer to the change of output, and they are different from normal rotation and reverse rotation of a motor.
0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

25.3.20 TSG3nOPT1 — TSG3n Option Register 1

This register sets the optional functions.

Access: This register can be read/written in 8-bit units.

Address: <TSG3n_base> +024_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	TSG3nSPC[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 25.26 TSG3nOPT1 Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2 to 0	TSG3nSPC [2:0]	Specifies the timer output pattern when software output function is enabled and in 120-DC mode. For the output pattern, see Section 25.4.7.8, Software Output Control Function , and Section 25.4.7.4, 120-DC Mode .

25.3.21 TSG3nTRG0 — TSG3n Trigger Register 0

This register controls the start of the timer.

Access: This register can be written only in 8-bit units.

Address: <TSG3n_base> + 030_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TSG3nTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 25.27 TSG3nTRG0 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset (or the fixed value).
0	TSG3nTS	This bit is a trigger bit that controls the start of the timer. 0: The timer is not started. 1: The timer is started (restarted if TSG3nSTR0.TSG3nTE = 1). When restarted, the 18-bit counter is initialized. This bit is always read as 0.

25.3.22 TSG3nTRG1 — TSG3n Trigger Register 1

This register controls the stop of the timer.

Access: This register can be written only in 8-bit units.

Address: <TSG3n_base> +034_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TSG3nTT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 25.28 TSG3nTRG1 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TSG3nTT	This is a trigger bit that controls the stop of the timer. 0: The timer is not stopped. 1: The timer is stopped (TSG3nSTR0.TSG3nTE = 0). This bit is always read as 0.

25.3.23 TSG3nTRG2 — TSG3n Trigger Register 2

TSG3nTRG2 is a trigger bit to reflect the PWM duty setting to TSG3nO1-6 in anytime rewrite mode of HT-PWM mode.

This register can be set to 1 only in HT-PWM mode and when anytime rewrite mode is selected (TSG3nRMC = 1). Do not rewrite this register in other modes (PWM mode, SP-PMW mode, 120-DC mode, HSP-PWM mode) or when reload mode is selected (TSG3nRMC = 0)

Access: This register can be written only in 8-bit units.

Address: <TSG3n_base> + 038_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TSG3nIMT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 25.29 TSG3nTRG2 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TSG3nIMT	Anytime Rewrite Trigger 0: Disabled 1: Changes in duty settings for U, V, and W phases are reflected to timer output in HT-PWM mode and when anytime rewrite mode is selected.

25.3.24 TSG3nCNT — TSG3n Counter Read Buffer Register

This register can access the 16 lower bits of the 18-bit register TSG3nCNTE.

For the operation of this register, see **Section 25.3.25, TSG3nCNTE — TSG3n Bit Extended Counter Read Buffer Register.**

Access: This register can be read only in 16-bit units.

Address: <TSG3n_base> + 028_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	16-bit counter															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

25.3.25 TSG3nCnTE — TSG3n Bit Extended Counter Read Buffer Register

The counter values can be read from this register. This register mirrors the contents of TSG3nCnT from which the 16 lower bits of this register can be accessed.

Access: This register can be read only in 32-bit units.

Address: <TSG3n_base> + 1A0_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSG3nCnTE (18-bit counter)	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG3nCnTE (18-bit counter)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

18-bit counter

This register is a timer read buffer register from which the 18-bit counter value can be read. In HT-PWM mode, the 18-bit counter provides the triangular waveform control in which the counter value is incremented and decremented by 2. Bit 0 is always read as 0.

In other modes, the 18-bit counter provides the sawtooth waveform control in which the counter value is incremented by 1.

Table 25.30 TSG3nCnTE Register Count Value

Operating mode	At the Beginning	Minimum Value	Maximum value
HT-PWM mode	TSG3nDTC0	TSG3nDTC0	TSG3nDTC0+TSG3nCnMP0E ^{*1}
Other modes	00000 _H	00000 _H	TSG3nCnMP0E

Note 1. Set the value as TSG3nDTC0+TSG3nCnMP0E < 3FFFF_H.

25.3.26 TSG3nSBC — TSG3n Sub-Counter Read Buffer Register

This register can access the 16 lower bits of the 18-bit register TSG3nSBCE.

For the operation of this register, see **Section 25.3.27, TSG3nSBCE — TSG3n Bit Extended Sub-Counter Read Buffer Register**.

Access: This register can be read only in 16-bit units.

Address: <TSG3n_base> + 02C_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	16-bit sub-counter															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

25.3.27 TSG3nSBCE — TSG3n Bit Extended Sub-Counter Read Buffer Register

The sub-counter values can be read from this register. This register mirrors the contents of TSG3nSBC from which the 16 lower bits of this register can be accessed.

Access: This register can be read only in 32-bit units.

Address: <TSG3n_base> + 1A4_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSG3nSBCE (18-bit sub-counter)	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG3nSBCE (18-bit sub-counter)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

18-bit counter

This register is a timer read buffer register from which the 18-bit sub-counter value can be read. In HT-PWM mode, the 18-bit counter provides the triangular waveform control in which the counter value is incremented and decremented by 2. Bit 0 is always read as 0. (Available only in HT-PWM mode.).

Table 25.31 TSG3nSBCE Register Count Value

Operating mode	At the Beginning	Minimum Value	Maximum Value
HT-PWM mode	TSG3nDTC0	00000 _H	TSG3nDTC0 + TSG3nDTC1 + TSG3nCMP0E ^{*1}
Other modes	00000 _H	00000 _H	00000 _H

Note 1. Set the value as TSG3nDTC0 + TSG3nDTC1 + TSG3nCMP0E < 3FFFF_H.

25.3.28 TSG3nCMP0 — TSG3n Compare Register 0

This register can access the 16 lower bits of the 18-bit register TSG3nCMP0E.

For the operation of this register, see **Section 25.3.29, TSG3nCMP0E — TSG3n Bit Extended Compare Register 0**.

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 058_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	16-bit compare register															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

25.3.29 TSG3nCMP0E — TSG3n Bit Extended Compare Register 0

This register is an 18-bit compare register that specifies the PWM period in all modes. This register mirrors the contents of TSG3nCMP0 from which the 16 lower bits of this register can be accessed.

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 14C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSG3nCMP0E (18-bit compare register)	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.32 TSG3nCMP0E Register Setting

Operating mode	At the Beginning	Minimum Value	Maximum Value
HT-PWM mode	TSG3nCMP0E ^{*1}	00002 _H	3FFFE _H
Other modes	TSG3nCMP0E + 1	1 (TSG3nCMP0E = 00000 _H)	40000 _H (TSG3nCMP0E = 3FFFF _H)

Note 1. In HT-PWM mode, the lowest bit is ignored.

25.3.30 TSG3nCMP1W — TSG3n Compare Register 1, 2

This register can access the 16 lower bits of the 18-bit register TSG3nCMP1E and TSG3nCMP2E.

For the operation of this register, see **Section 25.3.37, TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12.**

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 040_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25.3.34 TSG3nCMP9W — TSG3n Compare Registers 9, 10

This register can access the 16 lower bits of the 18-bit register TSG3nCMP9E and TSG3nCMP10E.

For the operation of this register, see **Section 25.3.37, TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12.**

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 048_H

Value after reset: 0000 0000_H

25.3.35 TSG3nCMP11W — TSG3n Compare Registers 11, 12

This register can access the 16 lower bits of the 18-bit register TSG3nCMP11E and TSG3nCMP12E.

For the operation of this register, see **Section 25.3.37, TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12.**

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 054_H

Value after reset: 0000 0000_H

25.3.36 TSG3nCMP1 to TSG3nCMP12 — TSG3n Compare Registers 1 to 12

These registers can access the 16 lower bits of the 18-bit registers TSG3nCMP1E-12E.

For the operation of these registers, see **Section 25.3.37, TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12.**

Access: This register can be read/written in 16-bit units.

Address: TSG3nCMP1 <TSG3n_base> + 080_H
 TSG3nCMP2 <TSG3n_base> + 084_H
 TSG3nCMP3 <TSG3n_base> + 098_H
 TSG3nCMP4 <TSG3n_base> + 09C_H
 TSG3nCMP5 <TSG3n_base> + 088_H
 TSG3nCMP6 <TSG3n_base> + 08C_H
 TSG3nCMP7 <TSG3n_base> + 0A0_H
 TSG3nCMP8 <TSG3n_base> + 0A4_H
 TSG3nCMP9 <TSG3n_base> + 090_H
 TSG3nCMP10 <TSG3n_base> + 094_H
 TSG3nCMP11 <TSG3n_base> + 0A8_H
 TSG3nCMP12 <TSG3n_base> + 0AC_H

Value after reset: 0000_H

25.3.37 TSG3nCMP1E to TSG3nCMP12E — TSG3n Bit Extended Compare Registers 1 to 12

The compare value is set by these registers. These registers mirror the contents of TSG3nCMP1-12, TSG3nCMP1W, 3W, 5W, 7W, 9W, and 11W from which the 16 lower bits of these registers can be accessed.

Access: This register can be read/written in 32-bit units.

Address: TSG3nCMP1E <TSG3n_base> + 17C_H
 TSG3nCMP2E <TSG3n_base> + 178_H
 TSG3nCMP3E <TSG3n_base> + 164_H
 TSG3nCMP4E <TSG3n_base> + 160_H
 TSG3nCMP5E <TSG3n_base> + 174_H
 TSG3nCMP6E <TSG3n_base> + 170_H
 TSG3nCMP7E <TSG3n_base> + 15C_H
 TSG3nCMP8E <TSG3n_base> + 158_H
 TSG3nCMP9E <TSG3n_base> + 16C_H
 TSG3nCMP10E <TSG3n_base> + 168_H
 TSG3nCMP11E <TSG3n_base> + 154_H
 TSG3nCMP12E <TSG3n_base> + 150_H

Value after reset: 0000 0000_H

Table 25.33 TSG3nCMP1E-TSG3nCMP12E Register Setting (1/2)

Register	PWM Mode	HT-PWM Mode	SP-PWM Mode	120-DC Mode	HSP-PWM Mode
TSG3nCMP1E	TSG3nO1 clear timing	TSG3nO1 clear timing /TSG3nO2 set timing		Duty when TSG3nO1, 3, or 5 output pattern is selected by TSG3nPAT0.	TSG3nO1 clear timing
TSG3nCMP2E	TSG3nO1 set timing	TSG3nO1 set timing/TSG3nO2 clear timing			TSG3nO1 set timing
TSG3nCMP3E	TSG3nO2 clear timing	—		Duty when TSG3nO2, 4, or 6 output pattern is selected by TSG3nPAT1.	TSG3nO2 clear timing
TSG3nCMP4E	TSG3nO2 set timing	—			TSG3nO2 set timing
TSG3nCMP5E	TSG3nO3 clear timing	TSG3nO3 clear timing/ TSG3nO4 set timing		Duty when TSG3nO1, 3, or 5 output pattern is selected by TSG3nPAT0.	TSG3nO3 clear timing
TSG3nCMP6E	TSG3nO3 set timing	TSG3nO3 set timing/TSG3nO4 clear timing			TSG3nO3 set timing
TSG3nCMP7E	TSG3nO4 clear timing	—		Duty when TSG3nO2, 4, or 6 output pattern is selected by TSG3nPAT1.	TSG3nO4 clear timing
TSG3nCMP8E	TSG3nO4 set timing	—			TSG3nO4 set timing
TSG3nCMP9E	TSG3nO5 clear timing	TSG3nO5 clear timing/ TSG3nO6 set timing		Duty when TSG3nO1, 3, or 5 output pattern is selected by TSG3nPAT0.	TSG3nO5 clear timing
TSG3nCMP10E	TSG3nO5 set timing	TSG3nO5 set timing/TSG3nO6 clear timing			TSG3nO5 set timing

Table 25.33 TSG3nCMP1E-TSG3nCMP12E Register Setting (2/2)

Register	PWM Mode	HT-PWM Mode	SP-PWM Mode	120-DC Mode	HSP-PWM Mode
TSG3nCMP11E	TSG3nO6 clear timing	—		Duty when TSG3nO2, 4, or 6 output pattern is selected by TSG3nPAT1.	TSG3nO6 clear timing
TSG3nCMP12E	TSG3nO6 set timing	—			TSG3nO6 set timing

NOTE

The dead time function is used in all operating modes.

In HT-PWM mode, the compare match signal is generated when a compare match occurs not only with the value of the TSG3nCNTE register but also with the value of the TSG3nSBCE register.

In 120-DC mode, the output from TSG3nO1-6 is controlled by the TSG3nCMPmE, TSG3nPAT0, and TSG3nPAT1 registers.

25.3.38 TSG3nDCMP0W — TSG3n Diagnostic Output Compare Register 0, 1

This register can access the 16 lower bits of the 18-bit register TSG3nDCMP0E and TSG3nDCMP1E.

For the operation of this register, see **Section 25.3.40, TSG3nDCMP0E to 2E — TSG3n Bit Extended Diagnostic Output Compare Register 0 to 2.**

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 05C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25.3.39 TSG3nDCMP2 — TSG3n Diagnostic Output Compare Register 2

This register can access the 16 lower bits of the 18-bit register TSG3nDCMP2E.

For the operation of this register, see **Section 25.3.40, TSG3nDCMP0E to 2E — TSG3n Bit Extended Diagnostic Output Compare Register 0 to 2.**

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 060_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25.3.40 TSG3nDCMP0E to 2E — TSG3n Bit Extended Diagnostic Output Compare Register 0 to 2

The compare value is set by these registers. These registers mirror the contents of TSG3nDCMP0W and TSG3nDCMP2 from which the 16 lower bits of these registers can be accessed.

Access: This register can be read/written in 32-bit units.

Address: TSG3nDCMP0E <TSG3n_base> + 148_H
 TSG3nDCMP1E <TSG3n_base> + 144_H
 TSG3nDCMP2E <TSG3n_base> + 140_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSG3nDCMP0E - TSG3nDCMP2E (18-bit compare register)	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG3nDCMP0E - TSG3nDCMP2E (18-bit compare register)

These registers control the diagnostic output timing or AD conversion trigger timing in all modes. A pulse is generated at the match timing of the 18-bit counter value with this register.

25.3.41 TSG3nPAT0W — TSG3n Pattern Register 0

This register specifies the output pattern.

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 064_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Output Pattern

This register controls UT/VT/WT output in 120-DC mode.

Table 25.34 TSG3nPAT0W Register Setting value and Output Control

PATmT Value	Output Control
000	Fixed Low level
001	PWM output set by TSG3nCMP1E
010	PWM output set by TSG3nCMP2E
011	PWM output set by TSG3nCMP5E
100	PWM output set by TSG3nCMP6E
101	PWM output set by TSG3nCMP9E
110	PWM output set by TSG3nCMP10E
111	Fixed High level

Note: m = 0, 1, 2, 3, 4, 5

25.3.42 TSG3nPAT1W — TSG3n Pattern Register 1

This register specifies the output pattern.

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 068_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PAT5B	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Output Pattern

This register controls UB/VB/WB output in 120-DC mode.

Table 25.35 TSG3nPAT1W Register Setting value and Output Control

PATmB Value	Output Control
000	Fixed Low level
001	PWM output set by TSG3nCMP3E
010	PWM output set by TSG3nCMP4E
011	PWM output set by TSG3nCMP7E
100	PWM output set by TSG3nCMP8E
101	PWM output set by TSG3nCMP11E
110	PWM output set by TSG3nCMP12E
111	Fixed High level

Note: m = 0, 1, 2, 3, 4, 5

25.3.43 TSG3nDTC0W — TSG3n Dead Time Control Register 0

This register sets the dead time value (the period from inverse phase inactivation to positive phase activation).

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 06C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Write Protection Code Check															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG3nDTC0(10-bit dead time compare)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

To rewrite TSG3nDTC0W[0:9], set bit 14 to bit 0 and TSG3nDTCM to 0 in TSG3nDTPR, and rewrite the TSG3nDTC0W. At this time, when the rewritten value of TSG3nDTC0W[30:16] and the TSG3nDTPR value match, TSG3nDTC0W is rewritten.

During timer operation (TSG3nSTR0.TSG3nTE = 1), rewriting should be performed in reload mode (TSG3nCTL3.TSG3nRMC = 0).

25.3.44 TSG3nDTC1W — TSG3n Dead Time Control Register 1

This register sets the dead time (the period from positive phase inactivation to inverse phase activation).

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 070_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Write Protection Code Check															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG3nDTC1(10-bit dead time compare)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

To rewrite TSG3nDTC1W[0:9], set bit 14 to bit 0 and TSG3nDTCM to 0 in TSG3nDTPR, and rewrite the TSG3nDTC1W. At this time, when the rewritten value of TSG3nDTC1W[30:16] and the TSG3nDTPR value match, TSG3nDTC1W is rewritten.

During timer operation (TSG3nSTR0.TSG3nTE = 1), rewriting should be performed in reload mode (TSG3nCTL3.TSG3nRMC = 0).

25.3.45 TSG3nCMPU — TSG3n HT-PWM U Phase Compare Register

This register can access the 16 lower bits of the 18-bit register TSG3nCMPUE.

For the operation of this register, see **Section 25.3.48, TSG3nCMPUE — TSG3n Bit Extended HT-PWM U Phase Compare Register.**

Access: This register can be read/written in 16-bit units.

Address: <TSG3n_base> + 0B0_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TSG3nCMPU(16-bit compare register)																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

25.3.46 TSG3nCMPV — TSG3n HT-PWM V Phase Compare Register

This register can access the 16 lower bits of the 18-bit register TSG3nCMPVE.

For the operation of this register, see **Section 25.3.49, TSG3nCMPVE — TSG3n Bit Extended HT-PWM V Phase Compare Register.**

Access: This register can be read/written in 16-bit units.

Address: <TSG3n_base> + 0B4_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TSG3nCMPV (16-bit compare register)																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

25.3.47 TSG3nCMPW — TSG3n HT-PWM W Phase Compare Register

This register can access the 16 lower bits of the 18-bit register TSG3nCMPWE.

For the operation of this register, see **Section 25.3.50, TSG3nCMPWE — TSG3n Bit Extended HT-PWM W Phase Compare Register.**

Access: This register can be read/written in 16-bit units.

Address: <TSG3n_base> + 0B8_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

25.3.48 TSG3nCMPUE — TSG3n Bit Extended HT-PWM U Phase Compare Register

This register sets the compare value for U phase in HT-PWM. In addition to the functions of TSG3nCMP1E and TSG3nCMP2E, this register can access specific registers.

The data written to this register is stored in the TSG3nCMP1E and TSG3nCMP2E registers which allows a generation of symmetry triangular waveform of PWM by one write access (see **Figure 25.2**). When this register is read, the same value as TSG3nCMP1E is returned. This register mirrors the contents of TSG3nCMPU from which the 16 lower bits of this register can be accessed.

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> +188_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 25.2 TSG3nCMPUE Register Accesses

25.3.49 TSG3nCMPVE — TSG3n Bit Extended HT-PWM V Phase Compare Register

This register sets the compare value for V phase in HT-PWM. In addition to the functions of TSG3nCMP5E and TSG3nCMP6E, this register can access specific registers.

The data written to this register is stored in the TSG3nCMP5E and TSG3nCMP6E registers which allows a generation of symmetry triangular waveform of PWM by one write access (see **Figure 25.3**). When this register is read, the same value as TSG3nCMP5E is returned. This register mirrors the contents of TSG3nCMPV from which the 16 lower bits of this register can be accessed.

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> +184_H

Value after reset: 0000 0000_H

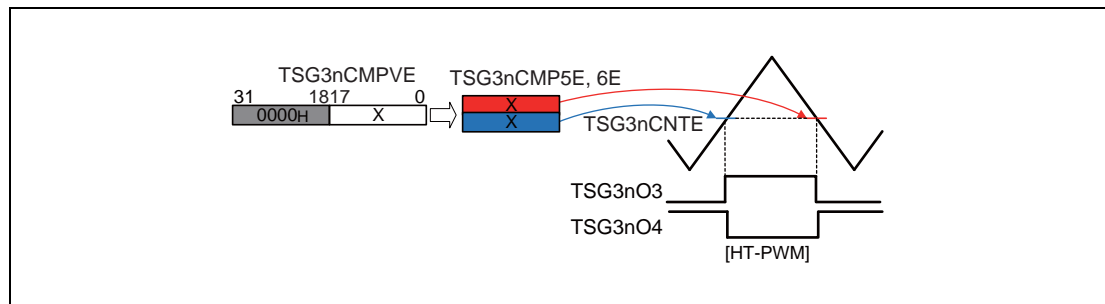

Figure 25.3 TSG3nCMPVE Register Accesses

25.3.50 TSG3nCMPWE — TSG3n Bit Extended HT-PWM W Phase Compare Register

This register sets the compare value for W phase in HT-PWM. In addition to the functions of TSG3nCMP9E and TSG3nCMP10E, this register can access specific registers.

The data written to this register is stored in the TSG3nCMP9E and TSG3nCMP10E registers which allows a generation of symmetry triangular waveform of PWM by one write access (see **Figure 25.4**). When this register is read, the same value as TSG3nCMP9E is returned. This register mirrors the contents of TSG3nCMPW from which the 16 lower bits of this register can be accessed.

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> +180_H

Value after reset: 0000 0000_H

25.3.54 TSG3nUPWE — TSG3n Bit Extended SP-PWM U Phase Active Width Register

This register sets the active width for U phase in SP-PWM mode. The sum of the TSG3nUPWE write data and the TSG3nCMP2E value is stored in TSG3nCMP1E (see **Figure 25.5**). When this register is read, the same value as TSG3nCMP1E is returned. This register mirrors the contents of TSG3nUPW from which the 16 lower bits of this register can be accessed.

Access: This register can be read/written in 32-bit units.

Address: <TSG3n_base> + 198_H

Value after reset: 0000 0000_H

25.3.63 TSG3nDTPR — TSG3n Dead Time Protection Register

This register controls protection of the write access to the dead time register.

Access: This register can be read/written in 16-bit units.

Address: <TSG3n_base> + 210_H

Value after reset: 0000 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG3nDTPR (Write Protection Code)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.36 TSG3nDTPR Register Contents

Bit Position	Bit Name	Function
15	TSG3nDTCM	Enables or disables rewriting of TSG3nDTC0 and TSG3nDTC1. 0: Enables rewriting of TSG3nDTC0 and TSG3nDTC1. 1: Disables rewriting of TSG3nDTC0 and TSG3nDTC1.
14 to 0	TSG3nDTPR [14:0]	Sets the write protection code (any value from 0000 to 7FFF).

This register protects TSG3nDTC0 and TSG3nDTC1 from illegal rewriting.

Functions are described below.

- TSG3nDTCM enables or disables rewriting of TSG3nDTC0 and TSG3nDTC1.
- Rewriting of TSG3nDTC0 and TSG3nDTC1 is enabled or disabled by double-checking a match of the write protection code (bits 30 to 16) of TSG3nDTC0 and TSG3nDTC1 with the write protection code of TSG3nDTPR, and the TSG3nDTCM setting.

CAUTION

This register should be set when the timer is stopped (TSG3nSTR0.TSG3nTE = 0). Only the same value can be written during timer operation (TSG3nSTR0.TSG3nTE = 1). If the different value is written to this register when TSG3nSTR0.TSG3nTE = 1, timer operation cannot be guaranteed. If this register is erroneously rewritten, set this register again after stopping the timer.

25.4 Function

Table 25.37 List of Modes

TSG3nCTL0 Register			Timer Mode
TSG3nMD2	TSG3nMD1	TSG3nMD0	
0	0	0	PWM mode
0	0	1	HT-PWM mode (HT-PWM)
0	1	0	Shift pulse PWM mode (SP-PWM)
0	1	1	120-DC mode
1	0	0	High-accuracy shift pulse PWM mode (HSP-PWM)
Other than above			Setting prohibited

25.4.1 Basic Operation

25.4.1.1 Basic Operation of 18-Bit Counter

The basic operation of the 18-bit counter is described. For details, see **Section 25.4.7, Operating Modes**.

Counting start

The 18-bit counter of TSG3n starts counting in HT-PWM mode when the initial value is 00000_H and after the TSG3nDTC0 value is loaded. The counter starts counting from the initial value 00000_H in all modes except for HT-PWM mode.

In HT-PWM mode, the counter value is incremented by 2 from the value of TSG3nDTC0 and decremented by 2 down to the value of TSG3nDTC0 after the counter value matches with the value of TSG3nCMP0E + TSG3nDTC0. The counter increments from 00000_H, 00001_H, 00002_H, 00003_H, ... in all modes except for HT-PWM mode.

Counter clear

The 18-bit counter is cleared by the match of the counter value and the value of TSG3nCMP0E in all modes except for HT-PWM mode. (Clearing operation is not available in HT-PWM mode.)

Counter read during counting

In the TSG3n, the 18-bit counter value during counting can be read through TSG3nCNTE.

Count stop operation

When count operation is stopped (when TS0TE is changed from 1 to 0), TSG3nCNTE and TSG3nSBCE retain the counter value when stopped.

Interrupt operation

In the TSG3n, the following interrupts are generated.

- INTTSG3nI0: A period interrupt by a match of the 18-bit counter value with the TSG3nDTC0 value in HT-PWM mode. A compare match interrupt of the 18-bit counter value with the TSG3nCMP0E buffer register in any mode other than HT-PWM mode.
- INTTSG3nI1: A compare match interrupt of the 18-bit counter value with the TSG3nCMP1E buffer register.
- INTTSG3nI2: A compare match interrupt of the 18-bit counter value with the TSG3nCMP2E buffer register.
- INTTSG3nI3: A compare match interrupt of the 18-bit counter value with the TSG3nCMP3E buffer register.
- INTTSG3nI4: A compare match interrupt of the 18-bit counter value with the TSG3nCMP4E buffer register.
- INTTSG3nI5: A compare match interrupt of the 18-bit counter value with the TSG3nCMP5E buffer register.
- INTTSG3nI6: A compare match interrupt of the 18-bit counter value with the TSG3nCMP6E buffer register.
- INTTSG3nI7: A compare match interrupt of the 18-bit counter value with the TSG3nCMP7E buffer register.
- INTTSG3nI8: A compare match interrupt of the 18-bit counter value with the TSG3nCMP8E buffer register.
- INTTSG3nI9: A compare match interrupt of the 18-bit counter value with the TSG3nCMP9E buffer register.
- INTTSG3nI10: A compare match interrupt of the 18-bit counter value with the TSG3nCMP10E buffer register.
- INTTSG3nI11: A compare match interrupt of the 18-bit counter value with the TSG3nCMP11E buffer register.
- INTTSG3nI12: A compare match interrupt of the 18-bit counter value with the TSG3nCMP12E buffer register.
- INTTSG3nIPEK: A peak interrupt when the 18-bit counter switches from incrementing to decrementing.
- INTTSG3nIVLY: A valley interrupt when the 18-bit counter switches from decrementing to incrementing.
- INTTSG3nIER: A simultaneous active state detection interrupt of the positive phase and inverse phase
- INTTSG3nIWN: A warning detection interrupt

25.4.1.2 Function of Compare Registers

The functions of the compare registers in each operating mode are shown in the following tables.

Table 25.38 Compare Register Functions in Each Mode (1/7)

Operating Mode	TSG3nCMP0E	TSG3nCMP1E	TSG3nCMP2E
PWM mode	PWM period	TSG3nO1 clear timing	TSG3nO1 set timing
HT-PWM mode	PWM period	TSG3nO1 clear timing TSG3nO2 set timing	TSG3nO1 set timing TSG3nO2 clear timing
SP-PWM mode	PWM period	TSG3nO1 clear timing TSG3nO2 set timing	TSG3nO1 set timing TSG3nO2 clear timing
120-DC mode	PWM period	Select TSG3nO1, TSG3nO3, or TSG3nO5 output by TSG3nPAT0	Select TSG3nO1, TSG3nO3, or TSG3nO5 output by TSG3nPAT0
HSP-PWM mode	PWM period	TSG3nO1 clear timing	TSG3nO1 set timing

TSG3nCMP5E-8E is set based on the TSG3nHSPCMVE set value and the set values of TSG3nCMP0E, TSG3nDTC0, TSG3nDTC1, and TSG3nHSPSHVE.	TSG3nCMP9E-12E is set based on the TSG3nHSPCMWE set value and the set values of TSG3nCMP0E, TSG3nDTC0, TSG3nDTC1, and TSG3nHSPSHWE.

25.4.1.3 Compare Register Rewrite Operation

TSG3 can be set to reload mode or anytime rewrite mode using the TSG3nRMC bit.

Reload mode is enabled when TSG3nRMC = 0. The registers listed as “Enable” on the “Reload” column in **Section 25.3.1, List of Registers** are simultaneously updated at the reload timing.

Anytime rewrite mode is enabled when TSG3nRMC = 1. The registers are updated independently every time the value is written to the relevant register.

The update timing of the registers to be reloaded in reload mode and anytime rewrite mode in each mode are listed in the following table.

Table 25.39 Updating Timing of Compare Registers by Mode

Mode	Anytime Rewrite TSG3nRMC = 1	Reload TSG3nRMC = 0
PWM mode	TSG3nCMP0E: At the next counter clear timing of the 18-bit counter	At reload timing
	Registers other than TSG3nCMP0E: At a write access to the register	
HT-PWM mode	TSG3nCMP0E: At the next peak or valley timing of TSG3nCnTE	At reload timing
	TSG3nCMP1E, 2E, 5E, 6E, 9E, 10E: At writing 1 to the TSG3nIMT bit	
	Registers other than TSG3nCMP0E, 1E, 2E, 5E, 6E, 9E, 10E: At a write access to the register	
SP-PWM mode	TSG3nCMP0E: At the next counter clear timing of the 18-bit counter	At reload timing
	Registers other than TSG3nCMP0E: At a write access to the register	
120-DC mode	Setting prohibited	At reload timing
HSP-PWM mode	Setting prohibited	At reload timing

Anytime Rewrite Mode

In this mode, the compare registers are rewritten independently. Whenever a value is written to the compare register, the written value is reflected at the timing of **Table 25.39**.

Reload mode (Simultaneous Rewrite Function)

Writing to TSG3nCMP1E (TSG3nCMP1, TSG3nCMP1W, TSG3nCMPUE, TSG3nCMPU, TSG3nUPWE, TSG3nUPW, and TSG3nHSPCMUE) enables reload (sets the reload request flag (TSG3nSTR0.TSG3nRSF)), and the values of all the pertinent registers are updated simultaneously at the next reload timing (reload).

The reload timing is the peak or valley timing of the 18-bit counter when the TSG3nTRG0.TSG3nTS bit is changed from 0 to 1. Reloading is controlled by TSG3nCTL4.TSG3nPRE and TSG3nVRE.

Writing to any register other than TSG3nCMP1E (TSG3nCMP1, TSG3nCMP1W, TSG3nCMPUE, TSG3nCMPU, TSG3nUPWE, TSG3nUPW, and TSG3nHSPCMUE) does not enable reloading.

Do not write to the registers to be reloaded until the next reload timing after reloading is enabled by writing to TSG3nCMP1E (TSG3nCMP1, TSG3nCMP1W, TSG3nCMPUE, TSG3nCMPU, TSG3nUPWE, TSG3nUPW, and TSG3nHSPCMUE). The pertinent registers should be rewritten when the reload request flag (TSG3nSTR0.TSG3nRSF) is 0.

Rewriting registers to be reloaded by DMA transfer

Some of the registers to be reloaded can be rewritten by DMA transfer. DMA transfer is performed as follows.

Table 25.40 Example of DMA Transfer Order of Registers to be Reloaded

Address	Register Name	DMA Transfer Order (Example)
<TSG3n_base> + 040 _H	TSG3nCMP1W	
<TSG3n_base> + 044 _H	TSG3nCMP5W	
<TSG3n_base> + 048 _H	TSG3nCMP9W	
<TSG3n_base> + 04C _H	TSG3nCMP3W	
<TSG3n_base> + 050 _H	TSG3nCMP7W	
<TSG3n_base> + 054 _H	TSG3nCMP11W	
<TSG3n_base> + 058 _H	TSG3nCMP0	
<TSG3n_base> + 05C _H	TSG3nDCMP0W	
<TSG3n_base> + 060 _H	TSG3nDCMP2	
<TSG3n_base> + 064 _H	TSG3nPAT0W	
<TSG3n_base> + 068 _H	TSG3nPAT1W	
<TSG3n_base> + 06C _H	TSG3nDTC0W	
<TSG3n_base> + 070 _H	TSG3nDTC1W	

Table 25.41 Example of DMA Transfer Order of Registers to be Reloaded

Address	Register Name	DMA Transfer Order (Example)
<TSG3n_base> + 140 _H	TSG3nDCMP2E	
<TSG3n_base> + 144 _H	TSG3nDCMP1E	
<TSG3n_base> + 148 _H	TSG3nDCMP0E	
<TSG3n_base> + 14C _H	TSG3nCMP0E	
<TSG3n_base> + 150 _H	TSG3nCMP12E	
<TSG3n_base> + 154 _H	TSG3nCMP11E	
<TSG3n_base> + 158 _H	TSG3nCMP8E	
<TSG3n_base> + 15C _H	TSG3nCMP7E	
<TSG3n_base> + 160 _H	TSG3nCMP4E	
<TSG3n_base> + 164 _H	TSG3nCMP3E	
<TSG3n_base> + 168 _H	TSG3nCMP10E	
<TSG3n_base> + 16C _H	TSG3nCMP9E	
<TSG3n_base> + 170 _H	TSG3nCMP6E	
<TSG3n_base> + 174 _H	TSG3nCMP5E	
<TSG3n_base> + 178 _H	TSG3nCMP2E	
<TSG3n_base> + 17C _H	TSG3nCMP1E	

Table 25.42 Duty Setting in HT-PWM Mode

Address	Register Name	DMA Transfer Order (Example)
<TSG3n_base> + 180 _H	TSG3nCMPWE	
<TSG3n_base> + 184 _H	TSG3nCMPVE	
<TSG3n_base> + 188 _H	TSG3nCMPUE	

Table 25.43 Active Width Setting in SP-PWM Mode

Address	Register Name	DMA Transfer Order (Example)
<TSG3n_base> + 190 _H	TSG3nWPWE	↓
<TSG3n_base> + 194 _H	TSG3nVPWE	
<TSG3n_base> + 198 _H	TSG3nUPWE	

Table 25.44 Shift Width and Duty Setting in HSP-PWM Mode

Address	Register Name	DMA Transfer Order (Example)
<TSG3n_base> + 120 _H	TSG3nHSPSHWE	↓
<TSG3n_base> + 124 _H	TSG3nHSPSHVE	
<TSG3n_base> + 128 _H	TSG3nHSPSHUE	
<TSG3n_base> + 12C _H	TSG3nHSPCMWE	
<TSG3n_base> + 130 _H	TSG3nHSPCMVE	
<TSG3n_base> + 134 _H	TSG3nHSPCMUE	

NOTES

1. TSG3nCTL4 and TSG3nIOC3 should be rewritten individually.
2. Since writing to TSG3nCMP1E (including TSG3nCMP1, TSG3nCMP1W, TSG3nCMPUE, TSG3nCMPU, TSG3nUPWE, TSG3nUPW, and TSG3nHSPCMUE) enables reloading, it should be rewritten after all the other registers to be reloaded have been rewritten (ready to be reloaded)

(1) Example of Operation in Anytime Rewrite Mode

In this mode, the values written to the compare registers (TSG3nCMP1E to TSG3nCMP12E) are transferred to the internal buffer registers immediately, and are compared with the counter value.

The values are transferred to the internal compare buffer registers one clock cycle (PCLK) after being written to the compare registers (TSG3nCMP1E to TSG3nCMP12E).

The transfer timing of the TSG3nCMP0E is the peak or valley timing (only in HT-PWM mode) of the 18-bit counter after being written to the compare registers, or at the match timing of the TSG3nCMP0E value with the 18-bit counter value (in any mode other than HT-PWM mode).

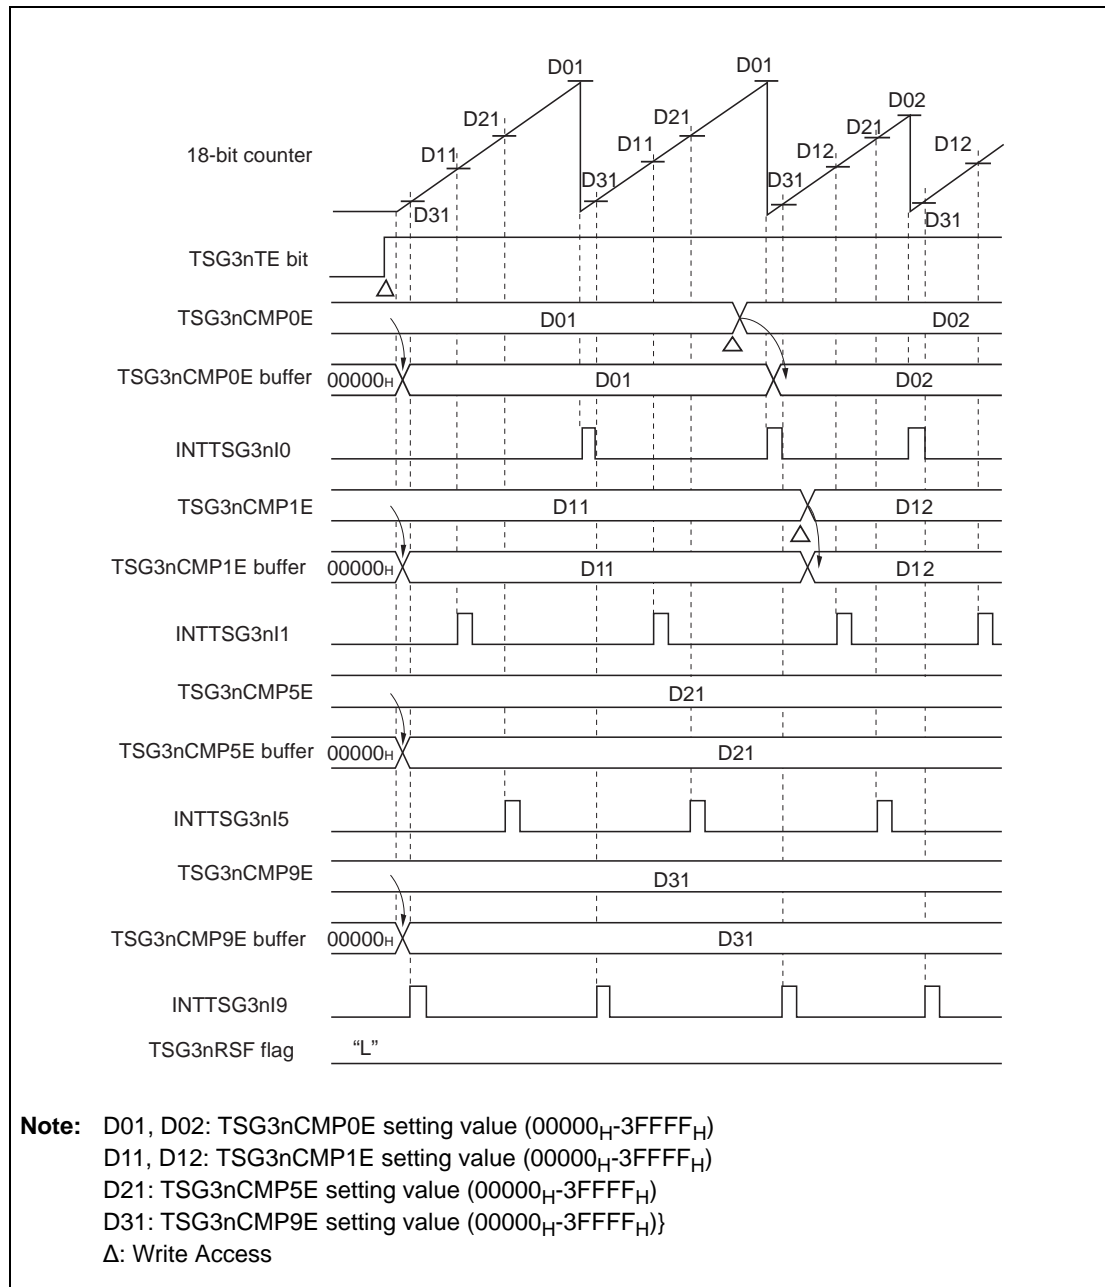

Figure 25.8 Anytime Rewrite Timing (Example in PWM Mode)

(a) Data reflection on PWM in Anytime Rewrite in HT-PWM

In anytime rewrite operation in HT-PWM mode, the values are transferred to the buffer at the timing when 1 is written to the TSG3nIMT bit after the settings of TSG3nCMP1E, 2E, 5E, 6E, 9E and 10E registers are modified and PWM output is forcibly set/cleared depending on the modified set value.

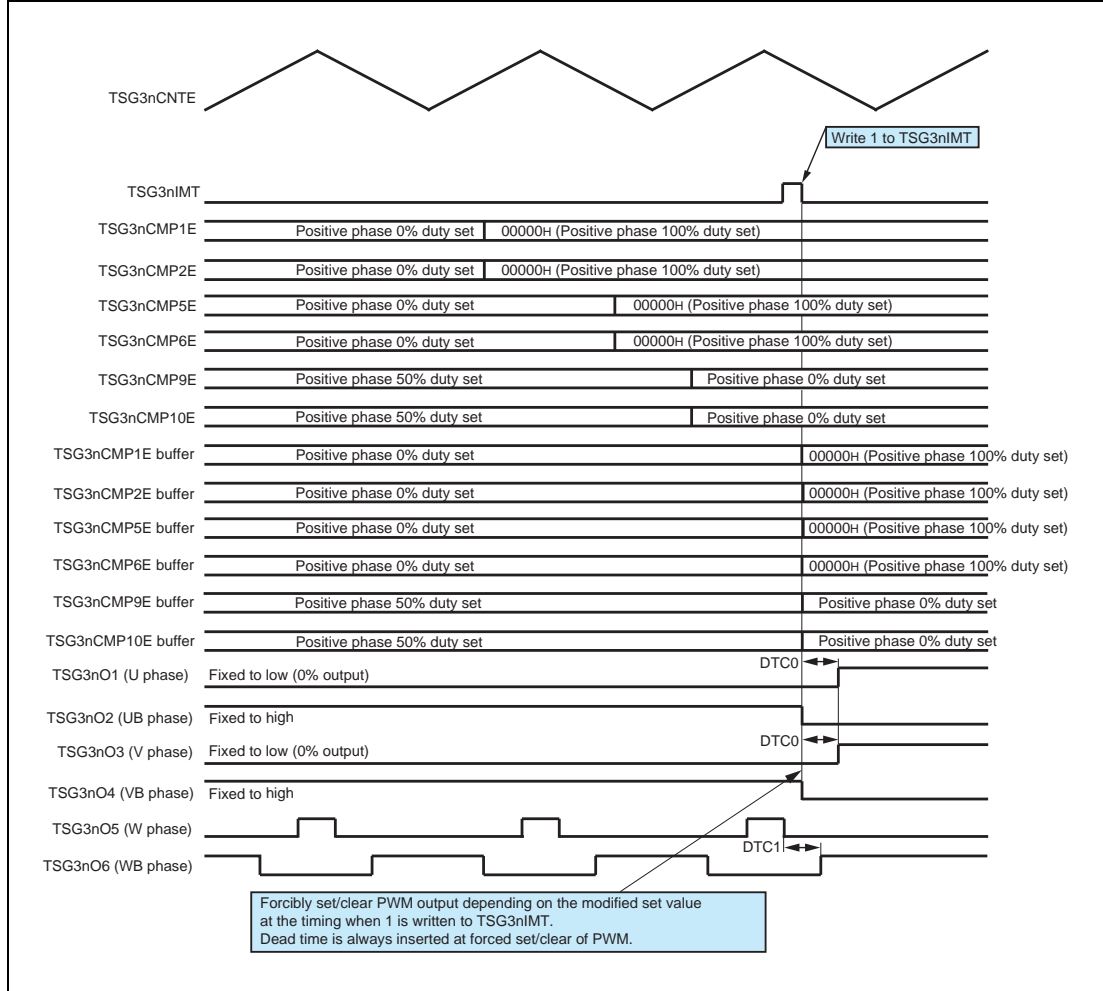

Figure 25.9 Update Timing of TSG3nCMP1E, 2E, 5E, 6E, 9E, and 10E at Anytime Rewrite Operation in HT-PWM Mode

(2) Example of Operation in Reload Mode (Simultaneous Rewrite Function)

The rewritten values of the registers to be reloaded (the registers listed in the **Section 25.3.1, List of Registers** with “Enabled” in the column of “Reload”) can be transferred to the corresponding buffer registers simultaneously at the reload timing.

The registers should be rewritten when the pertinent reload request flag (TSG3nSTR0.TSG3nRSF) is 0.

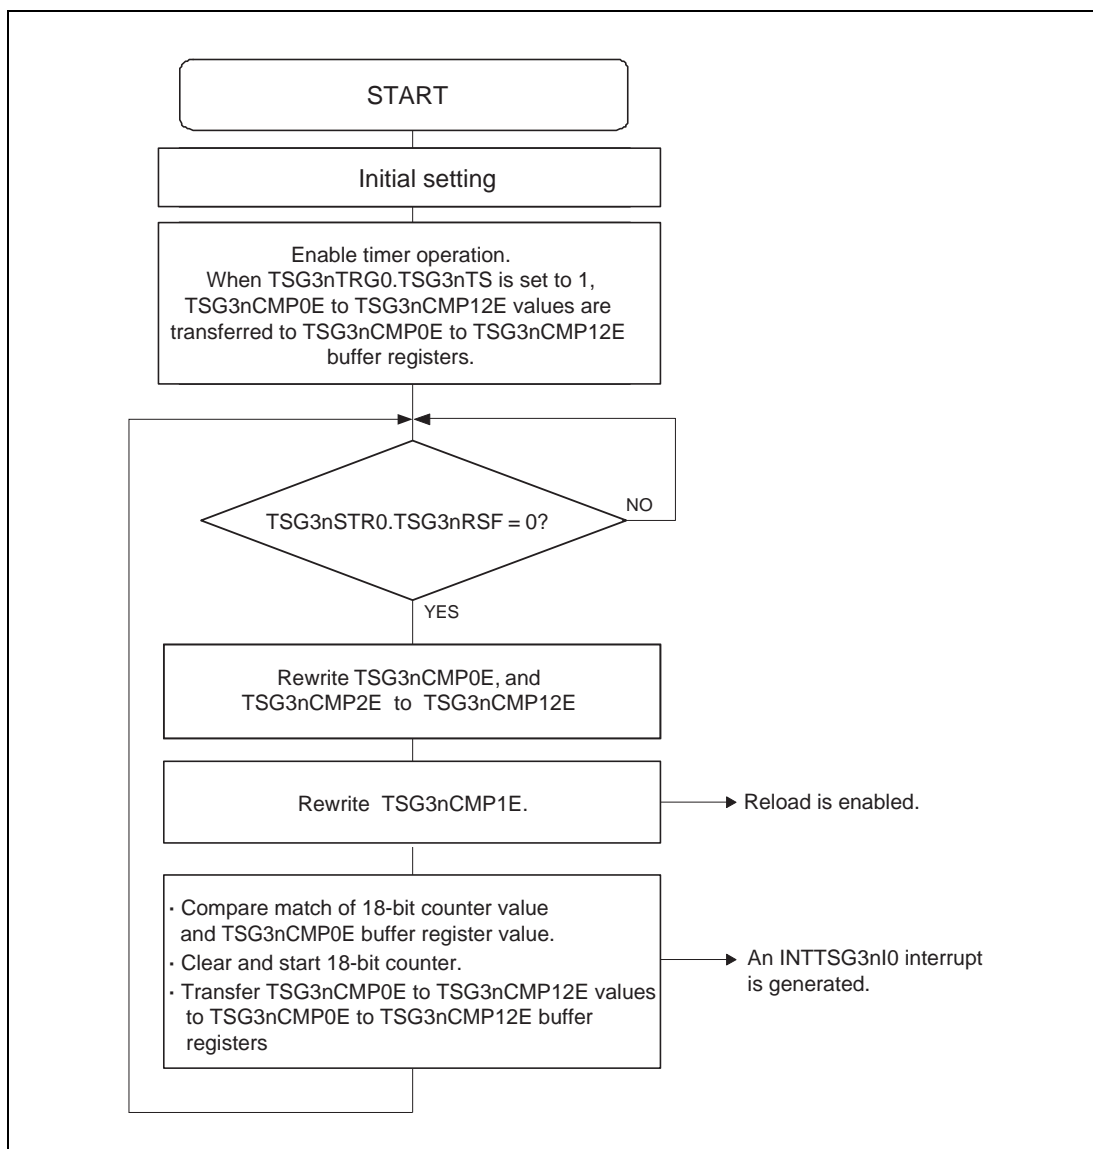

Figure 25.10 Basic Operation Flow in Reload Mode (Simultaneous Rewrite Function) (Example of PWM Mode)

CAUTION

Writing to TSG3nCMP1E also enables reloading. Therefore, TSG3nCMP1E should be rewritten after TSG3nCMP0E and TSG3nCMP2E to TSG3nCMP12E registers have been rewritten.

Figure 25.11 Simultaneous Rewrite Timing (Example of HT-PWM Mode) (1/2)

Figure 25.11 Simultaneous Rewrite Timing (Example of PWM Mode) (2/2)

(a) Reload Rewrite Setting Example in Each Mode

Reloading conditions and setting examples are shown in the following tables.

Table 25.45 List of Reload Settings (when TSG3nCTL3.TSG3nRIA = 0)

Mode	TSG3nCTL4. TSG3nPRE	TSG3nCTL4. TSG3nVRE	TSG3nCTL4. TSG3nPIE	TSG3nCTL4. TSG3nVIE	TSG3nCTL4. TSG3nRCC04- TSG3nRCC00	Reload
PWM mode	0	0/1	0/1	0/1	Any value	Setting prohibited
SP-PWM mode	1	0	0/1	0/1	Any value	When INTTSG3nI0 is generated.

	0	1	1	1	Any value	When INTTSG3nIVLY is generated
	1	0	0	0/1	Any value	Setting prohibited
	1	0	1	0/1	Any value	When INTTSG3nIPEK is generated
	1	1	0	0	Any value	Setting prohibited
	1	1	0	1	Any value	When INTTSG3nIVLY is generated
	1	1	1	0	Any value	When INTTSG3nIPEK is generated
	1	1	1	1	Any value	When INTTSG3nIPEK or INTTSG3nIVLY is generated

25.4.1.4 List of Outputs in Each Mode

The list of timer outputs (TSG3nO0-7 pins) in each mode is shown in the following tables.

Table 25.47 List of Timer Outputs in Each mode (1/3)

Operating Mode	TSG3nO0 Pin	TSG3nO1 Pin	TSG3nO2 Pin
PWM mode	— (Fixed to low.)	Outputs a PWM signal by compare match of TSG3nCMP1E and TSG3nCMP2E.	Outputs a PWM signal by compare match of TSG3nCMP3E and TSG3nCMP4E.
HT-PWM mode	Outputs the status indicating whether the 18-bit counter or 18-bit sub-counter is incremented or decremented.	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP1E and TSG3nCMP2E.	Outputs an inverse phase PWM signal (with dead time) to TSG3nO1 pin.
SP-PWM mode	— (Fixed to low.)	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP1E and TSG3nCMP2E.	Outputs an inverse phase PWM signal (with dead time) to TSG3nO1.
120-DC mode	— (Fixed to low.)	Outputs a PWM signal by TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E.	Outputs a PWM signal by TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, and TSG3nCMP12E.
HSP-PWM mode	— (Fixed to low.)	Outputs a PWM signal by compare match of TSG3nCMP1E and TSG3nCMP2E.	Outputs a PWM signal by compare match of TSG3nCMP3E and TSG3nCMP4E.

Table 25.47 List of Timer Outputs in Each mode (2/3)

Operating Mode	TSG3nO3 Pin	TSG3nO4 Pin	TSG3nO5 Pin
PWM mode	Outputs a PWM signal by compare match of TSG3nCMP5E and TSG3nCMP6E.	Outputs a PWM signal by compare match of TSG3nCMP7E and TSG3nCMP8E.	Outputs a PWM signal by compare match of TSG3nCMP9E and TSG3nCMP10E.
HT-PWM mode	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP5E and TSG3nCMP6E.	Outputs an inverse phase PWM signal (with dead time) to TSG3nO3.	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP9E and TSG3nCMP10E.
SP-PWM mode	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP5E and TSG3nCMP6E.	Outputs an inverse phase PWM signal (with dead time) to TSG3nO3.	Outputs a positive phase PWM signal (with dead time) by compare match of TSG3nCMP9E and TSG3nCMP10E.
120-DC mode	Outputs a PWM signal by TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E.	Outputs a PWM signal by TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, and TSG3nCMP12E.	Outputs a PWM signal by TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E.
HSP-PWM mode	Outputs a PWM signal by compare match of TSG3nCMP5E and TSG3nCMP6E.	Outputs a PWM signal by compare match of TSG3nCMP7E and TSG3nCMP8E.	Outputs a PWM signal by compare match of TSG3nCMP9E and TSG3nCMP10E.

Table 25.47 List of Timer Outputs in Each mode (3/3)

Operating Mode	TSG3nO6 Pin	TSG3nO7 Pin
PWM mode	Outputs a PWM signal by compare match of TSG3nCMP11E and TSG3nCMP12E.	Outputs a diagnostic signal or A/D conversion trigger.* ¹
HT-PWM mode	Outputs an inverse phase PWM signal (with dead time) to TSG3nO5.	Outputs a diagnostic signal or A/D conversion trigger.* ¹
SP-PWM mode	Outputs an inverse phase PWM signal (with dead time) to TSG3nO5.	Outputs a diagnostic signal or A/D conversion trigger.* ¹
120-DC mode	Outputs a PWM signal by TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, and TSG3nCMP12E.	Outputs a diagnostic signal or A/D conversion trigger.* ¹
HSP-PWM mode	Outputs a PWM signal by compare match of TSG3nCMP11E and TSG3nCMP12E.	Outputs a diagnostic signal or A/D conversion trigger.* ¹

Note 1. For TSG3nO7, See **Section 25.4.1.4 (a), TSG3nO7 Pin Output Control**

(a) TSG3nO7 Pin Output Control

The TSG3nO7 pin can output a pulse of A/D conversion trigger (TSG3nIOC1.TSG3nTGS = 0) or diagnostic output (TSG3nIOC1.TSG3nTGS = 1). When outputting a pulse of A/D conversion trigger, the TSG3nO7 pin is activated at the rising edge of the TSG3nADTRG0 signal, and inactivated at the rising edge of the TSG3nADTRG1 signal. When the TSG3nADTRG0 signal is detected while the TSG3nO7 pin is active, the TSG3nO7 pin remains active. When the TSG3nADTRG1 signal is detected while the TSG3nO7 pin is inactive, the TSG3nO7 pin remains inactive. If TSG3nADTRG0 and TSG3nADTRG1 signal triggers occur simultaneously, the TSG3nO7 pin is inactivated.

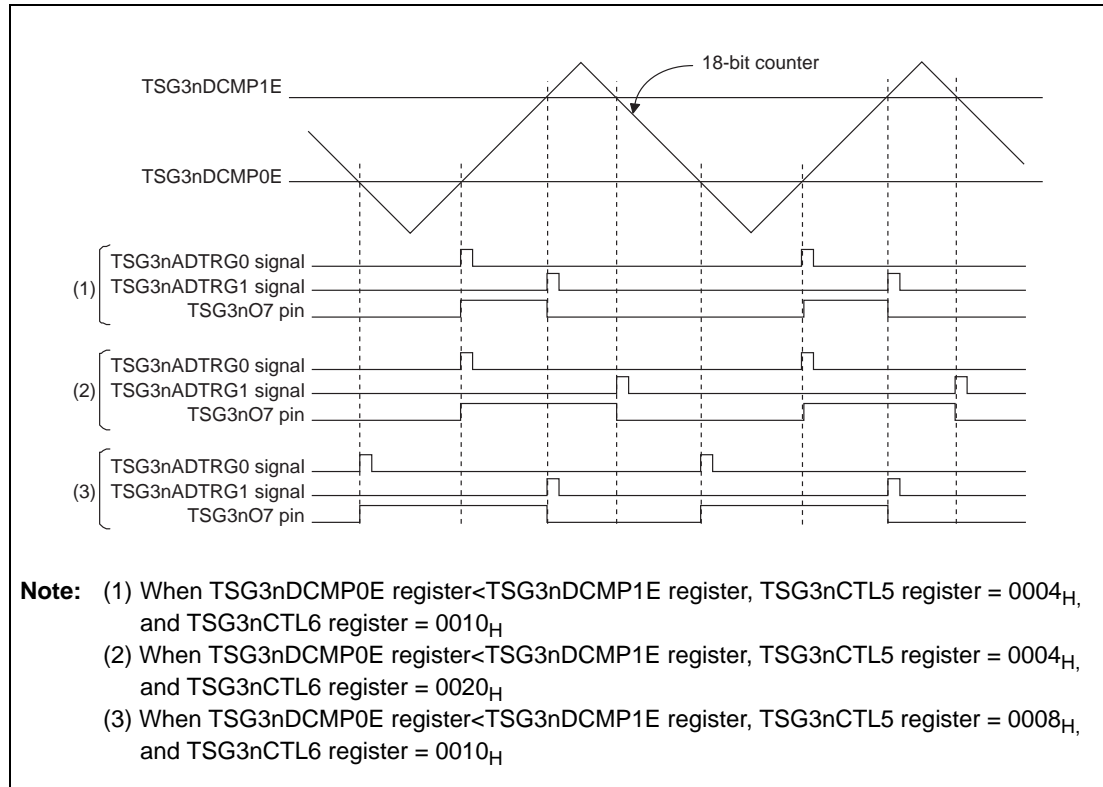

Figure 25.12 Example of A/D Trigger Output Timing of TSG3nO7 Pin (TSG3nIOC1.TSG3nTGS = 0)

During diagnostic output, the active level is output on the TSG3nO7 pin with the width specified by the TSG3nCTL0.TSG3nDWD bit when the values of the TSG3nDCMP0E to TSG3nDCMP2E bits match that of the 18-bit counter. If a TSG3nDCMP0E to TSG3nDCMP2E value again matches the value of the 18-bit counter value while the diagnostic output on the TSG3nO7 pin is already at the active level, pulse output on the TSG3nO7 pin continues for the number of cycles of PCLK (8 or 16) set by the TSG3nDWD bit from the point of the later match.

Figure 25.13 Example of TSG3nO7 Pin Diagnostic Pulse Output Timing (1) (TSG3nIOC1.TSG3nTGS = 1)

Figure 25.14 Example of TSG3nO7 Pin Diagnostic Pulse Output Timing (2) (with Pulse Output Width Overlapped)

25.4.1.5 Restart

Setting TSG3nTRG0.TSG3nTS to 1 or input to TSG3nTSST while the timer is operating (TSG3nSTR0.TSG3nTE = 1) leads to the following operations.

- Initializing the following counters;
 - 18-bit main counter, 18-bit sub-counter, interrupt skipping counter
- Initializing the following flags;
 - TSG3nCUF, TSG3nSUF, TSG3nRSF, and TSG3nTE of the TSG3nSTR0 register
 - TSG3nOPF2 to TSG3nOPF0 of the TSG3nSTR1 register (TSG3nTSF is not initialized)
 - TSG3nPPF, TSG3nPEF, TSG3nTDF, TSG3nNDF, TSG3nPRF, and TSG3nPTF of the TSG3nSTR2 register (TSG3nTBF2 to TSG3nTBF20 are not initialized)
- Reloading the following registers;
 - TSG3nCTL2, TSG3nCTL4, TSG3nIOC3, TSG3nCMP0, TSG3nCMP0E, TSG3nCMPmW (m = 1, 3, 5, 7, 9, or 11)
 - TSG3nCMP1 to TSG3nCMP12, TSG3nCMP1E to TSG3nCMP12E
 - TSG3nDCMP0W, TSG3nDCMP2, TSG3nDCMP0E to TSG3nDCMP2E
 - TSG3nPAT0W, TSG3nPAT1W
 - TSG3nCMPU, TSG3nCMPV, TSG3nCMPW
 - TSG3nCMPUE, TSG3nCMPVE, TSG3nCMPWE
 - TSG3nUPW, TSG3nVPW, TSG3nWPW
 - TSG3nUPWE, TSG3nVPWE, TSG3nWPWE
 - TSG3nHSPSHUE, TSG3nHSPSHVE, TSG3nHSPSHWE
 - TSG3nHSPCMUE, TSG3nHSPCMVE, TSG3nHSPCMWE
- Reflecting the settings in the following register;
 - TSG3nOPT0*¹

The dead time is always inserted because the dead time counter continues counting while the dead time control registers TSG3nDTC0W and TSG3nDTC1W are reloaded on restart.

If the counter is restarted while diagnostic output is in progress, the output is initialized.

Note 1. The settings in the TSG3nOPT0 register bits are reflected at the timings described below:

For TSG3nSOC

Switching from 0 to 1: immediately after written

Switching from 1 to 0: when the register is reloaded

For TSG3nSTE, TSG3nPOT, TSG3nPSS, TSG3nIDC, and TSG3nPSC

- At the next timer cycle
- When the output patterns are switched

25.4.2 Match Interrupt

The TSG3n can generate interrupts such as a compare match interrupt (INTTSG3nIm), a peak interrupt (INTTSG3nIPEK), and a valley interrupt (INTTSG3nIVLY). For an error interrupt and warning interrupt (INTTSG3nIER and INTTSG3nIWN), see **Section 25.4.6, Error/Warning Interrupt**.

A period interrupt (INTTSG3nI0) is generated for each timer period. In HT-PWM mode, it is generated when the TSG3nDTC0 buffer register value matches with the 18-bit counter value. When the 18-bit counter performs sawtooth waveform operation (PWM mode, SP-PWM mode, 120-DC mode, and HSP-PWM mode), it is generated after the 18-bit counter value has matched with the TSG3nCMP0E buffer register value.

A compare-match interrupt (INTTSG3nIm) is generated by a match of the TSG3nCMPmE buffer register value with the 18-bit counter value depending on the compare register to be used in each operating mode (m = 1 to 12).

A peak interrupt (INTTSG3nIPEK) is generated in all the modes. In HT-PWM mode, it is generated when the 18-bit counter switches from incrementing to decrementing. When the 18-bit counter performs sawtooth waveform operation (PWM mode, SP-PWM mode, 120-DC mode, and HSP-PWM mode), it is generated after the 18-bit counter value has matched with the TSG3nCMP0E buffer register value (the same timing as an INTTSG3nI0 interrupt).

A valley interrupt (INTTSG3nIVLY) is generated when the 18-bit counter switches from decrementing to incrementing in HT-PWM mode.

Figure 25.15 Interrupt Generation Example (Example of HT-PWM Mode)

Figure 25.16 Interrupt Generation Example (Example of PWM Mode)

Interrupt in each mode (INTTSG3nI0-INTTSG3nI12, INTTSG3nIPEK, INTTSG3nIVLY, INTTSG3nIER, and INTTSG3nIWN) are listed in **Table 25.48**

Table 25.48 List of Interrupts in Each Mode (1/5)

Operating Mode	INTTSG3nI0	INTTSG3nI1	INTTSG3nI2	INTTSG3nI3
PWM mode	TSG3nCMP0E compare match interrupt	TSG3nCMP1E compare match interrupt*1	TSG3nCMP2E compare match interrupt*1	TSG3nCMP3E compare match interrupt*1
HT-PWM mode	Period interrupt	TSG3nCMP1E compare match interrupt*2 when decrementing (TSG3nCUF = 1)	TSG3nCMP2E compare match interrupt*2 when incrementing (TSG3nCUF = 0)	TSG3nCMP3E compare match interrupt*2 when decrementing (TSG3nCUF = 1)
SP-PWM mode	TSG3nCMP0E compare match interrupt	TSG3nCMP1E compare match interrupt*1	TSG3nCMP2E compare match interrupt*1	—
120-DC mode	TSG3nCMP0E compare match interrupt	TSG3nCMP1E compare match interrupt*1	TSG3nCMP2E compare match interrupt*1	TSG3nCMP3E compare match interrupt*1
HSP-PWM mode	TSG3nCMP0E compare match interrupt	TSG3nCMP1E compare match interrupt*1	TSG3nCMP2E compare match interrupt*1	TSG3nCMP3E compare match interrupt*1

Note 1. A compare match interrupt is not generated when $TSG3nCMP0E < TSG3nCMPmE$ ($m = 1$ to 12).

Note 2. A compare match interrupt is not generated when $00000_H \leq TSG3nCMPmE < TSG3nDTC0$, $(TSG3nCMP0E + TSG3nDTC0) < TSG3nCMPmE$.

Table 25.48 List of Interrupts in Each Mode (2/5)

Operating Mode	INTTSG3nI4	INTTSG3nI5	INTTSG3nI6	INTTSG3nI7

25.4.3 Flags

Table 25.49 List of Flags

Number	Flag Name	Symbol	Registers	Operating Mode
(1)	Up count flag	TSG3nCUF	TSG3nSTR0	HT-PWM mode
		TSG3nSUF	TSG3nSTR0	
(2)	Positive phase and inverse phase simultaneous active state detection flag	TSG3nTBF0- TSG3nTBF2	TSG3nSTR2	All operating modes
(3)	Reload request flag	TSG3nRSF	TSG3nSTR0	All operating modes
(4)	Noise Detection Flag	TSG3nNDF	TSG3nSTR2	All operating modes
(5)	Pattern order detection flag	TSG3nTSF	TSG3nSTR1	All operating modes
(6)	Pattern error detection flag	TSG3nPEF	TSG3nSTR2	All operating modes
(7)	Pattern reversal detection flag	TSG3nPRF	TSG3nSTR2	All operating modes
(8)	TSG3nPTSI2 to TSG3nPTSI0 pin abnormal toggle detection flag	TSG3nPTF	TSG3nSTR2	All operating modes
(9)	TSG3nOPCI0 and TSG3nOPCI1 signal simultaneous trigger detection flag	TSG3nTDF	TSG3nSTR2	All operating modes
(10)	Pattern phase difference detection flag	TSG3nPPF	TSG3nSTR2	All operating modes
(11)	Timer output pattern flag	TSG3nOPF0 to TSG3nOPF2	TSG3nSTR1	All operating modes
(12)	Pattern switch detection signal (internal signal)	TSG3nPTE	—	All operating modes

25.4.3.1 Up Count Flag (TSG3nCUF and TSG3nSUF)

Name

Up count flag (TSG3nSTR0.TSG3nCUF and TSG3nSUF)

Description

There are following two up count flags.

TSG3nCUF is an up/down count flag of the 18-bit counter.

TSG3nSUF is an up/down count flag of the 18-bit sub-counter.

For both TSG3nCUF and TSG3nSUF, 0 means increment, and 1 means decrement.

TSG3nCUF and TSG3nSUF can be used only in HT-PWM mode.

Example of operation

Figure 25.17 Example of Up count flag operation

NOTES

1. TSG3nCUF value is:
 - 0 (up count) when $TSG3nDTC0 \leq 18\text{-bit counter} \leq (TSG3nCMP0E + TSG3nDTC0 - 2)$
 - 1 (down count) when $(TSG3nCMP0E + TSG3nDTC0) \geq 18\text{-bit counter} \geq TSG3nDTC0 + 2$
2. TSG3nSUF value is:
 - 0 (up count) when $0 \leq 18\text{-bit sub-counter} \leq (TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 - 2)$
 - 1 (down count) when $(TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1) \geq 18\text{-bit sub-counter} \geq 2$

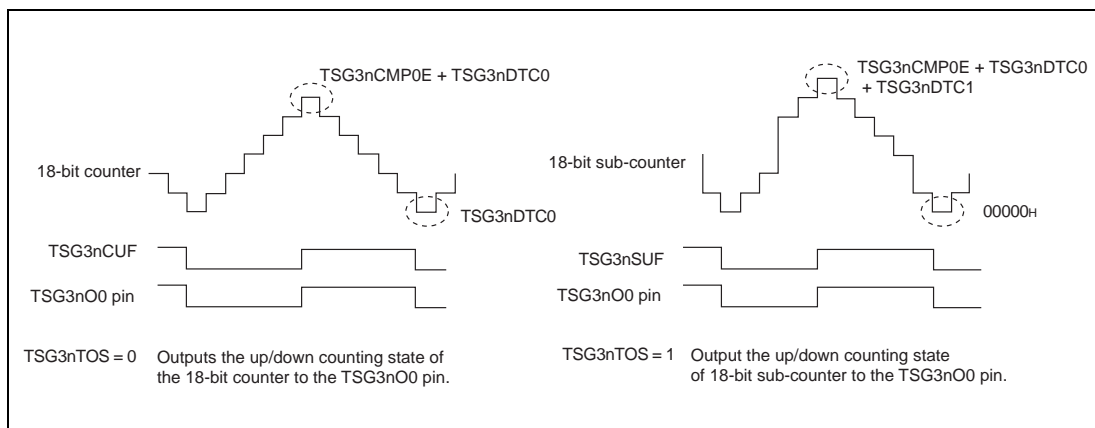

Figure 25.18 TSG3n00 Pin Output depending on TSG3nIOC1.TSG3nTOS Setting

Operating Mode

TSG3nCUF and TSG3nSUF can be used only in HT-PWM mode.

25.4.3.2 Positive Phase and Inverse Phase Simultaneous Active State Detection Flag (TSG3nTBF0 to TSG3nTBF2)

Name

Positive phase and inverse phase simultaneous active state detection flag (TSG3nSTR2.TSG3nTBF0 to TSG3nTBF2 flags)

Description

When any of TSG3nCTL1.TSG3nTBA2 to TSG3nTBA0 is 1, TSG3nTBF0 to TSG3nTBF2 can detect the simultaneous active state of the positive phase and inverse phase of TSG3n.

When the simultaneous active state of the positive phase and inverse phase of the TSG3n is detected, the corresponding TSG3nTBF0 to TSG3nTBF2 flags are set to 1, and an error interrupt (INTTSG3nIER) is generated. The flags are cleared when 1 is written to TSG3nSTC.TSG3nTBR0 to TSG3nTBR2, respectively.

Example of operation

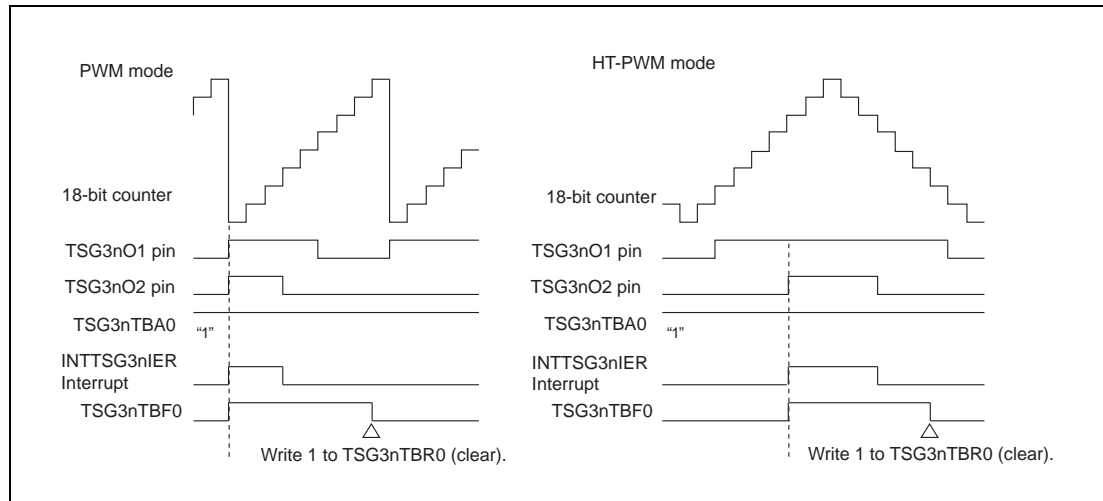

Figure 25.19 Example of Positive Phase and Inverse Phase Simultaneous Active State Detection Flag Operation

Operating Mode

Available in all operating modes.

CAUTION

TSG3nTBF0 to TSG3nTBF2 are valid only when TSG3nCTL1.TSG3nTBA0 to TSG3nTBA2 = 1 and TSG3nSTR0.TSG3nTE = 1.

25.4.3.3 Reload Request Flag (TSG3nRSF)

Name

Reload request flag (TSG3nSTR0.TSG3nRSF)

Description

TSG3nRSF is set to 1 when a reload request is generated (when a value is written to TSG3nCMP1E (TSG3nCMP1, TSG3nCMP1W, TSG3nCMPUE, TSG3nCMPU, TSG3nUPWE, TSG3nUPW, and TSG3nHSPCMUE)), and cleared to 0 when reload occurs and the value is transferred to all the buffer registers.

Example of operation

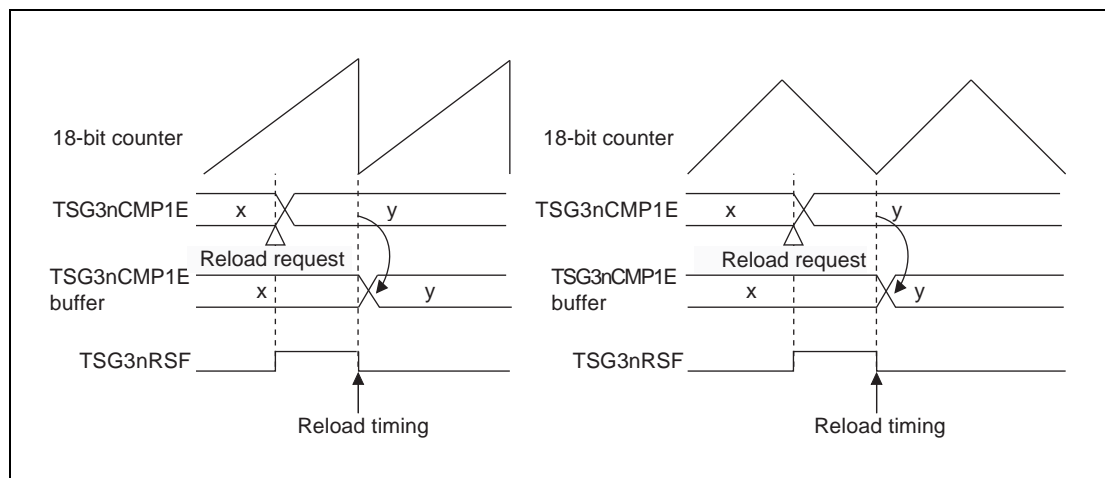

Figure 25.20 Example of Reload Request Flag Operation

Figure 25.21 Reload Request Flag and Reload Skipping Period

Operating Mode

Available in all operating modes.

25.4.3.4 Noise Detection Flag (TSG3nNDF)

Name

Noise detection flag (TSG3nSTR2.TSG3nNDF)

Description

TSG3nNDF can detect that two or more pins of TSG3nPTSI2 to TSG3nPTSI0 have changed simultaneously (a noise is generated).

TSG3nNDF is set to 1 when two or more pins of TSG3nPTSI2 to TSG3nPTSI0 have changed simultaneously (a noise is generated), and a warning interrupt (INTTSG3nIWN) is generated. The TSG3nNDF flag is cleared to 0 when 1 is written to the TSG3nSTC.TSG3nNDR bit.

Example of operation

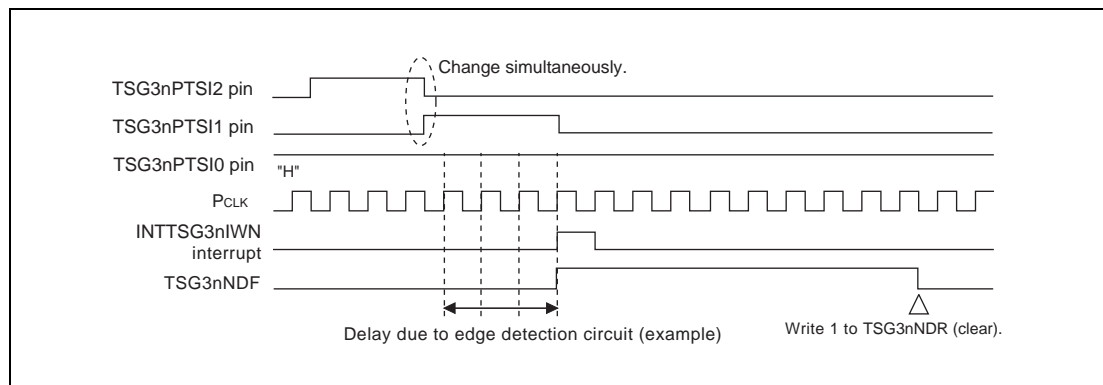

Figure 25.22 Example of Noise Detection Flag Operation

Operation mode

Available in all operating modes.

CAUTION

TSG3nNDF is valid only when TSG3nCTL1.TSG3nNDC = 1 and TSG3nSTR0.TSG3nTE = 1.

25.4.3.5 Pattern Order Detection Flag (TSG3nTSF)

Name

Pattern order detection flag (TSG3nSTR1.TSG3nTSF)

Description

TSG3nTSF can detect the order of patterns input to the TSG3nPTSI2 to TSG3nPTSI0 pins.

TSG3nTSF is set depending on the values input to the TSG3nPTSI2 to TSG3nPTSI0 pins as shown in the table below

Table 25.50 Pattern Order Detection Flag and Pattern Input Order

TSG3nTSF	Values input to TSG3nPTSI2 to TSG3nPTSI0 Pins
0	[1,0,1] → [1,0,0] → [1,1,0] → [0,1,0] → [0,1,1] → [0,0,1]
1	[1,0,1] ← [1,0,0] ← [1,1,0] ← [0,1,0] ← [0,1,1] ← [0,0,1]

Example of operation

(a) When Normal Input to TSG3nPTSI2 to TSG3nPTSI0 Pins is Detected

As shown in **Figure 25.23**, if the TSG3nPTSI2 to TSG3nPTSI0 pins change in the normal order, 0 or 1 is set according to the change order at the change timing.

Figure 25.23 Example of Pattern Order Detection Flag Operation (Normal Operation)

(b) Detection of Change in Input Pattern Order

Immediately after TSG3n starts operation, the rotation direction cannot be determined. Therefore, TSG3nTSF cannot detect the change (normal or reverse rotation) in the patterns input to the TSG3nPTS12 to TSG3nPTS10 pins. To enable detection of change immediately after the beginning of operation, TSG3nPSC should be set before operation starts (when TSG3nTE = 0, the TSG3nPSC value is reflected).

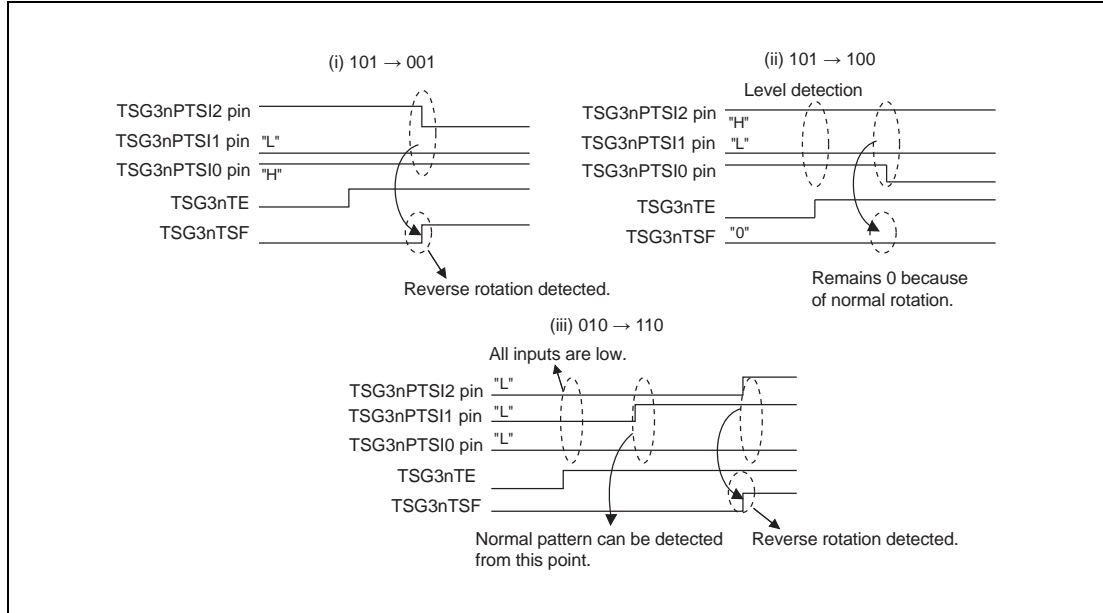

Figure 25.24 Example of Detecting Change (Normal/Reverse Rotation) in Pattern Input to TSG3nPTS12 to TSG3nPTS10 Pins

(c) When Abnormal Input to TSG3nPTS12 to TSG3nPTS10 Pins is Detected

Figure 25.25 Example of Operation when Values Input to Two Pins of TSG3nPTS12 to TSG3nPTS10 Change (Abnormal Operation)

- (1) TSG3nTSF does not change at this point because it expects the input pattern change to {0, 1, 0} or {0, 0, 1} (if values of two pins change, TSG3nTSF does not change).
- (2) TSG3nPTS12 to TSG3nPTS10 pins are determined to have been changed from {1, 0, 1} to {0, 0, 1}, and TSG3nTSF is set to 1.

Operation mode

Available in all operating modes.

25.4.3.6 Pattern Error Detection Flag (TSG3nPEF)

Name

Pattern error detection flag (TSG3nSTR2.TSG3nPEF)

Description

TSG3nPEF can detect that 000 or 111 is input to the TSG3nPTSI2 to TSG3nPTSI0 pins.

TSG3nPEF is set to 1 when the levels of the TSG3nPTSI2 to TSG3nPTSI0 pins are 111 or 000, and a warning interrupt (INTTSG3nIWN) is generated. TSG3nPEF is cleared to 0 when 1 is written to TSG3nSTC.TSG3nPER.

Example of operation

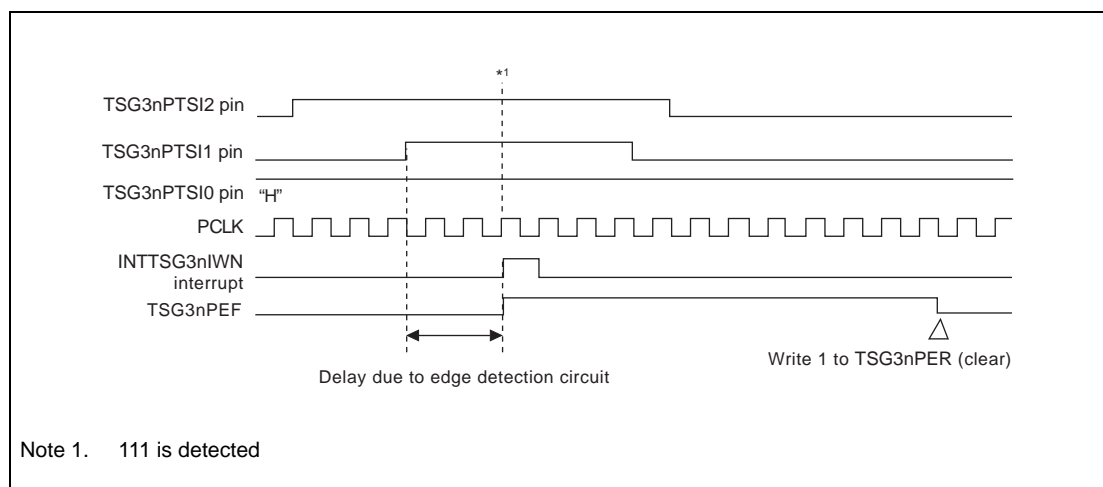

Figure 25.26 Example of Pattern Error Detection Flag Operation (TSG3nPTSI2 to TSG3nPTSI0 Pins = 111)

Operation mode

Available in all operating modes.

CAUTIONS

TSG3nPEF is valid only when TSG3nCTL1.TSG3nPEC = 1 and TSG3nSTR0.TSG3nTE = 1.

25.4.3.7 Pattern Reversal Detection Flag (TSG3nPRF)

Name

Pattern reversal detection flag (TSG3nSTR2.TSG3nPRF)

Description

TSG3nPRF can detect that the pattern change order of the TSG3nPTSI2 to TSG3nPTSI0 pins have been reversed.

TSG3nPRF is set to 1 when the pattern order detection flag (TSG3nTSF) changes, and a warning interrupt (INTTSG3nIWN) is generated. However, immediately after TSG3nSTR0.TSG3nTE is set to 1, TSG3nPRF becomes valid at the timing of the second and subsequent change in TSG3nPTSI2 to TSG3nPTSI0 pins.

TSG3nPRF is cleared to 0 when 1 is written to the TSG3nSTC.TSG3nPRR bit.

Example of operation

Figure 25.27 Example of Pattern Reversal Detection Flag Operation

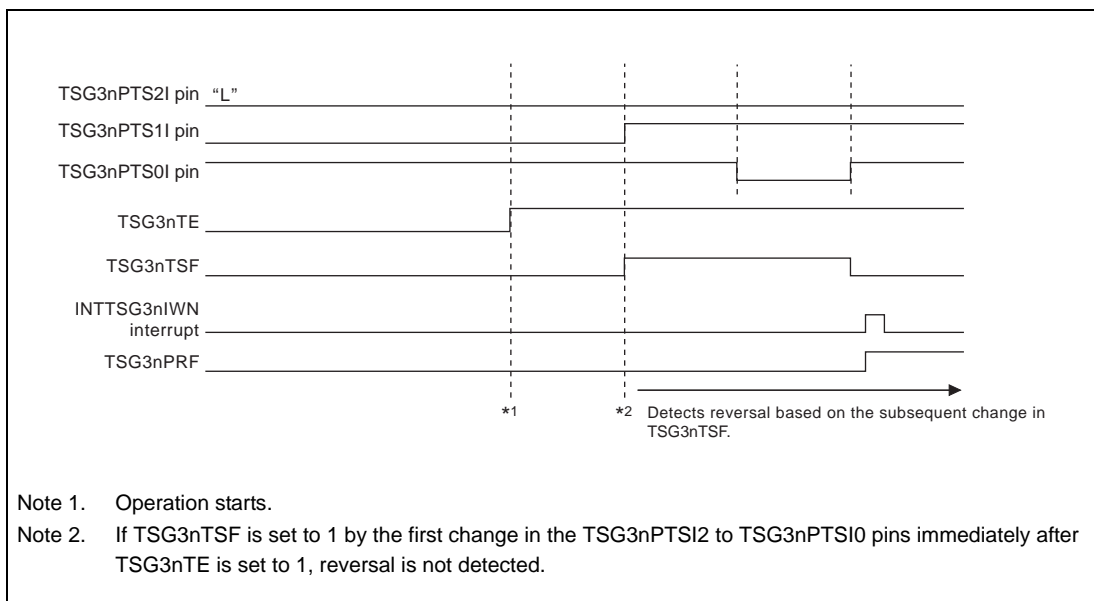

Figure 25.28 Example of Operation immediately after TSG3nTE Flag in TSG3nSTR0 is Set to 1

Operation mode

Available in all operating modes.

CAUTION

TSG3nPRF is valid only when TSG3nCTL1.TSG3nPRC = 1 and TSG3nSTR0.TSG3nTE = 1.

25.4.3.8 TSG3nPTSI2 to TSG3nPTSI0 Pin Abnormal Toggle Detection Flag (TSG3nPTF)

Name

TSG3nPTSI2 to TSG3nPTSI0 pin abnormal toggle detection flag (TSG3nSTR2.TSG3nPTF)

Description

TSG3nPTF can detect that the values of the TSG3nPTSI2 to TSG3nPTSI0 pins change three or more times during the TSG3nOPCI0 or TSG3nOPCI1 signal trigger.

TSG3nPTF is set to 1 when the third trigger of TSG3nOPCI0 or TSG3nOPCI1 signal occurs simultaneously with the change in TSG3nPTSI2 to TSG3nPTSI0, and a warning interrupt (INTTSG3nIWN) is generated.

TSG3nPTF is cleared to 0 when 1 is written to TSG3nSTC.TSG3nPTR.

Example of operation

Figure 25.29 Example of TSG3nPTSI2 to TSG3nPTSI0 Pin Abnormal Toggle Detection Flag Operation

Operating mode

Available in all operating modes.

NOTES

1. TSG3nPTF is valid only when TSG3nCTL1.TSG3nPTC1 bit = 1 and TSG3nSTR0.TSG3nTE = 1.
2. When TSG3nPTC0 bit = 1 and TSG3nPTC1 bit = 1, TSG3nO1 to TSG3nO6 pin output switch control is automatically switched to pattern switch method (TSG3nOPT0.TSG3nPOT bit = 0) if an abnormal toggle is detected.

25.4.3.9 TSG3nOPCI0 and TSG3nOPCI1 Signal Simultaneous Trigger Detection Flag (TSG3nTDF)

Name

TSG3nOPCI0 and TSG3nOPCI1 signal simultaneous trigger detection flag (TSG3nSTR2.TSG3nTDF)

Description

TSG3nTDF can detect that TSG3nOPCI0 and TSG3nOPCI1 signals are generated simultaneously.

TSG3nTDF is set to 1 when the TSG3nOPCI0 and TSG3nOPCI1 signals are generated simultaneously, and a warning interrupt (INTTSG3nIWN) is generated. TSG3nTDF is cleared to 0 when 1 is written to TSG3nSTC.TSG3nTDR.

Example of operation

Figure 25.30 Example of TSG3nOPCI0 and TSG3nOPCI1 Signal Simultaneous Trigger Detection Flag Operation

Operating mode

Available in all operating modes.

CAUTION

TSG3nTDF is valid only when TSG3nCTL1.TSG3nTDC = 1 and TSG3nSTR0.TSG3nTE = 1.

25.4.3.10 Pattern Phase Difference Detection Flag (TSG3nPPF)

Name

Pattern phase difference detection flag (TSG3nSTR2.TSG3nPPF)

Description

TSG3nPPF can detect the phase difference between the input pattern (TSG3nPTS12 to TSG3nPTS10 pins) and the output pattern (TSG3nSTR1.TSG3nOPF2 to TSG3nOPF0 flags).

TSG3nPPF is set to 1 when the pattern phase difference is detected when the TSG3nOPCI0 and TSG3nOPCI1 signal triggers are input, and a warning interrupt (INTTSG3nIWN) is generated. TSG3nPPF remains 1 until it is cleared to 0 when 1 is written to TSG3nSTC.TSG3nPPR by software. When the phase difference is detected, TSG3nPPF is set at each operation clock cycle (PCLK). TSG3nPPF should be cleared to 0 when no phase difference occurs.

Table 25.51 Correspondence between Normal Input Patterns and Output Patterns

TSG3nPTS12 to TSG3nPTS10 pins (input)	"1,0,1"	"1,0,0"	"1,1,0"	"0,1,0"	"0,1,1"	"0,0,1"
TSG3nOPF2 to TSG3nOPF0 flags (output)	"0,0,1"	"1,0,1"	"1,0,0"	"1,1,0"	"0,1,0"	"0,1,1"
	"1,0,1"	"1,0,0"	"1,1,0"	"0,1,0"	"0,1,1"	"0,0,1"
	"1,0,0"	"1,1,0"	"0,1,0"	"0,1,1"	"0,0,1"	"1,0,1"

Example of operation

Figure 25.31 Example of Pattern Difference Detection Flag Operation

Operating mode

Available in all operating modes.

CAUTIONS

1. TSG3nPPF is valid only when TSG3nCTL1.TSG3nPPC = 1 and TSG3nSTR0.TSG3nTE = 1.
2. When 000 or 111 is input to the TSG3nPTS12 to TSG3nPTS10 pins, or when TSG3nOPF2 to TSG3nOPF0 are set to 000 or 111, TSG3nPPF is not set.

25.4.3.11 Timer Output Pattern Flag (TSG3nOPF2-TSG3nOPF0)

Name

Timer output pattern flag (TSG3nSTR1.TSG3nOPF2 to TSG3nOPF0)

Description

TSG3nOPF2 to TSG3nOPF0 flags indicate the timer output patterns.

For details, see **Section 25.4.7.4, 120-DC Mode**, and **Section 25.4.7.8, Software Output Control Function**.

Operating mode

Available in all operating modes.

25.4.3.12 Pattern Switch Detection Signal (TSG3nPTE)

Name

Pattern switch detection signal (TSG3nPTE signal)

Description

The TSG3nPTE signal toggles when the input pattern (TSG3nPTSI2 to TSG3nPTSI0 pins) changes.

The toggle pattern is determined by the TSG3nPSC bit (TSG3nOPT0.TSG3nPSS = 1).

Table 25.52 Change Timing of Pattern Switch Detection Signal (1/2)

- TSG3nPSC = 0

		TSG3nPTSI2-TSG3nPTSI0 Pins after Change							
		000	111	101	100	110	010	011	001

Example of operation

Figure 25.32 Example of Pattern Switch Detection Signal Operation

Operating mode

Available in all operating modes.

CAUTION

The TSG3nPTE signal is valid only when TSG3nIOC1.TSG3nPTS = 1 and TSG3nSTR0.TSG3nTE = 1.

25.4.4 Interrupt Skipping Function

Operation related to the interrupt skipping function is described below.

- Peak interrupts (INTTSG3nIPEK) and valley interrupts (INTTSG3nIVLY) can be skipped.
- TSG3nCTL4.TSG3nPIE enables outputting of the INTTSG3nIPEK interrupt and specifies whether to skip the interrupts.
- TSG3nCTL4.TSG3nVIE enables outputting of the INTTSG3nIVLY interrupt and specifies whether to skip the interrupts.

When TSG3nCTL3.TSG3nRIA is set to 1 (with reload skipping), reload is executed at the same timing as the interrupt after being skipped.

When TSG3nCTL3.TSG3nRIA is set to 0 (without reload skipping), reload is executed at the specified reload timing regardless of interrupt skipping.

CAUTION

When a value is written to TSG3nCTL4, and TSG3nRCC04 to TSG3nRCC00 are transferred to the buffer register, the interrupt skipping counter is cleared. Therefore, when the interrupt skipping function is used, interrupt interval may temporarily become longer. To avoid this, the interrupt skipping count should be changed with the reload timing being set to the interrupts skipped (TSG3nCTL3.TSG3nRIA = 1).

25.4.4.1 Operation of Interrupt Skipping Function

Timing diagram of interrupt skipping function in various conditions are shown in the following figures.

Figure 25.33 Interrupt Skipping Operation when TSG3nPIE = 1 and TSG3nVIE = 1 in TSG3nCTL4 Register (Peak and Valley Interrupt Generation in HT-PWM Mode)

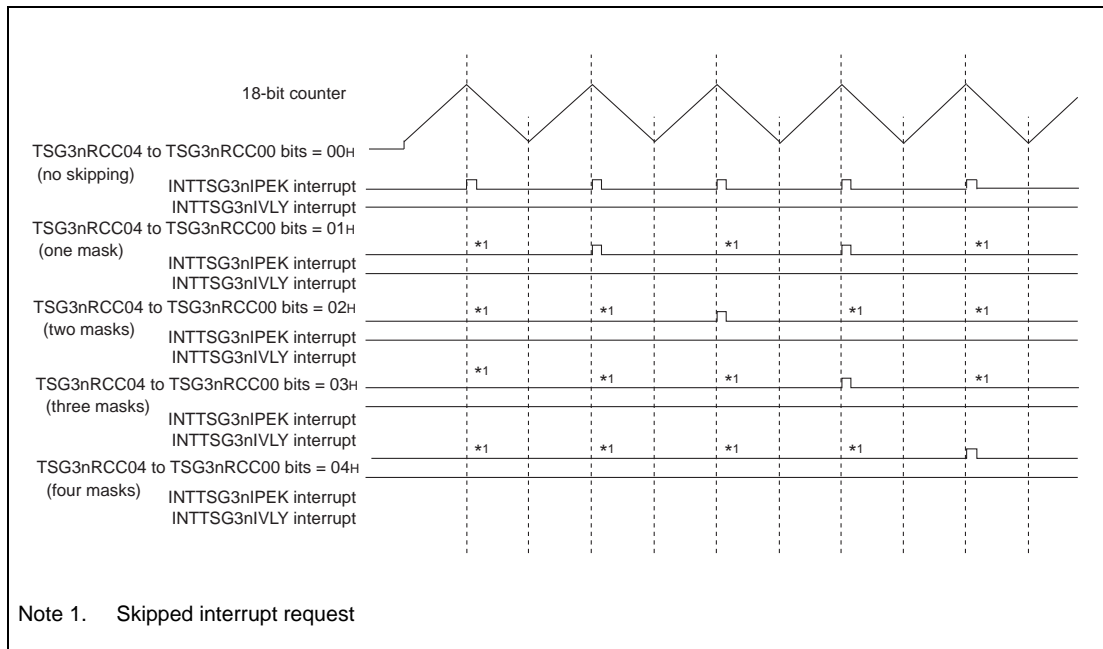

Figure 25.34 Interrupt Skipping Operation when TSG3nPIE = 1 and TSG3nVIE = 0 in TSG3nCTL4 Register (only Peak Interrupt Generation in HT-PWM Mode)

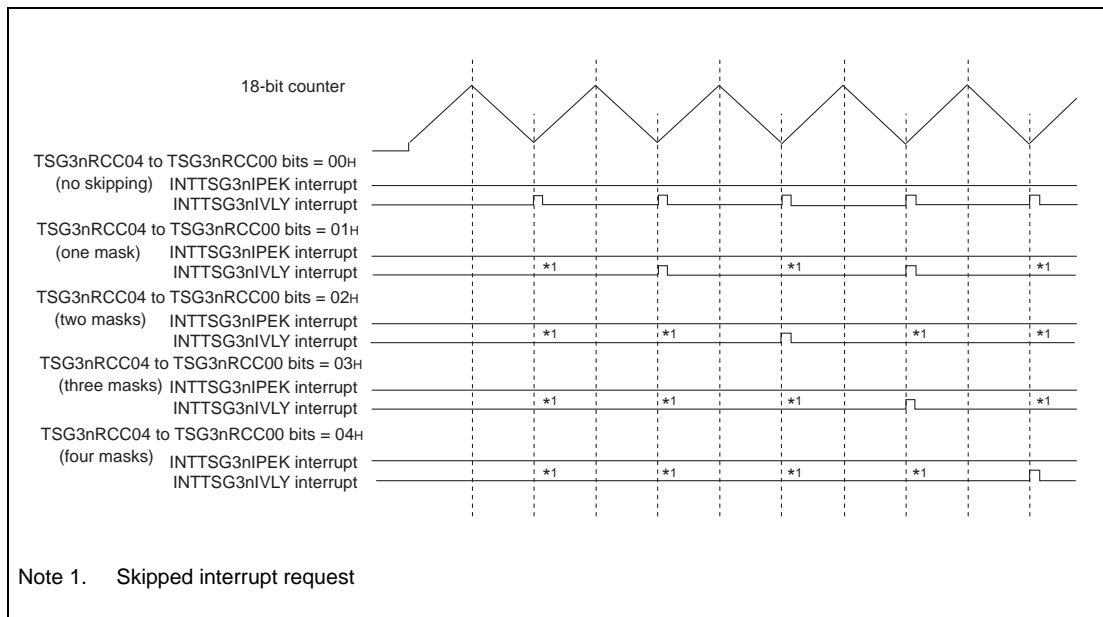

Figure 25.35 Interrupt Skipping Operation when TSG3nPIE = 0 and TSG3nVIE = 1 in TSG3nCTL4 Register (only Valley Interrupt Generation in HT-PWM Mode)

Figure 25.36 When TSG3nRMC = 0, TSG3nRIA = 1 in TSG3nCTL3 Register (with Reload Skipping)

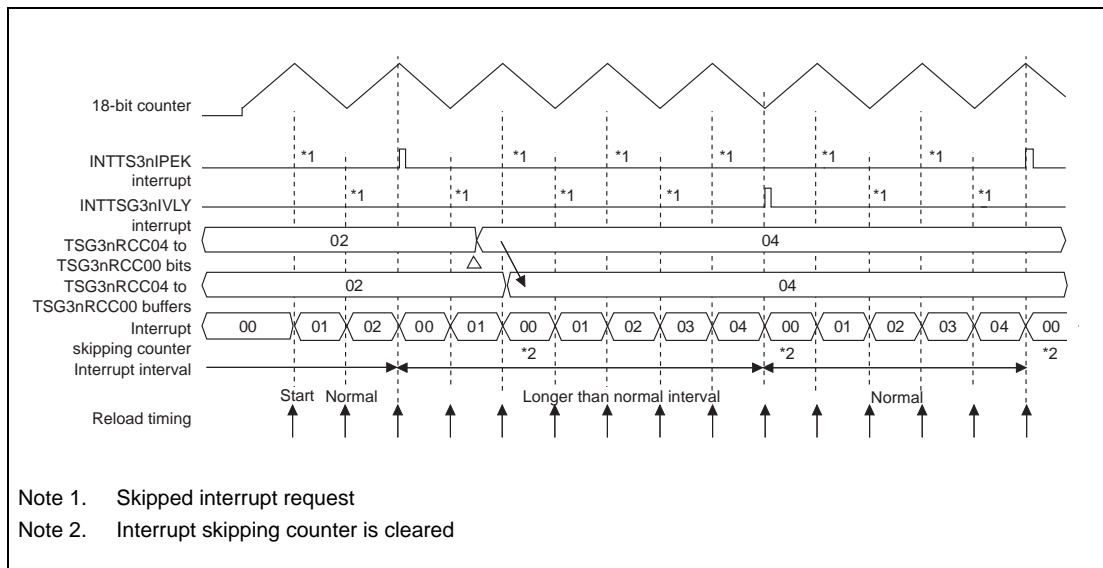

Figure 25.37 When TSG3nRMC = 0, TSG3nRIA = 0 in TSG3nCTL3 Register (without Reload Skipping)

CAUTION

Interrupt interval might be longer.

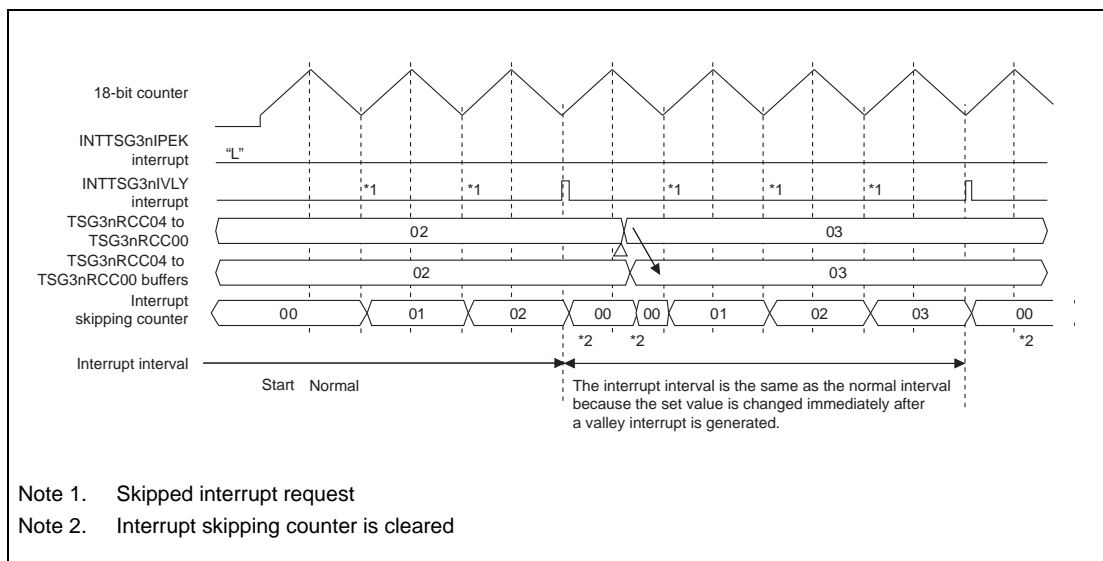

Figure 25.38 When TSG3nRMC = 1 in TSG3nCTL3 Register (Anytime Rewrite Mode)

NOTE

After rewriting, the value is reflected immediately regardless of the reload timing. The interrupt skipping counter is cleared when the value is transferred to the TSG3nRCC04 to TSG3nRCC00 buffers, not when the pertinent register is rewritten.

25.4.4.2 Example of Operation when Peak Interrupt is Generated (in PWM Mode)

Operation related to the interrupt skipping function in PWM mode is described below.

- Peak interrupts (INTTSG3nIPEK) can be skipped. In PWM mode, it is generated by compare match of TSG3nCMP0E buffer register and 18-bit counter.
- TSG3nCTL4.TSG3nPIE enables outputting of the INTTSG3nIPEK interrupt and specifies whether to skip the interrupts.
- The setting of TSG3nCTL4.TSG3nVIE is disabled. At this time, the INTTSG3nIVLY interrupt is not generated.

When TSG3nCTL3.TSG3nRIA is set to 1 (with reload skipping), reload is executed at the same timing as the interrupt after being skipped.

CAUTION

When a value is written to TSG3nCTL4, and TSG3nRCC04 to TSG3nRCC00 are transferred to the buffer register, the interrupt skipping counter is cleared. Therefore, when the interrupt skipping function is used, interrupt interval may be long temporarily. To avoid this, the interrupt skipping count should be changed with the reload timing being set to the interrupts skipped (TSG3nCTL3.TSG3nRIA = 1).

(1) Example of operation

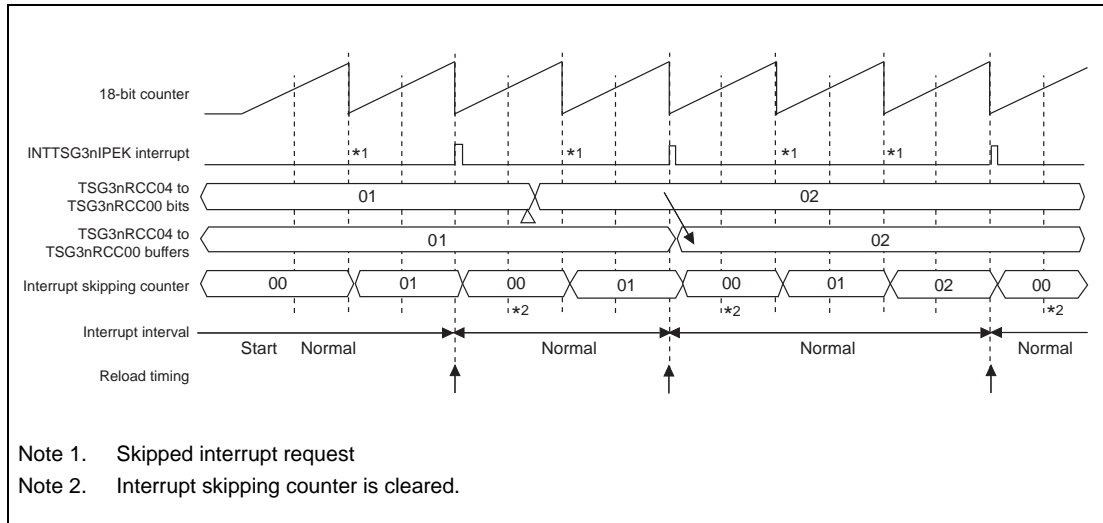

Figure 25.39 When TSG3nCTL3.TSG3nRMC = 0, TSG3nRIA = 1, TSG3nCTL4.TSG3nPRE = 1 (Recommended Setting)

NOTE

When TSG3nCTL3.TSG3nRIA = 1, reload is executed at the same timing as the interrupt after being skipped.

25.4.5 A/D Conversion Trigger Function

A/D conversion trigger operation is described below.

The TSG3nDCMP0E, TSG3nDCMP1E, and TSG3nDCMP2E registers are used as compare registers of the A/D conversion trigger function.

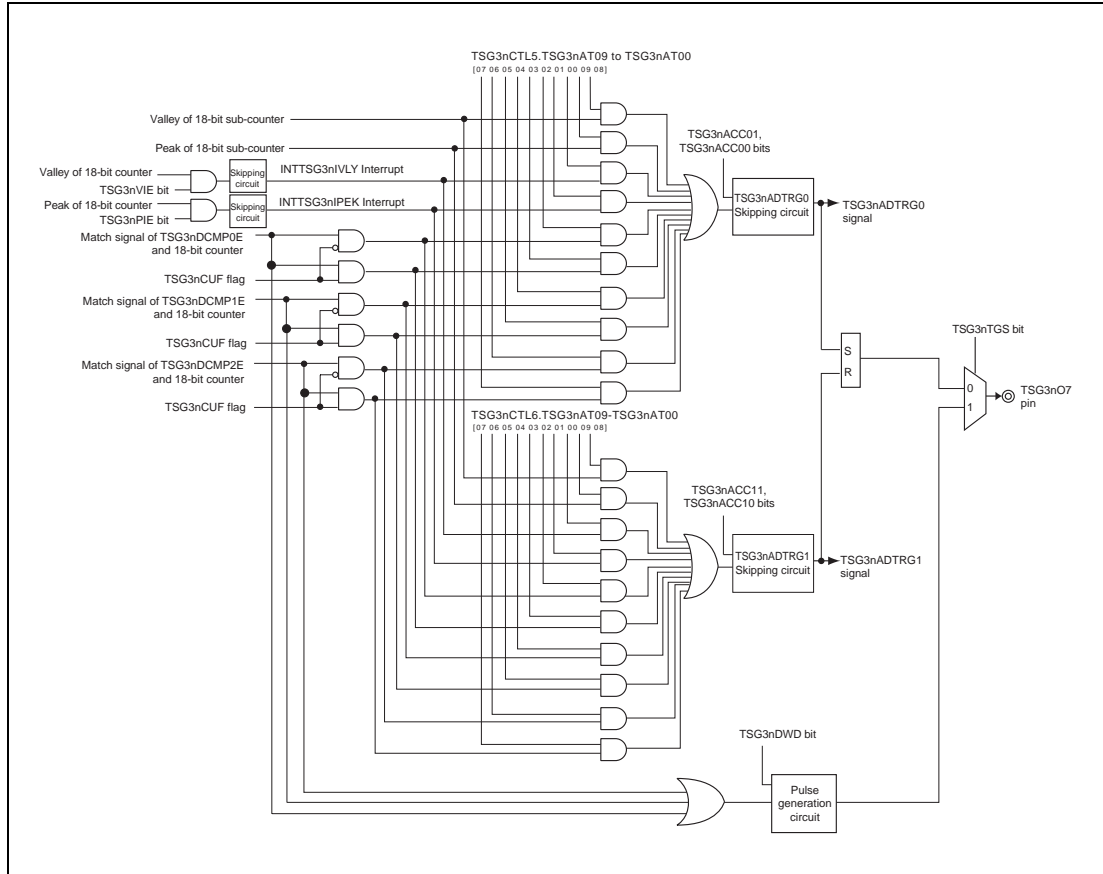

Figure 25.40 A/D Conversion Trigger and Diagnostic Output Control Circuit

As shown in **Figure 25.40**, a logical ORed signal can be generated by selecting the compare match of TSG3nDCMP0E to TSG3nDCMP2E with the 18-bit counter, a peak interrupt (INTTSG3nIPEK) and a valley interrupt (INTTSG3nIVLY) of the 18-bit counter, the peak timing of 18-bit sub-counter, and the valley timing of 18-bit sub-counter.

TSG3n has two channels of the identical A/D conversion trigger control circuits, which can be controlled independently. TSG3n also provides the A/D conversion trigger skipping function with the skipping rate of 1/1 (no skipping), 1/2, 1/4, or 1/8.

25.4.5.1 Operation of A/D Conversion Trigger

TSG3n has a function to generate A/D conversion start triggers (TSG3nADTRG0 and TSG3nADTRG1 signals) by selecting any of ten trigger sources as required. The trigger sources are selected by TSG3nAT09 to TSG3nAT00 in TSG3nCTL5 and TSG3nAT19 to TSG3nAT10 in TSG3nCTL6.

(1) TSG3nADTRG0/TSG3nADTRG1 Signal Output Control (TSG3nCTL5 and TSG3nCTL6)

[Trigger sources]

- TSG3nAT00/TSG3nAT10 = 1 : A valley interrupt (INTTSG3nIVLY) causes an A/D conversion trigger pulse to be generated.
- TSG3nAT01/TSG3nAT11 = 1 : A peak interrupt (INTTSG3nIPEK) causes an A/D conversion trigger pulse to be generated.
- TSG3nAT02/TSG3nAT12 = 1 : While the 18-bit counter is counting up, a TSG3nDCMP0E compare match enables A/D conversion trigger to be generated.
- TSG3nAT03/TSG3nAT13 = 1 : While the 18-bit counter is counting down, a TSG3nDCMP0E compare match enables A/D conversion trigger to be generated.
- TSG3nAT04/TSG3nAT14 = 1 : While the 18-bit counter is counting up, a TSG3nDCMP1E compare match enables A/D conversion trigger to be generated.
- TSG3nAT05/TSG3nAT15 = 1 : While the 18-bit counter is counting down, a TSG3nDCMP1E compare match enables A/D conversion trigger to be generated.
- TSG3nAT06/TSG3nAT16 = 1 : While the 18-bit counter is counting up, a TSG3nDCMP2E compare match enables A/D conversion trigger to be generated.
- TSG3nAT07/TSG3nAT17 = 1 : While the 18-bit counter is counting down, a TSG3nDCMP2E compare match enables A/D conversion trigger to be generated.
- TSG3nAT08/TSG3nAT18 = 1 : A valley timing of the 18-bit sub-counter (at a switch from decrementing to incrementing) enables A/D conversion trigger to be generated.
- TSG3nAT09/TSG3nAT19 = 1 : A peak timing of 18-bit sub-counter (at a switch from incrementing to decrementing) enables A/D conversion trigger to be generated.

[Skipping setting]

- TSG3nACC01, TSG3nACC00 and TSG3nACC11, TSG3nACC10 :
Set the skipping rate of TSG3nADTRG0/TSG3nADTRG1

All A/D conversion triggers selected by TSG3nAT09 to TSG3nAT00 and TSG3nAT19 to TSG3nAT10 are logically ORed, and the resultant signals are subjected to skipping control specified by TSG3nACC01 and TSG3nACC00, and TSG3nACC11 and TSG3nACC10, and then the TSG3nADTRG0 and TSG3nADTRG1 signals are generated.

A peak interrupt (INTTSG3nIPEK) and a valley interrupt (INTTSG3nIVLY) selected by TSG3nAT00 and TSG3nAT01, and TSG3nAT10 and TSG3nAT11 are interrupt signals obtained after skipping. Therefore, they are output at the timing according to interrupt skipping control. If the interrupt output is not enabled by TSG3nCTL4.TSG3nPIE and TSG3nVIE, A/D conversion trigger is not output.

TSG3nACC01, TSG3nACC00, and TSG3nAT09 to TSG3nAT00, and TSG3nACC11, TSG3nACC10, and TSG3nAT19 to TSG3nAT10 can be rewritten during timer operation.

If A/D conversion trigger setting bits are rewritten during operation, the rewritten values are reflected on the A/D conversion trigger output status immediately. Such control bits are rewritten anytime regardless of operating modes. If a write access is made to TSG3nCTL5 and TSG3nCTL6 (including a rewrite of the same value), the A/D conversion trigger skipping counter is cleared and starts counting from zero.

Figure 25.41 When TSG3nPIE = 1, TSG3nVIE = 1, and TSG3nRCC04 to TSG3nRCC00 = 00_H in TSG3nCTL4, and TSG3nACC01 and TSG3nACC00 = 00_B in TSG3nCTL5 (HT-PWM Mode)

Figure 25.42 When TSG3nPIE = 0, TSG3nVIE = 1, and TSG3nRCC04 to TSG3nRCC00 = 02_H in TSG3nCTL4 and TSG3nACC01 and TSG3nACC00 = 00_B in TSG3nCTL5 (HT-PWM Mode)

Figure 25.43 When TSG3nPIE = 0, TSG3nVIE = 1, and TSG3nRCC04 to TSG3nRCC00 = 02_H in TSG3nCTL4 and TSG3nACC01 and TSG3nACC00 = 00_B, and TSG3nAT09 to TSG3nAT00 = 0000 1001_B in TSG3nCTL5 (HT-PWM Mode)

(2) A/D Conversion Trigger Skipping Function

Example of operation of the A/D conversion trigger skipping function is shown in **Figure 25.44**.

Figure 25.44 Example of Operation of A/D Conversion Trigger Skipping Function

NOTE

Broken-lined pulses indicate A/D conversion trigger pulses skipped by the A/D conversion trigger skipping function.

Figure 25.45 Example of Operation of A/D Conversion Trigger Skipping Function

(3) Notes on A/D Conversion Trigger

- If the same value is written to TSG3nDCMP0E and TSG3nDCMP1E or TSG3nDCMP2E, and the same condition (when the 18-bit counter increments or decrements) is set as the valid A/D conversion trigger, A/D conversion trigger skipping counter is incremented by one and one trigger pulse is output upon a match of the 18-bit counter with these registers.
- In PWM mode, SP-PWM mode, 120-DC mode, and HSP-PWM mode, a valley interrupt (INTTSG3nIVLY) is not generated. Only a peak interrupt (INTTSG3nIPEK) is valid.
- In 120-DC mode, when TSG3nS120DCO is set to 0, the 18-bit counter may be cleared during the carrier period due to switch of the output pattern. The A/D conversion trigger is not generated if TSG3nDCMP2E to TSG3nDCMP0E values do not match with the 18-bit counter value and a peak interrupt (INTTSG3nIPEK) is not generated.

25.4.6 Error/Warning Interrupt

25.4.6.1 Error Interrupt Function

If the simultaneous active state of the positive phase and inverse phase is detected after the error interrupt function is enabled ($TSG3nIOC1.TSG3nEOC = 1$), $TSG3nSTR2.TSG3nTBF$ is set, and an error interrupt ($INTTSG3nIER$) of TSG3n is generated. Whether or not to detect an error of each phase ($TSG3nO1$ and $TSG3nO2$, $TSG3nO3$ and $TSG3nO4$, and $TSG3nO5$ and $TSG3nO6$ pins) can be selected by $TSG3nCTL1.TSG3nTBA2$ to $TSG3nTBA0$, respectively.

When an error occurs, outputs of the $TSG3nO1$ to $TSG3nO6$ pins can be set to high-impedance. For details, see **Section 26.4.1, Asynchronous Hi-Z Control Function**.

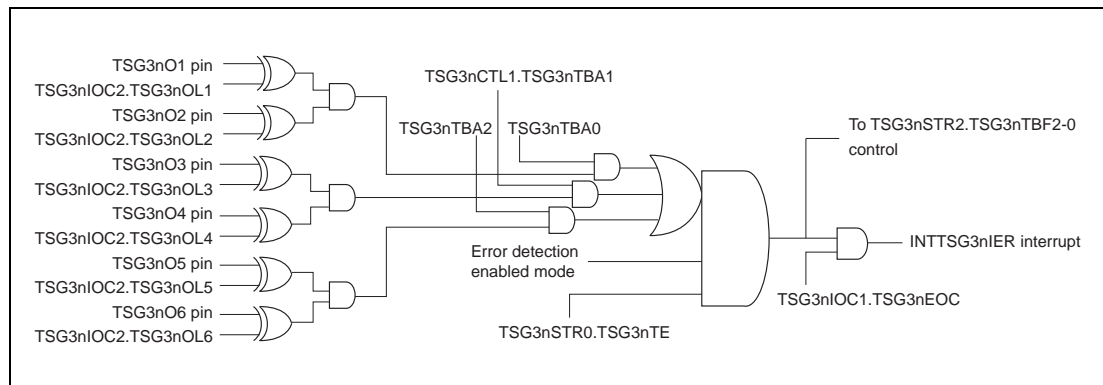

Figure 25.46 Error Interrupt ($INTTSG3nIER$) Generation Control Circuit

CAUTION

When an error interrupt is generated, the error status should be canceled (write 1 to $TSG3nSTC.TSG3nTBR2$ to $TSG3nSTC.TSG3nTBR0$) during error interrupt servicing. Otherwise, subsequent error interrupts are not generated.

(1) PWM Mode, 120-DC Mode and HSP-PWM Mode

In PWM mode and HSP-PWM mode, if TSG3nCMP1E and TSG3nCMP2E, and TSG3nCMP3E and TSG3nCMP4E are set so that the TSG3nO1 and TSG3nO2 pins output the active level simultaneously, an error interrupt (INTTSG3nIER) is generated. Likewise, if TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP9E, TSG3nCMP10E, TSG3nCMP11E, and TSG3nCMP12E are set so that the TSG3nO3 and TSG3nO4, and TSG3nO5 and TSG3nO6 pins output the active level simultaneously, an error interrupt (INTTSG3nIER) is generated.

In 120-DC mode, if TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, TSG3nCMP10E, TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, TSG3nCMP12E, TSG3nPAT0W, and TSG3nPAT1W are set so that the TSG3nO1 and TSG3nO2 pins output the active level simultaneously, an error interrupt (INTTSG3nIER) is generated. With the same setting, the TSG3nO3 and TSG3nO4, and TSG3nO5 and TSG3nO6 pins also output the active level simultaneously and an error interrupt (INTTSG3nIER) is generated.

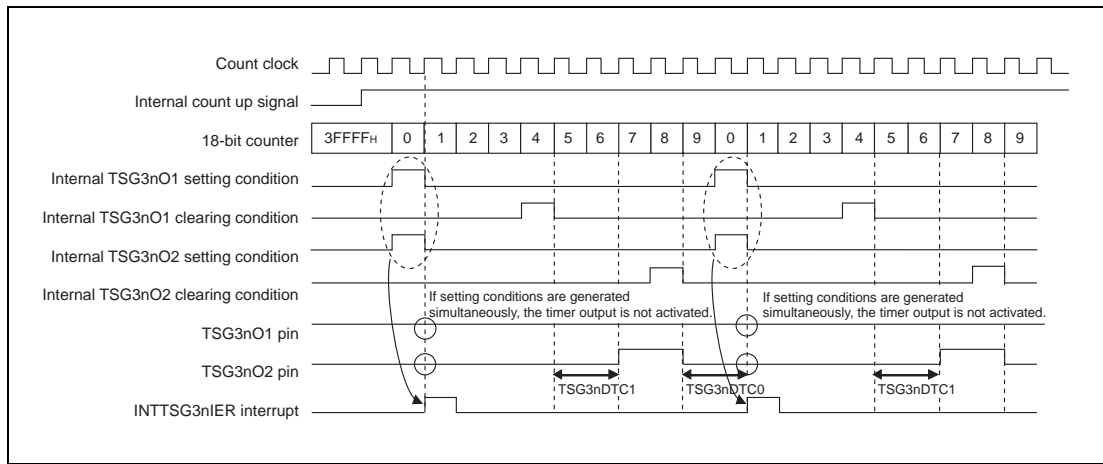

Figure 25.47 Example of Error Interrupt (INTTSG3nIER) Generation (PWM Mode)

NOTE

TSG3nO3 and TSG3nO4, and TSG3nO5 and TSG3nO6 behave the same.

When the active level of output is switched by manipulating TSG3nIOC2.TSG3nOL1 and TSG3nOL2, an error interrupt is generated as shown in the following figure.

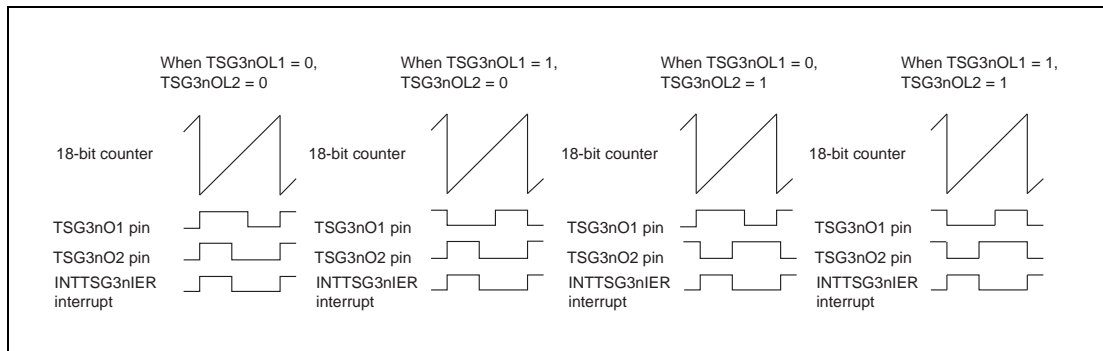

Figure 25.48 Example of Error Interrupt (INTTSG3nIER) Generation for each Active Level

(2) HT-PWM Mode and SP-PWM Mode

When either TSG3n dead time control register 0 or 1 (TSG3nDTC0W or TSG3nDTC1W) is 0000_H, an error may occur.

NOTE

If an error occurs when the dead time control function is used (both TSG3nDTC0W and TSG3nDTC1W are not 0000_H), internal circuit failure may have occurred.

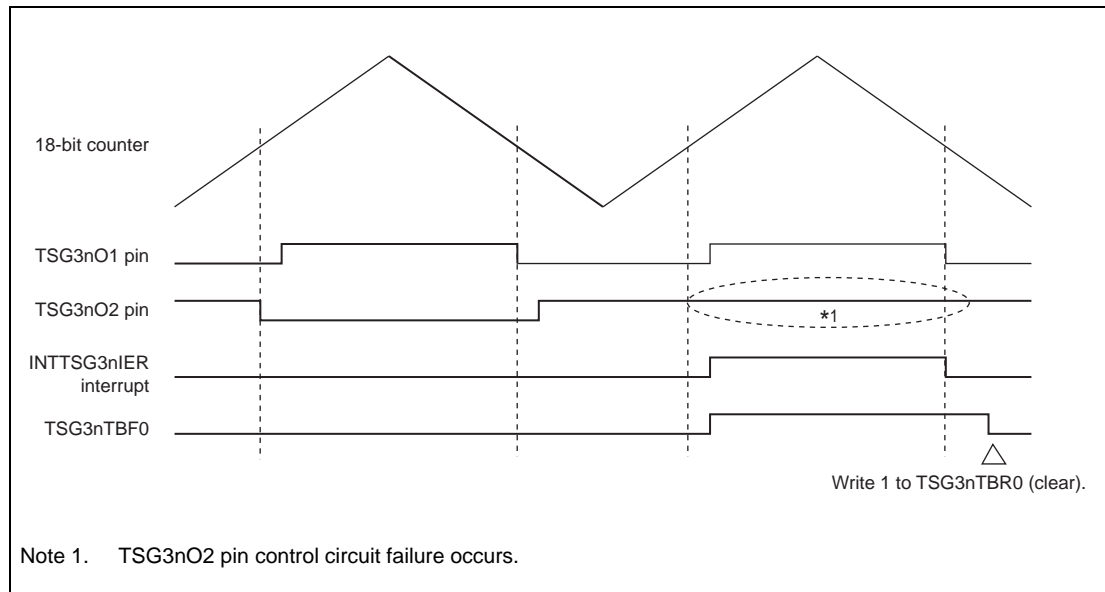

Figure 25.49 Example of Error Interrupt Operation

25.4.6.2 Warning Interrupt Function

TSG3n has a warning interrupt (INTTSG3nIWN).

Warning interrupt (INTTSG3nIWN) is generated when any of the following conditions is detected.

For details, see **Section 25.4.3, Flags**.

- When simultaneous change in two or more pins of TSG3nPTSI2 to TSG3nPTSI0 is detected:
See **Section 25.4.3.4, Noise Detection Flag (TSG3nNDF)**.
- When reversal is detected of the TSG3nPTSI2 to TSG3nPTSI0 pins:
See **Section 25.4.3.7, Pattern Reversal Detection Flag (TSG3nPRF)**.
- When 000 or 111 is detected from the TSG3nPTSI2 to TSG3nPTSI0 pins:
See **Section 25.4.3.6, Pattern Error Detection Flag (TSG3nPEF)**.
- When a toggle of the TSG3nPTSI2 to TSG3nPTSI0 pins is generated three or more times between TSG3nOPCI0 and TSG3nOPCI1 signal triggers.:
See **Section 25.4.3.8, TSG3nPTSI2 to TSG3nPTSI0 Pin Abnormal Toggle Detection Flag (TSG3nPTF)**.
- When the TSG3nOPCI0 and TSG3nOPCI1 signal triggers are detected simultaneously:
See **Section 25.4.3.9, TSG3nOPCI0 and TSG3nOPCI1 Signal Simultaneous Trigger Detection Flag (TSG3nTDF)**.
- When the phase difference between the input pattern (TSG3nPTSI2 to TSG3nPTSI0 pins) and output pattern (TSG3nOPF2 to TSG3nOPF0) is detected:
See **Section 25.4.3.10, Pattern Phase Difference Detection Flag (TSG3nPPF)**.

Figure 25.50 Detection of Abnormality of TSG3nPTSI2-TSG3nPTSI0 Pins

25.4.7 Operating Modes

25.4.7.1 PWM Mode

Overview

A PWM signal is output at the TSG3nO1 to TSG3nO6 pins according to set timing/clear timing of TSG3nCMP1E to TSG3nCMP12E registers with the PWM period set in the TSG3nCMP0E register.

Prerequisites

- Set the set timing to the compare register with an even number:
TSG3nCMP2E (set timing of the TSG3nO1 output), TSG3nCMP4E (set timing of the TSG3nO2 output), TSG3nCMP6E (set timing of the TSG3nO3 output), TSG3nCMP8E (set timing of the TSG3nO4 output), TSG3nCMP10E (set timing of the TSG3nO5 output) and TSG3nCMP12E (set timing of the TSG3nO6 output)
- Set the clear timing to the compare register with an odd number:
TSG3nCMP1E (clear timing of the TSG3nO1 output), TSG3nCMP3E (clear timing of the TSG3nO2 output), TSG3nCMP5E (clear timing of the TSG3nO3 output), TSG3nCMP7E (clear timing of the TSG3nO4 output), TSG3nCMP9E (clear timing of the TSG3nO5 output) and TSG3nCMP11E (clear timing of the TSG3nO6 output)

Functional description

Set the PWM period and set/clear timing of the TSG3nO1 to TSG3nO6 outputs. Set TSG3nTRG0.TSG3nTS = 1 to start the timer counter.

The TSG3nO1 to TSG3nO6 outputs are set to the inactive state at the same time the counting begins. The outputs are set to the active state by the match of the buffer registers TSG3nCMP2E, TSG3nCMP4E, TSG3nCMP6E, TSG3nCMP8E, TSG3nCMP10E, and TSG3nCMP12E with the 18-bit counter.

Next, the TSG3nO1 to TSG3nO6 outputs are set to the inactive state by the match of the buffer registers TSG3nCMP1E, TSG3nCMP3E, TSG3nCMP5E, TSG3nCMP7E, TSG3nCMP9E, and TSG3nCMP11E with the 18-bit counter.

During counting, a compare match interrupt (INTTSG3nI0 to INTTSG3nI12) is generated by the match of the buffer register TSG3nCMP0E-TSG3nCMP12E with the 18-bit counter.

CAUTION

Reload is executed when a value is written to the TSG3nCMP1E register while TSG3nCTL3.TSG3nRMC = 0. Therefore, even when it is needed to rewrite only the value of the TSG3nCMP0E register, a write operation to the TSG3nCMP1E register is necessary. When only the TSG3nCMP0E register is rewritten, reload is not done.

NOTE

The PWM mode is set when TSG3nCTL0.TSG3nMD2-TSG3nMD0 = 000_B.

(a) When TSG3nCMP0E and TSG3nCMP1E to TSG3nCMP12E are Not Rewritten during Timer Operation

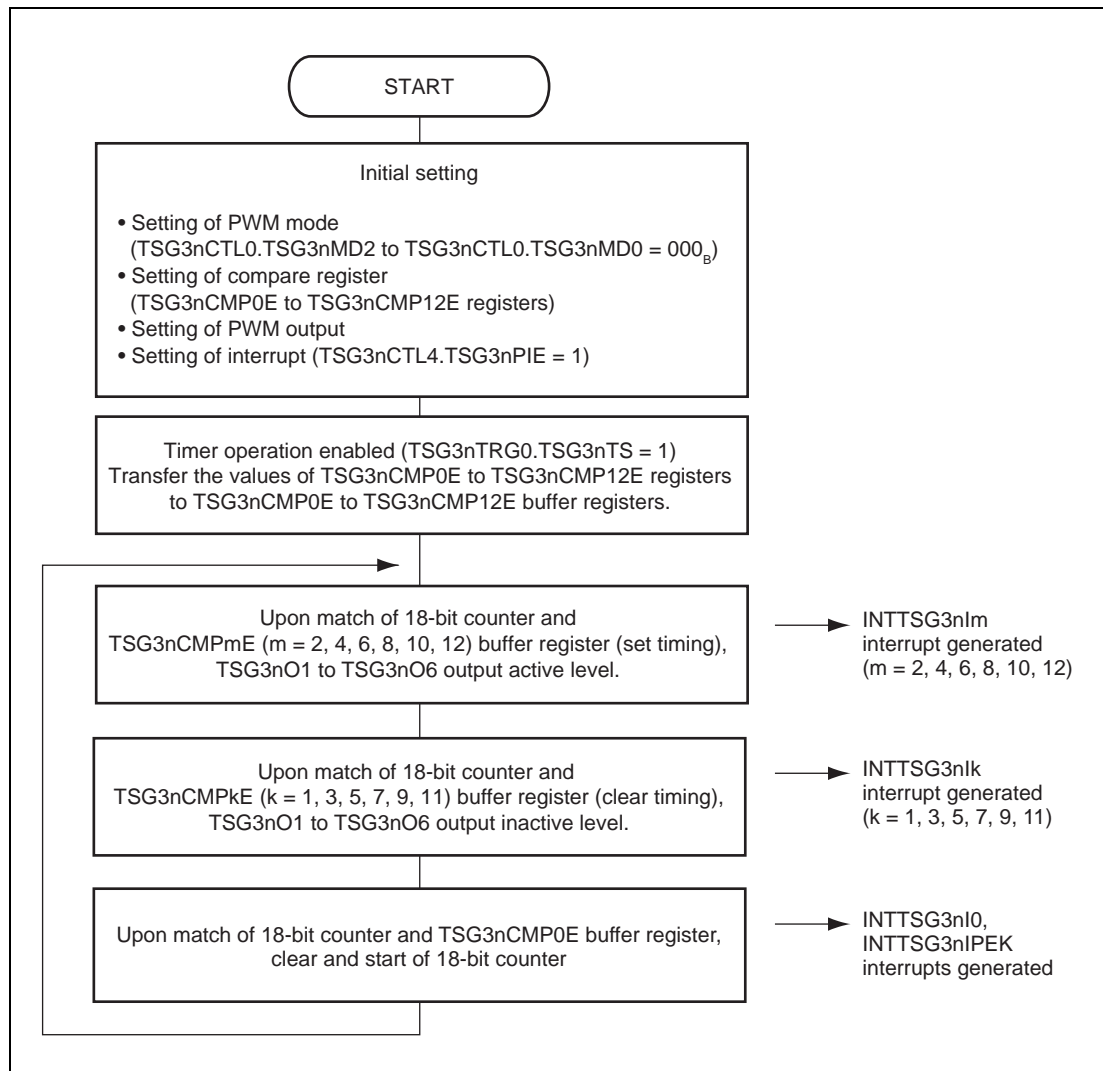

Figure 25.51 Basic Operation Flow of PWM Mode (1/2)

(b) When TSG3nCMP0E and TSG3nCMP1E to TSG3nCMP12E are Rewritten during Timer Operation

Figure 25.51 Basic Operation Flow of PWM Mode (2/2)

CAUTION

Please rewrite compare registers after confirming that the reload request flag TSG3nRSF is 0.

(1) List of Operations in PWM Mode**Table 25.53 Counter Functions in PWM Mode**

Operation		Setting condition
18-bit counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1, or a simultaneous start trigger
	Clear	Compare match of TSG3nCMP0E buffer register and 18-bit counter
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1

Table 25.54 Functions of Compare Registers and Dead Time Control Register in PWM Mode

Register	Rewriting Method	Rewrite during Operation	Function
TSG3nCMP0E	Reload/Anytime rewrite	Possible	Setting period
TSG3nCMPmE (m = 1 to 12)	Reload/Anytime rewrite	Possible	Setting set/clear timing
TSG3nDCMP0E, TSG3nDCMP1E, TSG3nDCMP2E	Reload/Anytime rewrite	Possible	Diagnostic output or A/D conversion trigger
TSG3nDTC0W, TSG3nDTC1W	Reload	Possible* ¹	Setting dead time

Note 1. For the detail see, **(3), Controlling Dead Time in PWM Mode.**

Table 25.55 Timer Input Function in PWM Mode

TSG3nCLKI	Clock enable input

Table 25.56 Timer Output Function in PWM Mode

Pin	Function
TSG3nOm (m = 1 to 6)	PWM output by compare match of TSG3nCMPkE buffer register and 18-bit counter (k = 1 to 12)
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger

Table 25.57 Interrupt Requests in PWM Mode

Interrupt	Function
INTTSG3nIm (m = 0 to 12)	Compare match of TSG3nCMPmE buffer register and 18-bit counter (m = 0 to 12)
INTTSG3nIER	Error (detection of simultaneous active state of TSG3nO1 and TSG3nO2, or TSG3nO3 and TSG3nO4, or TSG3nO5 and TSG3nO6)
INTTSG3nIVLY	—
INTTSG3nIPEK	Peak interrupt (generated at the same timing as INTTSG3nI0)
INTTSG3nIWN	Warning interrupt

Note: “—”: Not available in PWM mode

Table 25.58 Compare Match Timing in PWM Mode

Compare Match	Timing
TSG3nCMP0E	When 18-bit counter changes from TSG3nCMP0E to 00000 _H
TSG3nCMPmE (m = 1 to 12)	After detecting the match of 18-bit counter and TSG3nCMPmE (m = 1 to 12)

Table 25.59 Example of Setting each Timer Output Condition in PWM Mode

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TSG3nOm (m = 1 to 6)	PWM output	(TSG3nCMP0E + 1) x count clock	Output an inactive level throughout one period (duty cycle 0%)	TSG3nCMPmE = TSG3nCMP (m + 1)E or TSG3nCMP (m + 1)E > TSG3nCMP0E (m = 1, 3, 5, 7, 9, 11)
			Output an active level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m + 1)E + 1 TSG3nCMP (m + 1)E = TSG3nCMPmE - 1 (m = 1, 3, 5, 7, 9, 11)
			Output an inactive level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m + 1)E - 1 TSG3nCMP (m + 1)E = TSG3nCMPmE + 1 (m = 1, 3, 5, 7, 9, 11)
			Output an active level throughout one period (duty cycle 100%)	TSG3nCMPmE > TSG3nCMP0E TSG3nCMP (m + 1)E ≤ TSG3nCMP0E (m = 1, 3, 5, 7, 9, 11)

**When only TSG3nCMP2E is rewritten and TSG3nO1 is output
(TSG3nIOC0.TSG3nTOE1 = 1, TSG3nIOC2.TSG3nOL1 = 0)**

Figure 25.52 Example of Basic Operation Timing of PWM Mode (1/2)

NOTES

1. D00: Set values of TSG3nCMP0E and TSG3nCMP1E (00000_H-3FFFF_H)
D10, D11, D12 and D13: Set values of TSG3nCMP2E (00000_H-3FFFF_H)
2. TSG3nO1 (PWM) duty cycle = (TSG3nCMP1E-TSG3nCMP2E)×(count clock cycle)
TSG3nO1 (PWM) period = (Set value of TSG3nCMP0E + 1)×(count clock cycle)
3. TSG3nO2-TSG3nO6 pins behave similarly to the TSG3nO1 pin

When TSG3nCMP0E-TSG3nCMP2E are rewritten, and TSG3nO1 is output
(TSG3nIOC0.TSG3nTOE1 = 1, TSG3nIOC2.TSG3nOL1 = 0)

Figure 25.52 Example of Basic Operation Timing of PWM Mode (2/2)

NOTES

1. D00, D01, D02, D03: Set value of TSG3nCMP0E (00000_H-3FFFF_H)
D10, D11, D12, D13: Set value of TSG3nCMP1E (00000_H-3FFFF_H)
D20, D21, D22, D23: Set value of TSG3nCMP2E (00000_H-3FFFF_H)
2. Outputs from TSG3nO2 to TSG3nO6 behave similarly to the TSG3nO1 pin.

(2) Interrupt/Reload Skipping Function in PWM Mode

By setting TSG3nCTL4.TSG3nPRE and TSG3nPIE to 1 and setting the TSG3nRCC04 to TSG3nRCC00 and TSG3nCTL3.TSG3nRIA, the reload and interrupt skipping function can be used.

By setting TSG3nPRE to 1 and setting the TSG3nRCC04 to TSG3nRCC00, the interrupt skipping function can be used.

(3) Controlling Dead Time in PWM Mode

By setting the dead time values in the TSG3nDTC0W and TSG3nDTC1W registers in PWM mode, it is possible to control the dead time. The dead time is controlled according to the switch timing of the TSG3nO1 and TSG3nO2 outputs, the TSG3nO3 and TSG3nO4 outputs, or the TSG3nO5 and TSG3nO6 outputs.

Table 25.60 Dead Time in PWM Mode

Switch Timing	Dead Time
TSG3nO1: High level to low level and TSG3nO2: Low level to high level	Value of TSG3nDTC1W register
TSG3nO2: High level to low level and TSG3nO1: Low level to high level	Value of TSG3nDTC0W register
TSG3nO3: High level to low level and TSG3nO4: Low level to high level	Value of TSG3nDTC1W register
TSG3nO4: High level to low level and TSG3nO3: Low level to high level	Value of TSG3nDTC0W register
TSG3nO5: High level to low level and TSG3nO6: Low level to high level	Value of TSG3nDTC1W register
TSG3nO6: High level to low level and TSG3nO5: Low level to high level	Value of TSG3nDTC0W register

NOTE

Dead time counter keeps operating even when operation stop (TSG3nTE = 0) setting collided with dead time insert timing, and the dead time set in TSG3nO1 and TSG3nO2 are always inserted.

Figure 25.53 Example of Dead Time Control between TSG3nO1 and TSG3nO2 Outputs (1/2)

During (1), the dead time counter starts counting at the falling edge of the TSG3nO2 output. At this time, even after the 18-bit counter reaches 00000_H indicating that the TSG3nO1 output should be active, the TSG3nO1 output stays inactive because the dead time counter is still operating. The TSG3nO1 output becomes active at the timing when the dead time count operation ends.

At (2), the dead time counter starts counting at the falling edge of the TSG3nO1 output. Even after the match of the 18-bit counter and TSG3nCMP4E indicating that the TSG3nO2 output should be active, the TSG3nO2 output stays inactive because the dead time counter is still operating. The TSG3nO2 output becomes active at the timing when the dead time count operation ends.

NOTES

1. The TSG3nO1 and TSG3nO2 pins are set to active high
2. The TSG3nO3 and TSG3nO4 pins and the TSG3nO5 and TSG3nO6 pins outputs behave similarly.

Figure 25.53 Example of Dead Time Control between TSG3nO1 and TSG3nO2 Outputs (2/2)

During (1), the dead time counter starts counting at the falling edge of the TSG3nO1 output. Even after the 18-bit counter reaches 00000_H and the match occurs between the 18-bit counter and TSG3nCMP4E indicating that the TSG3nO2 output should be active, the TSG3nO2 output stays inactive because the dead time counter is still operating. Moreover, since the TSG3nCMP3E register compare match occurs before the operation of the dead time counter ends, the TSG3nO2 output stays inactive.

$$\text{TSG3nCMP1E} + \text{TSG3nDTC1} \geq \text{TSG3nCMP0E} + \text{TSG3nCMP2E}$$

(TSG3nO2 stays inactive)

$$\text{TSG3nCMP2E} + \text{TSG3nDTC0} \geq \text{TSG3nCMP0E} + \text{TSG3nCMP1E}$$

(TSG3nO1 stays inactive)

At (2), the INTTSG3nIER interrupt occurs because the TSG3nCMP2E register and the TSG3nCMP4E register are set so that the TSG3nO1 and TSG3nO2 outputs rise simultaneously. Here, both the TSG3nO1 and TSG3nO2 outputs become inactive.

At (3), compare match with the TSG3nCMP4E register while the TSG3nO1 output is active generates an INTTSG3nIER interrupt and both TSG3nO1 and TSG3nO2 outputs become inactive.

At (4), the falling edge (inactive) of the TSG3nO1 output is caused by the detection of simultaneous active state and the dead time counter starts counting. After the end of the dead time counter operation, the TSG3nO2 output becomes active.

NOTES

1. The TSG3nO1 and TSG3nO2 pins are set to active high.
2. The TSG3nO3 and TSG3nO4 pins and the TSG3nO5 and TSG3nO6 pins outputs behave similarly.

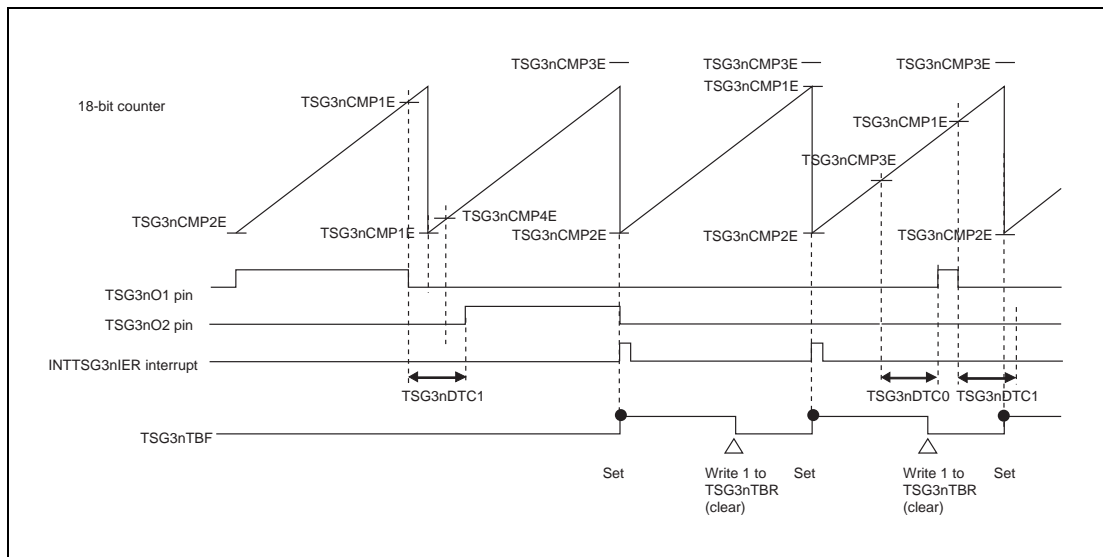

Figure 25.54 Example of 100% Duty Output at Dead Time Control

When the TSG3nO2 pin is set to duty cycle of 100% ($TSG3nCMP3E \geq TSG3nCMP0E + 1$), the output of the TSG3nO1 pin is fixed to a low level. This control is intended to mask the active condition of TSG3nO1 output since the TSG3nO2 output is active before the TSG3nO1 output becomes active. In this case, the INTTSG3nIER interrupt is also generated because TSG3nO1 and TSG3nO2 outputs become high simultaneously.

NOTES

1. The TSG3nO1 and TSG3nO2 pins are set to active high.
2. The TSG3nO3 and TSG3nO4 pins and the TSG3nO5 and TSG3nO6 pins outputs behave similarly.

(4) Dead Time Rewriting during Timer Operation in PWM Mode

In PWM mode, it is possible to rewrite TSG3n dead time control registers TSG3nDTC0W and TSG3nDTC1W while counting. The new settings are active at reload timing. It is not possible to change the dead time setting by rewriting at any time.

To enable reloading, write to the TSG3nCMP1E register.

25.4.7.2 HT-PWM mode (High accuracy Triangular - Pulse Width Modulation mode)

Overview

In this mode, the 18-bit counter (up/down count by ± 2 bits, practically 17 bits) and the 18-bit compare registers (LSB is used to control additional pulse) are used to generate a 6-phase PWM signal.

Prerequisites

- Set the carrier wave period with TSG3nCMP0E.
- Set the duty cycle of the voltage data signals of the U phase, V phase, and W phase with TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE (The values set in TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE are reflected immediately to the corresponding TSG3nCMPmE ($m = 1, 2, 5, 6, 9, 10$)).
- Symmetric triangular wave control is described in this section. Please refer to **Section 25.4.7.2 (10), Asymmetric Triangular Wave Control in HT-PWM Mode**, for asymmetric triangular wave control.

Functional description

In this mode, the carrier period and the duty cycle of the U phase, the V phase, and the W phase are configured. Counting up begins when TSG3nTRG0.TSG3nTS is set to 1.

The 18-bit counter counts up from TSG3nDTC0 as the minimum value, and counts down upon the match with the maximum value of TSG3nCMP0E + TSG3nDTC0.

The dead time is set with TSG3nDTC0 and TSG3nDTC1. TSG3nDTC0 sets the dead time of inverse phase (OFF) to positive phase (ON) switch and TSG3nDTC1 sets the dead time of positive phase (OFF) to inverse phase (ON) switch. The 10-bit counters (TSG3nDTT1 to TSG3nDTT3) for dead time generation load the set values of TSG3nDTC0 and TSG3nDTC1 by the compare match of the 18-bit counter and the TSG3nCMPm buffer register ($m = 1, 2, 5, 6, 9, 10$), and start down-counting.

INTTSG3nIm interrupts ($m = 1, 2, 5, 6, 9, 10$) are generated by the compare match of the 18-bit counter with TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E buffer registers.

INTTSG3nIm interrupts ($m = 3, 4, 7, 8, 11, 12$) are generated by the compare match of the 18-bit counter with TSG3nCMP3E, TSG3nCMP7E, and TSG3nCMP11E buffer registers when counting down (TSG3nCUF = 1), and with TSG3nCMP4E, TSG3nCMP8E, and TSG3nCMP12E buffer registers when counting up (TSG3nCUF = 0).

NOTE

The HT-PWM mode is enabled when TSG3nCTL0.TSG3nMD2-TSG3nMD0 = 001_B.

(1) Block Diagram and Basic Timing Chart

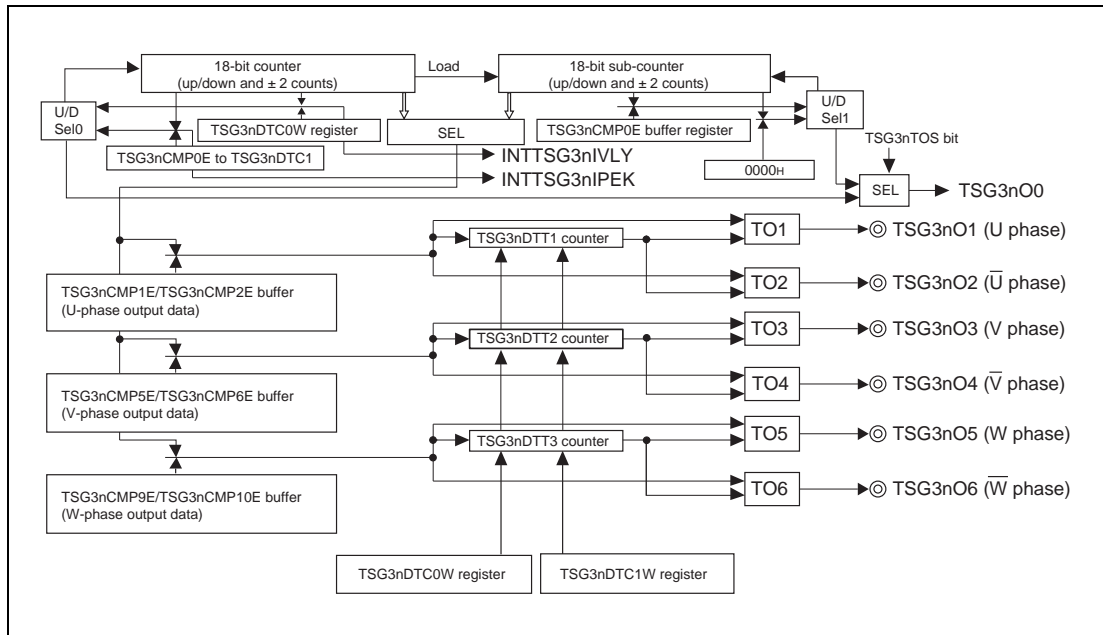

Figure 25.55 Block Diagram in HT-PWM Mode

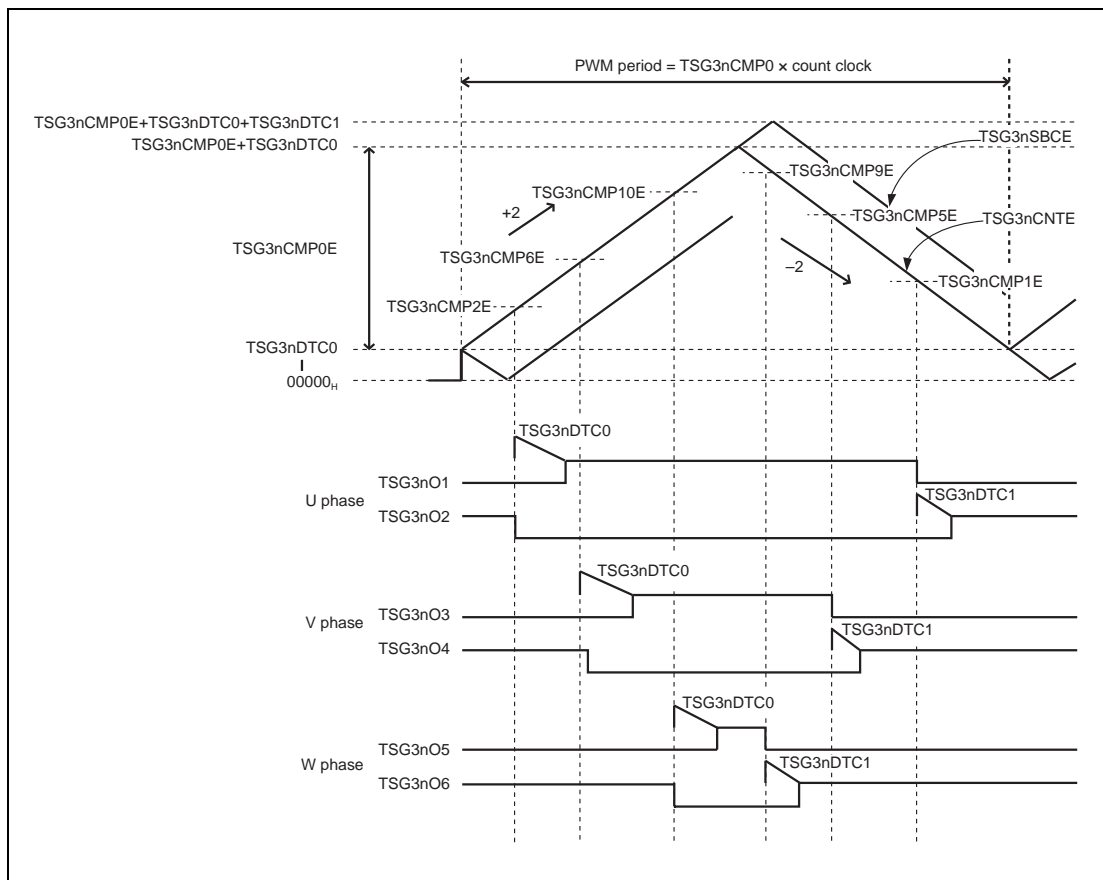

Figure 25.56 Basic Timing in HT-PWM Mode

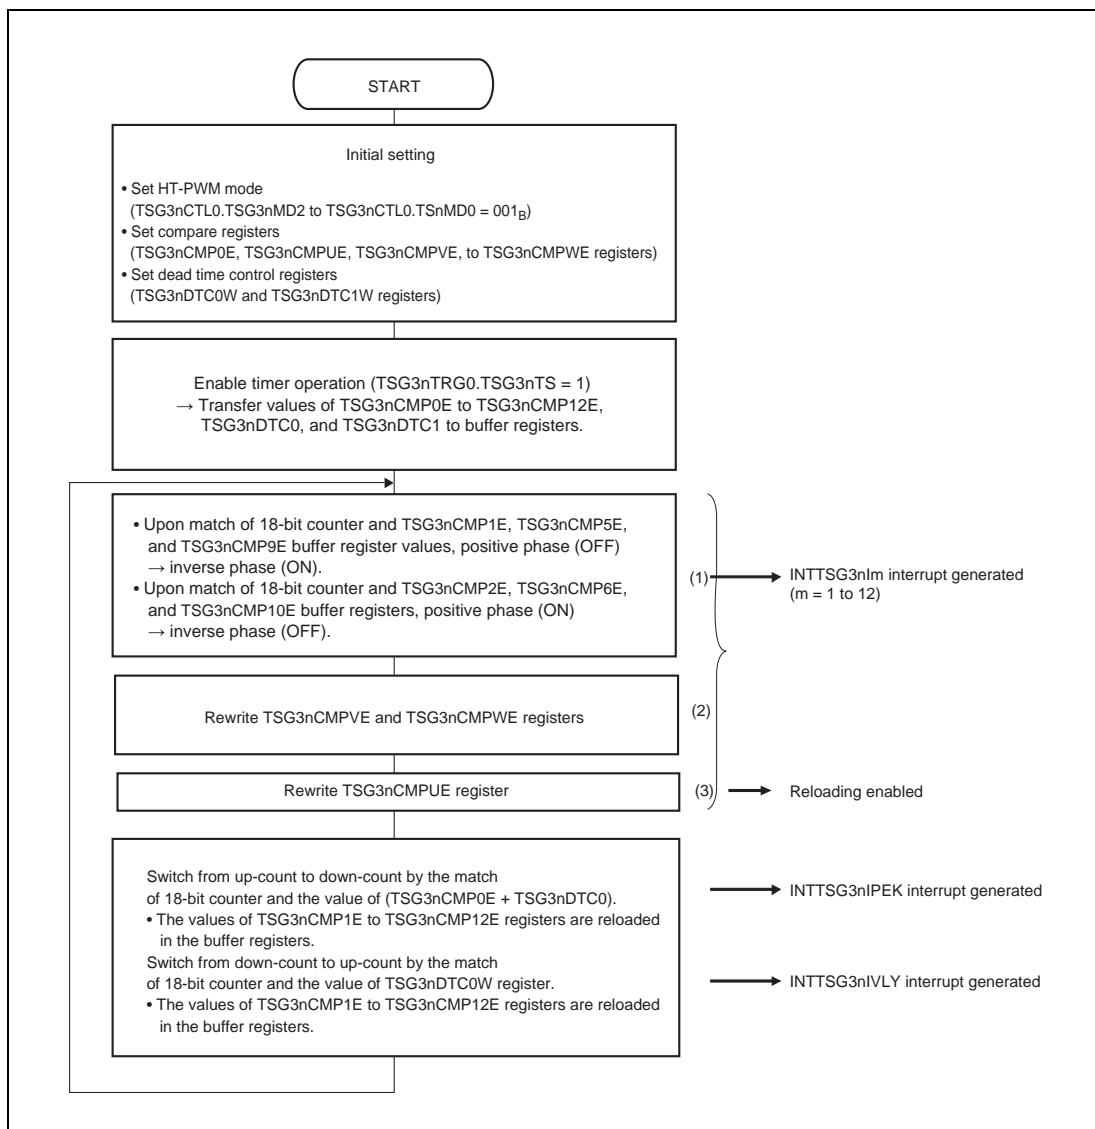

Figure 25.57 Basic Operation Flow in HT-PWM Mode

NOTE

- Write access to TSG3nCMPUE (TSG3nCMP1E) includes reloading enabling operation. Therefore, (3) must be done after (2).
- The INTTSG3nIPEK interrupt is generated only when TSG3nCTL4.TSG3nPIE = 1.
- The INTTSG3nIVLY interrupt is generated only when TSG3nCTL4.TSG3nVIE = 1.
- INTTSG3nI3, INTTSG3nI7, and INTTSG3nI11 outputs an interrupt at the match timing of TSG3nCMP3E, 7E, and 11E with TSG3nCnTE when counting down (TSG3nCnUF = 1). INTTSG3nI4, INTTSG3nI8, and INTTSG3nI12 outputs an interrupt at the match timing of TSG3nCMP4E, 8E, and 12E with TSG3nCnTE when counting up (TSG3nCnUF = 0).

(2) List of HT-PWM Mode Operations**Table 25.61 Counter Function in HT-PWM Mode**

Operation		Setting Condition
18-bit counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1 or simultaneous start trigger (counting up from TSG3nDTC0)
	Up count	Compare match of TSG3nDTC0 buffer register and 18-bit counter
	Down count	Compare match of TSG3nCMP0E + TSG3nDTC0 and 18-bit counter
	Clear	—
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1
18-bit sub-counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1 or simultaneous start trigger (counting down from TSG3nDTC0)
	Up count	Underflow
	Down count	Compare match of TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 buffer register and 18-bit sub-counter
	Load	<ul style="list-style-type: none"> TSG3nCMP0E + TSG3nDTC0: When value of 18-bit counter matches the value of buffer register TSG3nCMP0E + TSG3nDTC0 TSG3nDTC0: When value of 18-bit counter matches the value of the buffer register TSG3nDTC0
	Clear	—
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1

Table 25.62 Compare Register and Dead Time Control Register Functions in HT-PWM Mode

Register	Rewrite Method	Rewrite during Operation	Function
TSG3nCMP0E	Reload/Anytime rewrite	Possible	Setting period
TSG3nCMPUE	—	Possible	PWM control for U phase
TSG3nCMP1E, TSG3nCMP2E	Reload/Anytime rewrite		
TSG3nCMPVE	—	Possible	PWM control for V phase
TSG3nCMP5E, TSG3nCMP6E	Reload/Anytime rewrite		
TSG3nCMPWE	—	Possible	PWM control for W phase
TSG3nCMP9E, TSG3nCMP10E	Reload/Anytime rewrite		
TSG3nDCMP0E, TSG3nDCMP1E, TSG3nDCMP2E	Reload/Anytime rewrite	Possible	Diagnostic signal output or A/D conversion trigger
TSG3nDTC0W, TSG3nDTC1W	Reload	Possible conditionally	Period and dead time control

NOTE

- The rewritten values of TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE are set to TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E and TSG3nCMP10E.
- For rewriting method of TSG3nDTC0 and TSG3nDTC1, see **Section 25.4.7.2, (8), (a) TSG3nDTC0 and TSG3nDTC1 Rewriting.**

Table 25.63 Timer Output Function in HT-PWM Mode

Pin	Function
TSG3nO0	Active level output during up count, inactive level output at down count of the 18-bit counter/sub-counter
TSG3nO1	PWM output with dead time by compare match of TSG3nCMP1E buffer register and 18-bit counter (down count) and compare match of TSG3nCMP2E buffer register and 18-bit counter (up count) PWM output by compare match of TSG3nCMP1E buffer register and 18-bit sub-counter (during down counting) and compare match of TSG3nCMP2E buffer register and 18-bit sub-counter (during up counting) while TSG3nCMP1E < DTC0
TSG3nO2	Output negative phase with respect to TSG3nO1 (with dead time)
TSG3nO3	PWM output with dead time by compare match of TSG3nCMP5E buffer register and 18-bit counter (down count) and compare match of TSG3nCMP6E buffer register and 18-bit counter (up count). PWM output by compare match of TSG3nCMP3E buffer register and 18-bit sub-counter (during down counting) and compare match of TSG3nCMP6E buffer register and 18-bit sub-counter (during up counting) while TSG3nCMP5E < DTC0
TSG3nO4	Output negative phase with respect to TSG3nO3 (with dead time)
TSG3nO5	PWM output with dead time by compare match of TSG3nCMP9E buffer register and 18-bit counter (down count) and TSG3nCMP10E buffer register and 18-bit counter (up count). PWM output by compare match of TSG3nCMP5E buffer register and 18-bit sub-counter (during down counting) and compare match of TSG3nCMP10E buffer register and 18-bit sub-counter (during up counting) while TSG3nCMP9E < DTC0
TSG3nO6	Output negative phase with respect to TSG3nO5 (with dead time)
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger

NOTES

1. The target of TSG3nO0 status output can be switched with TSG3nIOC1.TSG3nTOS.
2. When the peak and valley values of the 18-bit sub-counter are set in TSG3nCMP1E and TSG3nCMP2E, clearing takes precedence.

Table 25.64 Interrupt Request in HT-PWM Mode

Interrupt	Function
INTTSG3nI0	Compare match of TSG3nDTC0 buffer register and 18-bit counter (periodic interrupt)
INTTSG3nIm (m = 1, 2, 5, 6, 9, 10)	Compare match of TSG3nCMPmE buffer register and 18-bit counter (m = 1, 2, 5, 6, 9, 10)
INTTSG3nIER	Error interrupt
INTTSG3nIVLY	Valley interrupt
INTTSG3nIPEK	Peak interrupt
INTTSG3nIWN	Warning interrupt

Table 25.65 Compare Match Timing in HT-PWM Mode

Compare Match	Timing
TSG3nCMP0E	When the 18-bit counter changes from TSG3nDTC0 to TSG3nDTC0 + 2
TSG3nCMPmE (m = 1, 2, 5, 6, 9, 10)	When 18-bit counter changes from TSG3nCMPmE to TSG3nCMPmE ± 2 (m = 1, 2, 5, 6, 9, 10)

Table 25.66 Example of Setting Each Timer Output Condition in HT-PWM Mode

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TSG3nO0	Toggle output	TSG3nCMP0E x count clock	Output an inactive level when counting up, and an active level when counting down.	—
TSG3nO1, TSG3nO3, TSG3nO5	PWM output	TSG3nCMP0E x count clock	Output an inactive level throughout one period (0% duty)	$TSG3nCMP0E \leq TSG3nCMPmE \leq TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1$ (m = U, V, W)
			Output an active level of one count clock in one period	$TSG3nCMPmE = TSG3nCMP0E - 1$ (m = U, V, W)
			Output an inactive level of one count clock in one period	$TSG3nCMPmE = 0001_H$ (m = U, V, W)
			Output an active level throughout one period (100% duty)	$TSG3nCMPmE = 0000_H$ (m = U, V, W)
TSG3nO2, TSG3nO4, TSG3nO6	PWM output	TSG3nCMP0E x count clock	Output an inactive level throughout one period (0% duty)	$TSG3nCMPmE \leq TSG3nDTC0 + TSG3nDTC1$ (m = U, V, W)
			Output an active level of one count clock in one period	$TSG3nCMPmE = TSG3nDTC0 + TSG3nDTC1 + 1$ (m = U, V, W)
			Output an inactive level of one count clock in one period	$TSG3nCMPmE = TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 - 1$ (m = U, V, W)
			Output an active level throughout one period (100% duty)	$TSG3nCMPmE = TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1$ (m = U, V, W)
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger	TSG3nCMP0E x count clock	See Section 25.4.5, A/D Conversion Trigger Function	

(3) Various Settings of HT-PWM Mode

Setting mode

HT-PWM mode is entered by setting TSG3nCTL0.TSG3nMD2-TSG3nMD0 to 001_B.

Setting timer output

The output pins TSG3nO1 to TSG3nO6 are controlled by setting TSG3nIOC0, TSG3nIOC2, and TSG3nIOC3.

The output pin TSG3nO0 indicates the up/down count status of the 18-bit counter or the 18-bit sub-counter. Switch between the 18-bit sub-counter and the 18-bit counter is done with the TSG3nIOC1.TSG3nTOS bit.

The TSG3nO7 pin provides output pulse as diagnostic output or A/D conversion trigger. The pin should be set as necessary.

Enabling error interrupt generation

Error interrupt (INTTSG3nIER) due to the detection of the simultaneous active state of the positive phase and inverse phase is enabled by setting TSG3nIOC1.TSG3nEOC to 1. In HT-PWM mode, no value specified in the compare register makes the positive phase and negative phase simultaneously active. For the detail, see **Section 25.4.6, Error/Warning Interrupt**.

Setting register rewriting timing with reload function

With TSG3nCTL3.TSG3nRMC, reload (simultaneous rewrite) or rewrite (anytime) is specified for the registers with reload function. The default setting is 0 (reload). To reload, set TSG3nCTL4.TSG3nPRE or TSG3nVRE to 1.

The reload timing is not generated if both TSG3nPRE bit and TSG3nVRE bit are set to 0.

When “anytime rewrite” is specified, unintended output may be generated depending on the rewrite timing.

Setting interrupts and skipping function

Interrupts and the skipping function are set with TSG3nCTL4. TSG3nPIE should be set to 1 when peak interrupt (INTTSG3nIPEK) is required and TSG3nVIE to 1 when valley interrupt (INTTSG3nIVLY) is required. To use the skipping function for peak/valley interrupts, set TSG3nRCC4 to TSG3nRCC0.

Setting A/D conversion trigger output

To set A/D conversion trigger 0 (TSG3nADTRG0 signal), use TSG3nCTL5.TSG3nAT09 to TSG3nAT00. With TSG3nAT09 to TSG3nAT00, A/D conversion trigger output is enabled or disabled at the match of 18-bit counter (during up count) with TSG3nDCMP2E to TSG3nDCMP0E, the match of the 18-bit counter (during down count) with TSG3nDCMP2E to TSG3nDCMP0E, the 18-bit counter peak interrupt (INTTSG3nIPEK), the 18-bit counter valley interrupt (INTTSG3nIVLY), the 18-bit sub-counter peak timing, and 18-bit sub-counter valley timing.

To set A/D conversion trigger 1 (TSG3nADTRG1 signal), use TSG3nCTL6.TSG3nAT19 to TSG3nAT10.

To set the match timing of 18-bit counter and TSG3nDCMP2E to TSG3nDCMP0E, set the compare value to the pertinent register.

The skipping function can be used for TSG3nADTRG0 and the TSG3nADTRG1 signals. Use TSG3nACC01, TSG3nACC00 of TSG3nCTL5, and TSG3nACC10, TSG3nACC11 of TSG3nCTL6 to select the skipping rate from 1/1 (no skipping), 1/2, 1/4, and 1/8.

CAUTION

Be sure to set TSG3nCTL5, TSG3nCTL6, and TSG3nDCMP2E to TSG3nDCMP0E correctly when the timing pulse of the A/D conversion trigger is output to TSG3nO7.

Setting dead time

The dead time can be set with TSG3nDTC0 and TSG3nDTC1.

The dead time is calculated by the following expressions:

$$\text{PCLK} \times \text{TSG3nDTC0}$$

$$\text{PCLK} \times \text{TSG3nDTC1}$$

TSG3nDTC0 can set the time between a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the inactive state and a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the active state, respectively.

TSG3nDTC1 can set the time between a change of TSG3nO1, TSG3nO3, TSG3nO5 to the inactive state and a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the active state, respectively.

TSG3nDTC0 and TSG3nDTC1 can only be set to an even value.

Carrier period

Set the carrier period with TSG3nCMP0E according to the following expression:

$$\text{TSG3nCMP0E} = \text{Carrier period/count clock period (PCLK)}$$

The following requirements regarding the dead time must be satisfied when setting the TSG3nCMP0E register:

- $\text{TSG3nCMP0E} + \text{TSG3nDTC0} + \text{TSG3nDTC1} \leq 3\text{FFFEH}$
- $\text{TSG3nCMP0E} > \text{TSG3nDTC0}$
- $\text{TSG3nCMP0E} > \text{TSG3nDTC1}$
- $\text{TSG3nCMP0E} > 3 \times \text{MAX}(\text{TSG3nDTC0}, \text{TSG3nDTC1})$
- TSG3nCMP0E: Even number

NOTE

MAX (A, B) indicates the larger value of A and B.

Setting duty (PWM width)

The duty of the U phase, the V phase, and the W phase is set with TSG3nCMPmE (m = U, V, W, or 1, 2, 5, 6, 9, and 10), respectively. The setting range of the compare registers is as follows:

$$00000_{\text{H}} \leq \text{TSG3nCMPmE} \leq \text{TSG3nCMP0E} + \text{TSG3nDTC0} + \text{TSG3nDTC1}$$

LSB (least significant bit) of TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE indicates the setting of an additional pulse. For example, when $\text{TSG3nCMPUE} = 00003_{\text{H}}$, the change in the inverse phase (TSG3nO2 output) occurs one count clock later compared to the $\text{TSG3nCMPUE} = 00002_{\text{H}}$

setting (when the 18-bit counter is up-counting). The additional pulse cannot be set to TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, or TSG3nCMP10E (only even numbers can be set to these registers).

(4) 18-bit counter Operation in HT-PWM Mode

The 18-bit counter is initialized to 00000_{16} and the value of TSG3nDTC0 is loaded immediately after the TSG3n timer operation starts (TSG3nTRG0.TSG3nTS = 1), and the counter is incremented by 2. After 18-bit counter reaches the value of TSG3nCMP0E + TSG3nDTC0, it is decremented by 2.

The following figure shows 18-bit counter operation.

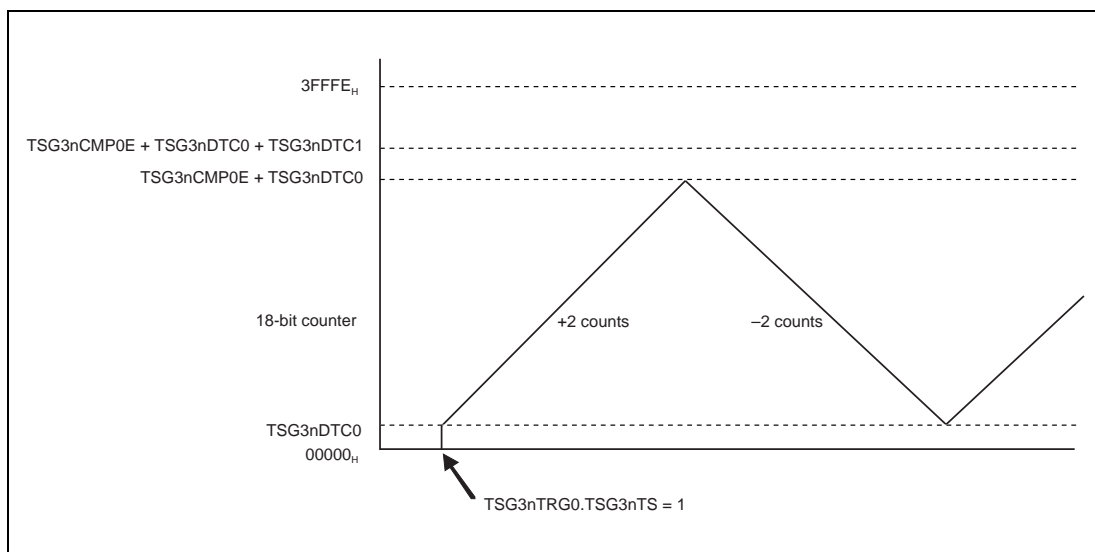

Figure 25.58 Example of 18-bit counter Operation in HT-PWM Mode

NOTE

Minimum 18-bit counter value: TSG3nDTC0

Maximum 18-bit counter value: TSG3nCMP0E + TSG3nDTC0

Carrier period: TSG3nCMP0E × count clock period (PCLK)

The 18-bit sub-counter is initialized to 00000_H and the value of TSG3nDTC0 is loaded immediately after the TSG3n timer operation starts ($TSG3nTRG0.TSG3nTS = 1$), and the counter is decremented by 2 until it reaches 00000_H , at which point increment by 2 begins. Next, the value of the 18-bit counter is loaded into the 18-bit sub-counter at a change timing of the 18-bit counter into the down count. Counting up by the 18-bit sub-counter continues until the value reaches the value of $TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1$, and then decrement by 2 begins. Similarly, when the 18-bit counter value matches the TSG3nDTC0 value, the 18-bit counter value is loaded to the 18-bit sub-counter and the down count is continued.

The following figure shows the 18-bit sub-counter operation.

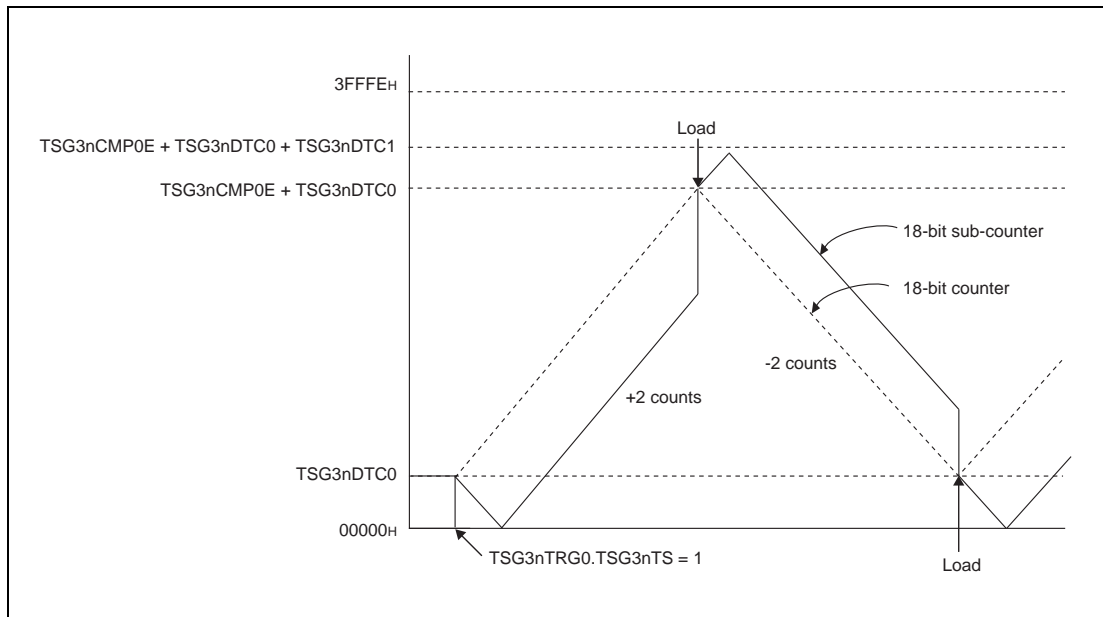

Figure 25.59 Example of 18-bit Sub-Counter Operation in HT-PWM Mode

NOTE

Minimum 18-bit sub-counter value: 00000_H

Maximum 18-bit sub-counter value: $TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1$

(5) Basic Operation of HT-PWM Mode

(a) Example of Timer Output Immediately after the Start of the TSG3n Timer Operation

The following figure shows the timing chart when TSG3nCMP0E = 0000E_H, TSG3nDTC0 = 002_H, TSG3nDTC1 = 004_H and TSG3nCMPUE = 00000_H to 00014_H (excerpt). In this example, TSG3nIOC2.TSG3nOL1 to TSG3nOL6 = 000000_B.

When operation starts (TSG3nTRG0.TSG3nTS = 1), the level of the TSG3nO2 pin changes to active. Afterwards, if TSG3nCMPUE ≤ TSG3nDTC0, the TSG3nO2 pin is cleared after 1 count clock cycle.

The TSG3nO2 pin is cleared upon a match of the 18-bit counter and the compare register (TSG3nCMP2E), or a match of the 18-bit sub-counter and the compare register (TSG3nCMP2E) if TSG3nCMPUE ≥ TSG3nDTC0. Afterwards, the TSG3nO1 pin is set after the set dead time period (the TSG3nO1 pin is not set if TSG3nCMPUE ≥ TSG3nCMP0E).

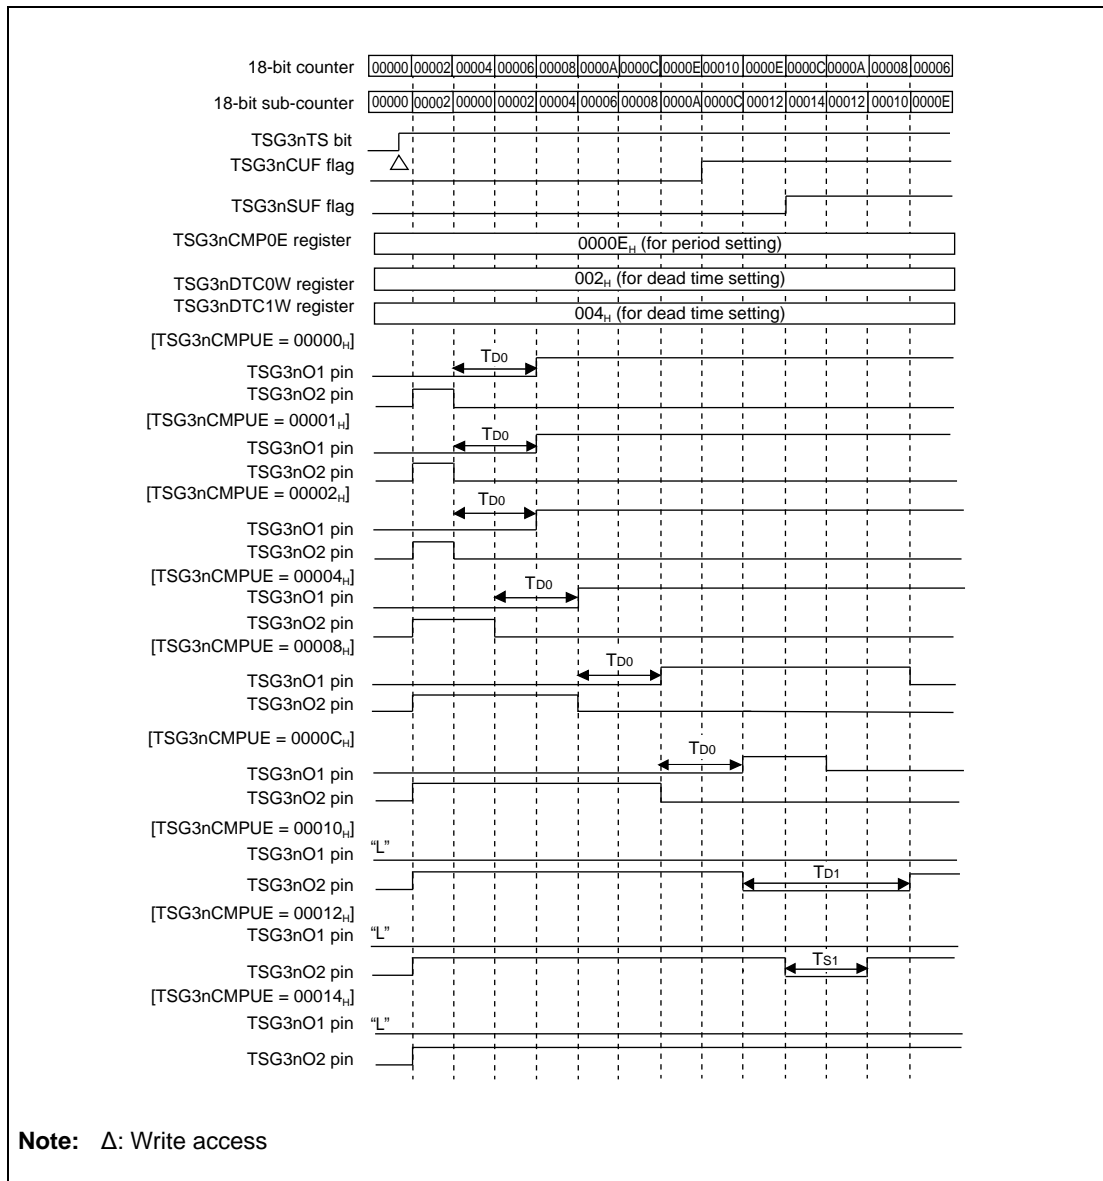

Figure 25.60 Example of Timer Output when TSG3nTS is Set to 1 (Initial Setting) in HT-PWM Mode

NOTES

1. TSG3nCMP0E = 0000E_H, TSG3nDTC0 = 002_H, TSG3nDTC1 = 004_H
 2. T_{D0}: Time depending on the dead time setting in the TSG3nDTC0W register
T_{D1}: Time depending on the dead time setting in the TSG3nDTC1W register
T_{S1}: Time determined by compare match of the 18-bit sub-counter and TSG3nCMPUE register, when TSG3nCMPUE > 18-bit counter maximum value
-

(b) Example of Timer Output during TSG3n Timer Operation

The following figure shows the timing chart when TSG3nCMP0E = 0000E_H, TSG3nDTC0 = 002_H, TSG3nDTC1 = 004_H, and TSG3nCMPUE is set to 00000_H-00014_H (excerpt). In this example, TSG3nIOC2.TSG3nOL1-TSG3nOL6 = 000000_B.

The range of the active (high level) width of a positive phase (TSG3nO1) output is 00000_H ≤ TSG3nCMPUE ≤ TSG3nCMP0E (for the additional pulse). The range of the active (high level) width of an inverse phase (TSG3nO2) output is TSG3nDTC0 + TSG3nDTC1 ≤ TSG3nCMPUE ≤ TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1.

Figure 25.61 Example of Timer Output during TSG3n Operation in HT-PWM Mode

NOTES

1. TSG3nCMP0E = 0000E_H, TSG3nDTC0 = 002_H, TSG3nDTC1 = 004_H
2. T_{DO}: Time depending on setting of the dead time in the TSG3nDTC0 register
 T_{D1}: Time depending on setting of the dead time in the TSG3nDTC1 register
 T_{S0}: Time determined by compare match of 18-bit sub-counter and the TSG3nCMPUE register, when TSG3nCMPUE < 18-bit counter minimum value
 T_{S1}: Time determined by compare match of the 18-bit sub-counter and the TSG3nCMPUE register, when TSG3nCMPUE > 18-bit counter maximum value

(6) Additional Pulse Control in HT-PWM Mode

The HT-PWM mode can generate an additional pulse by setting 1 to the LSB of the duty setting registers (TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE). This allows more precise control of the pulse duty than standard pulse control.

The following sections describe two examples of pulse output of TSG3nO1: additional pulse control is used in one example and additional pulse control is not used in another.

(a) Example of Pulse Output when Additional Pulse Control Is Used

Figure 25.62 shows the additional pulse control when an odd value is set to TSG3nCMPUE.

The arrows and numerical values show the duty cycle width of the TSG3nO1 output in one period.

As shown in **Figure 25.62**, when the additional pulse control is used, the output width of the TSG3nO1 (duty cycle) can be set within a range from 12 clock cycles to 0 clock cycles in one-clock-cycle step.

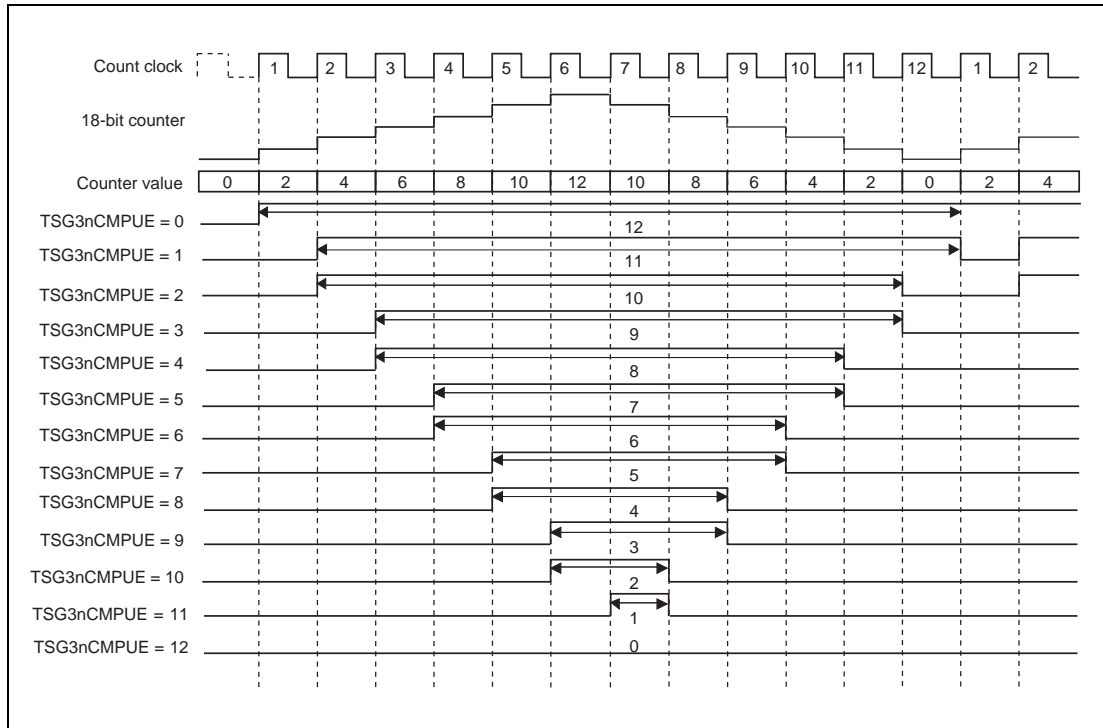

Figure 25.62 Example of TSG3nO1 Output when Additional Pulse Control Is Used in HT-PWM Mode

NOTE

TSG3nCMP0E = 12, TSG3nDTC0 = 0, TSG3nDTC1 = 0

(b) Example of Pulse Output when Additional Pulse Control Is Not Used

The arrows and numerical values in **Figure 25.63** show the duty cycle width of the TSG3nO1 output in one period.

When the additional pulse control is not used, the width of the TSG3nO1 output can be set within a range from 12 clock cycles to 0 clock cycles in two-clock-cycle step. In this case, the change in duty cycle is larger than that of the case when the additional pulse control is used.

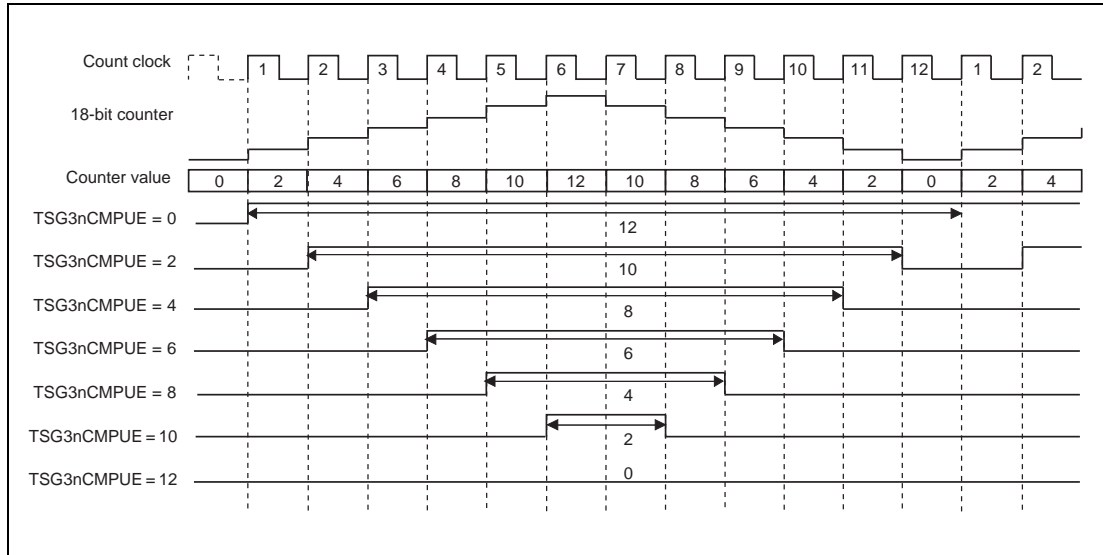

Figure 25.63 Example of TSG3nO1 Output when Additional Pulse Control Is Not Used in HT-PWM Mode

NOTE

TSG3nCMP0E = 12, TSG3nDTC0 = 0, TSG3nDTC1 = 0

(7) Dead Time Control in HT-PWM Mode

Duty setting are basically configured with the TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE registers in HT-PWM mode. The 6-phase PWM waveform of a variable duty is output by using these registers. To achieve the dead time control, there are two dead time control registers (TSG3nDTC0W and TSG3nDTC1W) and six 10-bit down counters that operate synchronously with the count clock of the 18-bit counter. TSG3nDTC0 is used for setting a dead time from a change of the inverse phase to the inactive state to a change of the positive phase to the active state. TSG3nDTC1 is used for setting a dead time from a change of the positive phase to the inactive state to a change of the inverse phase to the active state.

The following figure shows the output waveform when TSG3nDTC0 = x and TSG3nDTC1 = y.

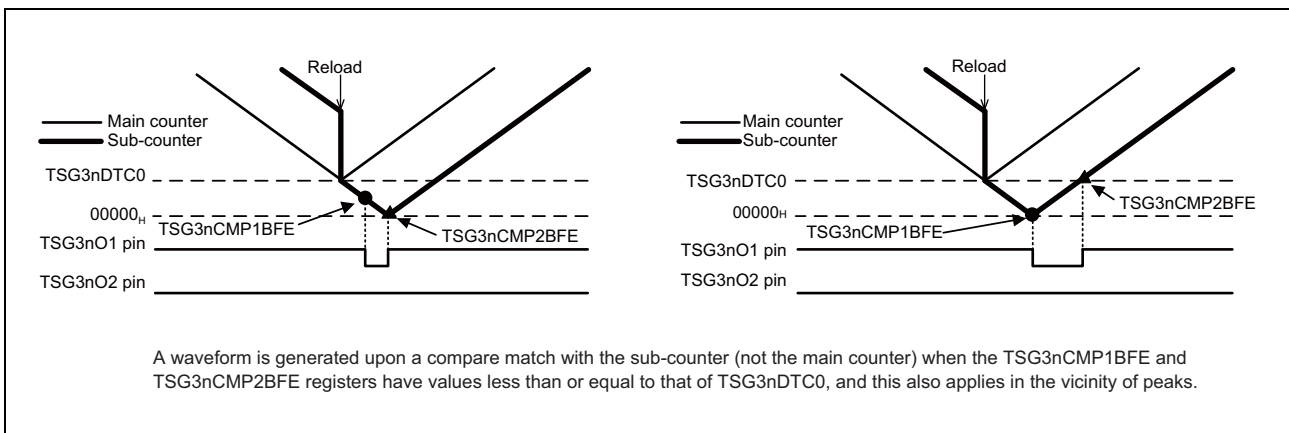

Figure 25.64 Example of Output Waveform with Dead Time in HT-PWM Mode

A waveform is generated upon a compare match with the sub-counter (not the main counter) when the TSG3nCMP1BFE and TSG3nCMP2BFE registers have values less than or equal to that of TSG3nDTC0, and this also applies in the vicinity of peaks.

Figure 25.65 Example of Output Waveform near Trough after Reloading

(8) Notes Concerning Dead Time Control in HT-PWM Mode

(a) TSG3nDTC0 and TSG3nDTC1 Rewriting

It is possible to rewrite the dead time setting in TSG3nDTC0 and TSG3nDTC1 registers during timer operation.

CAUTIONS

1. Rewrite TSG3nDTC0 and TSG3nDTC1 when the reload function is used (TSG3nRMC = 0).
2. The write protection code check function is applied when TSG3nDTC0 and TSG3nDTC1 are rewritten. For details, see the pertinent register descriptions (Section 25.3.43, Section 25.3.44, Section 25.3.63).
3. When the TSG3nCMP0E and Tsg3nDTC1 are updated at the peak of the 18-bit counter:
 If the set value of TSG3nCMPmE is greater than the updated TSG3nCMP0E + TSG3nDTC0 value (new maximum value of the main counter), the match interrupt (INTTSG3nlm) is not generated immediately after reloading (m = 2, 6, or 10).

Figure 25.66 Example of Operation During Reloading at 18-Bit Counter Peak Timing

4. When the TSG3nDTC0 is updated at the valley of the 18-bit counter:
 If the TSG3nCMPmE set value is smaller than the updated TSG3nDTC0 value (new minimum value of the main counter), the match interrupt (INTTSG3nlm) is not generated immediately after reloading (m = 1, 5, or 9).

Figure 25.67 Example of Operation During Reloading at 18-Bit Counter Trough Timing

(9) Software Output Control Function in HT-PWM Mode

TSG3nOPT0.TSG3nSOC, TSG3nIDC, and TSG3nOPT1.TSG3nSPC2-TSG3nSPC0 are used in HT-PWM mode for software control of timer output control.

As shown in **Figure 25.68**, with TSG3nSTE = 0, the output control is switched immediately when TSG3nSOC is set to 1. If the dead time is set, the period of the dead time is guaranteed. After that, when TSG3nSOC is set to 0, output control is retained and at the reload timing, output control is switched to HT-PWM mode output control.

For details, refer to **Section 25.4.7.8, Software Output Control Function**.

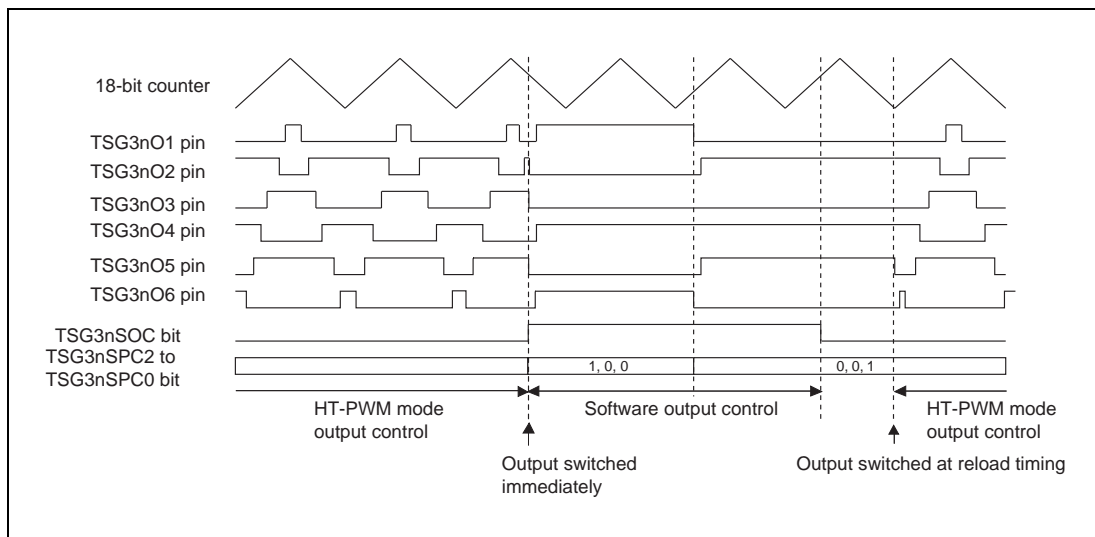

Figure 25.68 Example of Switching from HT-PWM Mode Control to Software Output Control

CAUTION

Use reload (simultaneous rewrite) mode (TSG3nCTL3.TSG3nRMC = 0) when software output control function is used.

(a) Procedure for Software Output Control

Figure 25.69 Flow of Software Output Control in HT-PWM Mode

The procedure for software output control is described below.

- (1) Set the output pattern to the TSG3nOPT1.TSG3nSPC2-TSG3nSPC0. To enable software output control, set TSG3nOPT0.TSG3nSOC to 1 simultaneously.
- (2) Change the output pattern setting of the TSG3nSPC2-TSG3nSPC0 to change the timer output.
- (3) Confirm that reload request flag TSG3nSTR0.TSG3nRSF = 0. In case TSG3nRSF = 1, do not proceed to the following step until TSG3nRSF = 0.
- (4) By setting TSG3nSOC = 0, the software control release process starts (it is not released yet at this point).
- (5) Set the compare register settings that are required after the software output control is released. Proceed to the following step when the register setting is not required. When configuring the registers with the reload function, set them at this point.
- (6) Write to TSG3nCMPUE (TSG3nCMP1E) to start reloading.
- (7) Reload is executed and software output is released.

CAUTION

Execute reload after completing steps (3), (4), (5), and (6). When reload cannot be executed, the software output cannot be released.

(10) Asymmetric Triangular Wave Control in HT-PWM Mode

In HT-PWM mode, it is possible to control output by an asymmetric triangular waveform by setting the different timings for setting and clearing the U, V, and W phases.

The following describes the differences of the asymmetric triangular wave control from the symmetric triangular wave control.

(a) PWM Setting

When a symmetric triangular wave is used, the output control of each of the U phase, V phase, and W phase is done by setting the set timing and the clear timing to the same value in TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE, respectively. When an asymmetric triangular wave is used, the output control of each phase is done by setting TSG3nCMPmE as follows ($m = 1, 2, 5, 6, 9, 10$).

Prerequisites

- The clear timing of PWM of the voltage data signal of U, V and W phases is set with TSG3nCMP1E, TSG3nCMP5E, and TSG3nCMP9E.
- The set timing of PWM of the voltage data signal of U, V, and W phases is set with TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E.
- The set and clear timings of each phase can also be set with TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E.
- TSG3nCMPmE can only be set to an even value ($m = 1, 2, 5, 6, 9, 10$).

(b) Timer Output

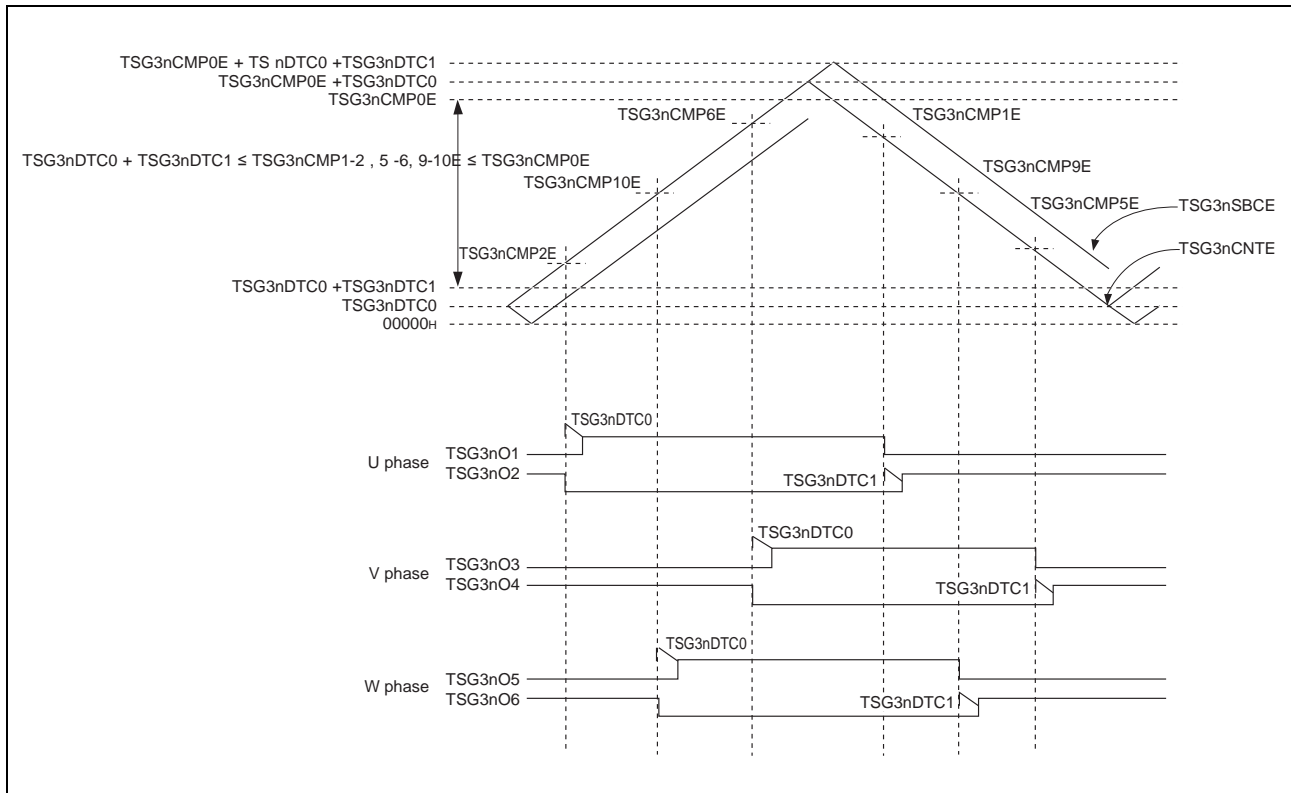

Figure 25.70 Example of Timer Output Waveform in HT-PWM Mode

NOTE

When output is controlled by the asymmetric triangular waveform, the following conditions apply to setting of TSG3nCMPmE (m = 1, 2, 5, 6, 9, 10).

- $TSG3nDTC0 + TSG3nDTC1 \leq TSG3nCMPmE \leq TSG3nCMP0E$
- Only when $TSG3nCMPmE = TSG3nCMP(m+1)E$, or $TSG3nCMPmE = TSG3nCMP(m+1)E + 2$, it is possible to set TSG3nCMPmE under the condition $0000_H \leq TSG3nCMPmE \leq TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1$, which also applies to the case where the symmetric triangular wave is used.

25.4.7.3 SP-PWM Mode (Shifted-pulse - Pulse Width Modulation Mode)

Overview

In this mode, a 6-phase PWM can be generated using the 18-bit counter and the 18-bit compare registers.

Prerequisites

- The PWM signal cycle is set in TSG3nCMP0E.
- The set timings of the U phase, V phase, and W phase are configured using TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E, while the clear timings of these phases are configured using TSG3nCMP1E, TSG3nCMP5E, and TSG3nCMP9E (when set timing and clear timing are used for control).
- The set timings of the U phase, V phase, and W phase are configured using TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E while the active periods of these phases are configured using TSG3nUPWE, TSG3nVPWE, and TSG3nWPWE. The sum of the set values of TSG3nCMP2E, TSG3nCMP6E, TSG3nCMP10E, and the set values of TSG3nUPWE, TSG3nVPWE, TSG3nWPWE are set to TSG3nCMP1E, TSG3nCMP5E, and TSG3nCMP9E respectively (when set timing and active period are used for control). The value after addition must be no greater than 3FFFF_H. Otherwise, values having 19 or more bits are truncated.

Functional description

In this mode, the carrier period, the set timings, and the duty cycle of the U phase, V phase, and W phase are configured. The counting up begins when TSG3nTRG0.TSG3nTS is set to 1.

The 18-bit counter counts up from 00000_H and is cleared by match with TSG3nCMP0E.

The dead time is set with TSG3nDTC0 and TSG3nDTC1. TSG3nDTC0 sets the dead time of inverse phase (OFF) to positive phase (ON) switch while TSG3nDTC1 sets that of positive phase (OFF) to inverse phase (ON) switch. The 10-bit counters (TSG3nDTT1 to TSG3nDTT3) for dead time generation load the set values of TSG3nDTC0 and TSG3nDTC1 at compare match of the 18-bit counter with the TSG3nCMPmE buffer register (m = 1, 2, 5, 6, 9, 10) and start down-counting.

INTTSG3nIm interrupts (m = 1, 2, 5, 6, 9, 10) are generated by the compare match of the 18-bit counter with the TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E buffer registers.

NOTE

SP-PWM mode is enabled when TSG3nCTL0.TSG3nMD2-TSG3nMD0 = 010_B.

(1) Basic Timing Chart

Figure 25.71 Basic Timing in SP-PWM Mode

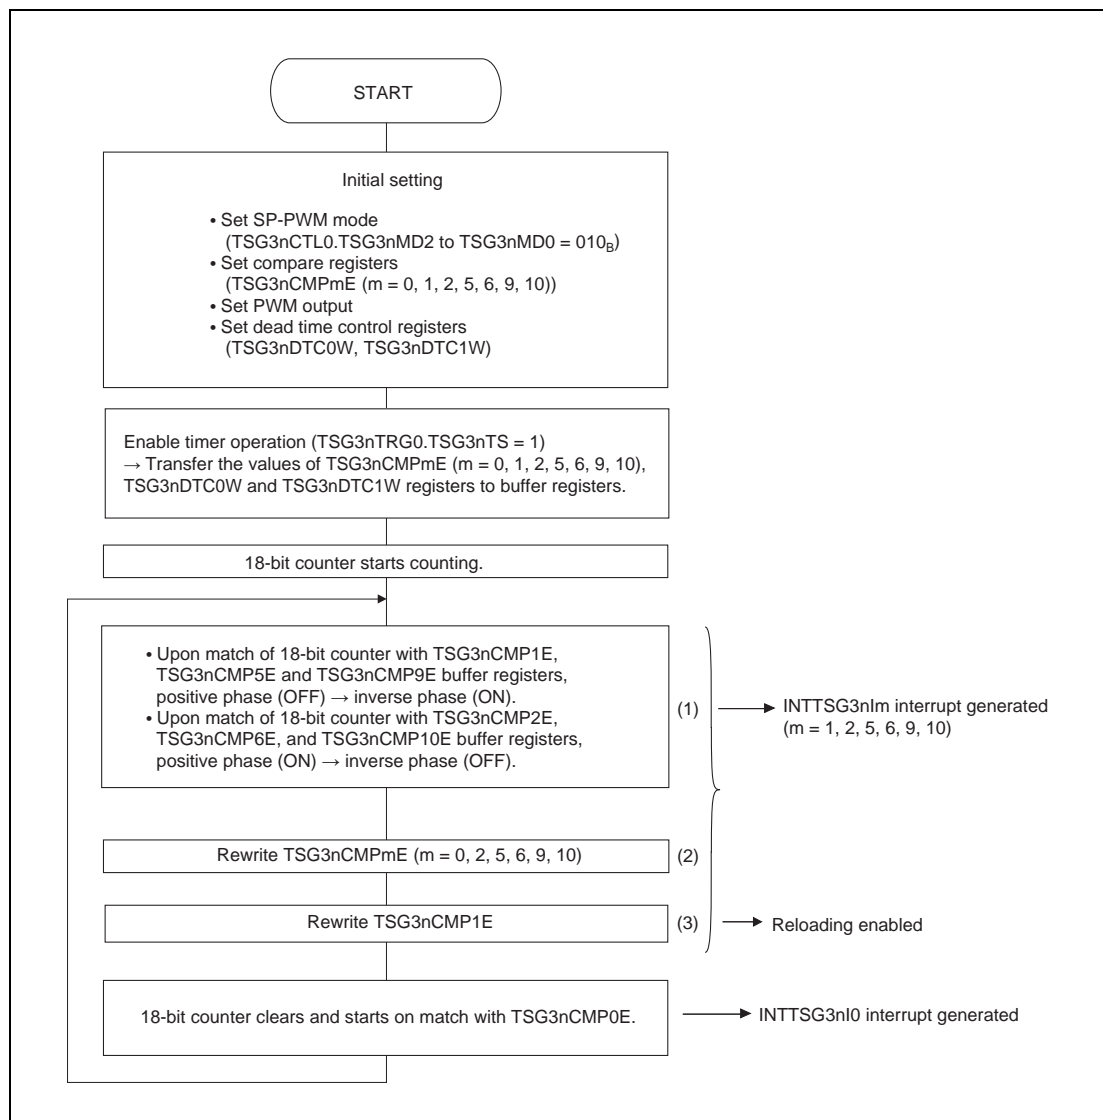

Figure 25.72 Basic Operation Flow in SP-PWM Mode

NOTE

The timing of (1) may be different depending on the rewriting timing of (2) and (3) and the TSG3nCMP1E value. Be sure to rewrite (2) before rewriting (3).

(2) List of SP-PWM Mode Operations

Table 25.67 Counter Functions in SP-PWM Mode

Operation	Setting Condition	
18-bit counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1 or simultaneous start trigger
	Clear	Compare match of TSG3nCMP0E buffer register with 18-bit counter
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1

Table 25.68 Compare Registers and Dead Time Control Register Functions in SP-PWM Mode

Register	Rewriting Method	Rewrite during Operation	Function
TSG3nCMP0E	Reload/Anytime rewrite	Possible	Setting period
TSG3nUPWE	Reload/Anytime rewrite	Possible	PWM control for U phase
TSG3nCMP1E, TSG3nCMP2E	Reload/Anytime rewrite		
TSG3nVPWE	Reload/Anytime rewrite	Possible	PWM control for V phase
TSG3nCMP5E, TSG3nCMP6E	Reload/Anytime rewrite		
TSG3nWPWE,	Reload/Anytime rewrite	Possible	PWM control for W phase
TSG3nCMP9E, TSG3nCMP10E	Reload/Anytime rewrite		
TSG3nDCMP0E, TSG3nDCMP1E, TSG3nDCMP2E	Reload/Anytime rewrite	Possible	Diagnostic output or A/D conversion trigger
TSG3nDTC0W, TSG3nDTC1W	Reload	Possible	Period and dead time

Table 25.69 Timer Input Function in SP-PWM Mode

Pin	Function
TSG3nCLKI	Clock enable input

Table 25.70 Output Functions in SP-PWM Mode

Pin	Function
TSG3nO1	PWM output with dead time by compare match of TSG3nCMP1E buffer register (clear timing) or TSG3nCMP2E buffer register (set timing) with 18-bit counter
TSG3nO2	Output inverse phase with respect to TSG3nO1 (with dead time)
TSG3nO3	PWM output with dead time by compare match of TSG3nCMP5E buffer register (clear timing) or TSG3nCMP6E buffer register (set timing) with 18-bit counter
TSG3nO4	Output inverse phase with respect to TSG3nO3 (with dead time)
TSG3nO5	PWM output with dead time by compare match of the TSG3nCMP9E buffer register (clear timing) or the TSG3nCMP10E buffer register (set timing) with the 18-bit counter
TSG3nO6	Output inverse phase with respect to TSG3nO5 (with dead time)
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger

Table 25.71 Interrupt Requests in SP-PWM Mode

Interrupt	Function
INTTSG3nIm (m = 0, 1, 2, 5, 6, 9, 10)	Compare match of TSG3nCMPmE buffer register with 18-bit counter (m = 0, 1, 2, 5, 6, 9, 10)
INTTSG3nIER	Error
INTTSG3nIVLY	—
INTTSG3nIPEK	Peak interrupt (generated at the same timing as INTTSG3nI0 interrupt)
INTTSG3nIWN	Warning

Table 25.72 Compare Match Timing in SP-PWM Mode

Compare Match	Timing
TSG3nCMP0E	When 18-bit counter changes from TSG3nCMP0E to 00000 _H
TSG3nCMPmE (m = 1, 2, 5, 6, 9, 10)	After match of 18-bit counter and TSG3nCMPmE is detected (m = 1, 2, 5, 6, 9, 10)

Table 25.73 Example of Setting Each Timer Output Condition in SP-PWM Mode

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TSG3nO1, TSG3nO3, TSG3nO5	PWM output	(TSG3nCMP0E + 1) x count clock	Output an inactive level throughout one period (duty 0%)	TSG3nCMPmE = TSG3nCMP (m + 1) E or TSG3nCMP (m + 1) E > TSG3nCMP0E (m = 1, 5, 9)
			Output an active level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m + 1) E + 1 TSG3nCMP (m + 1) E = TSG3nCMPmE - 1 (m = 1, 5, 9)
			Output an inactive level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m + 1) E - 1 TSG3nCMP (m + 1) E = TSG3nCMPmE + 1 (m = 1, 5, 9)
			Output an active level throughout one period (duty 100%)	TSG3nCMPmE > TSG3nCMP0E TSG3nCMP (m + 1) E ≤ TSG3nCMP0E (m = 1, 5, 9)
TSG3nO2, TSG3nO4, TSG3nO6	PWM output	(TSG3nCMP0E + 1) x count clock	Output an inactive level throughout one period (duty 0%)	TSG3nCMP (m - 1) E > TSG3nCMP0E (m = 2, 6, 10)
			Output an active level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m - 1) E - 1 TSG3nCMP (m - 1) E = TSG3nCMPmE + 1 (m = 2, 6, 10)
			Output an inactive level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m - 1) E + 1 TSG3nCMP (m - 1) E = TSG3nCMPmE - 1 (m = 2, 6, 10)
			Output an active level throughout one period (duty 100%)	TSG3nCMPmE = TSG3nCMP (m - 1) E or TSG3nCMPmE > TSG3nCMP0E (m = 2, 6, 10)
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger	(TSG3nCMP0E + 1) x count clock	Please refer to Section 25.4.5, A/D Conversion Trigger Function.	

(3) Various Settings of SP-PWM Mode

Setting mode

SP-PWM mode is entered by setting TSG3nCTL0.TSG3nMD2-TSG3nMD0 to 010_B.

Setting timer output

The output pins TSG3nO1-TSG3nO6 are controlled by setting TSG3nIOC0, TSG3nIOC2, and TSG3nIOC3.

The TSG3nO7 pin provides output pulse as diagnostic output or A/D conversion trigger. The pin should be set as necessary.

Enabling error interrupt generation

Error interrupt (INTTSG3nIER) due to the detection of the simultaneous active state of the positive and inverse phases is enabled by setting TSG3nIOC1.TSG3nEOC to 1. For details, refer to **Section 25.4.6, Error/Warning Interrupt**.

Setting rewriting timing of register with reload function

With the TSG3nCTL3.TSG3nRMC, reload (simultaneous rewrite) or rewrite (anytime) is specified for the registers with reload function. The default setting is 0 (reload). To reload, set TSG3nCTL4.TSG3nPRE to 1.

No reload timing is generated when TSG3nPRE = 0.

When “anytime rewrite” is specified, unintended output may be generated depending on the rewrite timing.

Setting A/D conversion trigger output

The A/D conversion trigger 0 (TSG3nADTRG0 signal) is set with TSG3nCTL5.TSG3nAT09 to TSG3nAT00.

TSG3nAT09 to TSG3nAT00 is used to enable or disable the A/D conversion trigger output at the match of TSG3nDCMP2E to TSG3nDCMP0E with the 18-bit counter (up count).

TSG3nCTL6.TSG3nAT19 to TSG3nAT10 is used to set the A/D conversion trigger 1 (TSG3nADTRG1 signal).

To set the match timing of the 18-bit counter and TSG3nDCMP2E to TSG3nDCMP0E, set the compare value to each register.

The skipping function can be used for TSG3nADTRG0 and TSG3nADTRG1 signals. TSG3nACC00 and TSG3nACC01 of TSG3nCTL5, and TSG3nACC10 and TSG3nACC11 of TSG3nCTL6 can be used to select the skipping rate from 1/1 (no skipping), 1/2, 1/4, and 1/8.

CAUTION

- Be sure to set TSG3nCTL5, TSG3nCTL6, and TSG3nDCMP2E to TSG3nDCMP0E correctly when the timing pulse of A/D conversion trigger is output to TSG3nO7.
- In SP-PWM mode, no valley interrupt (INTTSG3nIVLY) is generated. Therefore, TSG3nCTL5.TSG3nAT00 and TSG3nCTL6.TSG3nAT10 must be set to 0.
- In SP-PWM mode, the 18-bit sub-counter does not operate. Therefore, TSG3nAT09 and TSG3nAT08 in TSG3nCTL5, and TSG3nAT19 and TSG3nAT18 in TSG3nCTL6 must be set to 0.

- In SP-PWM mode, down counting by the 18-bit counter is not generated. Therefore, TSG3nAT07, TSG3nAT05, and TSG3nAT03 in TSG3nCTL5 and TSG3nAT17, TSG3nAT15, and TSG3nAT13 in TSG3nCTL6 should be set to 0.

Setting dead time

The dead time can be set with TSG3nDTC0 and TSG3nDTC1.

The dead time is calculated by the following expressions:

$$\text{PCLK} \times \text{TSG3nDTC0}$$

$$\text{PCLK} \times \text{TSG3nDTC1}$$

TSG3nDTC0 can set the time between a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the inactive state and a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the active state, respectively.

TSG3nDTC1 can set the time between a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the inactive state, and a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the active state, respectively.

Carrier period

Set the carrier period with TSG3nCMP0E according to the following expression:

$$\text{TSG3nCMP0E} = (\text{carrier period/count clock period}) - 1$$

CAUTION

PWM output with 100% duty cannot be produced when $\text{TSG3nCMP0E} = 3\text{FFFF}_{\text{H}}$.

Setting duty (PWM width)

The duty of U phase, V phase, and W phase is set with TSG3nCMPmE, TSG3nUPWE, TSG3nVPWE, and TSG3nWPWE (m = 1, 2, 5, 6, 9, 10), respectively.

- The set timings of the U phase, V phase, and W phase are configured using TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E, and the clear timings are configured using TSG3nCMP1E, TSG3nCMP5E, and TSG3nCMP9E (when set timing and clear timing are used for control).
- The set timings of U phase, V phase, and W phase are configured using TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E while the active periods of these phases are configured using TSG3nUPWE, TSG3nVPWE, and TSG3nWPWE.
The sum of the set values of TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E, and the set values of TSG3nUPWE, TSG3nVPWE, and TSG3nWPWE are set to TSG3nCMP1E, TSG3nCMP5E, and TSG3nCMP9E respectively (when set timing and active period are used for control).

(4) Dead Time Control in SP-PWM mode

Duty setting registers are TSG3nCMPmE (m = 1, 2, 5, 6, 9, 10), TSG3nUPWE, TSG3nVPWE, and TSG3nWPWE and register for setting the period is TSG3nCMP0E. The 6-phase PWM waveform of a variable duty is output by using these registers. To achieve the dead time control, there are six 10-bit down counters that operate synchronously with the count clock of the 18-bit counter and two dead time control registers (TSG3nDTC0W and TSG3nDTC1W). TSG3nDTC0W is used for setting a dead time from a change of the inverse phase to the inactive state to a change of the positive phase to the active state. TSG3nDTC1W is used for setting a dead time from a change of the positive phase to the inactive state to a change of the inverse phase to the active state.

Dead time counter keeps operating even when operation stop (TSG3nTE = 0) setting collided with dead time insert timing, and the dead time set in TSG3nO1 and TSG3nO2 are always inserted.

The following figure shows an example of the output waveform.

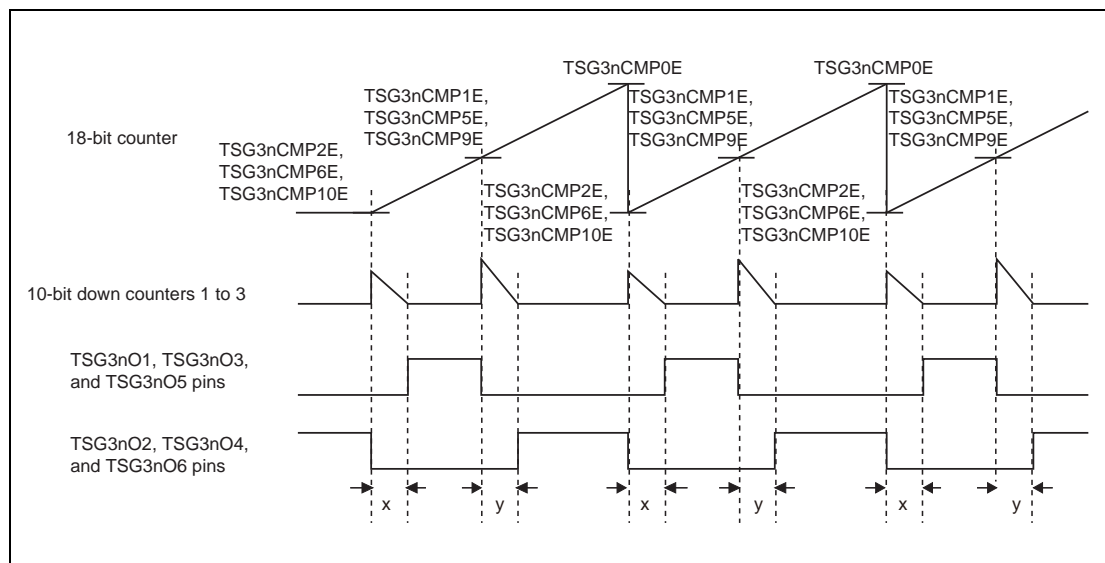

Figure 25.73 Example of Output Waveform in SP-PWM Mode

NOTE

x: TSG3nDTC0 register values, y: TSG3nDTC1 register values

(5) Software Output Control Function in SP-PWM Mode

TSG3nOPT0.TSG3nSOC, TSG3nIDC, and TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 are used to control timer output by software.

As shown in **Figure 25.74**, the output control is switched immediately when TSG3nSOC is set to 1. If the dead time is set, the period of the dead time is guaranteed. After that, when TSG3nSOC is set to 0, output control is retained, and at the reload timing, output control is switched to SP-PWM mode output control.

For details, refer to **Section 25.4.7.8, Software Output Control Function**.

Figure 25.74 Example of Switching from SP-PWM Mode Control to Software Output Control

(a) Procedure for Software Output Control Processing

Figure 25.75 Flow of Software Output Control

The procedure for software output control is described below.

- (1) Set TSG3nIDC to determine the electric current direction. The timer output has a 180-degree phase shift between when TSG3nIDC = 0 and when TSG3nIDC = 1. When this bit is rewritten with the software output control function, the output pattern will change according to the new setting at the next timer cycle.
- (2) Set the output pattern in TSG3nSPC2-0. At the same time, set TSG3nSOC to 1 to switch to software output control mode.
- (3) Change the output pattern setting for TSG3nSPC2-0 to change the timer output.
- (4) Ensure that the reload request flag TSG3nRSF is 0. If TSG3nRSF is 1, do not proceed to the following step until TSG3nRSF = 0.
- (5) By clearing TSG3nSOC to 0, software control release process starts (it is not released yet at this point).
- (6) Configure the compare register settings that are required after the software output control is released. Proceed to the following step when the register configuration is not required. When configuring the registers with the reload function, configure them at this point.
- (7) Write to TSG3nUPWE (TSG3nCMP1E) to start reloading.
- (8) Reload is executed and software output control is released.

CAUTION

Be sure to execute reload after completing steps (4), (5), (6), and (7). Unless reload can be executed, software output control cannot be released

25.4.7.4 120-DC Mode

Overview

In this mode, PWM output period set to TSG3nCMP0E and timer output (TSG3nO1 to TSG3nO6) according to the duty cycle set with TSG3nCMP1E to TSG3nCMP12E are controlled with three types of pattern inputs (software output control method, pattern switch method, and trigger switch method) to perform 120-DC control.

Prerequisites

- Set the PWM period with TSG3nCMP0E.
- Set the PWM duty with TSG3nCMP1E to TSG3nCMP12E and set the output pattern with TSG3nPAT0W and TSG3nPAT1W.

Functional description

In this mode, configure the PWM period, the duty cycle with each compare register, and the pattern to be output with each pattern register. Counting up begins when TSG3nTRG0.TSG3nTS is set to 1.

The 18-bit counter starts counting from 00000_H, and is cleared by the match with TSG3nCMP0E.

INTTSG3nI1 to INTTSG3nI12 interrupts are generated by a compare match of the 18-bit counter and TSG3nCMP1E to TSG3nCMP12E buffer registers, respectively.

NOTE

120-DC mode is enabled when TSG3nCTL0.TSG3nMD2-TSG3nMD0 = 011_B.

Figure 25.76 Block Diagram in 120-DC Mode

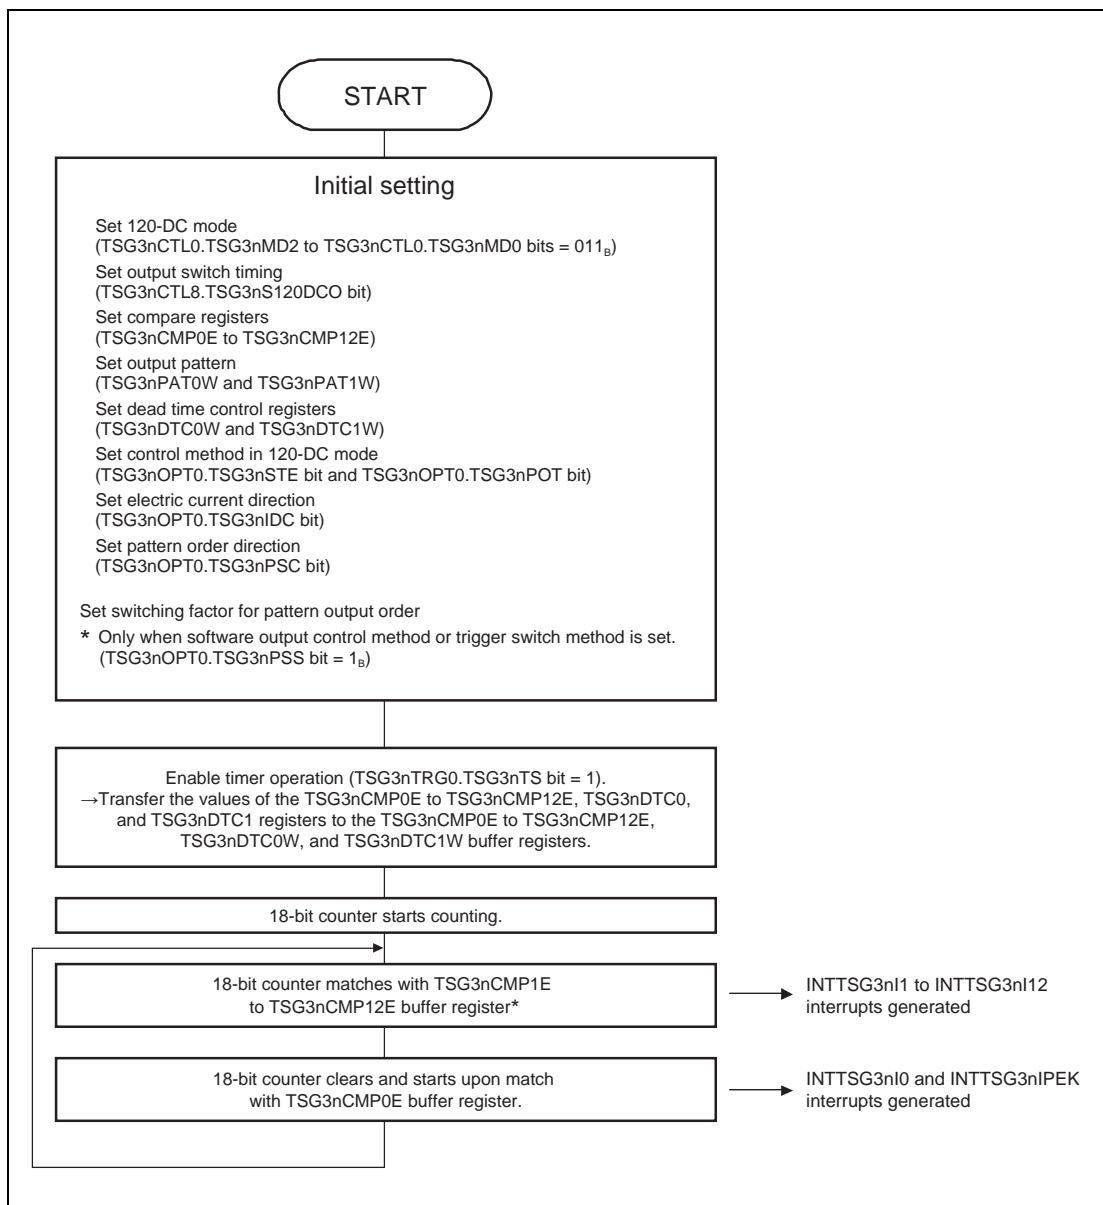

Figure 25.77 Basic Operation Flow in 120-DC Mode

NOTE

The 18-bit counter is not cleared by match of the 18-bit counter with the TSG3nCMP1E to TSG3nCMP12E buffer registers

(1) List of Operations in 120-DC Mode

Table 25.74 Counter Functions in 120-DC Mode

Operation	Setting Condition	
18-bit counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1 or simultaneous start trigger
	Clear	When TSG3nCTL8.TSG3nS120DCO is 0: timing of a match of TSG3nCMP0E value and 18-bit counter value or output pattern switch When TSG3nCTL8.TSG3nS120DCO is 1: timing of a match of TSG3nCMP0E value with 18-bit counter value
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1

Table 25.75 Functions of Compare Registers and Dead Time Control Registers in 120-DC Mode

Register	Rewrite Method	Rewrite during Operation	Function
TSG3nCMP0E	Reload	Possible	Setting period
TSG3nCMPmE (m = 1-12)	Reload	Possible	Setting PWM duty
TSG3nDCMP0E, TSG3nDCMP1E, TSG3nDCMP2E	Reload	Possible	Diagnostic signal output or A/D conversion trigger
TSG3nDTC0W, TSG3nDTC1W	Reload	Possible	Setting dead time

Table 25.76 Timer Input Function in 120-DC Mode

Pin/Signal	Function
TSG3nCLKI pin	Clock enable input
TSG3nPTSI2-TSG3nPTSI0 pins	Pattern input (3 phases)
TSG3nOPCI0, TSG3nOPCI1 signals	Trigger input

Table 25.77 Timer Output Function in 120-DC Mode

Pin/Signal	Function
TSG3nO1 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 1, 2, 5, 6, 9, 10) with the 18-bit counter and output pattern selected by TSG3nPAT0W setting.
TSG3nO2 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 3, 4, 7, 8, 11, 12) with the 18-bit counter and output pattern selected by TSG3nPAT1W setting.
TSG3nO3 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 1, 2, 5, 6, 9, 10) with the 18-bit counter and output pattern selected by TSG3nPAT0W setting.
TSG3nO4 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 3, 4, 7, 8, 11, 12) with the 18-bit counter and output pattern selected by TSG3nPAT1W setting.
TSG3nO5 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 1, 2, 5, 6, 9, 10) with the 18-bit counter and output pattern selected by TSG3nPAT0W setting.
TSG3nO6 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 3, 4, 7, 8, 11, 12) with the 18-bit counter and output pattern selected by TSG3nPAT1W setting.
TSG3nO7 pin	Diagnostic signal output or pulse output by A/D conversion trigger
TSG3nPTE signal	Toggle signal by change in input pattern

Table 25.78 Interrupt Requests in 120-DC Mode

Interrupt	Function
INTTSG3nIm (m = 0 to 12)	Compare match of TSG3nCMPmE buffer register and 18-bit counter (m = 0 to 12)
INTTSG3nIER	Error
INTTSG3nIVLY	—
INTTSG3nIPEK	Peak interrupt (generated at the same timing as INTTSG3nI0)
INTTSG3nIWN	Warning interrupt

Table 25.79 Compare Match Timing in 120-DC Mode

Compare Match	Timing
TSG3nCMP0E	When 18-bit counter changes from TSG3nCMP0E to 00000 _H
TSG3nCMPmE (m = 1 to 12)	After detecting the match of 18-bit counter and TSG3nCMPmE (m = 1 to 12)

Table 25.80 Example of Setting Each Timer Output Condition in 120-DC Mode

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TSG3nOm (m = 1 to 6)	PWM output	$(TSG3nCMP0E + 1) \times \text{count}$ clock	See (6), List of Output Patterns in 120-DC Mode.	—
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger	$(TSG3nCMP0E + 1) \times \text{count}$ clock	See Section 25.4.5, A/D Conversion Trigger Function.	—

(2) Various Settings of 120-DC Mode

Setting mode

120-DC mode is entered by setting TSG3nCTL0.TSG3nMD2-TSG3nMD0 to 011_B.

Setting timer output

The output pins TSG3nO1 to TSG3nO6 are controlled by setting TSG3nIOC0, TSG3nIOC2, and TSG3nIOC3.

The TSG3nO7 pin provides output pulse as diagnostic output or A/D conversion trigger. The pin should be set as necessary.

Enabling error interrupt generation

With TSG3nIOC1.TSG3nEOC = 1, the error interrupt (INTTSG3nIER) generation is enabled when the simultaneous active state of the positive phase and inverse phase is detected. For details, see **Section 25.4.6, Error/Warning Interrupt**.

Setting register rewrite timing

Reloading the registers with the reload function is activated with TSG3nCTL3.TSG3nRMC (simultaneous rewrite; default setting is 0 = reload). To reload, set TSG3nCTL4.TSG3nPRE to 1.

The reload timing is not generated if TSG3nPRE is 0.

Setting A/D conversion trigger output

To set A/D conversion trigger 0 (TSG3nADTRG0 signal), use TSG3nCTL5.TSG3nAT09 to TSG3nAT00.

With TSG3nAT09 to TSG3nAT00, A/D conversion trigger output is enabled or disabled at the match of the 18-bit counter and TSG3nDCMP2E to TSG3nDCMP0E (during up count).

To set A/D conversion trigger 1 (TSG3nADTRG1 signal), use TSG3nCTL6.TSG3nAT19 to TSG3nAT10.

To set the match timing of the 18-bit counter and TSG3nDCMP2E to TSG3nDCMP0E, set the compare value to the pertinent register.

The skipping function can be used for TSG3nADTRG0 and TSG3nADTRG1 signals. Use TSG3nACC01, TSG3nACC00 of TSG3nCTL5, and TSG3nACC11, TSG3nACC10 of TSG3nCTL6 to select the skipping rate from 1/1 (no skipping), 1/2, 1/4, and 1/8.

CAUTION

- Be sure to set TSG3nCTL5, TSG3nCTL6, and TSG3nDCMP2E to TSG3nDCMP0E correctly when the timing pulse of A/D conversion trigger is output to TSG3nO7.
- In 120-DC mode, a valley interrupt (INTTSG3nIVLY) is not generated. Therefore, TSG3nCTL5.TSG3nAT00 and TSG3nCTL6.TSG3nAT10 must be set to 0.
- In 120-DC mode, the 18-bit sub-counter does not operate. TSG3nAT09 and TSG3nAT08 in TSG3nCTL5, and TSG3nAT19 and TSG3nAT18 in TSG3nCTL6 must be set to 0.
- In 120-DC mode, the 18-bit counter does not decrement. Therefore, TSG3nAT07, TSG3nAT05, and TSG3nAT03 in TSG3nCTL5 and TSG3nAT17, TSG3nAT15, and

TSG3nAT13 in TSG3nCTL6 must be set to 0.

Setting dead time

The dead time can be set with TSG3nDTC0 and TSG3nDTC1.

The dead time is calculated by the following expressions

$$\text{PCLK} \times \text{TSG3nDTC0}$$

$$\text{PCLK} \times \text{TSG3nDTC1}$$

TSG3nDTC0 can set the time between a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the inactive state and a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the active state, respectively.

TSG3nDTC1 can set the time between a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the inactive state to a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the active state, respectively.

Carrier period

Set the carrier period with TSG3nCMP0E according to the following expression:

$$\text{TSG3nCMP0E} = (\text{carrier period/count clock period}) - 1$$

Setting duty (PWM width)

The duty of PWM output is set with TSG3nCMP1E to TSG3nCMP12E. The setting range of the compare registers is as follows:

$$00000_{\text{H}} \leq \text{TSG3nCmPmE} \leq \text{TSG3nCMP0E} + 1$$

CAUTION

Do not set TSG3nCmPmE = TSG3nCMP0E + 1 (m = 1 to 12) only when TSG3nCMP0E + 1 < TSG3nCmPmE, and TSG3nCMP0E = 3FFFF_H.

Setting output PWM

In 120-DC mode, the output pins TSG3nO1, TSG3nO3, and TSG3nO5 are controlled by TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E, and the output pins TSG3nO2, TSG3nO4, TSG3nO6 are controlled by TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, and TSG3nCMP12E. The duty cycle of a PWM period (TSG3nCMP0E) can be set with TSG3nCMP1E to TSG3nCMP12E. Setting TSG3nCMP1E to TSG3nCMP12E to 00000_H sets the PWM duty cycle to 0%. Setting TSG3nCMP1E to TSG3nCMP12E to TSG3nCMP0E + 1 value sets the PWM duty cycle to 100%. This allows chopping output control and rectangular wave output control.

(3) Control Methods in 120-DC Mode

Control methods in 120-DC mode are listed below.

Table 25.81 Control Method in 120-DC Mode

Control Method	Function
Software output control method	Switches the output pattern according to the TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 setting made by software.
Pattern switch method	Switches the output pattern by the pattern input signal of TSG3nPTSI0 to TSG3nPTSI2.
Trigger switch method	Switches the output pattern by the trigger switch method using the trigger input signals TSG3nOPCI0 and TSG3nOPCI1 or by the pattern input setting of TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 in the constant order.

Switch timing of timer output when changing input pattern of 120-DC mode can be set by TSG3nCTL8.TSG3nS120DCO.

Table 25.82 Setting of TSG3nS120DCO and Operation in 120-DC Mode

TSG3nS120DCO	Function
0	When input patterns are changed, the main counter (TSG3nCNTE) is cleared and the change of patterns is immediately reflected to timer output.
1	When input patterns are changed, the change of input patterns is reflected to timer output at the next timer cycle (after a match of the main counter (TSG3nCNTE) with TSG3nCMP0E).

Setting software output control method

Setting TSG3nOPT0.TSG3nSTE = 0 enables switching of output pattern by software output control. The TSG3nO1 to TSG3nO6 pin output is switched according to the settings of TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0.

The pattern output order at the beginning of operation is set with TSG3nOPT0.TSG3nIDC and TSG3nOPT0.TSG3nPSC.

Operation of software output control method

The PWM output of TSG3nO1 to TSG3nO6 pins (PWM output defined by TSG3nCMP1E to TSG3nCMP1E) is selected using TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 configured by software. As for the control of the dead time, the dead time counter is activated at the falling edge of the signals in each phase and the dead time is inserted.

The 18-bit counter counts according to the carrier period set in TSG3nCMP0E. The 18-bit counter is cleared by match of the 18-bit counter and TSG3nCMP0E or by a write access to TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 (when TSG3nS120DCO = 0).

In this method, the pattern, which is decoded using information consisting of the output pattern (TSG3nSPC2 to TSG3nSPC0), the electric current direction control bit (TSG3nOPT0.TSG3nIDC), and order detection control bit (TSG3nOPT0.TSG3nPSC), is output. **Figure 25.98** shows the timer output when the output pattern is changed by software output control.

Immediately after the operation starts (TSG3nTRG0.TSG3nTS = 1), the output pattern of TSG3nSPC2 to TSG3nSPC0 and the pattern set with TSG3nIDC and TSG3nPSC (TSG3nOPT0.TSG3nPSS = 1) are output.

Setting pattern switch method

Setting TSG3nOPT0.TSG3nSTE to 1 and TSG3nPOT to 0 selects the pattern switch method. The TSG3nO1 to TSG3nO6 pin output pattern is changed at the change timing of the TSG3nPTS12 to TSG3nPTS10 pins.

The output pattern at the beginning of operation is set with TSG3nOPT0.TSG3nIDC and with TSG3nOPT0.TSG3nPSC. However, after determining the rotation direction (after the value is set to TSG3nSTR1.TSG3nTSF), the setting of TSG3nPSC is disabled.

Operation of pattern switch method

After level detection is performed for the pins (three inputs from the hall sensor), the level-detected signals are decoded. From the decoding result, the PWM output of TSG3nO1 to TSG3nO6 pins (PWM output defined by TSG3nCMP1E to TSG3nCMP12E value) is selected. To control the dead time, the dead time counter is activated at the falling timing of signals in each phase and the dead time is inserted.

The 18-bit counter is cleared by a match of the 18-bit counter value with the TSG3nCMP0E value or by a change of the input pattern (TSG3nPTS12 to TSG3nPTS10 pins) while TSG3nS120DCO is 0.

In this method, the pattern, which is decoded by using information on input pattern (TSG3nPTS12 to TSG3nPTS10), the electric current direction control bit (TSG3nOPT0.TSG3nIDC), and TSG3nPTS12 to TSG3nPTS10 pattern order detection flag (TSG3nSTR1.TSG3nTSF), is output. **Figure 25.80** to **Figure 25.83** show the timer output when TSG3nPTS12 to TSG3nPTS10 pin inputs change.

Immediately after the operation starts (TSG3nTRG0.TSG3nTS = 1), the output pattern set by the levels input on the TSG3nPTS12 to TSG3nPTS10 pins and by the TSG3nIDC and TSG3nPSC bits is produced. If a level on any of the TSG3nPTS12 to TSG3nPTS10 pins is changed, TSG3nTSF is determined by the direction of the change to the order. After the TSG3nTSF value is determined, the pattern set by the TSG3nTSF bit replaces the pattern set by the TSG3nPSC bit.

CAUTION

When connecting the three-phase pulse input signal to the TSG3nPTS12 to TSG3nPTS10 pins, confirm that the three-phase pulse input value and the patterns output from the TSG3nO1 to TSG3nO6 pins satisfy the expected conditions. If the expected conditions are not satisfied, change the connection between the three-phase pulse input signal and the TSG3nPTS12 to TSG3nPTS10 pins.

Setting trigger switch method

Setting TSG3nOPT0.TSG3nSTE and TSG3nPOT to 1 selects the trigger switch method. The output patterns of pins TSG3nO1 to TSG3nO6 are changed at a rising edge of an external input (TSG3nOPCI1 and TSG3nOPCI0 signals).

For pattern output order, see **Section 25.4.7.4, (5) Operation in 120-DC Mode**.

The initial output pattern can be controlled with TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0.

The initial pattern is output when the TSG3n operation starts (TSG3nTRG0.TSG3nTS = 1) after TSG3nSPC2 to TSG3nSPC0 are configured. For details, see **Section 25.4.7.4, (6) List of Output Patterns in 120-DC Mode**.

Operation of trigger switch method

With the trigger input switch method, the rising edges of the TSG3nOPCI0 and TSG3nOPCI1 signals are detected and the output switch timing is generated. The initial timer output pattern is set with TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0. The subsequent output patterns are switched after rising of the TSG3nOPCI0 and TSG3nOPCI1 signals is detected. Furthermore, the output patterns can be switched by setting TSG3nOPT1.TSG3nSPC2 to TSG3nOPT1.TSG3nSPC0.

The 18-bit counter counts based on the carrier period set in TSG3nCMP0E. The 18-bit counter is cleared by match of the 18-bit counter and TSG3nCMP0E, by a write access to TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0, or by detecting a rising of TSG3nOPCI0 and TSG3nOPCI1 signals. (When TSG3nS120DCO = 0)

For examples of operation in 120-DC mode when trigger input switch method is used, see **Figure 25.80** to **Figure 25.83**.

CAUTION

The initial pattern should be set according to the read input level of the port to which TSG3nPTS12 to TSG3nPTS10 pins are connected.

(4) Timer Output in 120-DC Mode

In 120-DC mode, the PWM output is controlled with TSG3nPAT0W, TSG3nPAT1W, and TSG3nCMP1E to TSG3nCMP12E. TSG3nPAT0W, TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E are set to control the output of TSG3nO1, TSG3nO3, and TSG3nO5 pins. TSG3nPAT1W, TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, and TSG3nCMP12E are set to control the output of TSG3nO2, TSG3nO4, and TSG3nO6 pins.

With PWM output control, eight types of output patterns can be selected for each of TSG3nO1, TSG3nO3, and TSG3nO5 pins and TSG3nO2, TSG3nO4, and TSG3nO6 pins.

Table 25.83 TSG3nPAT0W Set Value and Output Control

PATmT Value	Output Control
000	Fixed to low
001	PWM output set with TSG3nCMP1E
010	PWM output set with TSG3nCMP2E
011	PWM output set with TSG3nCMP5E
100	PWM output set with TSG3nCMP6E
101	PWM output set with TSG3nCMP9E
110	PWM output set with TSG3nCMP10E
111	Fixed to high

Note: m = 0, 1, 2, 3, 4, 5

Figure 25.78 TSG3nO1, TSG3nO3, TSG3nO5 Pin Output of Each Output Pattern

Table 25.84 TSG3nPAT1W Set Value and Output Control

PATmB Value	Output Control
000	Fixed to low
001	PWM output set with TSG3nCMP3E
010	PWM output set with TSG3nCMP4E
011	PWM output set with TSG3nCMP7E
100	PWM output set with TSG3nCMP8E
101	PWM output set with TSG3nCMP11E
110	PWM output set with TSG3nCMP12E
111	Fixed to high

Note: m = 0, 1, 2, 3, 4, 5

Figure 25.79 TSG3nO2, TSG3nO4, TSG3nO6 Pin Output of Each Output Pattern

(5) Operation in 120-DC Mode

Figure 25.80 to **Figure 25.83** show examples of operation in 120-DC mode.

The TSG3nO1 to TSG3nO6 pins detect the input level change of the TSG3nPTSI2 to TSG3nPTSI0 pins, and then change the output pattern. The 18-bit counter produces sawtooth waveform and PWM output using TSG3nCMP0E to TSG3nCMP12E.

When TSG3nS120DCO = 0, the 18-bit counter is cleared to 00000_H each time the counter value matches with TSG3nCMP0E or a change in the TSG3nPTSI2 to TSG3nPTSI0 pins is detected. The timer output pattern is switched each time a change in the TSG3nPTSI2 to TSG3nPTSI0 pins is detected.

When TSG3nS120DCO = 1, the 18-bit counter is cleared to 00000_H when the counter value matches with TSG3nCMP0E but not cleared with a change in the TSG3nPTSI2 to TSG3nPTSI0 pins. The timer output pattern is switched to the one corresponding to the patterns of TSG3nPTSI2 to TSG3nPTSI0 pins at the next match timing of TSG3nCNTE and TSG3nCMP0E.

NOTE

PAT0T to PAT5T and PAT0B to PAT5B show PWM operation set by TSG3nCMP1E to TSG3nCMP12E, respectively.

Figure 25.80 Example of Operation in 120-DC Mode (Normal Rotation: TSG3nSTR1.TSG3nTSF = 0 and TSG3nOPT0.TSG3nIDC = 0)

NOTE

TSG3nOPT0.TSG3nSOC = 0

Figure 25.82 Example of Operation in 120-DC Mode (Reverse Rotation: TSG3nSTR1.TSG3nTSF = 1 and TSG3nOPT0.TSG3nIDC = 0)

NOTE

TSG3nOPT0.TSG3nSOC = 0

Figure 25.83 Example of Operation in 120-DC Mode (Reverse Rotation: TSG3nSTR1.TSG3nTSF = 1 and TSG3nOPT0.TSG3nIDC = 1)

NOTE

TSG3nOPT0.TSG3nSOC = 0

(6) List of Output Patterns in 120-DC Mode

In 120-DC mode, the output pattern is determined according to the electric current direction (TSG3nOPT0.TSG3nIDC) and the pattern order direction.

Table 25.85 Selection of Pattern Order Direction in 120-DC Mode

TSG3nOPT0			Pattern Order Direction
TSG3nSTE	TSG3nPOT	TSG3nPSS	
0	—	1	TSG3nPSC
1	0	—	TSG3nTSF (TSGnPSC only for initial setting at operation start)
1	1	1	TSG3nPSC

Table 25.86 List of Output Patterns in 120-DC Mode (1/4)

Electric current direction: normal (TSG3nIDC = 0)

Pattern order direction: normal (TSG3nTSF = 0 or TSG3nPSC = 0)

Output pins	TSG3nOPT1.TSG3nSPC2-TSG3nSPC0*1/TSG3nSTR1.TSG3nOPF2-TSG3nOPF0							
	101	100	110	010	011	001	000	111
TSG3nO1	PAT0T	PAT1T	PAT2T	PAT3T	PAT4T	PAT5T	Low	Low
TSG3nO2	PAT0B	PAT1B	PAT2B	PAT3B	PAT4B	PAT5B	Low	Low
TSG3nO3	PAT4T	PAT5T	PAT0T	PAT1T	PAT2T	PAT3T	Low	Low
TSG3nO4	PAT4B	PAT5B	PAT0B	PAT1B	PAT2B	PAT3B	Low	Low
TSG3nO5	PAT2T	PAT3T	PAT4T	PAT5T	PAT0T	PAT1T	Low	Low
TSG3nO6	PAT2B	PAT3B	PAT4B	PAT5B	PAT0B	PAT1B	Low	Low

Table 25.86 List of Output Patterns in 120-DC Mode (2/4)

Electric current direction: reverse (TSG3nIDC = 1)

Pattern order direction: normal (TSG3nTSF = 0 or TSG3nPSC = 0)

Output pins	TSG3nOPT1.TSG3nSPC2-TSG3nSPC0*1/TSG3nSTR1.TSG3nOPF2-TSG3nOPF0							
	101	100	110	010	011	001	000	111
TSG3nO1	PAT3T	PAT4T	PAT5T	PAT0T	PAT1T	PAT2T	Low	Low
TSG3nO2	PAT3B	PAT4B	PAT5B	PAT0B	PAT1B	PAT2B	Low	Low
TSG3nO3	PAT1T	PAT2T	PAT3T	PAT4T	PAT5T	PAT0T	Low	Low
TSG3nO4	PAT1B	PAT2B	PAT3B	PAT4B	PAT5B	PAT0B	Low	Low
TSG3nO5	PAT5T	PAT0T	PAT1T	PAT2T	PAT3T	PAT4T	Low	Low
TSG3nO6	PAT5B	PAT0B	PAT1B	PAT2B	PAT3B	PAT4B	Low	Low

Note 1. When TSG3nSPC2 to TSG3nSPC0 are written while the values of TSG3nSTE and TSG3nPOT are 1, the output pattern changes. Thereafter, when a pattern switch trigger is generated on rising of the TSG3nOPC10 and TSG3nOPC11 signals, the output is switched according to the order of pattern switching. When TSG3nS120DCO = 0, the output is switched immediately. When TSG3nS120DCO = 1, the output is switched when the main counter (TSG3nCNTE) matches with TSG3nCMP0E (from the next timer cycle). TSG3nSPC2 to TSG3nSPC0 remain unchanged even if the output pattern is switched.

NOTES

- PAT0T to PAT5T: PWM output set by TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, TSG3nCMP10E
- PAT0B to PAT5B: PWM output set by TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, TSG3nCMP12E

Note 1. When TSG3nSPC2 to TSG3nSPC0 are written while the values of TSG3nSTE and TSG3nPOT are 1, the output pattern changes. Thereafter, when a pattern switch trigger is generated on rising of the TSG3nOPC10 and TSG3nOPC11 signals, the output is switched according to the order of pattern switching. When TSG3nS120DCO = 0, the output is switched immediately.
 When TSG3nS120DCO = 1, the output is switched when the main counter (TSG3nCNTE) matches with TSG3nCMP0E (from the next timer cycle). TSG3nSPC2 to TSG3nSPC0 remain unchanged even if the output pattern is switched.

NOTES

- PAT0T to PAT5T: PWM output set by TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, TSG3nCMP10E
- PAT0B to PAT5B: PWM output set by TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, TSG3nCMP12E

(7) Operation Start Timing in 120-DC Mode

In 120-DC mode, when trigger switch control (TSG3nOPT0.TSG3nSTE=1, TSG3nOPT0.TSG3nPOT = 1) is used, pattern set with TSG3nOPT1.TSG3nSPC2 to TSG3nOPT1.TSG3nSPC0, TSG3nOPT0.TSG3nPSC, and TSG3nOPT0.TSG3nIDC can be output. However, when pattern switch control (TSG3nOPT0.TSG3nSTE=1, TSG3nOPT0.TSG3nPOT = 0) is used, the pattern of the TSG3nPTSI2 to TSG3nPTSI0 pins can be detected but the pattern order direction (TSG3nSTR1.TSG3nTSF) cannot be determined. Therefore, set the pattern order direction in TSG3nPSC when TSG3nTE is 0. The TSG3nPSC set value is loaded to TSG3nTSF, and the value can be used for the initial pattern setting.

- TSG3nOPT0.TSG3nSOC = 0, TSG3nPSC = 0, TSG3nPOT = 0, TSG3nIDC = 0, TSG3nSTE = 1

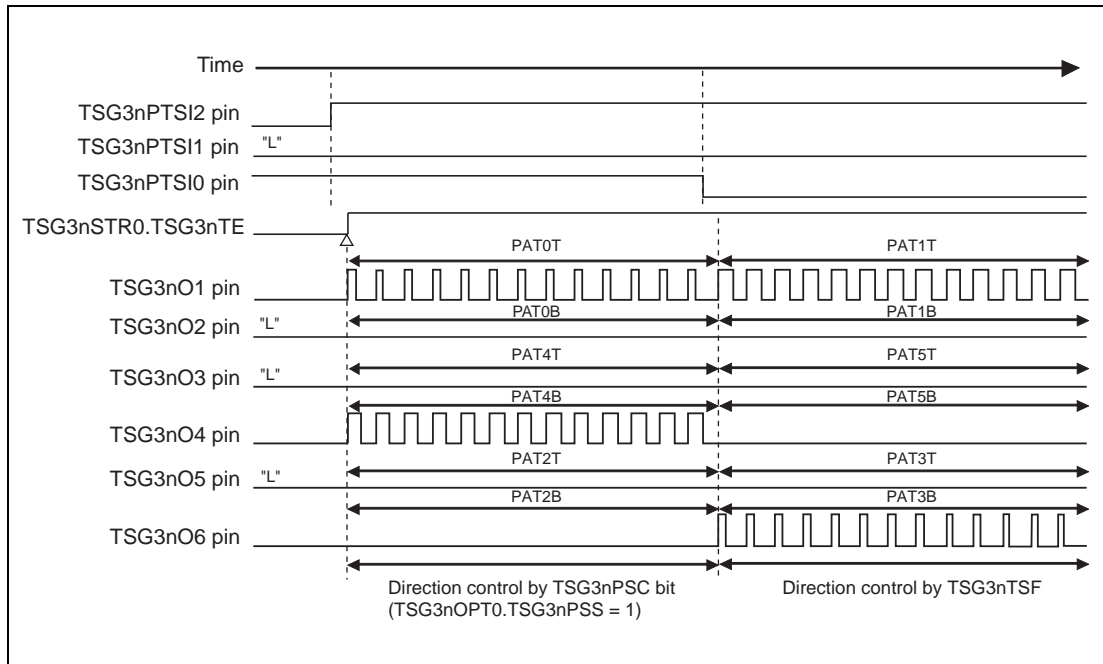

Figure 25.84 Control when Timer Output Starts in Normal Rotation (when Normal Pattern is Input)

- TSG3nOPT0.TSG3nSOC = 0, TSG3nPSC = 1, TSG3nPOT = 0, TSG3nIDC = 1, TSG3nSTE = 1

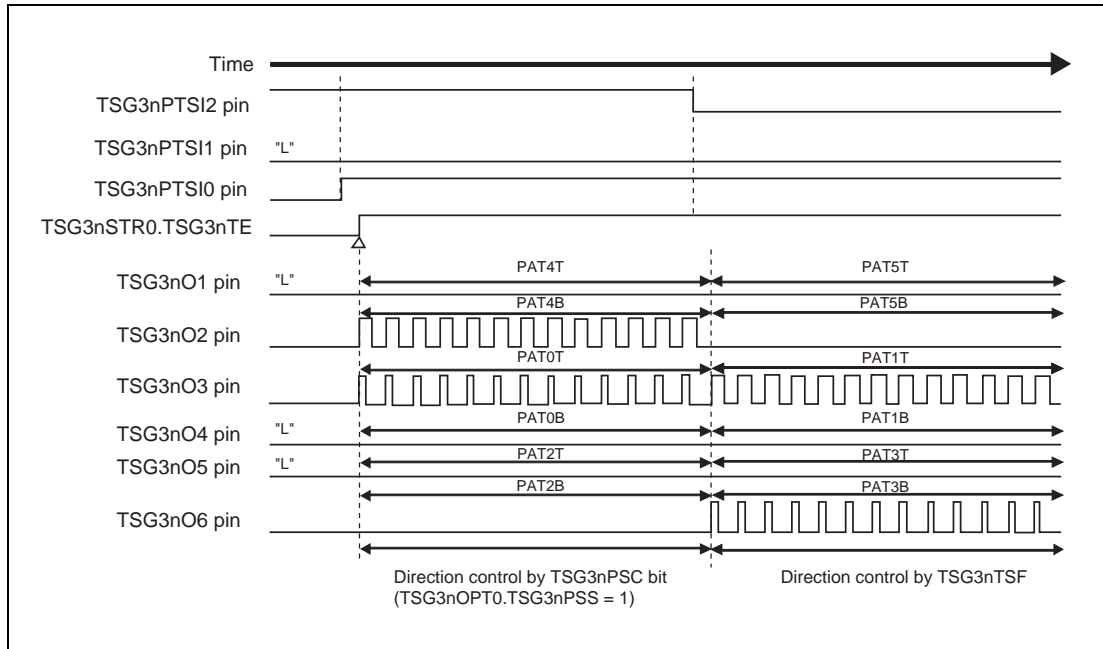

Figure 25.85 Control when Timer Output Starts in Reverse Rotation (when Normal Pattern is Input)

- TSG3nOPT0.TSG3nSOC = 0, TSG3nPSC = 0, TSG3nPOT = 0, TSG3nIDC = 0, TSG3nSTE = 1

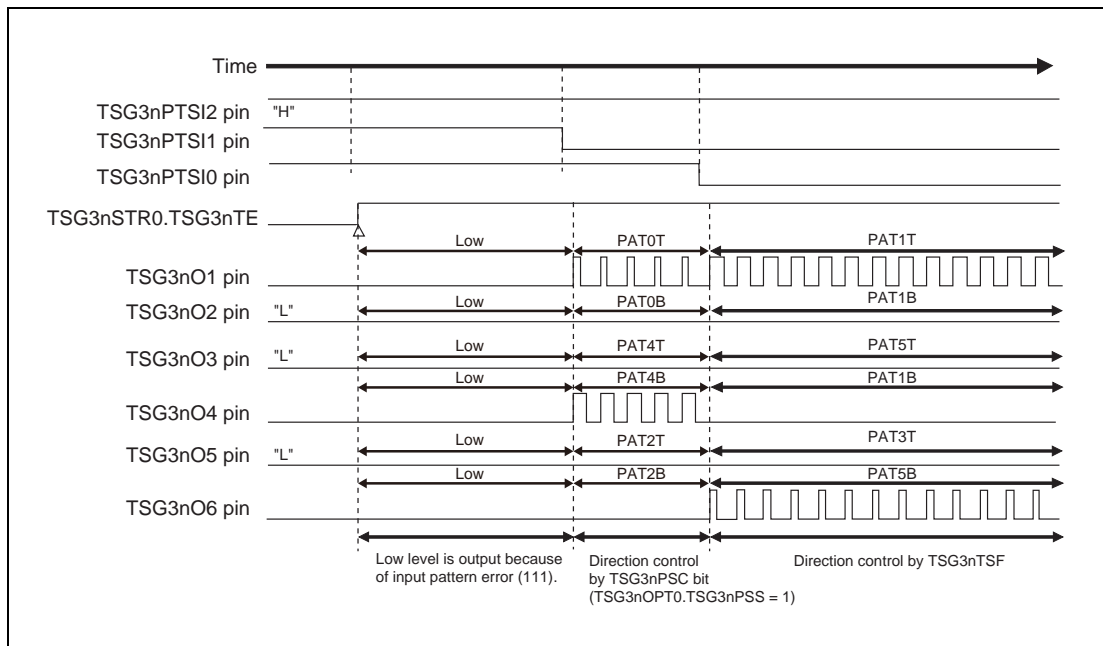

Figure 25.86 Control when Timer Output Starts in Normal Rotation (when Error Pattern is Input)

- TSG3nOPT0.TSG3nSOC = 0, TSG3nPSC = 1, TSG3nPOT = 0, TSG3nIDC = 1, TSG3nSTE = 1

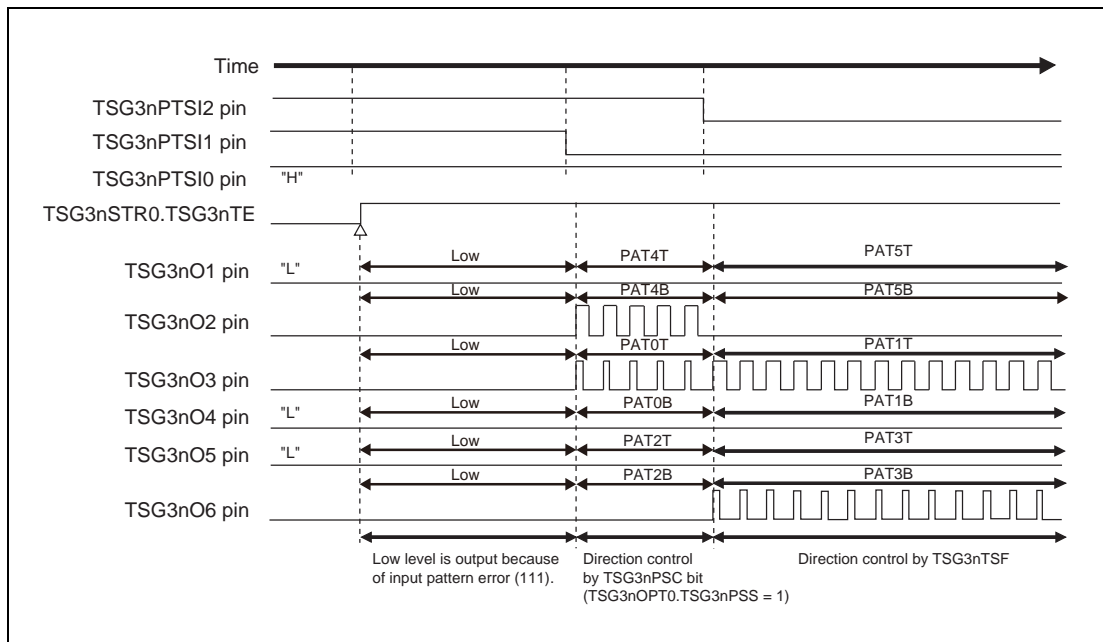

Figure 25.87 Control when Timer Output Starts in Reverse Rotation (when Error Pattern is Input)

(8) Output Switch Timing in 120-DC Mode (TSG3nS120DCO = 0)

As shown in **Figure 25.88** to **Figure 25.91**, in 120-DC mode, the external switch timing for output pattern (TSG3nOPCI0 and TSG3nOPCI1 signals, and TSG3nPTSI2 to TSG3nPTSI0 pins) is input irrespective of the 18-bit counter operation. When TSG3nS120DCO is 0, the output is switched to the new pattern by clearing the 18-bit counter using the pattern switch timing signal that is externally input.

In the pattern switch method, if a change in TSG3nPTSI2 to TSG3nPTSI0 pins occurs several times within one period, the output pattern is switched by clearing the 18-bit counter at each change. In the trigger switch method, if TSG3nOPCI0 and TSG3nOPCI1 signal trigger is input for several times within one period, the output pattern is switched by clearing the 18-bit counter each time the trigger is accepted.

If TSG3nSPC2 to TSG3nSPC0 are rewritten several times within one period, the output pattern is switched by clearing the 18-bit counter each time TSG3nSPC2 to TSG3nSPC0 are rewritten.

In case of a conflict between a rewrite to TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 and TSG3nOPCI0 and TSG3nOPCI1 trigger, rewriting of TSG3nSPC2 to TSG3nSPC0 takes precedence.

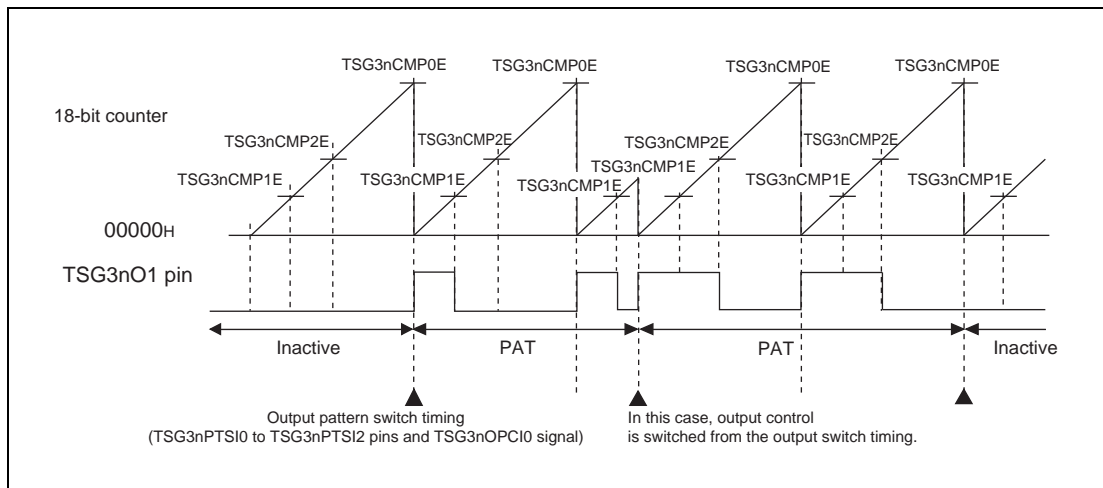

Figure 25.88 Output Switch Example (TSG3nPTSI2 to TSG3nPTSI0 Pins and TSG3nOPCI0 and TSG3nOPCI1 Signal Trigger Input)

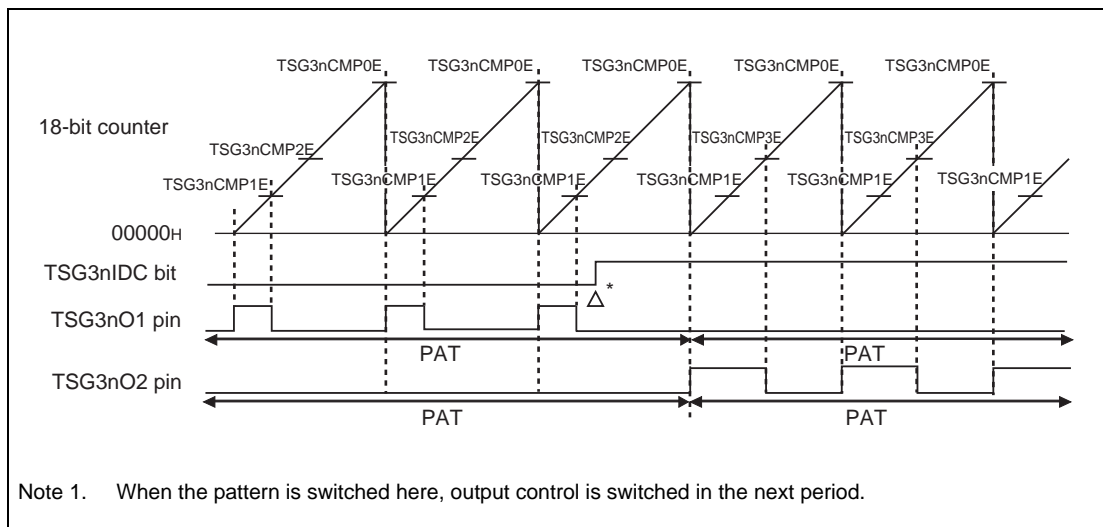

Figure 25.89 Output Switch Example (Switched by TSG3nOPT0.TSG3nIDC)

NOTE

If a change in the TSG3nPTSI2-0 pins occurs by the time next period when output control is switched by the TSG3nIDC bit, the 18-bit counter is cleared and output control is switched.

- TSG3nOPT0.TSG3nSTE = 1, TSG3nOPT0.TSG3nPOT = 1

Figure 25.90 Output Switch Example (Switched by TSG3nOPT0.TSG3nPSC)

- TSG3nOPT0.TSG3nSOC = 0, TSG3nOPT0.TSG3nSTE = 1, TSG3nOPT0.TSG3nPOT = 1

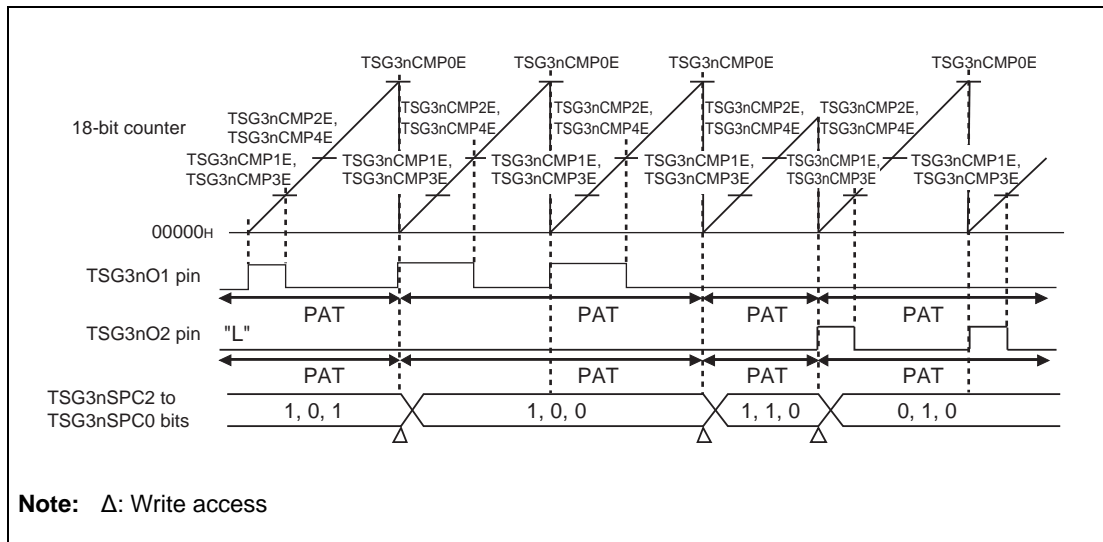

Figure 25.91 Output Switch Example (Switched by TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0)

(9) Compare Register Rewrite Timing in 120-DC Mode

Example of operation when TSG3nCMP1E is reloaded (rewritten simultaneously) is shown below.

Figure 25.92 shows an output example when TSG3nCMP1E is rewritten. After TSG3nCMP1E is changed, data is not transferred to the TSG3nCMP1E buffer register (changed data does not become valid) until the next reload timing; therefore, the specified output waveform can be obtained. However, do not write to TSG3nCMP1E again while the reload is suspended (period from when TSG3nCMP1E is changed to when simultaneous rewrite is executed). Be sure to read the reload request flag (TSG3nRSF) to confirm that the flag is 0 before writing to TSG3nCMP1E.

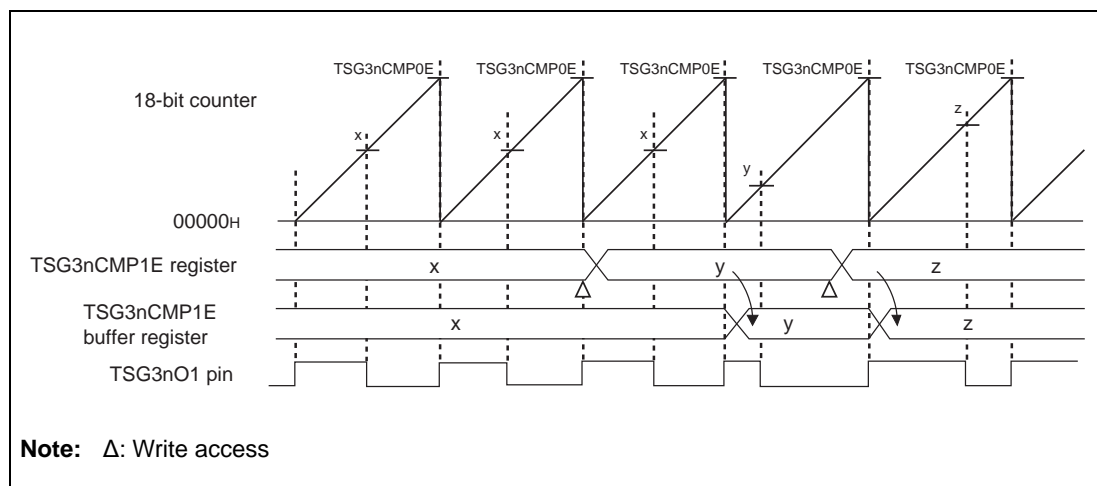

Figure 25.92 Output Example when TSG3nCMP1E is Rewritten

(10) Dead Time Control in 120-DC Mode

In 120-DC mode, the dead time is controlled on falling of each phase, and the dead time is added.

The dead time set in TSG3nDTC1W is inserted on falling of the positive phase, and the dead time set in TSG3nDTC0W is inserted on falling of the inverse phase.

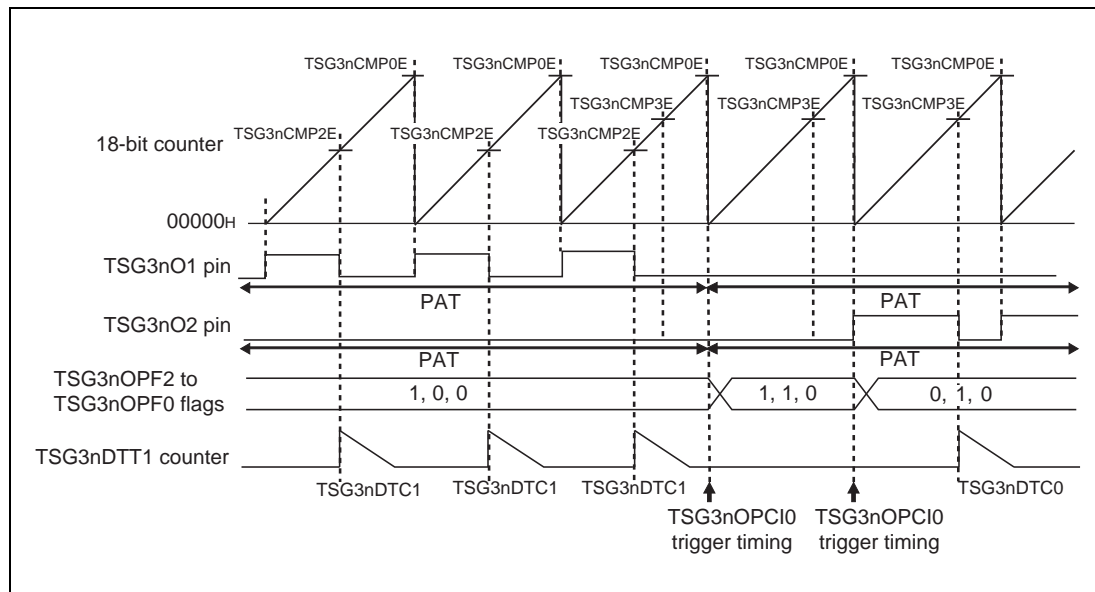

Figure 25.93 Output Switch Example

CAUTION

The dead time control method may affect the timer output. The timer output may not have the specified active level width due to the dead time control under the following conditions:

- When noise is generated on the input pattern in the pattern switch method
- When a change in the input pattern occurs earlier than the PWM period in the pattern switch method
- When TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 are changed and the output pattern is forcibly changed in the trigger switch method
- When switch method is changed
- When the current direction control bit (TSG3nOPT0.TSG3nIDC) is changed
- When the software output control function is used

(11) Output Switch in 120-DC Mode

In 120-DC mode, the output pattern can be controlled by writing values to TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 when the trigger switch method (TSG3nOPT0.TSG3nSTE = 1, and TSG3nPOT = 1) is used. The dead time is secured by hardware at the switch timing.

CAUTION

When 111_B or 000_B is written to TSG3nSPC2 to TSG3nSPC0, the TSG3nO1 to TSG3nO6 pins are driven low.

(12) Operation when Noise is Generated in TSG3nPTSI2 to TSG3nPTSI0 Pins in 120-DC Mode

Input to the TSG3nPTSI2 to TSG3nPTSI0 pins is assumed to be the hall sensor signals of the brushless DC motor. Depending on the system, a noise may be generated on the TSG3nPTSI2 to TSG3nPTSI0 pins. Operation when a noise is generated is described below.

For system product design, be sure to insert a noise filter circuit between the hall sensor and the TSG3nPTSI2 to TSG3nPTSI0 pins.

Figure 25.95 shows a case when a noise is generated on the TSG3nPTSI2 to TSG3nPTSI0 pins during operation with the pattern switch method used.

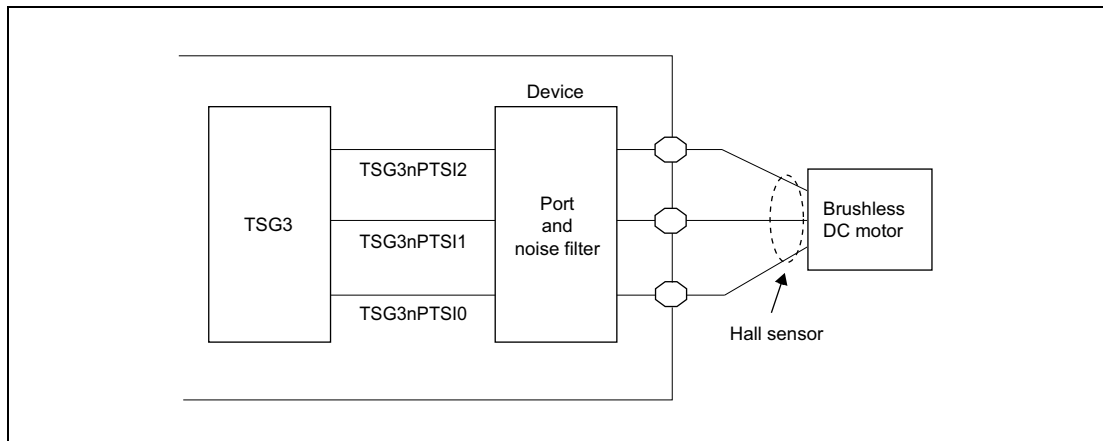

Figure 25.94 Example of Noise Filter Circuit Connection

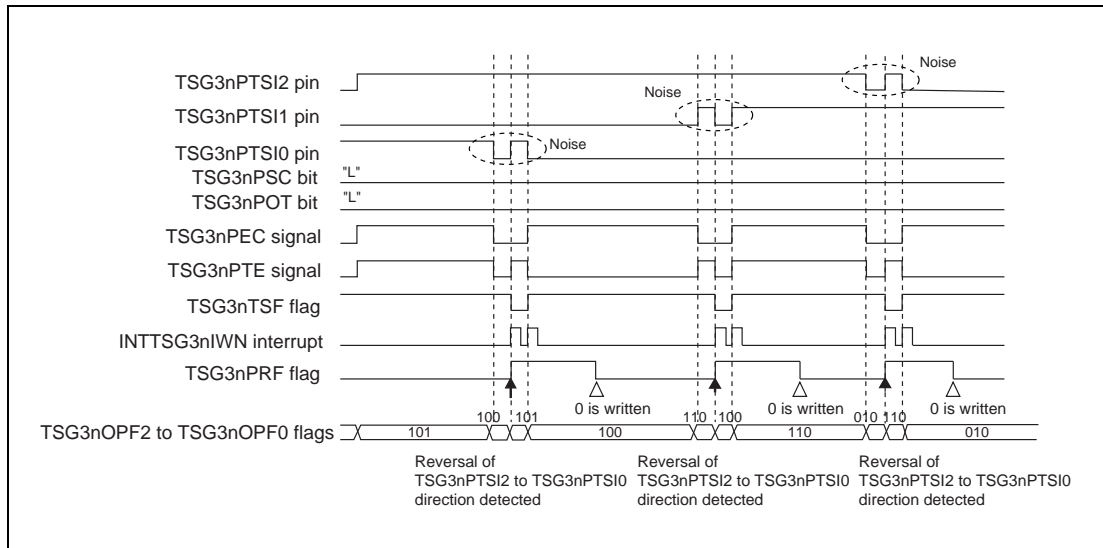

Figure 25.95 Example of Noise Generation at Level Change in TSG3nPTSI2 to TSG3nPTSI0 Pins (Pattern Switch Method)

(a) Change Timing of Input Pattern Change Detection Signal (TSG3nPTE)

The TSG3nPTE signal toggles when the input pattern (TSG3nPTSI2 to TSG3nPTSI0 pins) changes.

CAUTION

Be sure to specify the pattern order direction with the TSG3nPSC bit in the TSG3nOPT0 register (when the TSG3nPSS bit in the TSG3nOPT0 register is 1).

When TSG3nPSC = 0:

Table 25.87 TSG3nPTE Toggle Operation when TSG3nPSC is 0

		TSG3nPTSI2-TSG3nPTSI0 Pins after change							
		000	111	101	100	110	010	011	001

	011	—	—	—	—	—	Toggle	—	Toggle
	001	—	—	Toggle	—	—	—	Toggle	—

(c) Change Timing of TSG3nO1 to TSG3nO6 Pins

- When the pattern switch method is used, the output pattern changes when the input signal of the TSG3nPTSI2 to TSG3nPTSI0 pins*¹ changes. The output is also switched when two or more pins change simultaneously.
- When the trigger switch method is used, the output pattern changes at the rising edge of the TSG3nOPCI0 and TSG3nOPCI1 signals. The output also changes when data is written to TSG3nSPC2 to TSG3nSPC0*¹ in TSG3nOPT0.

Note 1. When the input pattern changes to 000 or 111, the TSG3nO1-TSG3nO6 pins are driven low. The output pattern of TSG3nO1-TSG3nO6 changes immediately only when TSG3nS120DCO = 0. When TSG3nS120DCO = 1, the output pattern is switched when the main counter (TSG3nCNT) matches with TSG3nCMP0E (from the next timer cycle).

(d) Change Timing of TSG3nTSF Flag

The TSG3nTSF flag toggles when the input pattern (TSG3nPTSI2 to TSG3nPTSI0 pins) changes

Table 25.90 Setting and Clearing of TSG3nTSF

		TSG3nPTSI2-TSG3nPTSI0 Pins after change							
		000	111	101	100	110	010	011	001
Current TSG3nPTSI2 to TSG3nPTSI0 Pins	000	—	—	—	—	—	—	—	—
	111	—	—	—	—	—	—	—	—
	101	—	—	—	0	—	—	—	1
	100	—	—	1	—	0	—	—	—
	110	—	—	—	1	—	0	—	—
	010	—	—	—	—	1	—	0	—
	011	—	—	—	—	—	1	—	0
	001	—	—	0	—	—	—	1	—

(e) Set Timing of TSG3nNDF Flag

This flag is set when two or more pins of the TSG3nPTSI2 to TSG3nPTSI0 pins change simultaneously, and cleared when 1 is written to the TSG3nNDR bit. The TSG3nNDF flag is valid when 1 is set to the TSG3nNDC bit.

(f) Set Timing of TSG3nPRF Flag

This flag is set when the TSG3nTSF flag changes, and cleared when 1 is written to the TSG3nPRR bit. The TSG3nPRF flag is valid when 1 is set to the TSG3nPRC bit.

(g) Set Timing of TSG3nPEF Flag

This flag is set when 000 or 111 is input to the TSG3nPTSI2 to TSG3nPTSI0 pins, and cleared when 1 is written to the TSG3nPER bit. The TSG3nPEF flag is valid when the TSG3nPEC bit is set to 1.

(13) Basic Control Flow in 120-DC Mode

In 120-DC mode, there are eight control states as listed in **Table 25.91**.

When TSG3nOPT0.TSG3nSTE = 1 and TSG3nPOT = 0, the pattern switch method is used for 120-DC control. This is defined as fixed phase control. The fixed phase control should be performed considering the factors such as delay from the hall sensor and delay from sensor level detection to timer output. However, acceleration or deceleration can be performed simply by changing the PWM duty.

When TSG3nOPT0.TSG3nSTE = 1 and TSG3nPOT = 1, the trigger switch method is selected for 120-DC control. This is defined as variable phase control. With the variable phase control, the timer output pattern is set prior to the hall sensor; therefore, acceleration or deceleration control according to the phase difference can be performed. However, control is more complex than the fixed phase control because offset width and predicted value with respect to the hall sensor should be considered. For details, **Section 29.2.3.9, Three-Phase Pulse Input Control Function**.

When TSG3nOPT0.TSG3nSTE = 1, TSG3nOPT0.TSG3nPOT = 1, and TSG3nPSS = 1, the pattern order direction of the motor can be set with the TSG3nPSC bit in the TSG3nOPT0 register. Set TSG3nPSC to 0 for normal rotation and set TSG3nPSC to 1 for reverse rotation.

The TSG3nIDC bit in the TSG3nOPT0 register sets the electric current direction. If the same value as the rotation direction of the motor (TSG3nPSC set value) is set, acceleration control is set. If the different value from the rotation direction of the motor is set, deceleration control is set.

Table 25.91 Timer Control Status

Status	TSG3nPSC in TSG3nOPT0	TSG3nTSF in TSG3nSTR1	TSG3nIDC in TSG3nOPT0	TSG3nPOT in TSG3nOPT0	Control
A	—	0	0	0	Normal rotation, acceleration, and fixed phase
B	0	—	0	1	Normal rotation, acceleration, and variable phase
C	0	—	1	1	Normal rotation, deceleration, and variable phase
D	—	0	1	0	Normal rotation, deceleration, and fixed phase
E	—	1	1	0	Reverse rotation, acceleration, and fixed phase
F	1	—	1	1	Reverse rotation, acceleration, and variable phase
G	1	—	0	1	Reverse rotation, deceleration, and variable phase
H	—	1	0	0	Reverse rotation, deceleration, and fixed phase

Generally, the state when the motor rotation stops is assumed to be the starting state and the control begins. First the fixed phase control is used to rotate the motor from the stopped state. Then, to accelerate the motor speed to the fast rotation, the variable phase control is switched on. Used in combination with encoder timer (ENCA), the variable phase control changes the timer output to a timing that is earlier than the change point (leading) of the hall sensors.

To decelerate the motor speed from fast rotation, the direction is switched to deceleration control by rewriting only TSG3nIDC in TSG3nOPT0. When the rotation count is reduced to low-speed rotation, the motor can be transitioned to the stopped state by decreasing the PWM duty.

State transition is shown in **Figure 25.96** and **Figure 25.97**.

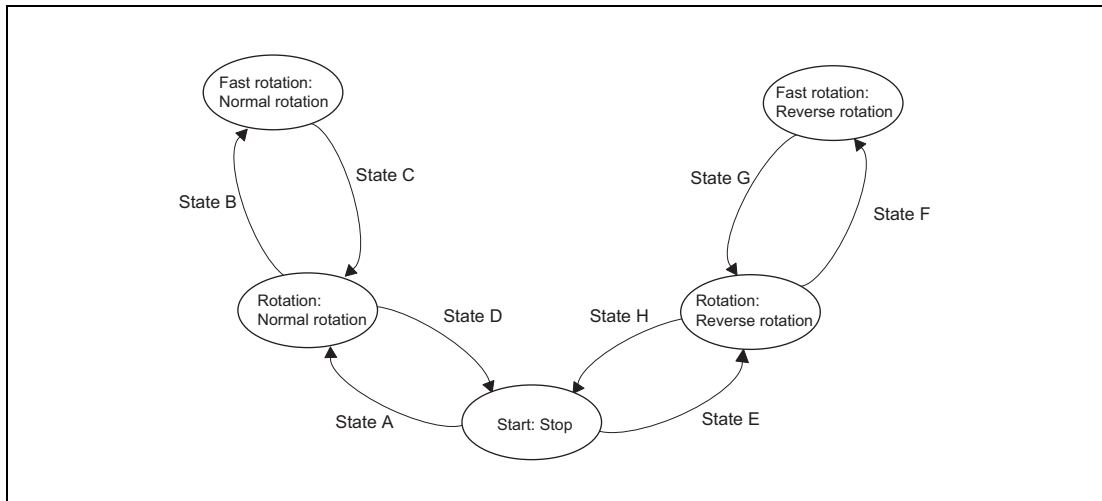

Figure 25.96 State Transition Diagram

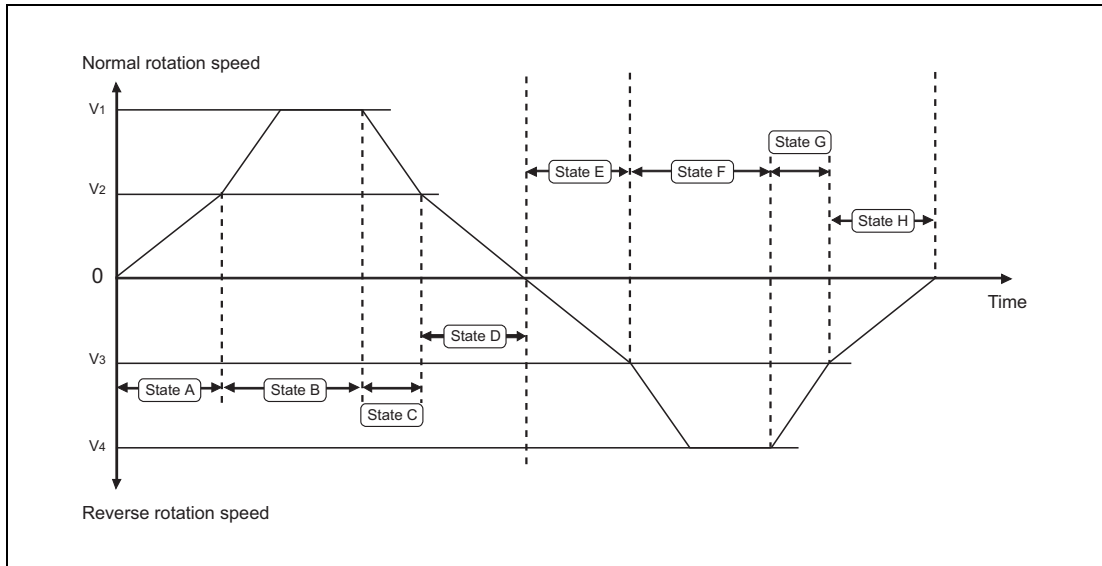

Figure 25.97 Relationship between State Transition and Rotation Speed of Motor

NOTE

V1 and V4: Fast rotation speed of normal rotation and reverse rotation
 V2 and V3: Low rotation speed of normal rotation and reverse rotation

(14) Software Output Control Function in 120-DC Mode

TSG3nOPT0.TSG3nSOC and TSG3nIDC, and TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 are used in 120-DC mode for timer output control by software.

As shown in **Figure 25.98**, the output control is switched immediately when TSG3nSOC is set to 1. If the dead time is set, the period of the dead time period is guaranteed. After that, to switch the output control from software output control to 120-DC control, set TSG3nSOC to 0. At this timing, output control is retained and at the reload timing, output control is switched to 120-DC mode.

For details on software output control function, see **Section 25.4.7.8, Software Output Control Function**.

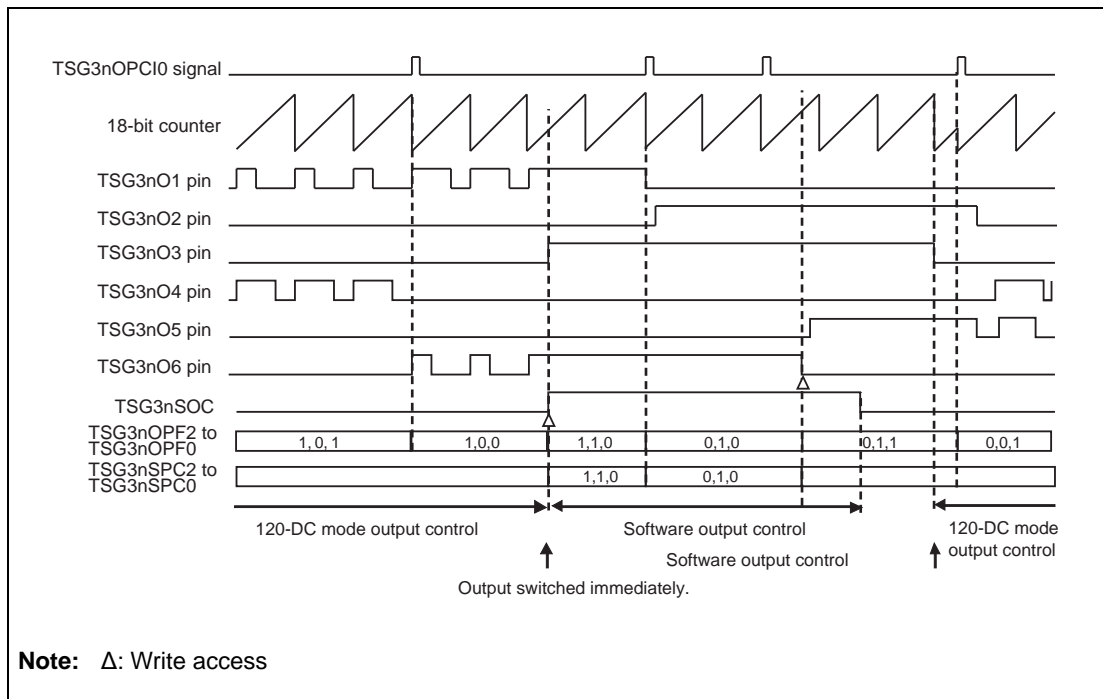

Figure 25.98 Example of Switching from 120-DC Mode to Software Output Control Function

(a) Procedure for Software Output Control

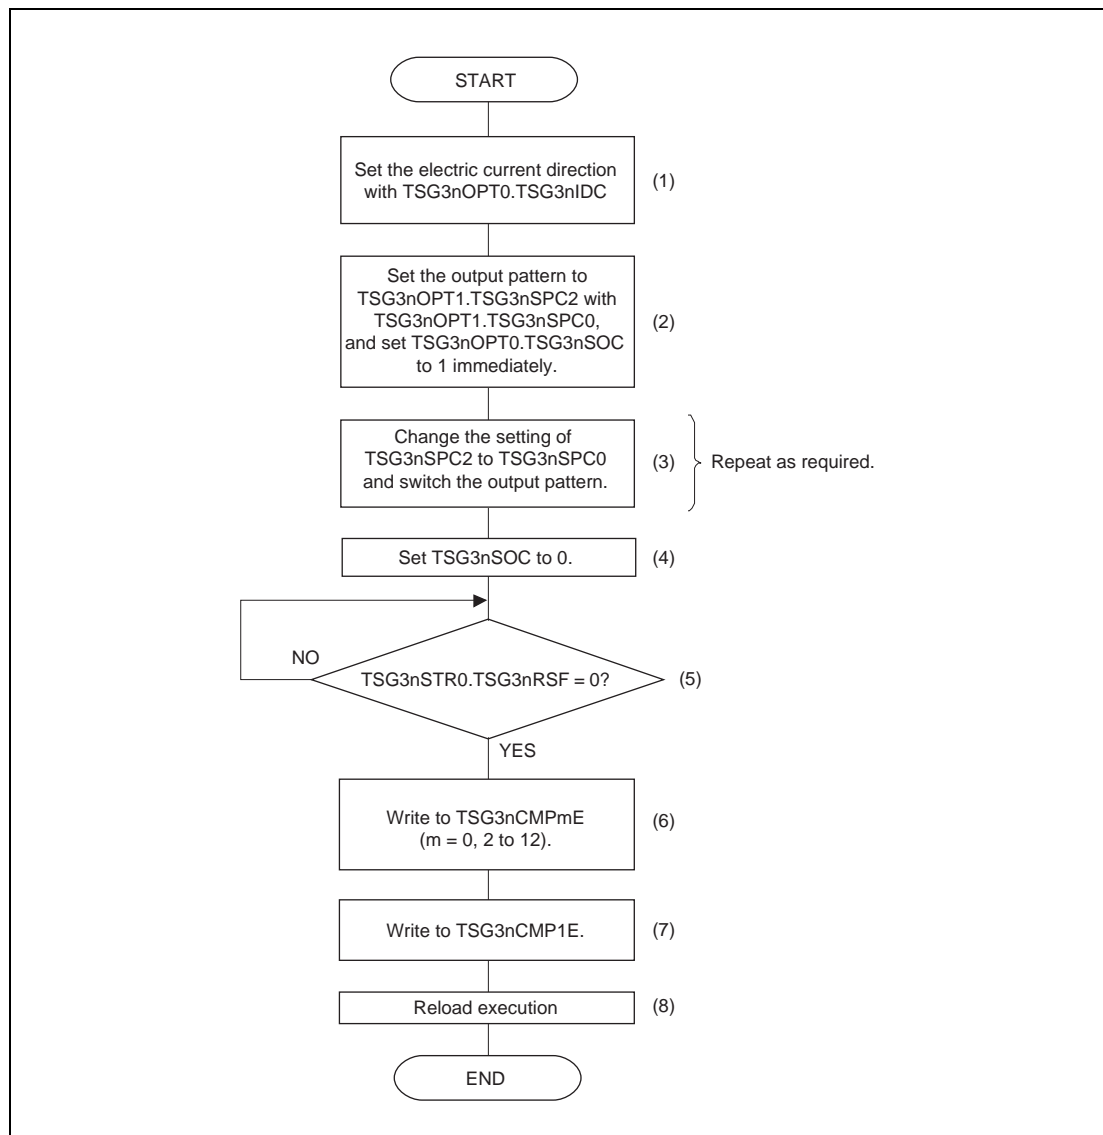

Figure 25.99 Process Flow of Software Output Control

The procedure for software output control is described below.

- (1) Set the TSG3nIDC bit. The phase of the timer output with TSG3nIDC = 0 is different by 180 degrees from that with TSG3nIDC = 1. With the software output control function, the timer output will not change only by rewriting this bit. However, if the period match occurs before step (2), the output pattern of 120-DC control changes. Therefore, specify a schedule that will prevent the period match from occurring before step (2).
- (2) Set the output pattern with TSG3nSPC2 to TSG3nSPC0. To enable software output control, set TSG3nSOC to 1 simultaneously.
- (3) Change the output pattern setting of TSG3nSPC2 to TSG3nSPC0 to change the timer output.
- (4) Confirm that the reload request flag (TSG3nRSF) = 0. If TSG3nRFS = 1, do not proceed to the following step until TSG3nRSF = 0.
- (5) By setting TSG3nSOC = 0 the software control release process starts (it is not released yet at this point).

- (6) Configure the compare register settings that are required after the software output control is released. Proceed to the following step when the register setting is not required. When setting the registers with the reload function, set them at this point.
- (7) Write to TSG3nCMP1E to start reloading.
- (8) Reload is executed and software output is released.

CAUTION

Execute reload after completing steps (4) to (7). When reload cannot be executed, the software output cannot be released.

25.4.7.5 HSP-PWM Mode (High accuracy Shifted-pulse - Pulse Width Modulation Mode)

Overview

In this mode, the 18-bit counter and the 18-bit compare register are used to generate a high accuracy sawtooth waveform PWM signal.

Prerequisites

- Set the PWM period to TSG3nCMP0E.
- Set PWM output width with the TSG3nHSPCMUE, TSG3nHSPCMVE, and TSG3nHSPCMWE registers. Set PWM shift width with the TSG3nHSPSHUE, TSG3nHSPSHVE, and TSG3nHSPSHWE registers. Set dead time with the TSG3nDTC0W and TSG3nDTC1W registers. The values set in these registers are immediately reflected to the corresponding TSG3nCMPmE (m = 1 to 12) based on the calculation described later.

Functional description

Set the PWM period, the dead time, and the PWM shift width. Then set the PWM output width. Counting up begins when TSG3nTRG0.TSG3nTS is set to 1.

The 18-bit counter starts counting from 00000_H and is cleared by the match with TSG3nCMP0E.

During counting, a compare match interrupt (INTTSG3nI0 to INTTSG3nI12) is generated by the match of the buffer register TSG3nCMP0E to TSG3nCMP12E with the 18-bit counter.

NOTE

The HSP-PWM mode is set when TSG3nCTL0.TSG3nMD2-TSG3nMD0 = 100_B.

(1) Basic Timing Chart

Figure 25.100 Basic Timing in HSP-PWM Mode

Figure 25.101 Basic Operation Flow in HSP-PWM Mode

NOTE

The timing may be different from the orders described above but be sure to execute (4) after (3).

CAUTIONS

1. When changing the settings for PWM output width in the TSG3nHSPCMUE, VE, and WE registers during operation, set the TSG3nHSPCMUE register last. When

only the settings for the V phase and W phase are changed but the PWM output width in the U phase is not, the existing value should be written back to the TSG3nHSPCMUE register.

2. After changing the PWM cycle by using the TSG3nCMP0E register, the PWM output width settings in the TSG3nHSPCMUE, VE, and WE registers must be reconfigured. Changing the settings for the PWM shift width in the TSG3nHSPSHUE, VE, and WE registers and the settings for the PWM cycle in the TSG3nCMP0E register at the same time is not allowed.
 3. Reconfigure the settings for PWM output width in the TSG3nHSPCMUE, VE, and WE registers after changing the settings for PWM shift width in the TSG3nHSPSHUE, VE, and WE registers.
-

(2) List of Operation in HSP-PWM

Table 25.92 Counter Function in HSP-PWM

Operation		Setting Condition
18-bit counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1 or simultaneous start trigger
	Clear	Compare match of TSG3nCMP0E buffer register and 18-bit counter
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1

Table 25.93 Functions of Compare Registers, Shift Width Setting Register, and Dead Time Control Register in HSP-PWM

Register	Rewriting Method	Rewrite during Operation	Function
TSG3nCMP0E	Reload	Possible	Setting period
TSG3nHSPCMUE	Reload	Possible	PWM control for U phase
TSG3nHSPSHUE			
TSG3nHSPCMVE	Reload	Possible	PWM control for V phase
TSG3nHSPSHVE			
TSG3nHSPCMWE	Reload	Possible	PWM control for W phase
TSG3nHSPSHWE			
TSG3nDCMP0E, TSG3nDCMP1E, TSG3nDCMP2E	Reload	Possible	Diagnostic output or A/D conversion trigger
TSG3nDTC0W, TSG3nDTC1W	Reload	Prohibited	Dead time

Table 25.94 Timer Output in HSP-PWM Mode

Pin	Function
TSG3nO1	PWM output by compare match of the TSG3nCMP1E buffer register (clear timing) or the TSG3nCMP2E buffer register (set timing) with the 18-bit counter.
TSG3nO2	PWM output by compare match of the TSG3nCMP3E buffer register (clear timing) or the TSG3nCMP4E buffer register (set timing) with the 18-bit counter.
TSG3nO3	PWM output by compare match of the TSG3nCMP5E buffer register (clear timing) or the TSG3nCMP6E buffer register (set timing) with the 18-bit counter.
TSG3nO4	PWM output by compare match of the TSG3nCMP7E buffer register (clear timing) or the TSG3nCMP8E buffer register (set timing) with the 18-bit counter.
TSG3nO5	PWM output by compare match of the TSG3nCMP9E buffer register (clear timing) or the TSG3nCMP10E buffer register (set timing) with the 18-bit counter.
TSG3nO6	PWM output by compare match of the TSG3nCMP11E buffer register (clear timing) or the TSG3nCMP12E buffer register (set timing) with the 18-bit counter.
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger

Compare Match	Timing
TSG3nCMP0E	When 18-bit counter changes from TSG3nCMP0E to 00000 _H
TSG3nCMPmE (m = 1 to 12)	After match of 18-bit counter and TSG3nCMPmE

(3) Various Settings of HSP-PWM Mode

Setting mode

HSP-PWM mode is entered by setting TSG3nCTL0.TSG3nMD2-TSG3nMD0 to 100_B.

Setting timer output

The output pins TSG3nO1-6 are controlled by setting TSG3nIOC0, TSG3nIOC2, and TSG3nIOC3.

The TSG3nO7 pin provides output pulse as diagnostic output or A/D conversion trigger. The pin should be set as necessary.

Enabling error interrupt generation

Error interrupt (INTTSG3nIER) due to the detection of the simultaneous active state of positive and inverse phases is enabled by setting TSG3nIOC1.TSG3nEOC to 1. For details, see **Section 25.4.6, Error/Warning Interrupt**.

Setting rewriting timing of register with reload function

This function is only available in reload mode. Set TSG3nCTL3.TSG3nRMC to 0.

Setting A/D conversion trigger output

The A/D conversion trigger 0 (TSG3nADTRG0 signal) is set with TSG3nCTL5.TSG3nAT09-TSG3nAT00.

TSG3nAT09-TSG3n00 is used to enable or disable the A/D conversion trigger output upon match of TSG3nDCMP2E-0E with 18-bit counter (up count).

TSG3nCTL6.TSG3nAT19-TSG3nAT10 is used to set the A/D conversion trigger 1 (TSG3nADTRG1 signal).

To set the match timing of the 18-bit counter and TSG3nDCMP2E-TSG3nDCMP0E, set the compare value to each register.

The skipping function can be used for TSG3nADTRG0, TSG3nADTRG1 signals. TSG3nACC01 and TSG3nACC00 of TSG3nCTL5, and TSG3nACC11 and TSG3nACC10 of TSG3nCTL6 can be used to select the skipping rate from 1/1 (no skipping), 1/2, 1/4, and 1/8.

CAUTION

- Be sure to set TSG3nCTL5, TSG3nCTL6, and TSG3nDCMP2E-0E correctly when the timing pulse of A/D conversion trigger is output to TSG3nO7.
- In HSP-PWM mode, no valley interrupt (INTTSG3nIVLY) is generated. Therefore, TSG3nCTL5.TSG3nAT00 and TSG3nCTL6.TSG3nAT10 must be set to 0.
- In HSP-PWM mode, the 18-bit sub-counter does not operate. Therefore, TSG3nCTL5.TSG3nAT09 and TSG3nAT08, and TSG3nCTL6.TSG3nAT19 and TSG3nAT18 must be set to 0.
- In HSP-PWM mode, down counting by the 18-bit counter is not generated. Therefore, TSG3nCTL5.TSG3nAT07, TSG3nAT05, and TSG3nAT03, and TSG3nCTL6.TSG3nAT17, TSG3nAT15, and TSG3nAT13 must be set to 0.

Setting PWM period

Set the PWM period with TSG3nCMP0E.

The PWM period is calculated by the following expression:

$$\text{PCLK} \times (\text{TSG3nCMP0E} + 1)$$

Setting PWM output width

The PWM output width is set with TSG3nHSPCMUE, TSG3nHSPCMVE, and TSG3nHSPCMWE (TSG3nCMP1E-12E).

Satisfy the following requirements when setting the TSG3nHSPCMUE, TSG3nHSPCMVE, and TSG3nHSPCMWE registers:

$$0 \leq \text{TSG3nHSPCMUE}, \text{TSG3nHSPCMVE}, \text{TSG3nHSPCMWE} \leq \text{TSG3nCMP0E} + \text{TSG3nDTC0} + \text{TSG3nDTC1} + 1$$

Set the PWM output width after setting TSG3nCMP0E, TSG3nHSPSHUE, TSG3nHSPSHVE, TSG3nHSPSHWE, TSG3nDTC0, and TSG3nDTC1.

Setting PWM shift width

PWM shift width is set with TSG3nHSPSHUE, TSG3nHSPSHVE, and TSG3nHSPSHWE.

Satisfy the following requirements when setting TSG3nHSPSHUE, TSG3nHSPSHVE, and TSG3nHSPSHWE.

$$\text{TSG3nHSPSHUE}, \text{TSG3nHSPSHVE}, \text{TSG3nHSPSHWE} \leq \text{TSG3nCMP0E}$$

Setting dead time

The dead time can be set with TSG3nDTC0 and TSG3nDTC1.

The dead time is calculated by the following expressions:

$$\text{PCLK} \times \text{TSG3nDTC0}$$

$$\text{PCLK} \times \text{TSG3nDTC1}$$

TSG3nDTC0 can set the time between a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the inactive state and a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the active state, respectively.

TSG3nDTC1 can set the time between a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the inactive state and a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the active state, respectively.

Satisfy the following requirements when setting TSG3nDTC0 and TSG3nDTC1.

$$(\text{TSG3nCMP0E} + \text{TSG3nDTC0} + \text{TSG3nDTC1} + 1) < 3\text{FFFF}_{\text{H}}$$

$$\text{TSG3nCMP0E} > 3 \times \text{TSG3nDTC0}$$

$$\text{TSG3nCMP0E} > 3 \times \text{TSG3nDTC1}$$

CAUTION

Do not modify the settings of TSG3nDTC0 and TSG3nDTC1 during timer operation in HSP-PWM (TSG3nTE = 1). Set TSG3nDTC0 and TSG3nDTC1 while TSG3nTE = 0.

Set dead time in HSP-PWM mode. Do not set 0 to TSG3nDTC0 and TSG3nDTC1.

Settings prohibited in HSP-PWM Mode

In HSP-PWM mode, use the following registers and bits with the settings shown below.

Do not modify the settings during operation (TSG3nTE = 1).

Table 25.97 Setting Prohibited in HSP-PWM Mode

Bit Name	Setting Value	Description
TSG3nCTL3.TSG3nRMC	0	Available only in reload mode.
TSG3nIOC3.TSG3nTOL6-1	000000 _B	Logical inverse of set/clear of PWM is prohibited (HSP-PWM mode limitation)
TSG3nOPT0.TSG3nSOC	0	Switching to software control function is prohibited.
TSG3nOPT0.TSG3nSTE	0	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nOPT0.TSG3nPOT	0	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nOPT0.TSG3nPSS	0	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nOPT0.TSG3nIDC	0	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nOPT0.TSG3nPSC	0	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nOPT1.TSG3nSPC2-0	000 _B	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nPAT0W	0000000 _H	Operation setting of 120-DC mode (value after reset).
TSG3nPAT1W	0000000 _H	Operation setting of 120-DC mode (value after reset).

CAUTION

In HSP-PWM mode, no setting should be made directly to the TSG3nCMPmE register (m = 1 to 12).

The PWM output width and the PWM shift width should be set with TSG3nHSPCMUE, VE, and WE registers and TSG3nHSPSHUE, VE, and WE registers.

25.4.7.6 Compare Register Setting in HSP-PWM Mode

In HSP-PWM mode, the PWM output width is set with TSG3nHSPCMUE, VE and WE.

With a write access to TSG3nHSPCMUE, VE, and WE, TSG3 calculates and sets the values to TSG3nCMP1E-12E based on the values written to the followings:

- TSG3nCMP0E (PWM period setting)
- TSG3nDTC0 (dead time control 0)
- TSG3nDTC1 (dead time control 1)
- TSG3nHSPSHUE/VE/WE (PWM shift width setting)
- TSG3nHSPCMUE/VE/WE (PWM output width setting)

The high accuracy PWM is realized by these values.

The algorithm to set compare register values are listed in the following table.

Table 25.98 Algorithm for Compare Setting in HSP-PWM Mode

Value Set In HSPCMUE				CMP4E	CMP3E	CMP2E	CMP1E
HSPCMUE = 0				if (HSPSHUE = 0) 0 else HSPCMUE - 1 + HSPSHUE	CMP0E + 1	0	0
0	<	HSPCMUE	≤ DTC0 + DTC1	HSPCMUE - 1 + HSPSHUE	if (HSPSHUE = 0) CMP0E else HSPSHUE - 1	0	0
DTC0 + DTC1	<	HSPCMUE	≤ CMP0E	HSPCMUE - 1 + HSPSHUE	if (HSPSHUE = 0) CMP0E else HSPSHUE - 1	DTC0 - 1 + HSPSHUE	HSPCMUE - DTC1 - 1 + HSPSHUE
CMP0E	<	HSPCMUE	≤ CMP0E + DTC1 + 1	0	0	DTC0 - 1 + HSPSHUE	HSPCMUE - DTC1 - 1 + HSPSHUE
CMP0E + DTC1 + 1	<	HSPCMUE	< CMP0E + DTC0 + DTC1 + 1	0	0	DTC0 - 1 + HSPSHUE	HSPCMUE - CMP0E - DTC1 - 2 + HSPSHUE
HSPCMUE = CMP0E + DTC0 + DTC1 + 1				0	0	DTC0 - 1 + HSPSHUE	CMP0E + 1

 : For the colored cells, subtract CMP0E + 1 when the calculated result is greater than CMP0E.

NOTE

“TSG3n” is omitted from the register names used in the calculation.

25.4.7.7 Timer Output Operation in HSP-PWM Mode

TSG3nO1-6 output is set by compare match of TSG3nCNTE with TSG3nCMP2E, 4E, 6E, 8E, 10E, and 12E, respectively, and cleared by compare match of TSG3nCNTE with TSG3nCMP1E, 3E, 5E, 7E, 9E, and 11E, respectively.

When PWM output width is set in TSG3nHSPCMUE, VE, and WE, the value is set in the TSG3nCMP1E-12E registers based on the calculation described in **Section 25.4.7.6, Compare Register Setting in HSP-PWM Mode** that enables a high accuracy PWM output from 0% to 100%.

PWM output timing can be shifted by setting desired width to TSG3nHSPSHUE, VE, WE.

(1) When TSG3nHSPCMUE, VE, and WE (PWM output width setting) is set to 0

When 0 is set to TSG3nHSPCMUE (U phase PWM output width setting), 0 is set to TSG3nCMP1E, 2E, and 4E, and “TSG3nCMP0E+1” is set to TSG3nCMP3E.

Setting of TSG3nO1 by the match of TSG3nCNTE with TSG3nCMP2E and clearing by the match with TSG3nCMP1E occur simultaneously, but clearing takes precedence. Therefore, TSG3nO1 output is fixed to inactive.

Setting of TSG3nO2 by the match of TSG3nCNTE with TSG3nCMP4E occurs when TSG3nCNTE = 0. Since TSG3nCMP0E + 1 is set to TSG3nCMP3E, TSG3nCNTE does not match TSG3nCMP3E. Therefore, TSG3nO2 output is fixed to active.

The same operation applies to TSG3nO3-6, which are the output pins for V phase and W phase when 0 is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

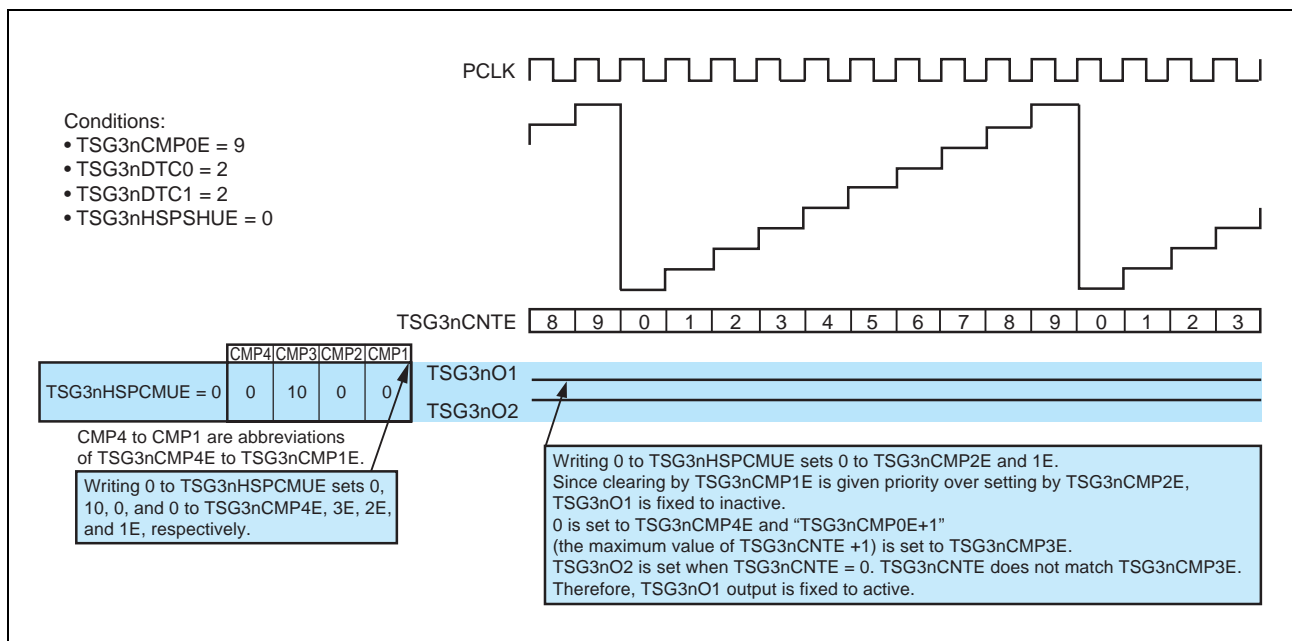

Figure 25.102 Waveform in HSP-PWM Mode (0 is set to TSG3nHSPCMUE)

(2) When TSG3nHSPCMUE/VE/WE (PWM output width setting) is set to the range $0 < \text{TSG3nHSPCMUE} \leq \text{TSG3nDTC0} + \text{TSG3nDTC1}$

When the value within this range is set to TSG3nHSPCMUE (U phase PWM output width setting), 0 is set to TSG3nCMP1E and 2E, “TSG3nHSPCMUE set value - 1” is set to TSG3nCMP4E, and the value of the TSG3nCMP0E is set to TSG3nCMP3E.

Setting of TSG3nO1 by the match of TSG3nCNTE with TSG3nCMP2E and clearing by the match with TSG3nCMP1E occurs simultaneously, but clearing takes precedence. Therefore, TSG3nO1 output is fixed to inactive.

TSG3nO2 is cleared by the match of TSG3nCNTE with TSG3nCMP3E and set by the match with TSG3nCMP4E. Here, the output is shifted according to the set value in TSG3nHSPCMUE, that is, TSG3nO2 is inactive for one cycle during PWM period when 1 is set, two cycles when 2 is set, and three cycles when 3 is set, and so on.

When the value other than 0 is set to TSG3nHSPSHUE (PWM shift width), set/clear timing of TSG3nO2 is shifted to the right for the number of cycles set in TSG3nHSPSHUE.

The same condition applies to TSG3nO3-6, which are the output pins for V phase and W phase when the value of “ $0 < \text{TSG3nHSPCMUE} \leq \text{TSG3nDTC0} + \text{TSG3nDTC1}$ ” is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

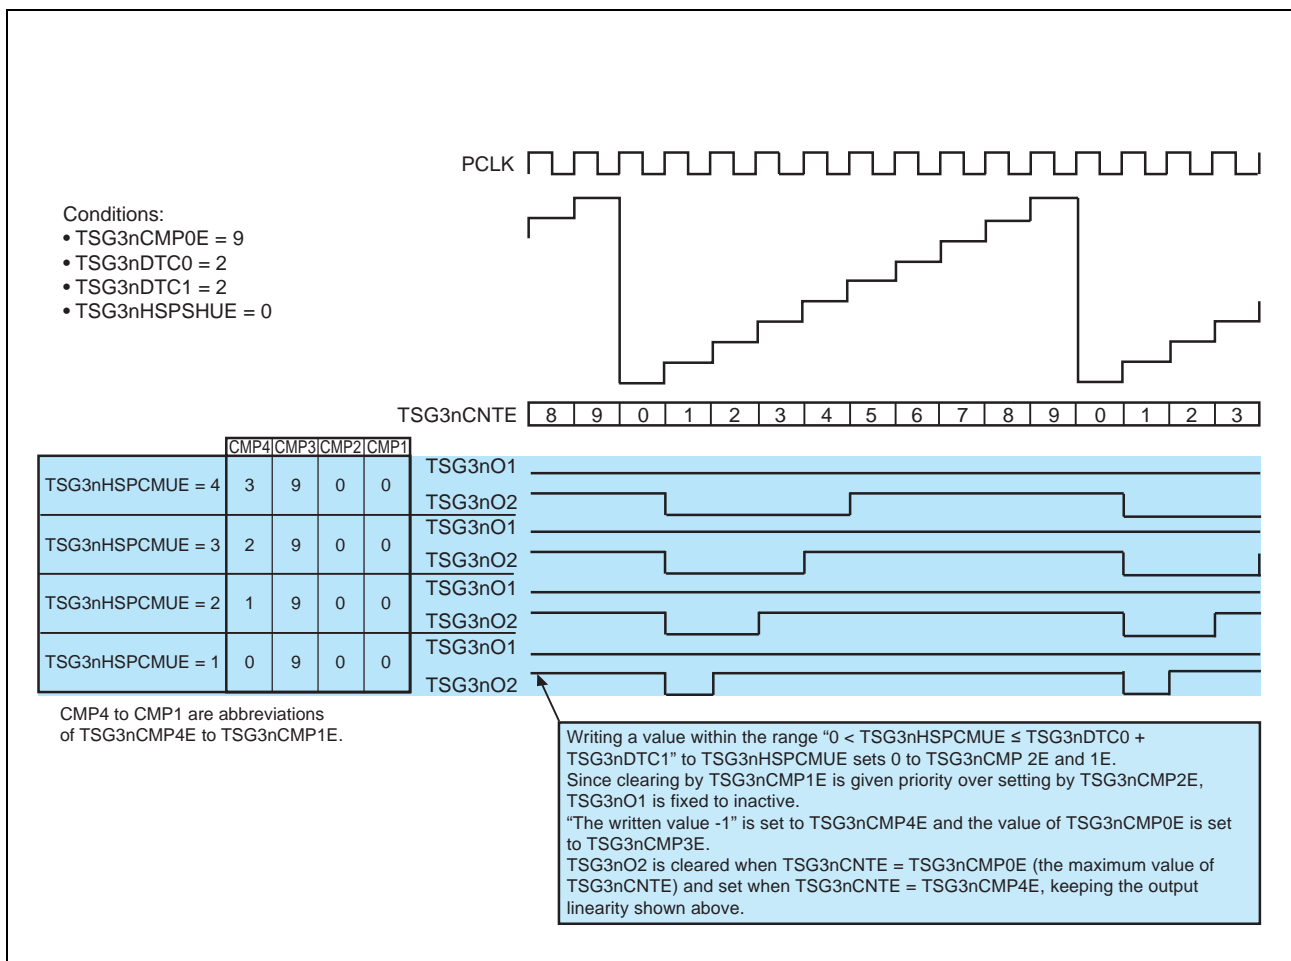

Figure 25.103 Waveform in HSP-PWM Mode (TSG3nHSPCMUE is set to $0 < \text{TSG3nHSPCMUE} \leq \text{TSG3nDTC0} + \text{TSG3nDTC1}$)

(3) When TSG3nHSPCMUE/VE/WE (PWM Output Width Setting) is set to the range $TSG3nDTC0 + TSG3nDTC1 < TSG3nHSPCMUE/VE/WE \leq TSG3nCMP0E$

When the value within this range is set to TSG3nHSPCMUE (U phase PWM output width setting), “TSG3nDTC0 - 1” is set to TSG3nCMP2E, “TSG3nHSPCMUE - TSG3nDTC1 - 1” is set to TSG3nCMP1E, “TSG3nHSPCMUE - 1” is set to TSG3nCMP4E, and the value of TSG3nCMP0E is set to TSG3nCMP3E.

TSG3nO1 is set by the match of TSG3nCNTE with TSG3nCMP2E and cleared by the match with TSG3nCMP1E while TSG3nO2 is set by the match of TSG3nCNTE with TSG3nCMP4E and cleared by the match with TSG3nCMP3E

Here, the outputs are shifted according to the set value in TSG3nHSPCMUE, that is, when “TSG3nDTC0 + TSG3nDTC1 + 1” is set, TSG3nO1 is active for one cycle during PWM period and TSG3nO2 is inactive for the cycles of “TSG3nDTC0 + TSG3nDTC1 + 1” during PWM period. When “TSG3nDTC0 + TSG3nDTC1 + 2” is set, TSG3nO1 is active for two cycles during PWM period and TSG3nO2 is inactive for the cycles of “TSG3nDTC0 + TSG3nDTC1 + 2” during PWM period, and so on.

When the value other than 0 is set to TSG3nHSPSHUE (PWM shift width), set/clear timing of TSG3nO1 and TSG3nO2 are shifted to the right for the number of cycles set in TSG3nHSPSHUE.

The same condition applies to TSG3nO3-6, which are the output pins for V phase and W phase when the value of “TSG3nDTC0 + TSG3nDTC1 < TSG3nHSPCMUE/VE/WE ≤ TSG3nCMP0E” is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

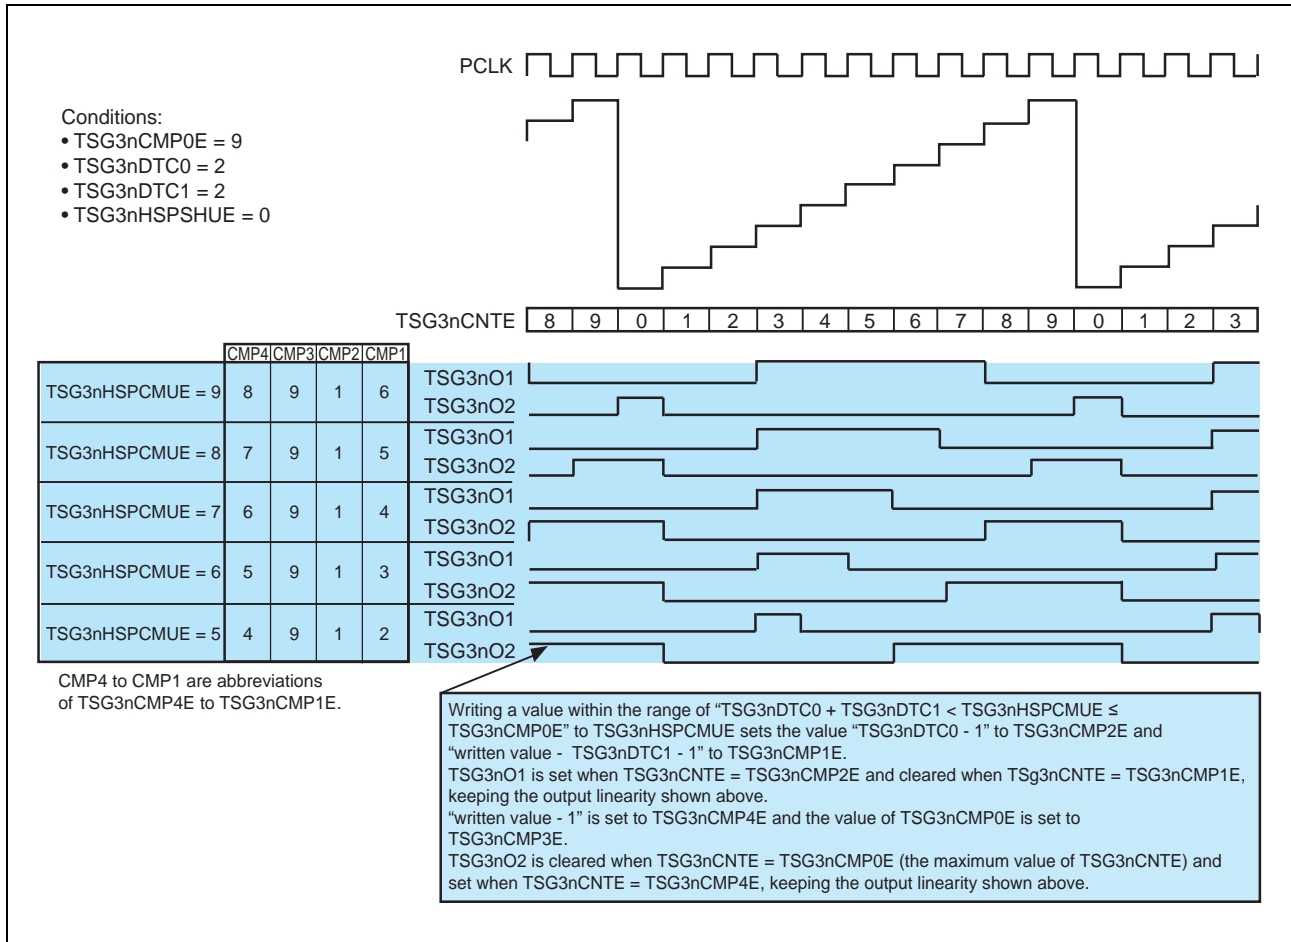

Figure 25.104 Waveform in HSP-PWM Mode (TSG3nHSPCMUE is set to $TSG3nDTC0 + TSG3nDTC1 < TSG3nHSPCMUE \leq TSG3nCMP0E$)

(4) When TSG3nHSPCMUE/VE/WE (PWM Output Width Setting) is set to the range TSG3nCMP0E < TSG3nHSPCMUE/VE/ WE < TSG3nCMP0E + TSG3nDTC1 + 1

When the value within this range is set to TSG3nHSPCMUE (U phase PWM output width setting), “TSG3nDTC0 - 1” is set to TSG3nCMP2E, “TSG3nHSPCMUE - TSG3nDTC1 - 1” is set to TSG3nCMP1E, and 0 is set to TSG3nCMP3E and 4E.

TSG3nO1 is cleared by the match of TSG3nCnTE with TSG3nCMP1E and set by the match with TSG3nCMP2E.

Here, the output is shifted according to the set value in TSG3nHSPCMUE, that is, TSG3nO1 is inactive for the cycles of “TSG3nDTC0 + TSG3nDTC1” during PWM period when “TSG3nCMP0E + 1” is set, inactive for the cycles of “TSG3nDTC0 + TSG3nDTC1 - 1” during PWM period when “TSG3nCMP0E + 2” is set, and so on.

Setting of TSG3nO2 by the match of TSG3nCnTE with TSG3nCMP4E and clearing by the match with TSG3nCMP3E occur simultaneously, but clearing takes precedence. Therefore, TSG3nO2 output is fixed to inactive.

When the value other than 0 is set to TSG3nHSPSHUE (U phase PWM shift width), set/clear timing of TSG3nO1 is shifted to the right for the number of cycles set in TSG3nHSPSHUE.

The same condition applies to TSG3nO3-6, which are the output pins for V phase and W phase when the value of “TSG3nCMP0E < TSG3nHSPCMUE/VE/ WE < TSG3nCMP0E + TSG3nDTC1 + 1” is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

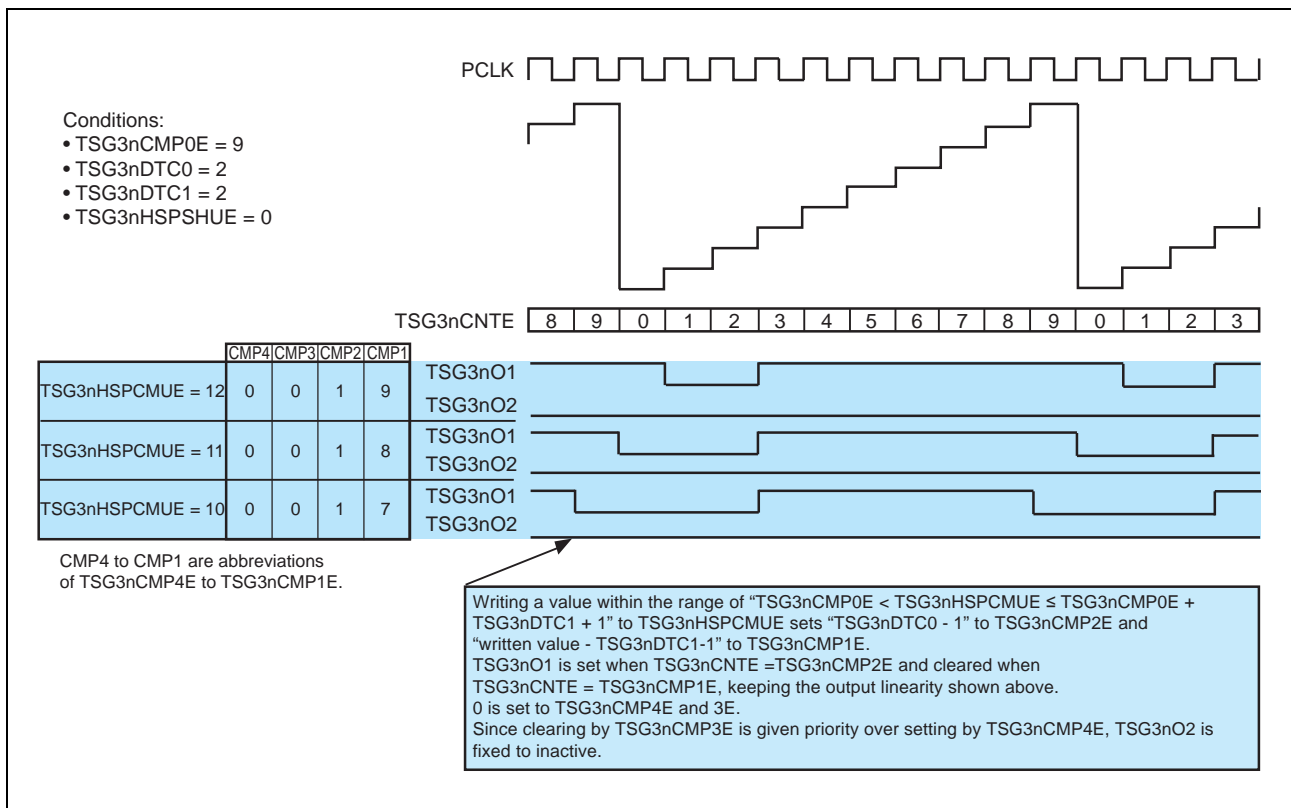

Figure 25.105 Waveform in HSP-PWM Mode (TSG3nHSPCMUE is set to TSG3nCMP0E < TSG3nHSPCMUE < TSG3nCMP0E + TSG3nDTC1 + 1)

(5) When TSG3nHSPCMUE/VE/WE (PWM Output Width Setting) is set to the range $TSG3nCMP0E + TSG3nDTC1 + 1 < TSG3nHSPCMUE/VE/WE < TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1$

When the value within this range is set to TSG3nHSPCMUE (U phase PWM output width setting), “TSG3nDTC0 - 1” is set to TSG3nCMP2E, “TSG3nHSPCMUE - TSG3nCMP0E - TSG3nDTC1 - 2” is set to TSG3nCMP1E, and 0 is set to TSG3nCMP3E and 4E.

TSG3nO1 is cleared by the match of TSG3nCnTE with TSG3nCMP1E and set by the match with TSG3nCMP2E. Here, the output is shifted according to the set value in TSG3nHSPCMUE, that is, TSG3nO1 is inactive for one cycle during PWM period when “TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1” (the maximum value of PWM output width - 1) is set, inactive for two cycles during PWM period when “TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 - 1” (the maximum value of PWM output width - 2) is set, and so on.

Setting of TSG3nO2 by the match of TSG3nCnTE with TSG3nCMP4E and clearing by the match with TSG3nCMP3E occur simultaneously, but clearing takes precedence. Therefore, TSG3nO2 output is fixed to inactive.

When the value other than 0 is set to TSG3nHSPSHUE (U Phase PWM shift width), set/clear timing of TSG3nO1 is shifted to the right for the number of cycles set in TSG3nHSPSHUE.

The same condition applies to TSG3nO3-6, which are the output pins for V phase and W phase when the value of “TSG3nCMP0E + TSG3nDTC1 + 1 < TSG3nHSPCMUE/VE/WE < TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1” is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

Figure 25.106 Waveform in HSP-PWM Mode (TSG3nHSPCMUE is set to $TSG3nCMP0E + TSG3nDTC1 + 1 < TSG3nHSPCMUE < TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1$)

(6) When TSG3nHSPCMUE/VE/WE (PWM Output Width Setting) is set to TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1

When “TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1” (the maximum value of PWM output width) is set to TSG3nHSPCMUE, “TSG3nDTC0 - 1” is set to TSG3nCMP2E, “TSG3nCMP0E + 1” is set to TSG3nCMP1E, and 0 is set to TSG3nCMP3E and 4E.

Setting of TSG3nO1 by the match of TSG3nCnTE with TSG3nCMP2E occurs when TSG3nCnTE = TSG3nDTC0 - 1.

Since TSG3nCMP0E + 1 is set to TSG3nCMP3E, TSG3nCnTE does not match TSG3nCMP3E. Therefore, TSG3nO1 output is fixed to active.

Setting of TSG3nO2 by the match of TSG3nCnTE with TSG3nCMP4E and clearing by the match with TSG3nCMP3E occur simultaneously, but clearing takes precedence. Therefore, TSG3nO2 output is fixed to inactive.

When the value other than 0 is set to TSG3nHSPSHUE, set timing of TSG3nO1 is shifted to the right for the number of cycles set in TSG3nHSPSHUE. Note that the set timing is shifted only at operation start (TSG3nTE from 0 to 1) because TSG3nO1 output is fixed to active. For the operation when operation start, see **Section 25.4.7.7, (8) Timer Output Operation at Operation Start in HSP-PWM Mode.**

The same condition applies to TSG3nO3-6, which are the output pins for V phase and W phase when “TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1” is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

Figure 25.107 Waveform in HSP-PWM (TSG3nHSPCMUE is set to TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1)

NOTES

1. In HSP-PWM mode, TSG3nO1 and TSG3nO2 can be set at the same timing by setting the same value to TSG3nCMP4E and 2E. In this case, both TSG3nO1 and TSG3nO2 become inactive.
 2. In HSP-PWM mode, dead time counter keeps operating even when TSG is stopped (TSG3nTE = 0) and the dead time set in TSG3nO1 and TSG3nO2 are always inserted.
-

(7) PWM Adjustment at Reload Timing in HSP-PWM Mode

In HSP-PWM mode, PWM output width is adjusted when TSG3nHSPCMUE/VE/WE (PWM output width setting) is modified during operation. TSG3nO1-6 are set/cleared at reload timing and immediately switched to the output reflecting the new PWM output width.

TSG3nO1-6 are forcibly set/cleared according to the following formula. Even for adjustment, the dead time set with TSG3nDTC0 and 1 is always inserted to TSG3nO1-6. If values are directly written to TSG3nCMP1-12E, output adjustment is not performed at reload timing.

Formula for reload adjustment operation

Table 25.99 Formula for Reload Adjustment Operation
When TSG3nHSPSHUE/VE/WE is 0 (PWM shift width is set to 0)

Pin	Set	Clear
TSG3nO1/3/5	$\text{CMP0E} + \text{DTC1} + 1 < \text{HSPCMUE/VE/WE}$	$\text{HSPCMUE/VE/WE} \leq \text{CMP0E} + \text{DTC1} + 1$
TSG3nO2/4/6	$\text{HSPCMUE/VE/WE} = 0$	$0 < \text{HSPCMUE/VE/WE}$

Table 25.100 Formula for Reload Adjustment Operation
When TSG3nHSPSHUE/VE/WE is not 0 (PWM shift width is not set to 0)

Pin	Set	Clear
TSG3nO1/3/5	(i) $\text{CMP0E} + \text{DTC1} + 1 - \text{HSPSHUE/VE/WE} < \text{HSPCMUE/VE/WE}$	$\text{HSPCMUE/VE/WE} \leq \text{CMP0E} + \text{DTC1} + 1 - \text{HSPSHUE/VE/WE}$
	(ii) $(\text{CMP0E} + 1) \times 2 + \text{DTC1} - \text{HSPSHUE/VE/WE} < \text{HSPCMUE/VE/WE}$	$\text{HSPCMUE/VE/WE} \leq (\text{CMP0E} + 1) \times 2 + \text{DTC1} - \text{HSPSHUE/VE/WE}$
TSG3nO2/4/6	$\text{HSPCMUE/VE/WE} \leq \text{CMP0E} + 1 - \text{HSPSHUE/VE/WE}$	$\text{CMP0E} + 1 - \text{HSPSHUE/VE/WE} < \text{HSPCMUE/VE/WE}$

If the value other than 0 is set as PWM shift width, set/clear condition for positive phase is determined whether the set shift width is greater than “CMP0E + DTC0 – 1” or not.

- (i) $\text{HSPSHUE/VE/WE} \leq \text{CMP0} - \text{DTC0} + 1$
- (ii) $\text{HSPSHUE/VE/WE} > \text{CMP0} - \text{DTC0} + 1$

“TSG3n” is omitted from the register names used in the calculation.

Figure 25.108 Detailed Timing Diagram of Reload Adjustment (Change of TSG3nHSPCMUE from 14 to 1)

(8) Timer Output Operation at Operation Start in HSP-PWM Mode

In HSP-PWM mode, TSG3nO1-6 are cleared when operation starts.

Then, TSG3nO1-6 are set/cleared as TSG3nCNTE counts up depending on the values set in TSG3nHSPCMUE/VE/WE (TSG3nCMP1E to 12E).

Even if TSG3nO1-6 are set before operation start and cleared at operation start, and then set again, the set dead time is always inserted.

Figure 25.109 Timing Diagram of Operation Start in HSP-PWM Mode (TSG3nHSPSHUE = 0 (shift width is set to 0))

Figure 25.110 Timing Diagram of Operation Start in HSP-PWM Mode
(TSG3nHSPSHUE = 5 (shift width is set to five clock cycles))

25.4.7.8 Software Output Control Function

Software output control function is available in any mode except HSP-PWM mode. This function can switch between six output patterns for the TSG3nO1 to TSG3nO6 pins using TSG3nOPT0.TSG3nSOC, TSG3nIDC, and TSG3nOPT0.TSG3nSPC2-0.

When TSG3nSOC is switched from 0 to 1, the output control method of the TSG3nO1 to TSG3nO6 pins is switched to the software output control immediately. On the other hand, when TSG3nSOC is switched from 1 to 0, the software output control is released at the reload timing.

Table 25.101 Registers Associated with Software Output Control Function

Register	Operation
TSG3nOPT0.TSG3nSOC	TSG3nSOC = 1
TSG3nOPT0.TSG3nSTE	TSG3nSTE = 0
TSG3nOPT1.TSG3nSPC2-TSG3nSPC0	Sets output patterns listed in the following Table 25.102 and Table 25.103 .
TSG3nOPT0.TSG3nIDC	Sets output pattern (electric current direction).

Table 25.102 Output Patterns by Software Output Control (TSG3nOPT0.TSG3nIDC = 0)

TSG3nOPT0.TSG3nSOC = 1, TSG3nSTE = 0, TSG3nIDC = 0

Section 26 Timer Option (TAPA)

The Timer optional unit (TAPA) is Hi-Z output control for motor systems. TAPA is implemented 4 units.

This function forcibly sets the motor control output to the Hi-Z state, independently of control by the CPU.

26.1 Features of RH850/P1M-E TAPA

26.1.1 Number of Units

This microcontroller has the following number of TAPA units.

Table 26.1 Number of Units

Product	RH850/P1M-E
Number of units	4
Name	TAPAn (n = 0 to 3)

Table 26.2 Index

Index	Meaning
n	Throughout this section, the individual TAPA units are identified by the index "n" (n = 0 to 3), for example, TAPAnFLG for the TAPAn flag register.

26.1.2 Register Base Address

TAPA register addresses are given as offsets from the given base address. Each of the TAPAn base addresses <TAPAn_base> is listed in the following table.

Table 26.3 Register Base Address

Base Address Name	Base Address
<TAPA0_base>	FFE9 0000 _H
<TAPA1_base>	FFE9 1000 _H
<TAPA2_base>	FFE9 2000 _H
<TAPA3_base>	FFE9 3000 _H

26.1.3 Clock Supply

Clock supply by and to TAPA is listed in the following table.

Table 26.4 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
TAPAn	PCLK	High-speed peripheral clock CLK_HSB

26.1.4 Interrupt Requests

Interrupts or DMA/DTS triggers are not provided to the TAPA module.

26.1.5 Reset Sources

Please refer to **Section 8, Reset Controller**.

26.1.6 Internal Signal

Internal signals of Timer Option are listed in the following table.

Table 26.5 TAPAn Internal Signals

TAPAn Signal	Function	Connected to
TAPA0		
TAPA0THASIN	Hi-Z control asynchronous input signal	PIC1 function
$\overline{\text{TAPA0THZOUT0}}$	Hi-Z control output signal 0 (U phase)	Hi-Z control of TAUD0 U phase output signals (TAUD0O10, TAUD0O11)
$\overline{\text{TAPA0THZOUT1}}$	Hi-Z control output signal 1 (V phase)	Hi-Z control of TAUD0 V phase output signals (TAUD0O12, TAUD0O13)
$\overline{\text{TAPA0THZOUT2}}$	Hi-Z control output signal 2 (W phase)	Hi-Z control of TAUD0 W phase output signals (TAUD0O14, TAUD0O15)
TAPA1		
TAPA1THASIN	Hi-Z control asynchronous input signal	PIC1 function
$\overline{\text{TAPA1THZOUT0}}$	Hi-Z control output signal 0 (U phase)	Hi-Z control of TAUD1 U phase output signals (TAUD1O10, TAUD1O11)
$\overline{\text{TAPA1THZOUT1}}$	Hi-Z control output signal 1 (V phase)	Hi-Z control of TAUD1 V phase output signals (TAUD1O12, TAUD1O13)
$\overline{\text{TAPA1THZOUT2}}$	Hi-Z control output signal 2 (W phase)	Hi-Z control of TAUD1 W phase output signals (TAUD1O14, TAUD1O15)
TAPA2		
TAPA2THASIN	Hi-Z control asynchronous input signal	PIC1 function
$\overline{\text{TAPA2THZOUT0}}$	Hi-Z control output signal 0	Hi-Z control of TSG30 output signals (TSG30O1-TSG30O6)
TAPA3		
TAPA3THASIN	Hi-Z control asynchronous input signal	PIC1 function
$\overline{\text{TAPA3THZOUT0}}$	Hi-Z control output signal 0	Hi-Z control of TSG31 output signals (TSG31O1-TSG31O6)

26.1.7 Peripheral Configuration

The following figure shows peripheral configuration of TAPA.

Figure 26.1 Peripheral Configuration of TAPA

The following describes peripheral configuration of TAPA.

- TAPAnTHASIN: Hi-Z control asynchronous input signal

This signal performs Hi-Z control by the source selected in PIC1.

For the sources selected in PIC1, see **Section 29.2.3.12, Hi-Z Control Function**.

26.2 Overview

26.2.1 Functional Overview

- Asynchronous Hi-Z control input signal (TAPAnTHASIN) enables individual asynchronous Hi-Z control of TAUD and TSG3 output.

26.2.2 Block Diagram

Figure 26.2 Block Diagram

26.3 Registers

26.3.1 List of Registers

TAPAn (n = 0 to 3) registers are listed in the following table.

<TAPAn_base> is defined in **Section 26.1.2, Register Base Address**.

Module	Register Name	Symbol	Address
TAPAn	TAPAn control register 0	TAPAnCTL0	<TAPAn_base> + 20 _H
TAPAn	TAPAn flag register	TAPAnFLG	<TAPAn_base> + 00 _H
TAPAn	TAPAn asynchronous control write enable register	TAPAnACWE	<TAPAn_base> + 04 _H
TAPAn	TAPAn asynchronous control start trigger register	TAPAnACTS	<TAPAn_base> + 08 _H
TAPAn	TAPAn asynchronous control stop trigger register	TAPAnACTT	<TAPAn_base> + 0C _H
TAPAn	TAPAn Hi-Z start trigger register	TAPAnOPHS	<TAPAn_base> + 14 _H
TAPAn	TAPAn Hi-Z stop trigger register	TAPAnOPHT	<TAPAn_base> + 18 _H

26.3.2 TAPAnCTL0 — TAPAn Control Register 0

Control register 0 is used to control Hi-Z.

A value in this register can only be rewritten in the following conditions.

- TAPAnFLG.TAPAnACE = 0 while TAPAn (n = 0, 1) and TAUDnTEm = 0 (m = 10 to 15) at the corresponding TAUDn master channel.
- TAPAnFLG.TAPAnACE = 0 while TAPAn (n = 2, 3).

Access This register can be read/written in 16-bit units.

Address <TAPAn_base> + 20_H

Value after reset 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R

Table 26.6 TAPAnCTL0 Register Contents

Bit Position	Bit Name	Function															
15 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.															
4	TAPAnDCM	Clearing Condition Specification This control bit specifies the condition for clearing of the Hi-Z control outputs. 0: Manipulation of TAPAnOPHT0 is enabled regardless of the TAPAnTHASIN signal input level. 1: Manipulation of TAPAnOPHT0 is disabled when the TAPAnTHASIN input signal is at the active level. Manipulation of TAPAnOPHT0 is enabled when the TAPAnTHASIN signal input is inactive.															
3, 2	TAPAnDCN, TAPAnDCP	Hi-Z Input Edge Selection These control bits specify the valid edge of TAPAnTHASIN. <table border="1" data-bbox="678 1350 1420 1624"> <thead> <tr> <th>TAPAnDCN</th> <th>TAPAnDCP</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Does not detect valid edges</td> </tr> <tr> <td>0</td> <td>1</td> <td>Detects a rising edge as the valid edge (active level = high)</td> </tr> <tr> <td>1</td> <td>0</td> <td>Detects a falling edge as the valid edge (active level = low)</td> </tr> <tr> <td>1</td> <td>1</td> <td>Setting is prohibited.</td> </tr> </tbody> </table>	TAPAnDCN	TAPAnDCP	Description	0	0	Does not detect valid edges	0	1	Detects a rising edge as the valid edge (active level = high)	1	0	Detects a falling edge as the valid edge (active level = low)	1	1	Setting is prohibited.
TAPAnDCN	TAPAnDCP	Description															
0	0	Does not detect valid edges															
0	1	Detects a rising edge as the valid edge (active level = high)															
1	0	Detects a falling edge as the valid edge (active level = low)															
1	1	Setting is prohibited.															
1, 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.															

26.3.3 TAPAnFLG — TAPAn Flag Register

This flag register is used to control Hi-Z.

Access This register can only be read in 16-bit units.

Address <TAPAn_base> + 00_H

Value after reset 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	TAPAnH OF2	TAPAnH OF1	TAPAnH OF0	—	—	—	—	—	—	—	TAPAnA CE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 26.7 TAPAnFLG Register Contents

Bit Position	Bit Name	Function
15 to 11	Reserved	When read, the value after reset is read.
10 to 8	TAPAnHOF _m	<p>HZOUT_m output monitor bit (<i>m</i> = 0 to 2)</p> <p>This bit monitors the $\overline{\text{TAPAnTHZOUT}}_m$ output.</p> <p>0: The $\overline{\text{TAPAnTHZOUT}}_m$ output is at the high level.</p> <p>1: The $\overline{\text{TAPAnTHZOUT}}_m$ output is at the low level.*1</p>
7 to 1	Reserved	When read, the value after reset is read.
0	TAPAnACE	<p>Asynchronous Hi-Z Control Enable</p> <p>This bit indicates the state of asynchronous Hi-Z control (TAPAnTHASIN).</p> <p>0: Asynchronous Hi-Z control is disabled.</p> <p>1: Asynchronous Hi-Z control is enabled.</p> <p>The conditions for setting and clearing this bit are as follows.</p> <p>Clearing condition: Writing 1 to TAPAnACTT while TAPAnACWE = 1.</p> <p>Setting condition: Writing 1 to TAPAnACTS while TAPAnACWE = 1.</p>

Note 1. TAPAnHOF_m (*m* = 1, 2) is enabled when TAPAn (*n* = 0, 1).

26.3.4 TAPAnACWE — TAPAn Asynchronous Control Write Enable Register

This register enables writing for asynchronous Hi-Z control.

Access This register can be read/written in 8-bit units.

Address <TAPAn_base> + 04_H

Value after reset 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAnACWE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 26.8 TAPAnACWE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TAPAnACWE	Asynchronous Control Write Enable This is a write-enable bit for asynchronous Hi-Z control. After 1 has been written to this bit, it is automatically cleared to 0 by writing 1 to TAPAnACTS or TAPAnACTT. 0: Disables writing to TAPAnACTS and TAPAnACTT. 1: Enables writing to TAPAnACTS and TAPAnACTT.

26.3.5 TAPAnACTS — TAPAn Asynchronous Control Start Trigger Register

This register enables the start trigger for asynchronous Hi-Z control.

Access This register can only be written in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base> + 08_H

Value after reset 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAnACTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 26.9 TAPAnACTS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAPAnACTS	Asynchronous Control Start Trigger This bit enables the start trigger for asynchronous Hi-Z control. The setting of this bit is only valid when TAPAnACWE = 1. 0: Writing 0 to this bit is ignored (no function). 1: Enables asynchronous Hi-Z control if TAPAnACWE = 1.

26.3.6 TAPAnACTT — TAPAn Asynchronous Control Stop Trigger Register

This register enables the stop trigger for asynchronous Hi-Z control.

Access This register can only be written in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base> + 0C_H

Value after reset 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAnACTT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 26.10 TAPAnACTT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAPAnACTT	Asynchronous Control Stop Trigger This bit enables the stop trigger for asynchronous Hi-Z control. The setting of this bit is only valid when TAPAnACWE = 1. 0: Writing 0 to this bit is ignored (no function). 1: Stops asynchronous Hi-Z control if TAPAnACWE = 1.

26.3.7 TAPAnOPHS — TAPAn Hi-Z Start Trigger Register

This register sets the start trigger for a Hi-Z control signal ($\overline{\text{TAPAnTHZOUTm}}$) ($m = 0$ to 2^{*1})

Note 1. TAPAn ($n = 2, 3$) are not available when $m = 1, 2$.

Access This register can only be written in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base> + 14_H

Value after reset 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAnOPHS0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 26.11 TAPAnOPHS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAPAnOPHS0	Hi-Z Control Signal Start Trigger 0 This bit sets the start trigger for a Hi-Z control signal. 0: The read value is always 0 and writing 0 to this bit is ignored. 1: Sets the Hi-Z control signal ($\overline{\text{TAPAnTHZOUTm}}$) ($m = 0$ to 2^{*1}) to the low level.

26.3.8 TAPAnOPHT — TAPAn Hi-Z Stop Trigger Register

This register sets the stop trigger for a Hi-Z signal ($\overline{\text{TAPAnTHZOUTm}}$) ($m = 0$ to 2^{*1})

Note 1. TAPAn ($n = 2, 3$) are not available when $m = 1, 2$.

Access This register can only be written in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base> + 18_H

Value after reset 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAnOPHT0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 26.12 TAPAnOPHT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAPAnOPHT0	Hi-Z Control Signal Stop Trigger 0 Sets the stop trigger for a Hi-Z control signal. 0: The read value is always 0 and writing 0 to this bit is ignored. 1: Sets Hi-Z control signal ($\overline{\text{TAPAnTHZOUTm}}$) ($m = 0$ to 2^{*1}) to the high level.

26.4 Function

26.4.1 Asynchronous Hi-Z Control Function

Abnormal operation in timer motor-control under CPU control leads to rotation of the externally connected motor also becoming abnormal. In such cases, this function forcibly sets the motor control output to the Hi-Z state, independently of control by the CPU.

26.4.1.1 Overview

The following method is available for controlling Hi-Z.

- Asynchronous input Hi-Z control by Hi-Z control asynchronous input signal (TAPAnTHASIN)
 - Controls the Hi-Z control output signals $\overline{\text{TAPAnTHZOUT0}}$ (U phase), $\overline{\text{TAPAnTHZOUT1}}$ (V phase), $\overline{\text{TAPAnTHZOUT2}}$ (W phase) asynchronously at TAPAn (n = 0, 1).
 - Controls the Hi-Z control output signals $\overline{\text{TAPAnTHZOUT0}}$ asynchronously at TAPAn (n = 2, 3).

Asynchronous Hi-Z Control and Its Operation

Function	Operation
Asynchronous Hi-Z control corresponding to the pin input	This function detects asynchronous pin inputs and forcibly stops TOUTn output from the corresponding timer module (TAUD, TSG3) in response. Device port outputs become Hi-Z while TAPAnTHASIN is active and until software sends a stop request.

26.4.1.2 Example of System Configuration

When an external error detection signal is received, an interrupt is generated and, at the same time, the motor-driving signal output is set to the Hi-Z state.

This module assumes that microcontroller operation may hang when an error occurs. To handle such situations, external error detection signals are continuously processed so that the motor-driving signal can be set to the Hi-Z state even if no clock signal is being supplied.

This module only detects an error when the edge of an error-detection signal is detected. A fixed output level is not detected as an error (the signal has no edge.)

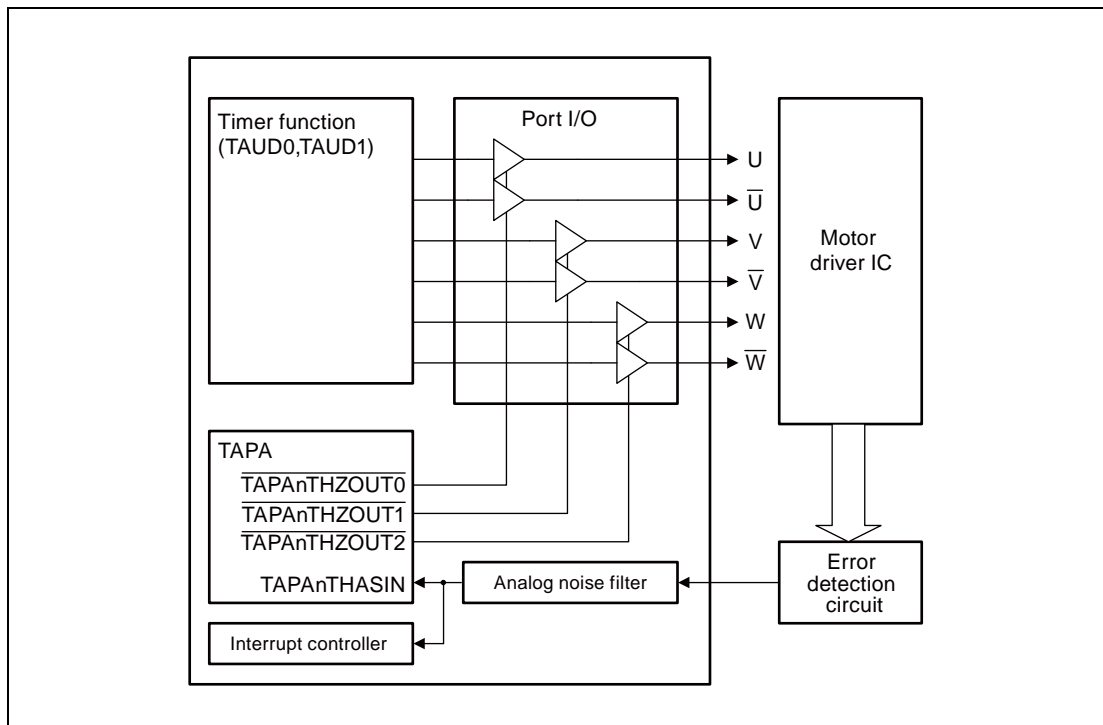

Figure 26.3 Example of System Configuration of Asynchronous Hi-Z Control for Pin Inputs (TAUD0, TAUD1)

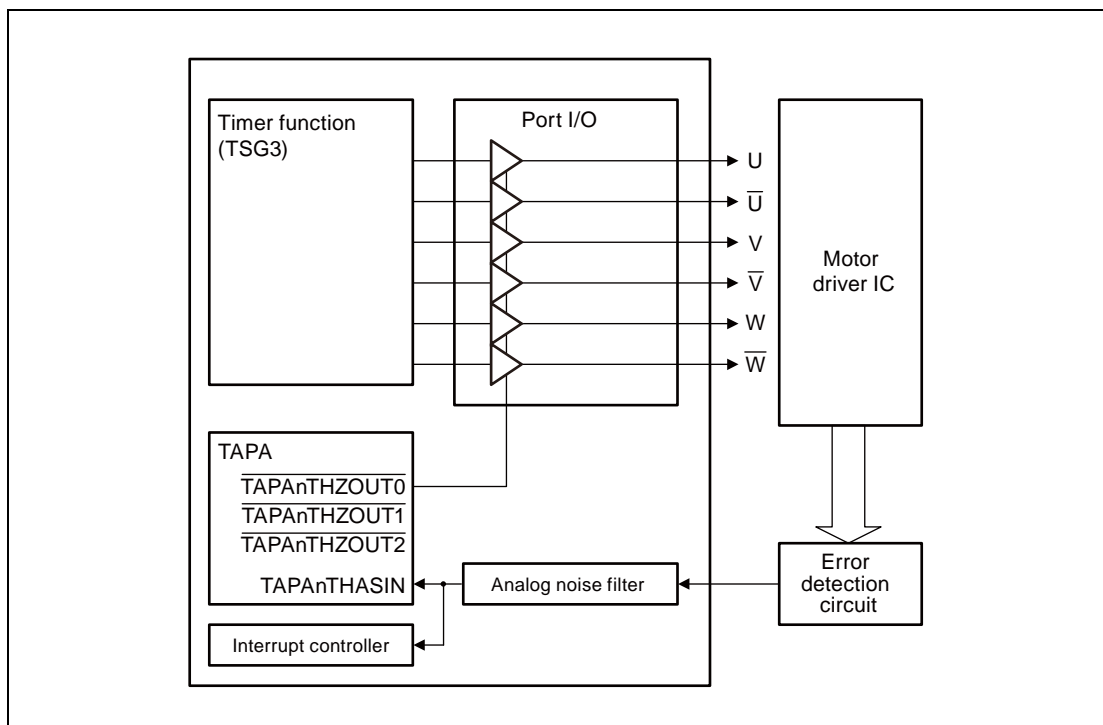

Figure 26.4 Example of System Configuration of Asynchronous Hi-Z Control for Pin Inputs (TSG30, TSG31)

26.4.1.3 Basic Operation

Setting examples are described as follows.

When $TAPAnCTL0.TAPAnDCM = 0$, $TAPAnDCP = 1$, and $TAPAnDCN = 0$

$\overline{TAPAnTHZOUT0}$ goes to the low level on detection of a valid edge of the asynchronous input ($TAPAnTHASIN$).

Output is forcibly stopped (by port control for Hi-Z output) as long as the $\overline{TAPAnTHZOUT0}$ output is at the low level.

$\overline{TAPAnTHZOUT0}$ goes to the high level in response to writing 1 to the bit 0 of TAPAn Hi-Z stop trigger ($TAPAnOPHT0$), regardless of the level of $TAPAnTHASIN$.

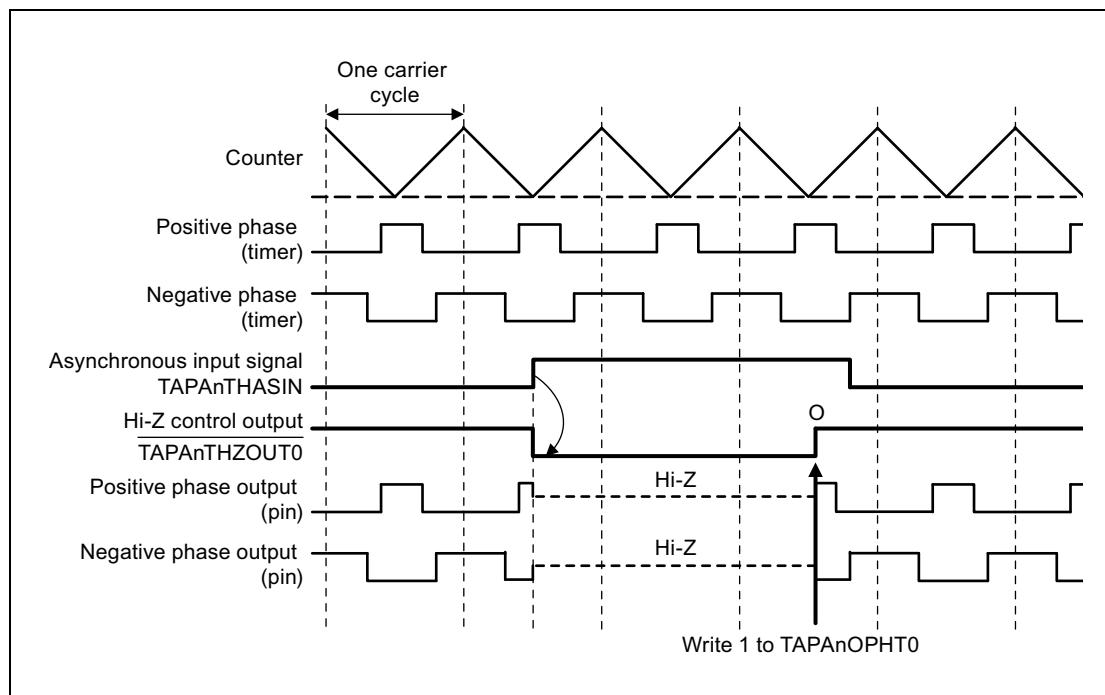

Figure 26.5 $\overline{TAPAnTHZOUT0}$ Operation when $TAPAnDCM = 0$, $TAPAnDCP = 1$, and $TAPAnDCN = 0$

When TAPAnCTL0.TAPAnDCM = 1, TAPAnDCP = 1, and TAPAnDCN = 0

$\overline{\text{TAPAnTHZOUT0}}$ goes to the low level in response to detection of a valid edge of the asynchronous input signal (TAPAnTHASIN).

Output is forcibly stopped (by port control for Hi-Z output) as long as the $\overline{\text{TAPAnTHZOUT0}}$ output is at the low level.

Writing of 1 to Hi-Z stop trigger 0 (TAPAnOPHT0) is ignored as long as the asynchronous input signal (TAPAnTHASIN) is at the active level (high because TAPAnDCP = 1).

After the asynchronous input signal (TAPAnTHASIN) is switched to the inactive level (low because TAPAnDCP = 1), $\overline{\text{TAPAnTHZOUT0}}$ goes to the high level when 1 is written to Hi-Z stop trigger 0 (TAPAnOPHT0).

Figure 26.6 $\overline{\text{TAPAnTHZOUT0}}$ Operation when TAPAnDCM = 1, TAPAnDCP = 1, and TAPAnDCN = 0

26.4.1.4 Asynchronous Hi-Z Control by Software Trigger

This module allows software control of the output of Hi-Z control signals.

Hi-Z start trigger 0 (TAPAnOPHS0) and Hi-Z stop trigger 0 (TAPAnOPHT0) are used to control TAPAnTHZOUT0, TAPAnTHZOUT1*1, and TAPAnTHZOUT2*1.

Note 1. Not available when TAPAn (n = 2, 3).

Operation of the Hi-Z Start Trigger (TAPAnOPHS)

TAPAnDCM	Operation
0/1	Writing 1 to the TAPAnOPHS0 bit places the TAPAnTHZOUT0, TAPAnTHZOUT1, and TAPAnTHZOUT2 at the low level.

Operation of the Hi-Z Stop Trigger (TAPAnOPHT) during Asynchronous Input Hi-Z Control

The Hi-Z stop trigger is enabled in the following conditions.

TAPAnDCM	Operation
0	Writing 1 to the TAPAnOPHT0 bit places the TAPAnTHZOUT0, TAPAnTHZOUT1, and TAPAnTHZOUT2 at the high level.
1	If TAPAnTHASIN is at the inactive level, writing 1 to the TAPAnOPHT0 bit places the TAPAnTHZOUT0, TAPAnTHZOUT1, and TAPAnTHZOUT2 at the high level. If TAPAnTHASIN is at the active level, writing of 1 to the TAPAnOPHT0 bit is ignored.

Figure 26.7 TAPAnTHZOUT0 Operation TAPAnDCM = 1, TAPAnDCP = 1, and TAPAnDCN = 0

26.4.1.5 Operating Procedure

An example of the operating procedure for Hi-Z control in response to asynchronous input is as follows (the table only covers settings for the timer option module because this operation does not depend on timer operations).

	Operation	State of TAPA
Initial settings	Setting in the TAPAnCTL0 register. Set TAPAnDCP and TAPAnDCN (input edge selection). Set TAPAnDCM (clearing mode selection).	Hi-Z control in response to asynchronous input is stopped (TAPAnFLG.TAPAnACE = 0).
Starting operation	Setting in the TAPAnACWE register: Set the TAPAnACWE bit to 1. Setting in the TAPAnACTS register: Set the TAPAnACTS bit to 1.	Writing to TAPAnACTS is enabled. TAPAnFLG.TAPAnACE = 1, enabling Hi-Z control in response to asynchronous input.
During operation	To start Hi-Z control of an output from the timer: <ul style="list-style-type: none"> – Controlled by the TAPAnOPHS0 in TAPA. – Controlled by the Hi-Z control asynchronous input signal (TAPAnTHASIN). To stop Hi-Z control of output from the timer: <ul style="list-style-type: none"> – Controlled by the TAPAnOPHT0 in TAPA. (TAPAnDCM = 0) – Controlled by the TAPAnOPHT0 when Hi-Z input signal in TAPA (TAPAnTHASIN) is inactive level. The state of TAPA operations can be read from the TAPAnFLG register at all times.	On detection of input of the starting edge of the Hi-Z input signal (TAPAnTHASIN) or setting of the start trigger bit (TAPAnOPHS0 = 1), the Hi-Z controller switches the <u>TAPAnTHZOUT0</u> , <u>TAPAnTHZOUT1*1</u> , and <u>TAPAnTHZOUT2*1</u> pins to low-level output. In accord with the operating mode settings in TAPAnDCM, the Hi-Z controller switches the <u>TAPAnTHZOUT0</u> , <u>TAPAnTHZOUT1*1</u> , and <u>TAPAnTHZOUT2*1</u> pins to high-level outputs in response to setting of the stop trigger bit (TAPAnOPHT0 = 1).
Stopping operation	Setting in the TAPAnACWE register: Set the TAPAnACWE bit to 1. Setting in the TAPAnACTT register: Set the TAPAnACTT bit to 1.	Writing to TAPAnACTT is enabled. TAPAnFLG.TAPAnACE = 0, stopping asynchronous Hi-Z control

Note 1. Not available when TAPAn (n = 2, 3).

Section 27 Timer Pattern Buffer (TPBA)

The Timer Pattern Buffer (TPBA) is 16-bit PWM timer with the duty setting buffer. TPBA is implemented 2 units.

27.1 Features of RH850/P1M-E TPBA

27.1.1 Units and Channels

This microcontroller has the following number of TPBA units.

Each TPBA unit has one channel interface.

Table 27.1 Number of Units

Product Name	RH850/P1M-E 100 pins	RH850/P1M-E 144 pins
Number of units	2	2
Name	TPBA _n (n = 0, 1)	TPBA _n (n = 0, 1)

Table 27.2 Index

Index	Meaning
n	Throughout this section, the individual TPBA units are identified by the index “n” (n = 0, 1); for example, TPBA _n CTL is the TPBA _n control register.
m	The number of buffers are indicated by the index “m” (m = 00 to 63).

27.1.2 Register Base Address

TPBA base addresses are listed in the following table.

TPBA register addresses are given as offsets from the base addresses in general.

Table 27.3 Register Base Address

Base Address Name	Base Address
<TPBA0_base>	FFEA 0000 _H
<TPBA1_base>	FFEA 1000 _H

27.1.3 Clock Supply

Clock supply by and to TPBA is listed in the following table.

Table 27.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
TPBA _n	PCLK	High-speed peripheral clock CLK_HSB

27.1.4 Interrupt Requests

TPBA interrupt requests are listed in the following table.

Table 27.5 Interrupt Requests

Unit Interrupt Name	Outline	Interrupt Number	DMA/DTS Trigger Number
TPBA0			
INTTPBA0IPRD	TPBA0 Period match detection interrupt	286	111
INTTPBA0IDTY	TPBA0 Duty match detection interrupt	287	112
INTTPBA0IPAT	TPBA0 Pattern number matching detection interrupt	288	113
TPBA1			
INTTPBA1IPRD	TPBA1 Period match detection interrupt	289	114
INTTPBA1IDTY	TPBA1 Duty match detection interrupt	290	115
INTTPBA1IPAT	TPBA1 Pattern number matching detection interrupt	291	116

27.1.5 Reset Sources

Please refer to **Section 8, Reset Controller**.

27.1.6 External Input/Output Signals

External input/output signals of TPBA are listed in the following table.

Table 27.6 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
TPBA0			
TPBA0O	O	Timer output	TPBA0O
TPBA1			
TPBA1O	O	Timer output	TPBA1O

27.2 Overview

27.2.1 Functional Overview

TPBA_n is a 16-bit PWM timer with the duty setting buffer.

- Count clock resolution: Min. 12.5 ns (count clock: 80 MHz)
- 16-bit counter
- 16-bit duty register
- 16-bit period setting register
- 7-bit address counter register
- 7-bit pattern number setting register
- Interrupt request signals
 - Period-matched detection interrupt
 - Duty-cycle-matched detection interrupt
 - Number-of-patterns matched detection interrupt
- Number of duty patterns
 - 64 patterns (16 bits) or 128 patterns (8 bits)
- Automatic duty generation according to the number of patterns
- Output control by software
- The count clock can be selected from PCLK, PCLK/2, PCLK/4, and PCLK/8 according to the prescaler set value.
- Synchronous start with another timer

27.2.2 Block Diagram

The following block diagram shows the main components of TPBA.

Figure 27.1 Block Diagram of TPBA

- TPBAnTSST Simultaneous start trigger (input by PIC function)

27.3 Registers

27.3.1 List of Registers

TPBA registers are listed in the following table.

For information on <TPBA_base>, see **Section 27.1.2, Register Base Address**.

Table 27.7 List of Registers

Module Name	Register Name	Symbol	Address
TPBA _n	TPBA _n control register	TPBA _n CTL	<TPBA _n _base> + 200 _H
TPBA _n	TPBA _n reload data mode register	TPBA _n RDM	<TPBA _n _base> + 118 _H
TPBA _n	TPBA _n reload status register	TPBA _n RSF	<TPBA _n _base> + 110 _H
TPBA _n	TPBA _n reload data trigger register	TPBA _n RDT	<TPBA _n _base> + 114 _H
TPBA _n	TPBA _n timer output enable register	TPBA _n TOE	<TPBA _n _base> + 120 _H
TPBA _n	TPBA _n timer output register	TPBA _n TO	<TPBA _n _base> + 11C _H
TPBA _n	TPBA _n timer output level register	TPBA _n TOL	<TPBA _n _base> + 124 _H
TPBA _n	TPBA _n period setting register	TPBA _n CMP0	<TPBA _n _base> + 100 _H
TPBA _n	TPBA _n duty setting register	TPBA _n BUF _m	<TPBA _n _base> + m × 4 _H
TPBA _n	TPBA _n pattern number setting register	TPBA _n CMP1	<TPBA _n _base> + 104 _H
TPBA _n	TPBA _n timer counter register	TPBA _n CNT0	<TPBA _n _base> + 108 _H
TPBA _n	TPBA _n address counter register	TPBA _n CNT1	<TPBA _n _base> + 10C _H
TPBA _n	TPBA _n enable status register	TPBA _n TE	<TPBA _n _base> + 128 _H
TPBA _n	TPBA _n start trigger register	TPBA _n TS	<TPBA _n _base> + 12C _H
TPBA _n	TPBA _n stop trigger register	TPBA _n TT	<TPBA _n _base> + 130 _H

27.3.2 TPBA_nCTL — TPBA_n Control Register

This register specifies the operation of the TPBA_n.

Access: This register can be read/written in 8-bit units.

Address: <TPBA_n_base> + 200_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	TPBA _n PRS[1:0]		—	—	—	TPBA _n DPS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R	R/W

Table 27.8 TPBA_nCTL Register Contents

Bit Position	Bit Name	Function															
7, 6	Reserved	When read, the value after reset is read. When writing, write the value after reset.															
5, 4	TPBA _n PRS [1:0]	Selects the count clock. <table border="1" data-bbox="678 891 1417 1081"> <thead> <tr> <th>TPBA_nPRS1</th> <th>TPBA_nPRS0</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>PCLK is selected.</td> </tr> <tr> <td>0</td> <td>1</td> <td>PCLK/2 is selected.</td> </tr> <tr> <td>1</td> <td>0</td> <td>PCLK/4 is selected.</td> </tr> <tr> <td>1</td> <td>1</td> <td>PCLK/8 is selected.</td> </tr> </tbody> </table>	TPBA _n PRS1	TPBA _n PRS0	Description	0	0	PCLK is selected.	0	1	PCLK/2 is selected.	1	0	PCLK/4 is selected.	1	1	PCLK/8 is selected.
TPBA _n PRS1	TPBA _n PRS0	Description															
0	0	PCLK is selected.															
0	1	PCLK/2 is selected.															
1	0	PCLK/4 is selected.															
1	1	PCLK/8 is selected.															
3 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.															
0	TPBA _n DPS	Selects the duty setting pattern mode. 0: 16 bits × 64 patterns mode 1: 8 bits × 128 patterns mode															

CAUTION

This register should be set when the timer is stopped (TPBA_nTE = 0). If this register is erroneously rewritten, set the register again after stopping the timer.

27.3.3 TPBAnRDM — TPBAn Reload Data Mode Register

This register controls the reload timing of the TPBAn period setting register and TPBAn timer output level register values.

Access: This register can be read/written in 8-bit units.

Address: <TPBAn_base> + 118_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBAnRDM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 27.9 TPBAnRDM Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TPBAnRDM0	Controls the reload timing of the TPBAn period setting register (TPBAnCMP0) and TPBAn timer output level register (TPBAnTOL) values. 0: Reloads the values synchronously with a number-of-patterns matched detection interrupt (INTTPBAnIPAT). 1: Reloads the values synchronously with a period-matched detection interrupt (INTTPBAnIPRD).

CAUTION

Although this register can be rewritten during operation, the rewritten value is reflected immediately. Accordingly, during operation, this register should be rewritten when the reload request flag (TPBAnRSF) is 0.

27.3.4 TPBAnRSF — TPBAn Reload Status Register

This register indicates whether or not reload requests from the corresponding registers have been generated.

Access: This register can be read in 8-bit units.

Address: <TPBAn_base> + 110_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TPBAnRSF1	TPBAnRSF0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 27.10 TPBAnRSF Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read.
1	TPBAnRSF1	Indicates whether or not a reload request from TPBAnCMP1 has been generated. 0: No reload request generated or reload completed. 1: Reload request has been generated. This bit is set to 1 when 1 is written to the TPBAnRDT1 bit in the TPBAnRDT register. This bit is cleared at the timing when reload is performed.
0	TPBAnRSF0	Indicates whether or not a reload request from TPBAnCMP0 and TPBAnTOL has been generated. 0: No reload request generated or reload completed. 1: Reload request has been generated. This bit is set to 1 when 1 is written to the TPBAnRDT0 bit in the TPBAnRDT register. This bit is cleared at the timing when reload is performed.

27.3.5 TPBA_nRDT — TPBA_n Reload Data Trigger Register

This register enables reload of the register values.

Access: This register can be written in 8-bit units. It is always read as 0.

Address: <TPBA_n_base> + 114_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TPBA _n RDT1	TPBA _n RDT0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	W	W

Table 27.11 TPBA_nRDT Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When writing, write the value after reset.
1	TPBA _n RDT1	Enables reload of the TPBA _n CMP1 values. 0: Write access is ignored. 1: Reload is enabled (TPBA _n RSF1 is set to 1). The values are updated simultaneously at the next reload timing (reload).
0	TPBA _n RDT0	Enables reload of the TPBA _n CMP0 and TPBA _n TOL values. 0: Write access is ignored. 1: Reload is enabled (TPBA _n RSF0 is set to 1). The values are updated simultaneously at the next reload timing (reload).

27.3.6 TPBA_nTOE — TPBA_n Timer Output Enable Register

This register enables or disables the timer output.

Access: This register can be read/written in 8-bit units.

Address: <TPBA_n_base> + 120_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBA _n TOE0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 27.12 TPBA_nTOE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TPBA _n TOE0	Enables or disables the timer output (TPBA _n O). 0: Disables the timer output based on counter operation. 1: Enables the timer output based on counter operation. <ul style="list-style-type: none"> When the timer output is disabled, the level specified in TPBA_nTO is output from the TPBA_nO pin, and can be controlled by software. When the timer output is enabled, TPBA_nTO is set or cleared by the timer operation, and a PWM signal is output. Write access is prohibited (ignored).

27.3.7 TPBA_nTO — TPBA_n Timer Output Register

This register controls or reads timer output level.

Access: This register can be read/written in 8-bit units.

Address: <TPBA_n_base> + 11C_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBA _n TO0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 27.13 TPBA_nTO Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TPBA _n TO0	Sets or indicates the output level of TPBA _n O pin <ul style="list-style-type: none"> When the timer output is disabled (TPBA_nTOE.TPBA_nTOE0 = 0) <ul style="list-style-type: none"> 0: Outputs low level. 1: Outputs high level. The output level can be controlled by rewriting this register while the timer output is disabled. When the timer output is enabled (TPBA_nTOE.TPBA_nTOE0 = 1) <ul style="list-style-type: none"> 0: Low level is being output by the timer output. 1: High level is being output by the timer output. When the timer output is enabled, rewrite to this register is ignored.

27.3.8 TPBA_nTOL — TPBA_n Timer Output Level Register

This register controls the timer output level.

Access: This register can be read/written in 8-bit units.

Address: <TPBA_n_base> + 124_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBA _n TOL0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 27.14 TPBA_nTOL Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TPBA _n TOL0	Specifies the active level of the timer output. 0: High 1: Low. <ul style="list-style-type: none"> Setting of this bit is enabled when the timer output is enabled (TPBA_nTOE.TPBA_nTOE0 = 1). Setting of this bit is reflected when the timer output is started, and change of the output level is reflected at the next reload timing.

CAUTION

This register is a register to be reloaded. Rewrite during timer operation is reflected at the next reload timing. For details on reload, see **Section 27.4.2, Compare Register Rewrite Operation**.

27.3.9 TPBAnCMP0 — TPBAn Period Setting Register

This is a 16-bit compare register for setting the PWM period.

Access: This register can be read/written in 16-bit units.

Address: <TPBAn_base> + 100_H

Value after reset: 0000_H

Table 27.15 TPBAnCMP0 Register Setting

Operating Mode	PWM Period	Minimum Value (Period)	Maximum Value (Period)
8 bits	TPBAnCMP0 + 1	1	100 _H
16 bits	TPBAnCMP0 + 1	1	10000 _H

CAUTION

- The PWM period is (TPBAnCMP0 + 1) count clock periods. Accordingly, for PWM output with 100% duty cycle, the maximum settable value is FFFE_H (FE_H).
- This register is a register to be reloaded. Rewrite during timer operation is reflected at the next reload timing. For details on reload, see **Section 27.4.2, Compare Register Rewrite Operation**.

27.3.10 TPBAnBUFm — TPBAn Duty Setting Register

This register is a 16×64 buffer register for duty setting.

Access: This register can be read/written in 16-bit units.

Address: <TPBAn_base> + m × 4_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TPBAnBUFm															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.16 TPBAnBUFm Register Contents

Bit Position	Bit Name	Function
15 to 0	TPBAnBUFm15 to TPBAnBUFm0	Sets the duty value. This register can set the duty value either in 16 bits × 64 patterns mode (TPBAnDPS = 0) or 8 bits × 128 patterns mode (TPBAnDPS = 1) by setting the TPBAnDPS bit. In either mode, this register is accessed in 16-bit units by the CPU. For details, see Section 27.4.3, Duty Rewrite Operation .

CAUTION

The value set to this register is transferred to the duty setting buffer register (TPBAnCB2) synchronously with a period-matched detection interrupt (INTTPBAnIPRD). Rewrite during timer operation is reflected immediately. For details, see **Section 27.4.3, Duty Rewrite Operation**.

- When duty setting register with 8 bits × 128 patterns is used, the duty is set in the range from 00_H to FF_H.

The formula to output a waveform of duty 100% is: $TPBAnBUFm = TPBAnCMP0 + 1 \leq 00FF_{H}$.

Therefore, when PWM output of duty 100% is required, the maximum value of TPBAnCMP0 is 00FE_H. When TPBAnBUFm is greater than TPBAnCMP0 + 1, duty value exceeds 100%, but the output is restricted to 100%.

- When duty setting register with 16 bits × 64 patterns is used, the duty is set in the range from 0000_H to FFFF_H.

The formula to output a waveform of duty 100% is: $TPBAnBUFm = TPBAnCMP0 + 1 \leq FFFF_{H}$.

Therefore, when PWM output of duty 100% is required, the maximum value of TPBAnCMP0 is FFFE_H.

When TPBAnBUFm is greater than TPBAnCMP0 + 1, the duty value exceeds 100%, but the output is restricted to 100%.

27.3.11 TPBAnCMP1 — TPBAn Pattern Number Setting Register

This register sets the number of PWM output patterns.

Access: This register can be read/written in 8-bit units.

Address: <TPBAn_base> + 104_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	TPBAnCMP1						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.17 TPBAnCMP1 Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	TPBAnCMP1 [6:0]	Sets the number of patterns within the following range. TPBAnDPS = 0: 0 to 63 TPBAnDPS = 1: 0 to 127

CAUTION

- This register is a register to be reloaded. Rewrite during timer operation is reflected at the next reload timing. For details on reload, see **Section 27.4.2, Compare Register Rewrite Operation**.
- If 64 or a greater number is set as the number of patterns when the duty setting pattern is in 16 bits × 64 patterns mode (TPBAnDPS = 0), the address pointer changes from 63 to 00, and the duty value is transferred from 00 again. A number-of-patterns matched detection interrupt signal (INTTPBAnIPAT) is output by the match of the specified number of patterns and the lower 7-bit values of TPBAnCNT1.

27.3.12 TPBAncNT0 — TPBAnc Timer Counter Register

This register is a timer counter register that generates PWM output.

Access: This register can only be read in 16-bit units.

Address: <TPBAnc_base> + 108_H

Value after reset: FFFF_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TPBAncNT0															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

16-bit counter

This register is a counter register through which the 16-bit counter value can be read.

27.3.13 TPBAncNT1 — TPBAnc Address Counter Register

This register is a counter register that indicates the address pointer to the duty setting register.

Access: This register can only be read in 8-bit units.

Address: <TPBAnc_base> + 10C_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	TPBAncNT1						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

7-bit counter

This register is a counter register that indicates the address of the TPBAncBUFm register.

27.3.14 TPBA_nTE — TPBA_n Enable Status Register

This register indicates whether the timer counter is operating or stopped.

Access: This register can only be read in 8-bit units.

Address: <TPBA_n_base> + 128_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBA _n TE0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 27.18 TPBA_nTE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read.
0	TPBA _n TE0	Indicates whether the timer counter is operating or stopped. 0: The timer counter is stopped. 1: The timer counter is operating. <ul style="list-style-type: none"> The TPBA_nTE0 bit is set to 1 when 1 is written to the TPBA_nTS bit or when a simultaneous start trigger is input. The TPBA_nTE0 bit is cleared to 0 when 1 is written to the TPBA_nTT bit.

27.3.15 TPBA_nTS — TPBA_n Start Trigger Register

This register controls the timer counter start trigger.

Access: This register can only be written in 8-bit units. It is always read as 0.

Address: <TPBA_n_base> + 12C_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBA _n TS0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 27.19 TPBA_nTS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TPBA _n TS0	This bit is a trigger bit that enables the timer counter. 0: Write access is ignored. 1: Starts counting (TPBA _n TE = 1).

CAUTION

Write access to this register during counting (TPBA_nTE = 1) is ignored.

27.3.16 TPBA_nTT — TPBA_n Stop Trigger Register

This register controls the timer counter stop trigger.

Access: This register can only be written in 8-bit units. It is always read as 0.

Address: <TPBA_n_base> + 130_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBA _n TT0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 27.20 TPBA_nTT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TPBA _n TT0	This bit is a trigger bit that disables the timer counter. 0: Write access is ignored. 1: Disables counting (TPBA _n TE = 0).

27.4 Function

27.4.1 Basic Operation

27.4.1.1 Basic Operation of 16-Bit Counter (TPBAnCNT0)

Counting start

The 16-bit counter (TPBAnCNT0) starts counting from the value after reset $FFFF_H$.

Counter clear

The 16-bit counter is cleared by the match of the counter value and the buffer register (TPBAnCB0) set value of TPBAnCMP0.

Counter read during counting

The 16-bit counter value during counting can be read through TPBAnCNT0.

27.4.1.2 Basic Operation of 7-Bit Counter (TPBAnCNT1)

Counting start

The 7-bit counter (TPBAnCNT1) is initialized to 00_H and starts counting. Subsequently, the counter value is incremented synchronously with a period-matched detection interrupt (INTTPBAnIPRD).

Counter clear

The 7-bit counter is cleared by the match of the counter value and the buffer register (TPBAnCB1) set value of TPBAnCPM1.

Counter read during counting

The 7-bit counter value during counting can be read through TPBAnCNT1. The read value indicates TPBAnBUFm in which the duty value to be transferred next is stored.

27.4.2 Compare Register Rewrite Operation

The following registers are rewritten by reload.

- TPBAnCMP0
- TPBAnCMP1
- TPBAnTOL

Reload mode (simultaneous rewrite function)

Writing to TPBAnRDT enables reload of the registers corresponding to the set bits (sets the reload request flag (TPBAnRSF.TPBAnRSFk)), and the values of all the registers to be reloaded are updated simultaneously at the next reload timing (reload).

The reload timing of TPBAnCMP0 and TPBAnTOL is set by TPBAnRDM.

The reload timing of TPBAnCMP1 is the match timing (INTTPBAnIPAT) of the 7-bit counter (TPBAnCNT1) and the buffer register (TPBAnCB1) of TPBAnCMP1.

The registers to be reloaded should be rewritten when the reload request flag (TPBAnRFS.TPBAnRSFk) is 0.

Note: k = 0, 1

Setting Flow for Registers to Be Reloaded

The rewritten values of the registers to be reloaded (TPBAnCMP0, TPBAnCMP1, and TPBAnTOL) can be transferred to the respective buffer registers simultaneously at the reload timing.

Figure 27.2 Basic Operation Flow of Reload (Simultaneous Rewrite Function)

CAUTION

Setting the TPBAnRDTk bit to 1 enables reload. Accordingly, the TPBAnRDTk bit should be rewritten after the registers to be reloaded have been rewritten.

Figure 27.3 Simultaneous Rewrite Timing (TPBAnDPS = 0, TPBAnRDM = 0, and TPBAnTOL = 0)

27.4.3 Duty Rewrite Operation

TPBAnBUFm can be rewritten during operation.

The rewritten setting is reflected immediately.

27.4.3.1 TPBAnBUFm Setting Flow

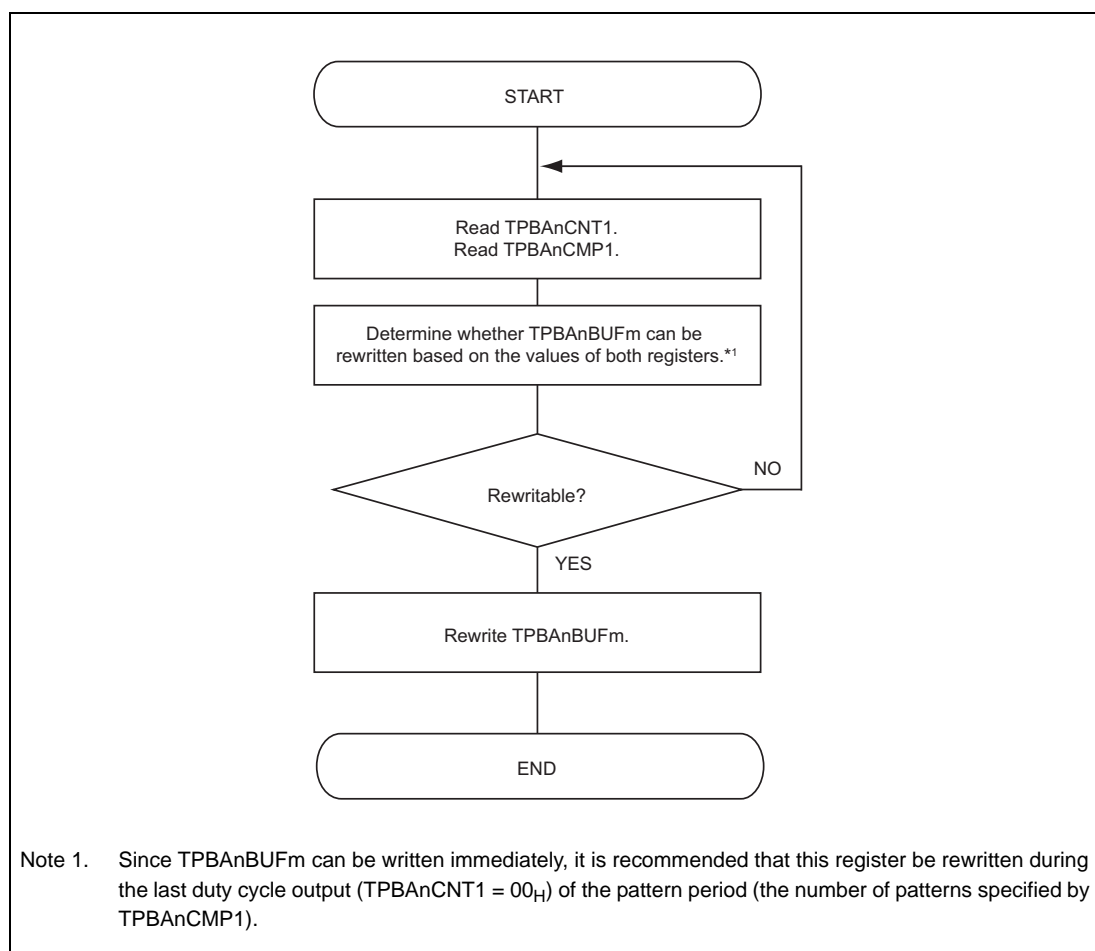

Figure 27.4 Basic Rewrite Flow of TPBAnBUFm

27.4.3.2 Access to TPBAnBUFm

TPBAnBUFm is accessed in 16 bit units. The following shows the access in 16 bits × 64 patterns mode and the access in 8 bits × 128 patterns mode.

- In 16 bits × 64 patterns mode (TPBAnDPS = 0)
This register is accessed by the CPU in units of one 16-bit pattern.

15	0	
Pattern 64		00FC _H
Pattern 63		00F8 _H
:		:
Pattern 3		0008 _H
Pattern 2		0004 _H
Pattern 1		0000 _H

- In 8 bits × 128 patterns mode (TPBAnDPS = 1)
This register is accessed by the CPU in units of two 8-bit patterns.

15	8	7	0	
Pattern 128		Pattern 127		00FC _H
Pattern 126		Pattern 125		00F8 _H
:		:		:
Pattern 6		Pattern 5		0008 _H
Pattern 4		Pattern 3		0004 _H
Pattern 2		Pattern 1		0000 _H

27.4.3.3 Relationship between TPBAnCNT1 Read Value and TPBAnBUFm

The duty value of the currently output PWM waveform can be obtained by reading the TPBAnCNT1 count value during operation. TPBAnBUFm in which the currently output duty value is stored can be found by one of the following formulas.

Table 27.21 TPBAnBUFm Formula

TPBAnDPS Bit	Formula		
	TPBAnCNT1 \neq 00 _H		TPBAnCNT1 = 00 _H
0: 16 bits \times 64 patterns mode	TPBAnCNT1 - 01 _H ⁽¹⁾		TPBAnCMP1 ⁽²⁾
1: 8 bits \times 128 patterns mode	TPBAnCNT1 value is an odd number	TPBAnCNT1/2 ⁽³⁾	TPBAnCMP1/2 ⁽⁵⁾
	TPBAnCNT1 value is an even number	(TPBAnCNT1 / 2) - 01 _H ⁽⁴⁾	

- (1) When TPBAnDPS = 0 and the TPBAnCNT1 \neq 00_H
The applicable register is found by the formula TPBAnCNT1 - 01_H.
(Example) When TPBAnCNT1 = 08_H: 08_H - 01_H = 07_H \rightarrow TPBA0BUF07
- (2) When TPBAnDPS = 0 and the TPBAnCNT1 = 00_H
The applicable register is found by the TPBAnCMP1 value.
(Example) When TPBAnCMP1 = 08_H: TPBAnBUF08
- (3) When TPBAnDPS = 1 and the TPBAnCNT1 = an odd number
The applicable register is found by the formula TPBAnCNT1 / 2
(Example) When TPBAnCNT1 = 07_H: 07_H / 02_H = 03_H \rightarrow TPBAnBUF03 (lower 8 bits)
- (4) When TPBAnDPS = 1 and the TPBAnCNT1 = an even number
The applicable register is found by the formula (TPBAnCNT1 / 2) - 01_H.
(Example) When TPBAnCNT1 = 08_H: (08_H / 02_H) - 01_H = 03_H \rightarrow TPBAnBUF03 (upper 8 bits)
- (5) When TPBAnDPS = 1 and the TPBAnCNT1 = 00_H
The applicable register is found by the formula TPBAnCMP1 / 2.
(Example) When TPBAnCMP1 = 08_H: 08_H / 2 = 04_H \rightarrow TPBAnBUF04 (lower 8 bits)

27.4.4 Basic Operation Example

Overview

A PWM signal is output from the TPBA_nO pin according to the PWM period set in the TPBA_nCMP0 register and duty cycle set in the TPBA_nBUF00 to TPBA_nBUF63 registers.

Prerequisites

- Select 16 bits × 64 patterns mode or 8 bits × 128 patterns mode by setting TPBA_nDPS.
- Set the duty cycle to TPBA_nBUF00 to TPBA_nBUF63.
- Set the number of patterns to TPBA_nCMP1.

Functional description

Set the PWM period, the number of patterns, duty cycle, and level to be output. Set TPBA_nTS.TPBS_nTS0 = 1 (or input a simultaneous start trigger) to start incrementing the timer counter value.

The TPBA_nO output is set to the active level at the same time the counting begins. TPBA_nCNT1 is incremented, and points to the address of the buffer in which the subsequent duty value is stored.

The output is set to the inactive level by the match of the 16-bit counter and the TPBA_nBUF_m buffer register (TPBA_nCB2).

The duty value is then transferred from TPBA_nBUF_m to the buffer register (TPBA_nCB2) by the match of the 16-bit counter and the TPBA_nCMP0 buffer register (TPBA_nCB0). Then, TPBA_nCNT1 is incremented, and a period-matched detection interrupt (INTTPBA_nIPRD) is generated. The TPBA_nO output is set to the active level after one count clock.

During counting, a duty-cycle-matched detection interrupt (INTTPBA_nIDTY) is generated by the match of the 16-bit counter and the buffer register (TPBA_nCB2) of TPBA_nBUF_m.

A number-of-patterns matched detection interrupt (INTTPBA_nIPAT) is generated by the match of the 7-bit counter and the TPBA_nCMP1 buffer register (TPBA_nCB1).

27.4.4.1 List of Operations

Table 27.22 16-Bit Counter Function

Operation		Setting Condition
16-bit counter	Start	Writing 1 to TPBA _n TS or set simultaneous start trigger.
	Clear	Compare match of TPBA _n CMP0 buffer register and 16-bit counter
	Stop	Writing 1 to TPBA _n TT

Table 27.23 7-Bit Counter Function

Operation		Setting Condition
7-bit counter	Start	Writing 1 to TPBA _n TS or set simultaneous start trigger.
	Clear	Compare match of TPBA _n CMP1 buffer register and 7-bit counter
	Stop	Writing 1 to TPBA _n TT

Table 27.24 Functions of Compare Registers and Buffer Registers

Register (Data)	Buffer Register	Rewrite Method	Rewrite during Operation	Function
TPBA _n CMP0	TPBA _n CB0	Reload	Possible	Setting period
TPBA _n CMP1	TPBA _n CB1	Reload	Possible	Setting number of patterns
TPBA _n BUF _m	TPBA _n CB2	Rewrite immediately	Possible	Setting duty
TPBA _n TOL	TPBA _n TOLB	Reload	Possible	Setting output level

Buffer Registers

The registers that specify period, the number of patterns, duty, and timer output level consist of data registers that a user can directly set and buffer registers that a user cannot directly set.

Table 27.25 Timer Output Function

Pin	Function
TPBA _n O	<ul style="list-style-type: none"> When output is enabled (TPBA_nTOE = 01_H) PWM output by compare match of the TPBA_nBUF_m buffer register (TPBA_nCB2) and the 16-bit counter When output is disabled (TPBA_nTOE = 00_H) TPBA_nTO set value

Table 27.26 Interrupt Requests

Interrupt	Function
INTTPBA _n IPRD	Period-matched detection interrupt
INTTPBA _n IDTY	Duty-cycle-matched detection interrupt
INTTPBA _n IPAT	Number-of-patterns matched detection interrupt

Table 27.27 Compare Match Timing

Compare Match	Timing
TPBA _n CMP0	When the 16-bit counter changes from match with TPBA _n CMP0 to 0000 _H .
TPBA _n CMP1	When the 7-bit counter changes from match with TPBA _n CMP1 to 01 _H .
TPBA _n BUF _m	When the 16-bit counter matches with the buffer register (TPBA _n CB2).

Table 27.28 Example of Setting Each Timer Output Condition

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TPBAnO	PWM output	$(\text{TPBAnCMP0} + 1) \times$ count clock	Outputs an inactive level throughout one period (duty cycle 0%).	$\text{TPBAnBUFm} = 0000_{\text{H}}$
			Outputs an active level of one count clock in one period.	$\text{TPBAnBUFm} = 0001_{\text{H}}$
			Outputs an inactive level of one count clock in one period	$\text{TPBAnBUFm} =$ TPBAnCMP0
			Outputs an active level throughout one period (duty cycle 100%).	$\text{TPBAnBUFm} \geq$ $\text{TPBAnCMP0} + 1$

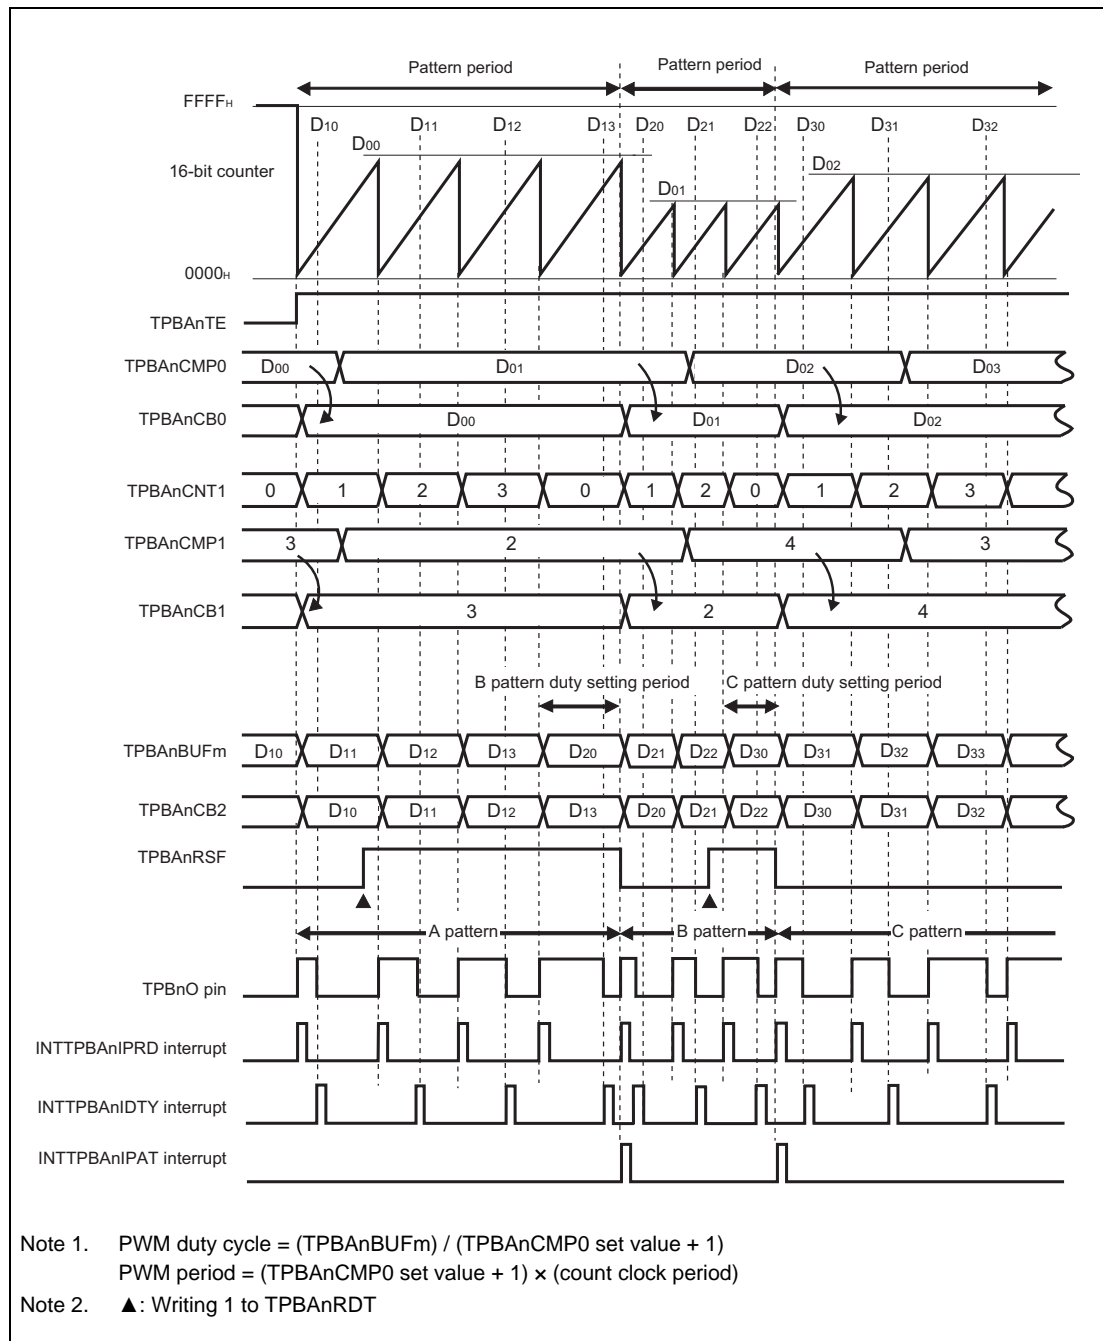

Figure 27.5 Example of Basic Timing (1/2)

CAUTION

TPBAnO outputs active level 1 count clock after output of INTTPBAnIPRD and outputs inactive level at INTTPBAnIDTY output timing.

When a number-of-patterns matched detection interrupt is used as a trigger of the TPBAnCMP0 and TPBAnTOL reload timing (TPBAnIRDM.TPBAnRDM0 = 0 and TPBAnTOL = 0)

Figure 27.6 Example of Basic Timing (2/2)

CAUTION

TPBAnO outputs active level 1 count clock after output of INTTPBAnIPRD and outputs inactive level at INTTPBAnIDTY output timing.

When a period-matched detection interrupt is used as a trigger of the TPBAnCMP0 and TPBAnTOL reload timing (TPBAnIRDM.TPBAnRDM0 = 1 and TPBAnTOL = 0)

Section 28 Encoder Timer (ENCA)

The Encoder Timer (ENCA) operates the timer counter with counter up/down control and clear control by encoder inputs. ENCA is implemented 2 units.

28.1 Features of RH850/P1M-E ENCA

28.1.1 Units and Channels

This microcontroller has the following number of ENCA units.

Each ENCA unit has one channel ENCA. “Number of channels” is used with the same meaning as “number of units” in this section.

Table 28.1 Number of Units

Product	RH850/P1M-E 100 pins (eVR)	RH850/P1M-E 100 pins (DPS)	RH850/P1M-E 144 pins (eVR)	RH850/P1M-E 144 pins (DPS)
Number of Units	2			
Name	ENCA _n (n = 0, 1)			

Table 28.2 Unit Configurations and Channels

Unit Name (Channel Name) ENCA _n	Channels per Unit	RH850/P1M-E 100 pins (eVR)	RH850/P1M-E 100 pins (DPS)	RH850/P1M-E 144 pins (eVR)	RH850/P1M-E 144 pins (DPS)
ENCA0	1	√	√	√	√
ENCA1	1	√	√	√	√

Table 28.3 Index

Index	Description
n	Throughout this section, the individual ENCA units are identified by the index “n” (n = 0, 1); for example, ENCA _n CTL is the ENCA _n control register.

28.1.2 Register Base Address

ENCA_n base addresses are listed in the following table.

ENCA_n register addresses are given as offsets from the base addresses.

Table 28.4 Register Base Addresses

Base Address Name	Base Address
<ENCA0_base>	FFE8 0000 _H
<ENCA1_base>	FFE8 1000 _H

28.1.3 Clock Supply

Clock supply by and to ENCA_n is listed in the following table.

Table 28.5 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
ENCA _n	PCLK	High-speed peripheral clock CLK_HSB

28.1.4 Interrupt Requests

ENCA_n interrupt requests are listed in the following table.

Table 28.6 Interrupt Requests

Unit Interrupt Name	Outline	Interrupt Number	DMA/DTS Trigger Number	Others
ENCA0				
INTENCA0IOV	ENCA0 overflow interrupt	276	—	—
INTENCA0I0	ENCA0 capture/compare match interrupt 0	277	107	—
INTENCA0I1	ENCA0 capture/compare match interrupt 1	278	108	PIC2
INTENCA0IUD	ENCA0 underflow interrupt	279	—	PIC1
INTENCA0IEC	ENCA0 encoder clear interrupt	280	—	PIC1
ENCA1				
INTENCA1IOV	ENCA1 overflow interrupt	281	—	—
INTENCA1I0	ENCA1 capture/compare match interrupt 0	282	109	—
INTENCA1I1	ENCA1 capture/compare match interrupt 1	283	110	PIC2
INTENCA1IUD	ENCA1 underflow interrupt	284	—	—
INTENCA1IEC	ENCA1 encoder clear interrupt	285	—	PIC1

28.1.5 Reset Sources

Please refer to **Section 8, Reset Controller**.

28.1.6 External Input/Output Signals

External input/output signals of ENCA_n are listed below.

Table 28.7 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
ENCA0			
ENCA0TTIN0	I	ENCA0 capture trigger input 0 ^{*1}	ENCA0TIN0 ^{*2}
ENCA0TTIN1	I	ENCA0 capture trigger input 1 ^{*1}	ENCA0TIN1 ^{*2}
ENCA0E0	I	ENCA0 encoder input 0 ^{*1}	ENCA0E0 ^{*2}
ENCA0E1	I	ENCA0 encoder input 1 ^{*1}	ENCA0E1 ^{*2}
ENCA0EC	I	ENCA0 encoder clear input ^{*1}	ENCA0EC ^{*2}
ENCA1			
ENCA1TTIN0	I	ENCA1 capture trigger input 0 ^{*1}	ENCA1TIN0 ^{*1}
ENCA1TTIN1	I	ENCA1 capture trigger input 1 ^{*1}	ENCA1TIN1 ^{*2}
ENCA1E0	I	ENCA1 encoder input 0 ^{*1}	ENCA1E0 ^{*2}
ENCA1E1	I	ENCA1 encoder input 1 ^{*1}	ENCA1E1 ^{*2}
ENCA1EC	I	ENCA1 encoder clear input ^{*1}	ENCA1EC ^{*2}

Note 1. Setting of the noise filter for the port is required when the input pin is used. For details, see **Section 2.6, Noise Filter and Edge Level Detection Circuit**.

Note 2. The input signal can be selected by the PIC function. For details, see **Section 29.2.2.23, PIC1AREG30 — Timer Input/Output Control Register 30**.

28.1.7 Internal Input/Output Signals

Table 29.8 shows the input/output signals connecting ENCA and PIC.

Table 28.8 Internal Input/Output Signals

Unit Signal Name	Description	Connected to
ENCATSST	Simultaneous start trigger	PIC
ENCATTIN1	ENCA _n capture trigger input 1	PIC

28.2 Overview

28.2.1 Functional Overview

- Generation of the counter control signal from the encoder input signal, and performs count operation in synchronization with PCLK.
- Capture function for capturing the counter value with an external trigger signal
- Compare function for compare match judgment with the counter value
- Two capture/compare registers that can be set separately for capture operation and for compare operation
- Interrupt mask function for masking the interrupt request signal output as a result of compare match judgment during compare operation
- Function for loading the value of the capture/compare register to the counter upon underflow occurrence
- Encoder input signal can be used as the timer counter clear condition
- Edge or level can be selected for determining the presence of the encoder input signal that is used as the timer counter clear condition
- Detection of counter overflow and underflow and output of error flags and error interrupts
- Five interrupts: 2 capture/compare interrupts, 1 counter clear interrupt, 1 overflow interrupt, and 1 underflow interrupt

28.2.2 Block Diagram

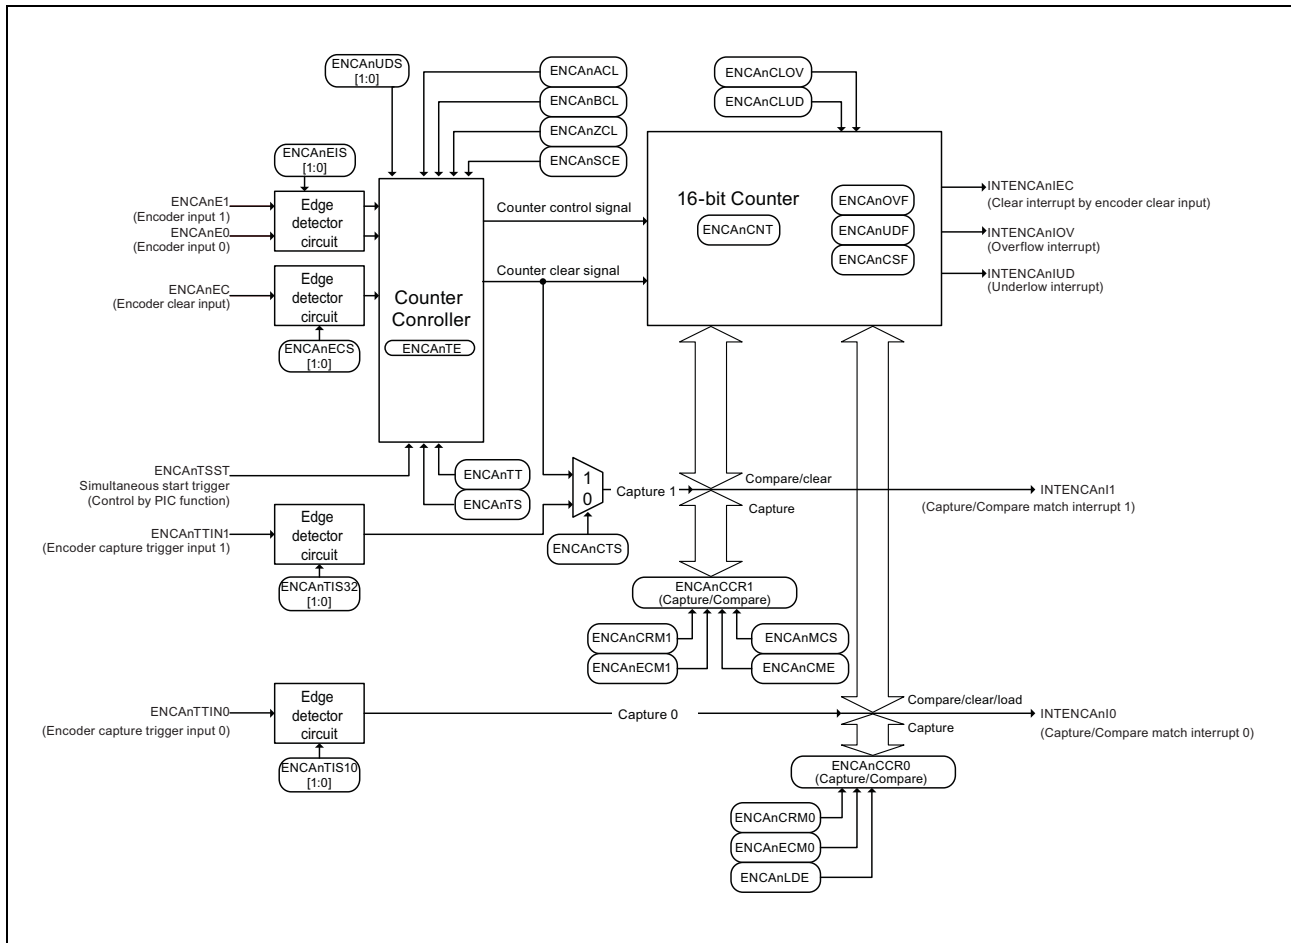

Figure 28.1 Encoder Timer Block Diagram

28.3 Registers

28.3.1 List of Registers

ENCA registers are listed in the following table.

For details about <ENCA_base>, see **Section 28.1.2, Register Base Address**.

Table 28.9 Registers

Module	Register	Symbol	Address
ENCAn	ENCA capture/compare register 0	ENCAnCCR0	<ENCAn_base>
ENCAn	ENCA capture/compare register 1	ENCAnCCR1	<ENCAn_base> + 04 _H
ENCAn	ENCA counter register	ENCAnCNT	<ENCAn_base> + 08 _H
ENCAn	ENCA status flag register	ENCAnFLG	<ENCAn_base> + 0C _H
ENCAn	ENCA status flag clear register	ENCAnFGC	<ENCAn_base> + 10 _H
ENCAn	ENCA timer enable status register	ENCAnTE	<ENCAn_base> + 14 _H
ENCAn	ENCA timer start trigger register	ENCAnTS	<ENCAn_base> + 18 _H
ENCAn	ENCA timer stop trigger register	ENCAnTT	<ENCAn_base> + 1C _H
ENCAn	ENCA I/O control register 0	ENCAnIOC0	<ENCAn_base> + 20 _H
ENCAn	ENCA control register	ENCAnCTL	<ENCAn_base> + 40 _H
ENCAn	ENCA I/O control register 1	ENCAnIOC1	<ENCAn_base> + 44 _H

28.3.2 ENCACTL — ENCA Control Register

This register is used to configure various operation settings of the Encoder Timer.

Access: This register can be read/written in 16-bit units.
Writing to this register during operation is prohibited.

Address: <ENCA_n_base> + 40_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ENCA _n CME	ENCA _n MCS	—	—	—	—	ENCA _n CRM1	ENCA _n CRM0	ENCA _n CTS	—	—	ENCA _n LDE	ENCA _n ECM1	ENCA _n ECM0	ENCA _n UDS [1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Table 28.10 ENCACTL Register Contents (1/2)

Bit Position	Bit Name	Function
15	ENCA _n CME	Encoder Clear Mask Enable This bit is used to enable/disable masking of compare match interrupt detection when the compare function is used. 0: Disables the compare match interrupt (INTENCA _n I1) mask function for the ENCA _n CCR1 register 1: Enables the compare match interrupt (INTENCA _n I1) mask function for the ENCA _n CCR1 register. This bit is valid only when ENCA _n CRM1 = 0. When this bit is set to 1, setting ENCA _n ECM1 to 1 is prohibited.
14	ENCA _n MCS	Encoder Mask Clear Select This bit is used to select the trigger for cancelling masking of compare match interrupt detection INTENCA _n I1 when the compare function is used. This bit is valid only when ENCA _n CRM1 = 0. 0: Masking of compare match interrupt detection is cancelled when the ENCA _n CCR1 register is written. 1: Masking of compare match interrupt detection is cancelled when one of the following three operations is performed. – Encoder clear input operation – Timer counter clear operation upon compare match between ENCA _n CNT and ENCA _n CCR0 when ENCA _n ECM0 = 1 – Loading from ENCA _n CCR0 to timer counter upon underflow detection when ENCA _n LDE = 1
13 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	ENCA _n CRM1	ENCA _n CCR1 Register Mode 0: ENCA _n CCR1 used as compare register. 1: ENCA _n CCR1 used as capture register.
8	ENCA _n CRM0	ENCA _n CCR0 register mode bit 0: ENCA _n CCR0 used as compare register. 1: ENCA _n CCR0 used as capture register.
7	ENCA _n CTS	ENCA _n CCR1 Capture Trigger Select This is a trigger selection bit for the capture operation to the ENCA _n CCR1 register. This bit is valid only when ENCA _n CRM1 = 1. 0: Uses ENCA _n TTIN1 of capture trigger 1 signal as the trigger for capturing to the ENCA _n CCR1 register. 1: Uses the encoder clear signal selected by ENCA _n SCE as the capture trigger to the ENCA _n CCR1 register.
6, 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.

Table 28.10 ENCA_nCTL Register Contents (2/2)

Bit Position	Bit Name	Function
4	ENCA _n LDE	<p>ENCA_n Counter Load Enable</p> <p>This bit is used to enable/disable setting value loading to the counter upon underflow occurrence.</p> <p>This bit is valid only when ENCA_nCRM0 = 0.</p> <p>When ENCA_nCRM0 = 1, loading of the ENCA_nCCR0 register setting value to the counter upon occurrence of an underflow is not performed, regardless of the value of this bit.</p> <p>0: Disable loading of ENCA_nCCR0 register setting value to counter upon occurrence of a counter underflow.</p> <p>1: Enable loading of ENCA_nCCR0 register setting value to counter upon occurrence of a counter underflow.</p>
3	ENCA _n ECM1	<p>Encoder Clear Mode 1</p> <p>This bit is used to set the counter clear operation upon match between the counter value and ENCA_nCCR1 setting value.</p> <p>This bit is valid only when ENCA_nCRM1 = 0.</p> <p>0: Does not clear the counter to 0000_H upon match of timer counter value and ENCA_nCCR1 setting value.</p> <p>1: Clears the counter to 0000_H upon match of timer counter value and ENCA_nCCR1 setting value if the next count is a down-count.</p>
2	ENCA _n ECM0	<p>Encoder Clear Mode 0</p> <p>This bit is used to set the counter clear operation upon match between the counter value and ENCA_nCCR0 setting value.</p> <p>This bit is valid only when ENCA_nCRM0 = 0.</p> <p>0: Does not clear the counter to 0000_H upon match of timer counter value and ENCA_nCCR0 setting value.</p> <p>1: Clears the counter to 0000_H upon match of timer counter value and ENCA_nCCR0 setting value if the next count is a up-count.</p>
1, 0	ENCA _n UDS[1:0]	<p>Up/down Count Selection 1 and 0</p> <p>These are the counter up/down control bits that use ENCA_nE0 and ENCA_nE1.</p> <p>00: Upon detection of valid edge of ENCA_nE0, - down-count when ENCA_nE1 = H, - up-count when ENCA_nE1 = L</p> <p>01: Upon detection of valid edge of ENCA_nE0, up-count, Upon detection of valid edge of ENCA_nE1, down-count</p> <p>10: At rising edge of ENCA_nE0, down-count At falling edge of ENCA_nE0, up-count However, count operation is performed only when ENCA_nE1 = L.</p> <p>11: Detection of both edges of ENCA_nE0 and ENCA_nE1. Judgment of count operation combining both detected edge and level.</p>

28.3.3 ENCAIOC0 — ENCA I/O Control Register 0

This register is used to select the input edge of capture triggers 0 and 1 (ENCAnTTIN0, ENCAntTIN1).

Access: This register can be read/written in 8-bit units.

Address: <ENCAn_base> + 20_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	ENCAnTIS32[1:0]		ENCAnTIS10[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 28.11 ENCAIOC0 Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3, 2	ENCAnTIS32 [1:0]	Input Edge Selection for Capture Trigger 1 These bits are valid only when the ENCAntCTL register's ENCAntCRM1 = 1 and ENCAntCTS = 0. All other settings of ENCAntCRM1 and ENCAntCTS are invalid. 00: No edge detection 01: Rising edge detection 10: Falling edge detection 11: Both edges detection
1, 0	ENCAnTIS10 [1:0]	Input Edge Selection for Capture Trigger 0 These bits are valid only when ENCAntCTL.ENCAntCRM0 = 1. 00: No edge detection 01: Rising edge detection 10: Falling edge detection 11: Both edges detection

28.3.4 ENCAIOC1 — ENCA I/O Control Register 1

This register is used to perform the clear condition setting and edge selection upon encoder input.

Access: This register can be read/written in 8-bit units.
Writing to this register during operation is prohibited.

Address: <ENCA_n_base> + 44_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	ENCA _n SCE	ENCA _n ZCL	ENCA _n BCL	ENCA _n ACL	ENCA _n ECS[1:0]		ENCA _n EIS[1:0]

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.12 ENCAIOC1 Register Contents

Bit Position	Bit Name	Function
7	ENCA _n SCE	Encoder Special-clear Enable This is an encoder special clear enable bit. When setting this bit to 1, set ENCA _n UDS[1:0] to 10 _B or 11 _B . The operation is not guaranteed if this bit is set to 1 with ENCA _n UDS[1:0] set to 00 _B or 01 _B . 0: Clears the counter upon detection of ENCA _n EC valid edge (set with ENCA _n ECS[1:0]). 1: Clears the counter upon detection of input level condition of ENCA _n EC, ENCA _n E1, and ENCA _n E0 (set with ENCA _n ZCL bit, ENCA _n BCL bit, and ENCA _n ACL bit).
6	ENCA _n ZCL	Input-Z Clear Condition Selection This bit is used to set the condition for clearing the encoder clear input (ENCA _n EC) when using the encoder special clear function. This bit is valid only when ENCA _n SCE = 1; it is invalid when ENCA _n SCE = 0. 0: Clear condition: Low level 1: Clear condition: High level
5	ENCA _n BCL	Input-B Clear Condition Selection This bit is used to set the condition for clearing the encoder input 1 (ENCA _n E1) when using the encoder special clear function. This bit is valid only when ENCA _n SCE = 1; it is invalid when ENCA _n SCE = 0. 0: Clear condition: Low level 1: Clear condition: High level
4	ENCA _n ACL	Input-A Clear Condition Selection This bit is used to set the condition for clearing the encoder input 0 input (ENCA _n E0) when using the encoder special clear function. This bit is valid only when ENCA _n SCE = 1; it is invalid when ENCA _n SCE = 0. 0: Clear condition: Low level 1: Clear condition: High level
3, 2	ENCA _n ECS[1:0]	Encoder Clear Input Edge Selection 1 and 0 These are the encoder clear input edge selection bits. These bits are valid only when ENCA _n SCE = 0; they are invalid when ENCA _n SCE = 1. 00: No edge detection 01: Rising edge detection 10: Falling edge detection 11: Both edges detection
1, 0	ENCA _n EIS[1:0]	Encoder Edge Input Selection 1 and 0 These are the encoder input edge selection bits. These bits are valid when ENCA _n UDS[1:0] is 00 _B or 01 _B , and are invalid when ENCA _n UDS[1:0] is 10 _B or 11 _B . 00: No edge detection 01: Rising edge detection 10: Falling edge detection 11: Both edges detection

28.3.5 ENCA_nFLG — ENCA Status Flag Register

This register holds the status flags of the timer counter of ENCA_n.

Access: This register can only be read in 8-bit units.

Address: <ENCA_n_base> + 0C_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	ENCA _n CSF	ENCA _n UDF	ENCA _n OVF
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 28.13 ENCA_nFLG Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is read.
2	ENCA _n CSF	Counter Status Flag This bit reflects the current timer counter operation. This bit is cleared at the start of count operation. 0: Timer counter in up-count status 1: Timer counter in down-count status
1	ENCA _n UDF	Underflow Flag This bit reflects the occurrence of an underflow during the timer counter operation. This bit is cleared at the start of count operation. 0: This flag is cleared to 0 upon any of the following events: <ul style="list-style-type: none"> – 1 is written to ENCA_nFGC.ENCA_nCLUD – ENCA_nTS is set while ENCA_nTE = 0 – The input signal of ENCA_nTSST is set to “High level” 1: This flag is set to 1 upon occurrence of an underflow during the encoder timer count operation.
0	ENCA _n OVF	Overflow Flag This bit reflects the occurrence of an overflow during the timer counter operation. This bit is cleared at the start of count operation. 0: This flag is cleared to 0 upon any of the following events: <ul style="list-style-type: none"> – 1 is written to ENCA_nFGC.ENCA_nCLOV – ENCA_nTS is set while ENCA_nTE = 0 – The input signal of ENCA_nTSST is set to “High level” 1: This flag is set to 1 upon occurrence of an overflow during the encoder timer count operation.

28.3.6 ENCA_nFGC — ENCA Status Flag Clear Register

This register is used to clear the timer counter status flags of ENCA_nFLG.

Access: This register can only be written in 8-bit units.
This register always returns 0 when read.

Address: <ENCA_n_base> + 10_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	ENCA _n CLUD	ENCA _n CLOV
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	W	W

Table 28.14 ENCA_nFGC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When writing, write the value after reset.
1	ENCA _n CLUD	Underflow Flag Clear This bit clears the underflow flag. 0: Writing is ignored. 1: Clears ENCA _n UDF of the ENCA _n FLG register (clears underflow detection).
0	ENCA _n CLOV	Overflow Flag Clear This bit clears the overflow flag. 0: Writing is ignored. 1: Clears ENCA _n OVF of the ENCA _n FLG register (clears overflow detection).

28.3.7 ENCA_nCCR0 — ENCA Capture/Compare Register 0

This register is a 16-bit capture/compare register 0.

Access: This register can only be read/written in 16-bit units.
When used as a capture register, this register is only readable. Writing to this register is ignored.
When used as a compare register, this register is readable/writable.

Address: <ENCA_n_base> + 00_H

Value after reset: 0000_H

Table 28.15 ENCA_nCCR0 Register Contents

Bit Position	Bit Name	Function
15 to 0	ENCA _n CCR0 [15:0]	Capture/Compare Register 0 Upon occurrence of an underflow, the setting value of this register may be loaded to the counter according to the ENCA _n CTL.ENCA _n LDE setting. See the description of the ENCA _n LDE bit in ENCA control register ENCA _n CTL for details. <ul style="list-style-type: none"> If ENCA_nCTL.ENCA_nCRM0 = 0: ENCA_nCCR0 is compare register. Set the value to be compared with the timer counter value. If ENCA_nCTL.ENCA_nCRM0 = 1: ENCA_nCCR0 is capture register. The captured timer counter value is stored.

28.3.8 ENCA_nCCR1 – ENCA Capture/Compare Register 1

This register is a 16-bit capture/compare register 1.

Access: This register can only be read/written in 16-bit units.
When used as a capture register, this register is only readable. Writing to this register is ignored.
When used as a compare register, this register is readable/writable.

Address: <ENCA_n_base> + 04_H

Value after reset: 0000_H

Table 28.16 ENCA_nCCR1 Register Contents

Bit Position	Bit Name	Function
15 to 0	ENCA _n CCR1 [15:0]	Capture/Compare Register 1 During capture operation, the trigger for capturing to this register differs according to the ENCA _n CTL.ENCA _n CTS setting. See the description of the ENCA _n CTS bit in ENCA control register ENCA _n CTL for details. <ul style="list-style-type: none"> If ENCA_nCTL.ENCA_nCRM1 = 0: ENCA_nCCR1 is compare register Set the value to be compared with the timer counter value. If ENCA_nCTL.ENCA_nCRM1 = 1: ENCA_nCCR1 is capture register The captured timer counter value is stored.

28.3.9 ENCAncNT — ENCA Counter Register

This register is the 16-bit timer counter register.

Access: This register can be read/written in 16-bit units.
This register can be written only when the operation is stopped.

Address: <ENCAnc_base> + 08_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ENCAncNT[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.17 ENCAncNT Register Contents

Bit Position	Bit Name	Function
15 to 0	ENCAncNT [15:0]	Counter Register <ul style="list-style-type: none"> • ENCAncTE.ENCAncTE status: 0 (initial setting): Count stop An arbitrary value can be set to timer counter. • ENCAncTE.ENCAncTE status: 0 → 1 (operation start): Count operation start Up/down count operation is started with the set arbitrary value. • ENCAncTE.ENCAncTE status: 1 (operating): Counting Up/down count operation is performed. • ENCAncTE.ENCAncTE status: 1 → 0 (stopped): Count stop The counter value immediately before the operation was stopped is held, and the count operation is stopped.

28.3.10 ENCA_nTE — ENCA Timer Enable Status Register

This register indicates the operating status of ENCA_n.

Access: This register can only be read in 8-bit units.

Address: <ENCA_n_base> + 14_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ENCA _n TE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 28.18 ENCA_nTE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read.
0	ENCA _n TE	<p>Timer Status Enable</p> <p>This is a status bit that indicates the operation enabled/stopped status of ENCA_n.</p> <p>This bit is cleared to 0 when 1 is written to ENCA_nTT.ENCA_nTT.</p> <p>This bit is set to 1 when 1 is written to ENCA_nTS.ENCA_nTS, or when the input signal of ENCA_nTSST is set to High level.</p> <p>0: Operation stopped status</p> <p>1: Operation enabled status</p>

28.3.11 ENCA_nTS — ENCA Timer Start Trigger Register

This register provides the trigger bit for setting the ENCA_n to the operation enabled state.

Access: This register can only be written in 8-bit units.
This register always returns 00_H when read.

Address: <ENCA_n_base> + 18_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ENCA _n TS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 28.19 ENCA_nTS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	ENCA _n TS	Timer Start Trigger This is the trigger bit that sets the ENCA _n to the operation enabled state. 0: Writing is ignored. 1: The ENCA _n is set to the operation enabled state by setting ENCA _n TE.ENCA _n TE = 1.

28.3.12 ENCA_nTT — ENCA Timer Stop Trigger Register

This register provides the trigger bit for setting the ENCA_n to the operation stopped state.

Access: This register can only be written in 8-bit units.
This register always returns 00_H when read.

Address: <ENCA_n_base> + 1C_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ENCA _n TT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 28.20 ENCA_nTT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	ENCA _n TT	Timer Stop Trigger This is the trigger bit that sets the ENCA _n to the operation stopped state. 0: Writing is ignored. 1: Clears ENCA _n TE. ENCA _n TE to 0, to set the ENCA _n to the count operation stopped state.

28.4 Operation

The ENCA_n operates the timer counter with counter up/down control and clear control by encoder inputs. The ENCA_nCCR0 and ENCA_nCCR1 registers can be used as dedicated compare registers or as dedicated capture registers.

28.4.1 Timer Counter Operation

The timer counter operations of the ENCA_n are described below.

The figure below shows the operation phases. See the corresponding section with the section number for detailed descriptions on each operation.

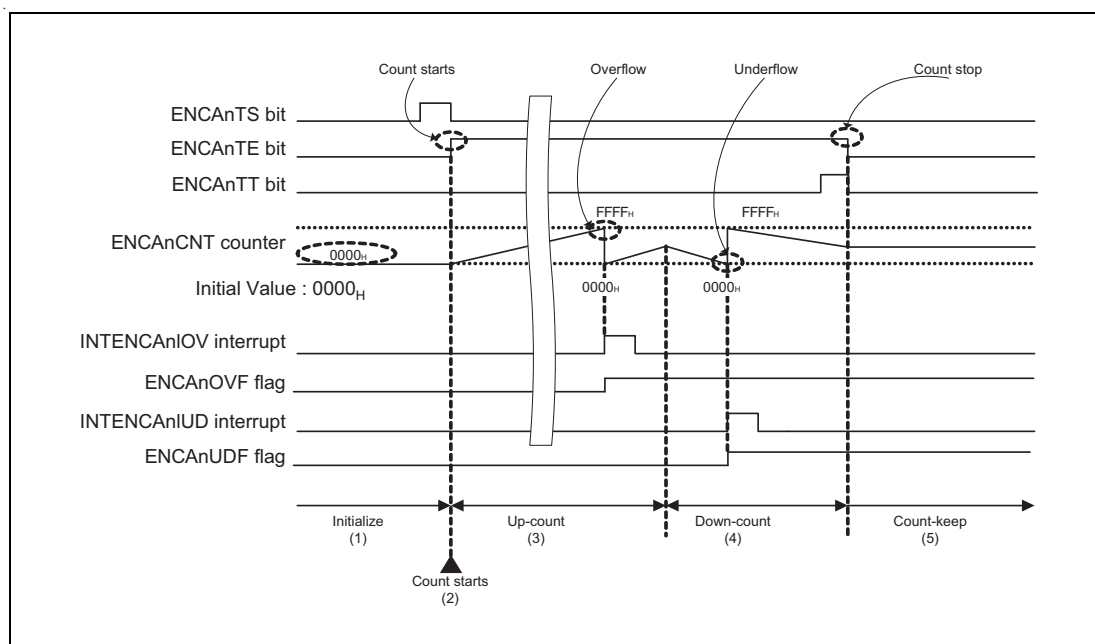

Figure 28.2 Timer Counter Initial Setting Value Setting/Start/Stop

(1) Timer counter initial setting value setting

The initial setting value of the ENCA_n counter register (ENCA_nCNT) can be set in the counter operation stopped status (ENCA_nTE = 0).

(2) Timer counter startup

By writing 1 to the timer start trigger bit (ENCA_nTS), the timer status enable bit (ENCA_nTE) is set to 1, the count operation is enabled, and counting operation is performed upon detection of the valid edge of the encoder input.

(3) Overflow operation

An overflow occurs when up-counting is performed when the counter value is FFFF_H. If the counter value changes from FFFF_H to 0000_H, an overflow interrupt (INTENCA_nIOV) is generated, and the overflow flag (ENCA_nOVF) is set to 1. The overflow flag (ENCA_nOVF) is cleared to 0 when 1 is set to the overflow flag (ENCA_nCLOV). For details about the operation, see **Section 28.6.1, Overflow Occurrence and Overflow Flag Clear Operation**.

(4) Underflow operation

An underflow occurs when down-counting is performed when the counter value is 0000_H. If the counter value changes from 0000_H to FFFF_H, an underflow interrupt (INTENCA_nIUD) is generated, and the underflow flag (ENCA_nUDF) is set to 1. The underflow flag (ENCA_nUDF) is cleared to 0 when 1 is set to the underflow flag (ENCA_nCLUD). For details about the operation, see **Section 28.6.2, Underflow Occurrence and Underflow Flag Clear Operation**.

(5) Timer counter stop

By writing 1 to the timer stop trigger bit (ENCA_nTT), the timer status enable bit (ENCA_nTE) is cleared to 0, and the count operation is stopped. At this time, the timer counter is not reset to 0000_H and holds the value before count operation stop.

28.4.2 Up/Down Control of Timer Counter

Up/down control is performed by judging the phase of the encoder inputs (ENCAnE0, ENCAne1) according to the settings of ENCAAnUDS[1:0].

28.4.2.1 When ENCAAnUDS[1:0] Bits in ENCAAnCTL = 00_B

Table 28.21 When ENCAAnUDS[1:0] = 00_B

ENCAAnUDS1	ENCAAnUDS0	Operation Description			
		ENCAAnE0 input	ENCAAnE1 input	Counting operation	
0	0	Rising edge	High level	Down	
		Falling edge			
		Both edges			
		Rising edge	Low level		Up
		Falling edge			
		Both edges			

The valid edge for ENCAAnE0 is specified by setting ENCAAnEIS[1:0].

“Counting operation” indicates that counting up or down proceeds when the valid edges of the ENCAAnE0 signal matches the valid level ENCAAnE1 signal.

The following timing chart shows counting operation when ENCAAnUDS[1:0] = 00_B.

Figure 28.3 Counting Operation when ENCAAnUDS[1:0] in ENCAAnCTL = 00_B

28.4.2.2 When ENCA_nUDS[1:0] Bits in ENCA_nCTL = 01_B

Table 28.22 When ENCA_nUDS[1:0] = 01_B

ENCA _n UDS1	ENCA _n UDS0	Operation Description			
		ENCA _n E0 input	ENCA _n E1 input	Counting operation	
0	1	Low level	Rising edge	Down	
			Falling edge		
			Both edges		
		High level	Rising edge		
			Falling edge		
			Both edges		
		Rising edge	Low level	Up	
		Falling edge			
		Both edges			
		Rising edge	High level		
		Falling edge			
		Both edges			
		Simultaneous input			Hold

The valid edges for ENCA_nE0 and ENCA_nE1 are specified by setting ENCA_nEIS[1:0].

“Counting operation” indicates that counting up or down proceeds when the valid edges and levels of the signals on ENCA_nE0 and ENCA_nE1 match.

The following timing chart shows counting operation when ENCA_nUDS[1:0] = 01_B.

Figure 28.4 Counting Operation when ENCA_nUDS[1:0] in ENCA_nCTL = 01_B

28.4.2.3 When ENCA_nUDS[1:0] Bits in ENCA_nCTL = 10_B

Table 28.23 When ENCA_nUDS[1:0] = 10_B

ENCA _n UDS1	ENCA _n UDS0	Operation Description		
		ENCA _n E0 input	ENCA _n E1 input	Counting operation
1	0	Rising edge	Low level	Down
		Rising edge	Falling edge	
		Falling edge	Low level	Up
		Falling edge	Falling edge	
		Low level	Rising edge	Hold
		Rising edge	Rising edge	
		High level	Rising edge	
		Falling edge	Rising edge	
		Low level	Falling edge	
		Rising edge	High level	
		High level	Falling edge	
		Falling edge	High level	

Valid edge specification for ENCA_nE0 and ENCA_nE1 (setting to ENCA_nEIS[1:0]) is invalid.

The following timing chart shows counting operation when ENCA_nUDS[1:0] = 10_B.

Figure 28.5 Counting Operation when ENCA_nUDS[1:0] in ENCA_nCTL = 10_B

28.4.2.4 When ENCA_nUDS[1:0] Bits in ENCA_nCTL = 11_B

Table 28.24 When ENCA_nUDS[1:0] = 11_B

ENCA _n UDS1	ENCA _n UDS0	Operation Description			
		ENCA _n E0 input	ENCA _n E1 input	Counting operation	
1	1	Low level	Falling edge	Down	
		Rising edge	Low level		
		High level	Rising edge		
		Falling edge	High level		
		Rising edge	High level	Up	
		High level	Falling edge		
		Falling edge	Low level		
		Low level	Rising edge		
		Simultaneous input			Hold

Valid edge specification for ENCA_nE0 and ENCA_nE1 (settings of ENCA_nEIS[1:0]) is invalid.

When the valid edges of the signals on ENCA_nE0 and ENCA_nE1 coincide, the count is retained.

The following timing chart shows counting operation when ENCA_nUDS[1:0] = 11_B

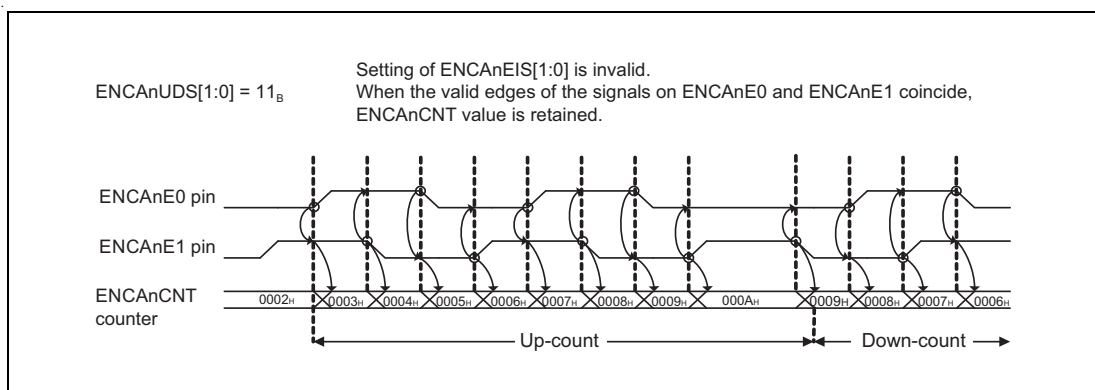

Figure 28.6 Counting Operation when ENCA_nUDS[1:0] = 11_B

28.4.3 Timer Counter Clear Control by Encoder Input

The following conditions lead to clearing of the timer counter to 0000_H.

- Detection of a valid edge of the encoder clearing input signal (signal on the ENCA_nEC pin)
- Level detection of the encoder input and encoder clearing input signals (signals on the ENCA_nE0, ENCA_nE1, and ENCA_nEC pins)

Two types of clearing methods can be selected by controlling the ENCA_nSCE, ENCA_nZCL, ENCA_nBCL, ENCA_nACL, ENCA_nECS[1:0] bits of the ENCA_nIOC1 register.

Table 28.25 Timer Counter Clear Control by Encoder Input

Clearing method	ENCA _n SCE	ENCA _n ZCL	ENCA _n BCL	ENCA _n ACL	ENCA _n ECS[1:0]
(1)	0	Invalid	Invalid	Invalid	Valid
(2)	1	Valid	Valid	Valid	Invalid

28.4.3.1 Clearing Method when ENCA_nSCE = 0

- Upon detection of the valid edge of ENCA_nEC, the timer counter is cleared to 0000_H in synchronization with the operation clock.
- The valid edge of ENCA_nEC is specified by the setting of the ENCA_nECS[1:0] bits.
- The settings of the ENCA_nZCL, ENCA_nBCL, and ENCA_nACL bits are invalid.
- An encoder clear interrupt request signal (INTENCA_nIEC) is output simultaneously with timer counter clearing.

For details about clear operation when ENCA_nSCE = 0, see the timing chart in **Section 28.6.19, Capture Operation Performed upon Clearing by ENCA_nEC when ENCA_nSCE = 0.**

28.4.3.2 Clearing Method when ENCA_nSCE = 1

- When the clear levels of the ENCA_nEC, ENCA_nE1, and ENCA_nE0 inputs are detected, the timer counter is cleared to 0000_H in synchronization with the operating clock.
- Specify the clear levels of the ENCA_nEC, ENCA_nE1, and ENCA_nE0 inputs by the settings of the ENCA_nZCL, ENCA_nBCL, and ENCA_nACL bits.
- The settings of the ENCA_nECS[1:0] bits are invalid.
- An encoder clear interrupt request signal (INTENCA_nIEC) is output simultaneously with timer counter clearing.

The clearing conditions of the timer counter according to the ENCA_nZCL, ENCA_nBCL, and ENCA_nACL settings are listed in the table below.

Table 28.26 Clearing Conditions of Timer Counter

Counter Clear Condition Setting			Encoder Input Level		
ENCA _n ZCL	ENCA _n BCL	ENCA _n ACL	ENCA _n EC	ENCA _n E1	ENCA _n E0
0	0	0	Low	Low	Low
0	0	1	Low	Low	High
0	1	0	Low	High	Low
0	1	1	Low	High	High
1	0	0	High	Low	Low
1	0	1	High	Low	High
1	1	0	High	High	Low
1	1	1	High	High	High

28.4.4 Functions of ENCA_nCCR0

28.4.4.1 Compare Function

- When ENCA_nCRM0 = 0, the ENCA_nCCR0 register functions as a dedicated compare register.
- Upon compare match between the value of the timer counter and the ENCA_nCCR0 setting value, a compare 0 match interrupt (INTENCA_nI0) is output.
- When ENCA_nECM0 = 1, the timer counter is cleared to 0000_H in synchronization with the operating clock upon compare match if the next count operation is up-count.

Table 28.27 Compare Function of ENCA_nCCR0

ENCA _n CCR0 function	Compare match clear control	Next count operation	Timer counter clearing upon compare match with ENCA _n CCR0
ENCA _n CRM0	ENCA _n ECM0		
0 (Compare)	0	Up-count	Does not clear (continues count operation).
		Down-count	
	1	Up-count	Clears timer counter to 0000 _H .
		Down-count	Does not clear (continues count operation).

When ENCA_nLDE = 1

- Upon occurrence of an underflow, the setting value of the ENCA_nCCR0 register is loaded to the timer counter.
- An underflow interrupt (INTENCA_nIUD) is output.

NOTE

For the timing chart when ENCA_nLDE = 1, see the timing charts in **Section 28.6.8, Using the ENCA_nLDE Function Immediately after Startup** and **Section 28.6.12, Up-count after Conflict between ENCA_nLDE Function (Loading Counter Value) and Clear Operation by Encoder Clear Input**.

28.4.4.2 Capture Function

- When ENCA_nCRM0 = 1, the ENCA_nCCR0 register functions as a dedicated capture register.
- Upon valid edge detection of the capture trigger input 0 (ENCA_nTTIN0), the value of the timer counter is stored into ENCA_nCCR0.
- A capture 0 interrupt (INTENCA_nI0) is output during capture operation.

NOTE

For details about capture operation to ENCA_nCCR0, see the timing charts in **Section 28.6.14, Capture Operation between Count Clocks (ENCA_nCCR0)** and **Section 28.6.17, Encoder operation when compare match clear control is disabled**.

28.4.5 Functions of ENCA_nCCR1

28.4.5.1 Compare Function

- When ENCA_nCRM1 = 0, the ENCA_nCCR1 register functions as a dedicated compare register.
- Upon compare match between the value of the timer counter and the ENCA_nCCR1 setting value, a compare 1 match interrupt (INTENCA_n1) is output.
- When ENCA_nECM1 = 1, the timer counter is cleared to 0000_H in synchronization with the operating clock upon compare match if the next count operation is down-count.

Table 28.28 Compare Function of ENCA_nCCR1

ENCA _n CCR1 function	Compare match clear control	Next count operation	Timer counter clearing upon compare match with ENCA _n CCR1.
ENCA _n CRM1	ENCA _n ECM1		
0 (Compare)	0	Up-count	Does not clear (continues count operation).
		Down-count	
	1	Up-count	Does not clear (continues count operation).
		Down-count	Clears timer counter to 0000 _H .

Compare match interrupt detection mask function

- When ENCA_nCME = 1, the compare 1 match interrupt detection mask function is enabled. In this state, the compare 1 match interrupt is output upon the first match of the value of the timer counter and the ENCA_nCCR1 setting value, and interrupts are then masked for the second and subsequent compare matches.
- When ENCA_nMCS = 0, the compare 1 match interrupt detection mask function is disabled by a write operation to the ENCA_nCCR1 register.
- When ENCA_nMCS = 1, the compare 1 match interrupt detection mask function is disabled by a timer counter clear operation accompanying phase Z or by a timer counter clear operation upon match between the ENCA_nCCR0 register value and the timer counter value.
- When ENCA_nMCS = 1 and ENCA_nLDE = 1, the compare 1 match interrupt detection mask function is disabled by a loading operation of the ENCA_nCCR0 register to the timer counter upon underflow detection.
- Setting ENCA_nECM1 to 1 is prohibited when enabling the compare 1 match interrupt detection mask function.

Table 28.29 Compare Match Interrupt Detection Mask Function of ENCA_nCCR1

ENCA _n CCR1 function	Compare 1 match interrupt mask	Interrupt mask cancel trigger		Compare 1 match interrupt output upon compare match with ENCA _n CCR1
ENCA _n CRM1	ENCA _n CME	ENCA _n MCS	Underflow occurrence upon ENCA _n LDE = 1	
0 (Compare)	0 (Mask function disabled)	(Setting invalid)	—	Outputs compare 1 match interrupt upon each compare match.
	1 (Mask function enabled)		0 (Write operation to ENCA _n CCR1)	Occurred (Loading of ENCA _n CCR0 to timer counter)
1 (Timer counter clear operation)				

28.4.5.2 Capture Function

When ENCA_nCRM1 = 1, the ENCA_nCCR1 register functions as a dedicated capture register.

NOTE

For details about capture operation to ENCA_nCCR1, see the timing chart in **Section 28.6.13, Capture Operation between Count Clocks (ENCA_nCCR1)**.

The operations for each of the ENCA_nCTS settings are shown in the table below.

Table 28.30 Operations for each of the ENCA_nCTS settings

ENCA _n CCR1 function	Capture trigger selection	Capture trigger signal	Timer counter clearing	Interrupt occurrence
ENCA _n CRM1	ENCA _n CTS			
1 (Capture)	0	Capture trigger 1 input (ENCA _n TTIN1)	Does not clear timer counter.	(1) Capture 1 interrupt (INTENCA _n I1)
	1	Encoder clear input (specified by ENCA _n SCE)	Clears timer counter.	(1) Capture 1 interrupt (INTENCA _n I1) (2) Encoder clear interrupt (INTENCA _n IEC)

NOTE

For details about the timing chart when ENCA_nCTS = 0 or ENCA_nCTS = 1, see the following: **Section 28.6.3, Count Clear and Capture Operation by Encoder Clear Input (ENCA_nEC pin)**, **Section 28.6.4, Conflict between Overflow Occurrence and Clear Operation by Encoder Clear Input (ENCA_nEC Pin)**, **Section 28.6.5, Conflict between Underflow Occurrence and Clear Operation by Encoder Clear Input (ENCA_nEC Pin)**, **Section 28.6.11, Conflict between ENCA_nLDE Function (Loading Counter Value) and Clear Operation by Encoder Clear Input** and **Section 28.6.12, Up-count after Conflict between ENCA_nLDE Function (Loading Counter Value) and Clear Operation by Encoder Clear Input**.

28.4.5.3 Timer Counter Clearing upon Compare Register Match

Timer counter clearing upon compare match between the value of the timer counter and the ENCA_nCCR0/ENCA_nCCR1 setting value, according to the settings of the ENCA_nECM1 and ENCA_nECM0 bits in the ENCA_nCTL register, is detailed in the following table.

Table 28.31 Timer Counter Clearing Operation upon Compare Register Match

ENCA _n ECM1 and ENCA _n ECM0	Next count operation	Timer counter clearing upon compare match with ENCA _n CCR1	Timer counter clearing upon compare match with ENCA _n CCR0
00	Up-count	Does not clear (continues count operation).	Does not clear (continues count operation).
	Down-count	Does not clear (continues count operation).	Does not clear (continues count operation).
01	Up-count	Does not clear (continues count operation).	Clears timer counter to 0000 _H .
	Down-count	Does not clear (continues count operation).	Does not clear (continues count operation).
10	Up-count	Does not clear (continues count operation).	Does not clear (continues count operation).
	Down-count	Clears timer counter to 0000 _H .	Does not clear (continues count operation).
11	Up-count	Does not clear (continues count operation).	Clears timer counter to 0000 _H .
	Down-count	Clears timer counter to 0000 _H .	Does not clear (continues count operation).

28.4.6 Startup/Stop of Timer Counter

28.4.6.1 Startup of Timer

The timer operation can be started by setting the ENCA_nTS bit to 1. Simultaneous start with other timer can be possible by setting the PIC. For details, see **Section 29.2.3.1, Simultaneous Start Trigger Function**

28.4.6.2 Stop of Timer

When the ENCA_nTT bit is set to 1, the ENCA_nTE bit becomes 0 and the timer stops.

28.5 ENCA Setting Sequences

28.5.1 Encoder timer setting procedure

The encoder timer setting procedure is described below.

Table 28.32 Encoder Timer Setting Procedure

	Action	Setting status
Initial Setting	Reset deassertion	Power-on status, operation stopped status (Writing to each register is enabled)
ENCAn initial Settings	Perform the following initial settings. <ul style="list-style-type: none"> Setting for counter Setting for counter clear Setting for ENCAAnCCR0 register Setting for ENCAAnCCR1 register 	This is the count operation stopped status. The value of the ENCAAnTE bit indicating the operating status is 0.
	Perform the counter initial value settings. <ul style="list-style-type: none"> Set any 16-bit value to ENCAAnCNT register. (When, after setting this register, the ENCAAnTS bit is set to 1, the counter operation starts from the set count value.) 	The set value is set as the initial value of the counter register value.
Operation Start	Perform the counter operation start setting. <ul style="list-style-type: none"> Set the ENCAAnTS bit to 1. 	This is the counter operation start status. The value of the ENCAAnTE bit indicating the operating status is 1, and the count clock is supplied to the internal circuit.
Operating	Only those registers whose setting can be changed during operation can be rewritten. <ul style="list-style-type: none"> ENCAAnCCR0 register setting ENCAAnCCR1 register setting ENCAAnIOC0 register setting 	The count operation set with the initial setting is performed, and up/down counting is performed according to the ENCAAnE0 and ENCAAnE1 pins.
Operation Stop	Perform the counter operation stop setting during operation. <ul style="list-style-type: none"> Set the ENCAAnTT bit to 1. 	This is the counter operation stopped status. The value of the ENCAAnTE bit indicating the operating status is 0.
ENCA stop	Reset	The setting registers are initialized.

28.5.1.1 Initial Setting Procedure for Counter

28.5.1.4 Setting Procedure for ENCA_nCCR1 Register

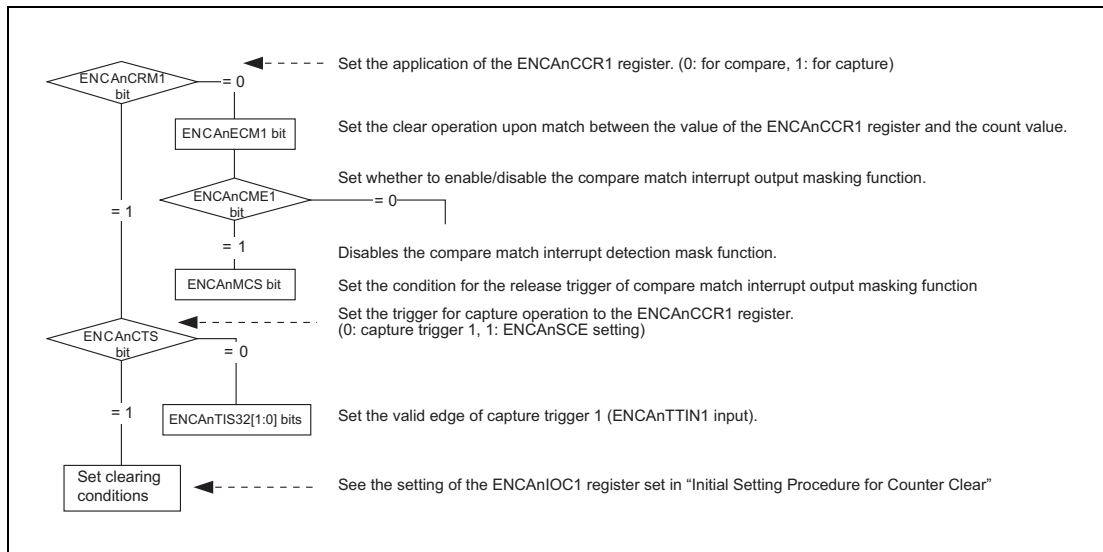

Figure 28.10 Setting Procedure for ENCA_nCCR1 register

28.6 Timing Chart

28.6.1 Overflow Occurrence and Overflow Flag Clear Operation

When an up-counting is performed while the counter value is FFFF_H, an overflow occurs. If an overflow occurs, an overflow interrupt (INTENCAnIOV) is output and the overflow flag (ENCAnOVF) is set to 1. The overflow flag clear bit (ENCAnCLOV) is set to 1, the overflow flag (ENCAnOVF) is cleared to 0.

The overflow occurrence and overflow flag clear operation are described as follows.

Figure 28.11 Overflow Occurrence and Overflow Flag Clear Setting

- (1) The count value is up-counted from FFFE_H to FFFF_H.
- (2) When the count value changes from FFFF_H to 0000_H, an overflow occurs. At the same time, an overflow interrupt is output, and the overflow flag is set to 1.
- (3) An overflow flag is cleared to 0 by setting 1 to the ENCAncCLOV bit in the ENCAncFGC register according to the clearing procedure. In addition, an overflow flag is also cleared by setting the ENCAncTS bit in the ENCAncTS register to 1 while ENCAncTE.ENCAncTE is 0, or by setting an input signal of the ENCAncTSST (simultaneous start trigger input) to high.

28.6.2 Underflow Occurrence and Underflow Flag Clear Operation

When down-counting is performed while the counter value is 0000_H , an underflow occurs. If an underflow occurs, an underflow interrupt (INTENCAnUD) is output and the underflow flag (ENCAnUDF) is set to 1. The underflow flag clear bit (ENCAnCLUD) is set to 1, the underflow flag (ENCAnUDF) is cleared to 0.

The underflow occurrence and underflow flag clear operation are described as follows.

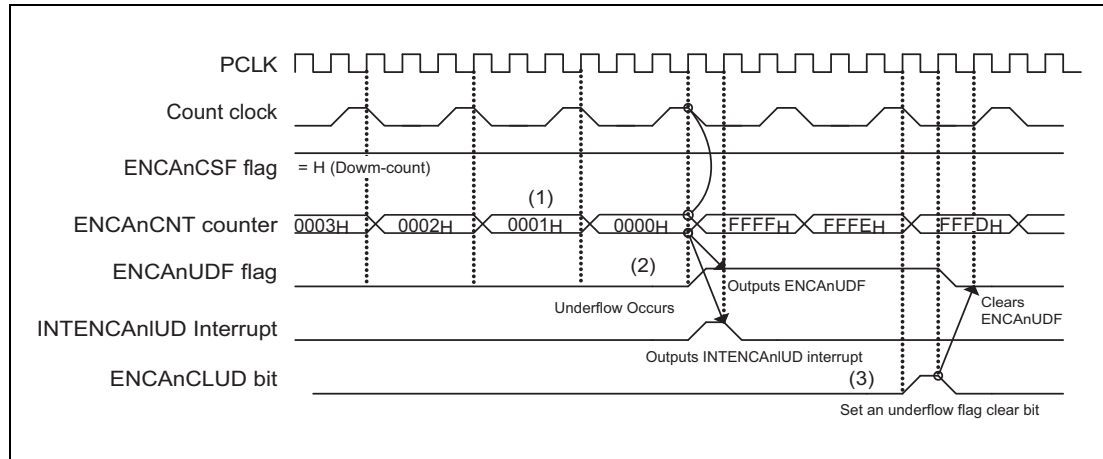

Figure 28.12 Underflow Occurrence and Underflow Flag Clear Setting

- (1) The count value is down-counted from 0001_H to 0000_H .
- (2) When the count value changes from 0000_H to $FFFF_H$, an underflow occurs. At the same time, an underflow interrupt is output, and the underflow flag is set to 1.
- (3) An underflow flag is cleared to 0 by setting 1 to the ENCAncCLUD bit in the ENCAncFGC register according to the clearing procedure. In addition, an underflow flag is also cleared by setting the ENCAncTS bit in the ENCAncTS to 1 while ENCAncTE.ENCAncTE is 0, or by setting an input signal of the ENCAncTSST (simultaneous start trigger input) to high.

28.6.3 Count Clear and Capture Operation by Encoder Clear Input (ENCAnEC pin)

Figure 28.13 Timing Diagram of Count Clear and Capture Operation by Encoder Clear Input (ENCAnEC pin)

[Setting Conditions]

- ENCAAnCTL.ENCAAnCRM1 = 1
(ENCAAnCCR1 register is selected as capture)
- ENCAAnCTL.ENCAAnCTS = 1
(ENCAAnEC pin input is selected as a capture trigger input)
- ENCAAnIOC1.ENCAAnECS[1:0] bits = 01_B
(Selected as a rising edge detection of the ENCAAnEC pin input)

- (1) Capture operation is performed by the rising edge of the ENCAAnEC pin trigger.
- (2) Clear operation is performed by an input to the ENCAAnEC pin and the count value is reset to 0000_H.
- (3) The counter value (0002_H) is captured to the ENCAAnCCR1 at the rising edge of the ENCAAnEC pin.
- (4) At the same time, by the ENCAAnEC pin input, a clear interrupt (INTENCAAnIEC) and capture interrupt (INTENCAAn1) are output.

28.6.4 Conflict between Overflow Occurrence and Clear Operation by Encoder Clear Input (ENCA_nEC Pin)

Figure 28.14 Conflict between Overflow Occurrence and Clear Operation by Encoder Clear Input (ENCA_nEC pin)

- (1) An up-count from FFFD_H is continuously performed.
- (2) When an overflow occurs if the count value is FFFF_H, and the rising edge of ENCA_nEC is detected simultaneously, clear operation by the encoder clear input is performed. The counter value is cleared to 0000_H.
- (3) When the counter value is cleared by the encoder clear input, a clear interrupt (INTENCA_nIEC) by encoder clear input is output simultaneously. Because a clear operation by the phase Z input is performed simultaneously with the overflow occurrence, an overflow interrupt is not output (An overflow does not occur. Clear operation is performed by the phase Z input).
- (4) Because an overflow does not occur as is the case with step 3, the overflow flag is not set.

28.6.5 Conflict between Underflow Occurrence and Clear Operation by Encoder Clear Input (ENCAnEC Pin)

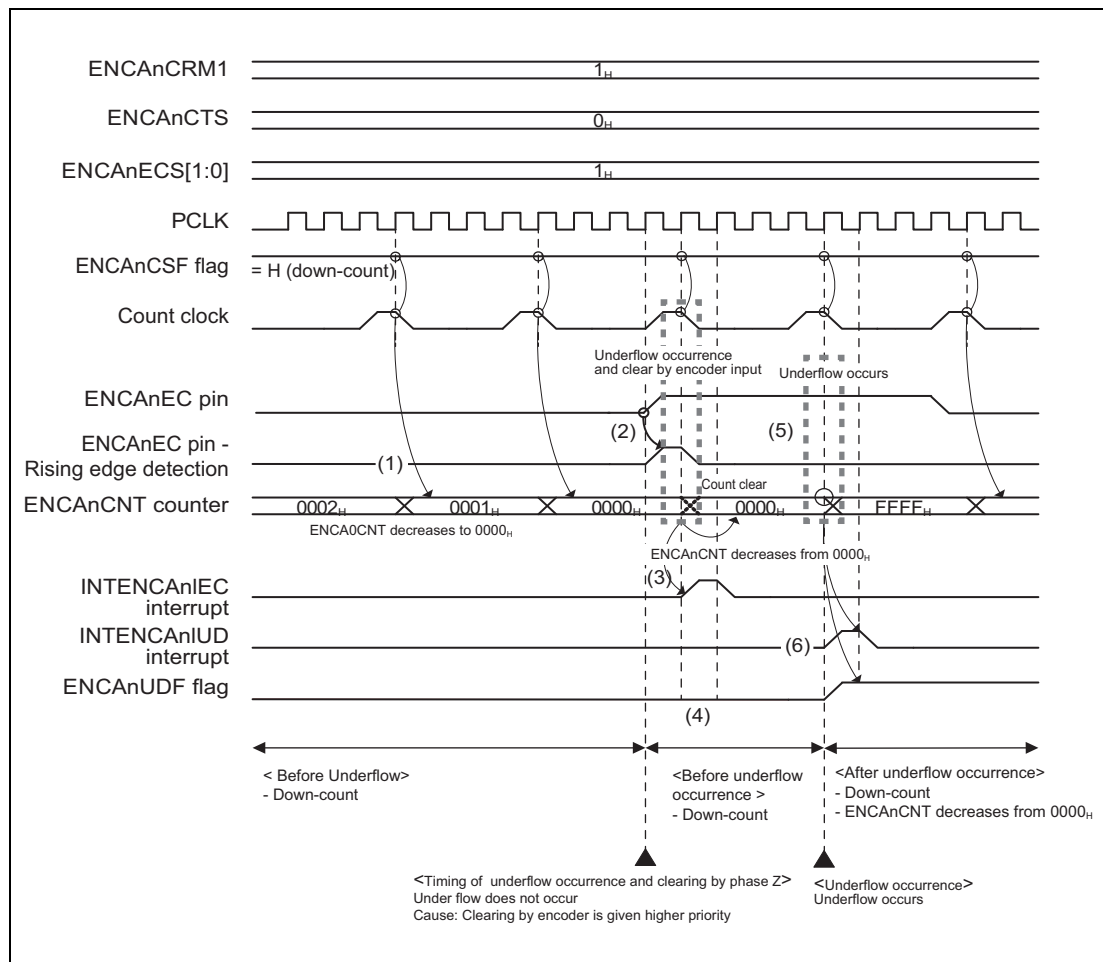

Figure 28.15 Conflict between Underflow Occurrence and Clear Operation by Encoder Clear Input (ENCAnEC Pin)

- (1) A down-count from 0002_H is continuously performed.
- (2) When an underflow occurs if the count value is 0000_H, and the rising edge of ENCAAnEC is detected simultaneously, clear operation by the encoder clear input is performed. Even if the next clock signal is input during clear operation, the counter value remains at 0000_H.
- (3) When the counter value is cleared by the encoder clear input, an encoder clear interrupt (INTENCAAnIEC) is output simultaneously. Because a clear operation by the encoder clear input is performed simultaneously with the underflow occurrence, an underflow interrupt is not output (An underflow does not occur. Clear operation is performed by the encoder clear input).
- (4) Because an underflow does not occur as is the case with step 3, the underflow flag is not set.
- (5) When a further down-count is performed after the counter value changes to 0000_H by clear operation by the encoder clear input, the counter value changes from 0000_H to FFFF_H, and an underflow occurs.
- (6) When an underflow occurs, an underflow interrupt (INTENCAAnIUD) is output, and the underflow flag (ENCAAnUDF) is set.

28.6.6 Overflow Operation Immediately after Startup

Figure 28.16 Overflow Operation Immediately after Startup

- (1) When the $\overline{\text{RESET}}$ value changes from 0 to 1, the status changes from “reset” to “reset release”.
- (2) The timer counter is set to FFFF_H as the initial value.
- (3) ENCA nTS is set to 1, and operation starts. ENCA nTE changes to 1, which indicates that operation is enabled.
- (4) When an up-count is performed from FFFF_H which is the initially set count value, the counter value changes from FFFF_H to 0000_H , and an overflow occurs immediately after operation starts.
- (5) At the same time, by an overflow occurrence immediately after operation starts, an overflow interrupt (INTENCA nIOV) is output, and the overflow flag (ENCA nOVF) is set.

28.6.7 Underflow Operation Immediately after Startup

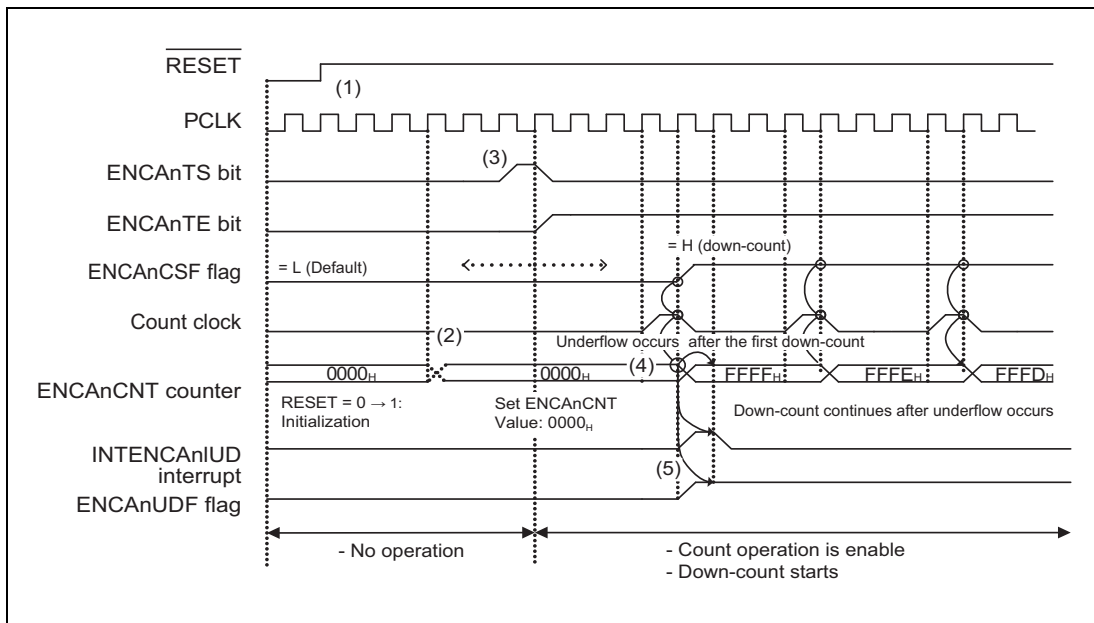

Figure 28.17 Underflow Operation Immediately after Startup

- (1) When the $\overline{\text{RESET}}$ value changes from 0 to 1, the status changes from “reset” to “reset release”.
- (2) The timer counter is set to 0000_H as the initial value.
- (3) ENCAAnTS is set to 1, and operation starts. ENCAAnTE changes to 1, which indicates that operation is enabled.
- (4) When a down-count is performed from 0000_H which is the initially set count value, the counter value changes from 0000_H to FFFF_H, and an underflow occurs immediately after operation starts.
- (5) At the same time, by an underflow occurrence immediately after operation starts, an underflow interrupt (INTENCAAnUD) is output, and the underflow flag (ENCAAnUDF) is set.

28.6.8 Using the ENCA_nLDE Function Immediately after Startup

Figure 28.18 Using the ENCA_nLDE Function Immediately after Startup

- (1) When the $\overline{\text{RESET}}$ value changes from 0 to 1, the status changes from “reset” to “reset release”.
- (2) The load enable bit (ENCA_nLDE) is set to 1, capture/compare register 0 (ENCA_nCCR0) is set to 3C5A_H, and the timer counter is set to the initial value 0000_H.
- (3) ENCA_nTS is set to 1, and operation starts. ENCA_nTE changes to 1, which indicates that operation is enabled.
- (4) When a down-count is performed from 0000_H which is the initially set count value, an underflow occurs immediately after operation starts. Because ENCA_nLDE is set to 1, the ENCA_nCCR0 value, 3C5A_H, is loaded to the timer counter (INTENCA_nI0 is not output during loading).
- (5) At the same time, by an underflow occurrence immediately after operation starts, an underflow interrupt (INTENCA_nUD) is output, and the underflow flag (ENCA_nUDF) is set (after an underflow occurs, down-count operation from the loaded value (3C5A_H) continues).
- (6) After the ENCA_nCCR0 value is loaded to ENCA_nCNT, a match with ENCA_nCCR0 is detected, and INTENCA_nI0 is output.

28.6.9 ENCA_nLDE Function (Loading Count Value)

(1) <When ENCA_nLDE = 0>

Figure 28.19 ENCA_nLDE Function (when ENCA_nLDE = 0)

- (1) ENCA_nLDE is set to 0 (even if an underflow occurs, the ENCA_nCCR0 value is not loaded).
- (2) A down-count is performed: 0002_H → 0001_H → 0000_H
- (3) When a further down-count is performed after the counter value changes to 0000_H, an underflow occurs.
- (4) Because ENCA_nLDE is set to 0, the setting value of the ENCA_nCCR0 register is not loaded to the counter even if an underflow occurs.
- (5) Operation changes to underflow operation (counter value: 0000_H → FFFF_H).
- (6) An underflow interrupt (INTENCA_nIUD) is output, and the underflow flag (ENCA_nUDF) is set.

(2) <When ENCA_nLDE = 1>Figure 28.20 ENCA_nLDE Function (when ENCA_nLDE = 1)

- (1) ENCA_nLDE is set to 1 (if an underflow occurs, the ENCA_nCCR0 value is loaded to the counter).
- (2) A down-count is performed: 0002_H → 0001_H → 0000_H
- (3) When a further down-count is performed after the counter value changes to 0000_H, an underflow occurs.
- (4) An underflow interrupt is output, and the underflow flag is set.
- (5) Because ENCA_nLDE is set to 1, the setting value of the ENCA_nCCR0 register is loaded to the counter if an underflow occurs. ENCA_nCNT is set to 3C5A_H.
- (6) After the ENCA_nCCR0 value is set to ENCA_nCNT, if the ENCA_nCNT value matches with the ENCA_nCCR0 value on a count clock, a compare match interrupt (INTENCA_nI0) is output.

28.6.10 Conflict between ENCA_nLDE Function (Loading Counter Value) and Rewrite of ENCA_nCCR0 Register

Figure 28.21 Conflict between ENCA_nLDE Function and Rewrite of ENCA_nCCR0 Register

- (1) The ENCA_nCCR0 register is currently set to 5555_H.
- (2) ENCA_nLDE is currently set to 1.
- (3) A down-count is performed (0002_H → 0001_H → 0000_H), and an underflow occurs.
- (4) An underflow interrupt is output, and the underflow flag is set.
- (5) When an underflow occurs, the ENCA_nCCR0 register value is changed from 5555_H to AAAA_H.
- (6) When an underflow occurs, the ENCA_nCCR0 value before the rewrite was performed (5555_H) is set in ENCA_nCNT.

28.6.11 Conflict between ENCA_nLDE Function (Loading Counter Value) and Clear Operation by Encoder Clear Input

Figure 28.22 Conflict between ENCA_nLDE Function and Clear Operation by Encoder Clear Input

- (1) The values are set as follows: ENCA_nCTS = 0, ENCA_nECS1 and ENCA_nECS0 = 01_B, ENCA_nLDE = 1, and ENCA_nCCR0 = 5555_H.
- (2) A down-count is performed: 0002_H → 0001_H → 0000_H
- (3) When the count value becomes 0000_H, the rising edge of ENCA_nEC is detected, and clear operation by the encoder clear input is performed.
- (4) Because a count clear is performed when the count value reaches 0000_H, a counter clear interrupt (INTENCA_nIEC) by the encoder clear input is output. An underflow does not occur because a down-count is not performed when the count value is 0000_H. Therefore, an underflow interrupt (INTENCA_nIUD) is not output, and the underflow flag (ENCA_nUDF) is not set.
- (5) After the count value is cleared to 0000_H by clear operation by the encoder clear input, a down-count is performed and an underflow occurs.
- (6) An underflow interrupt (INTENCA_nIUD) is output, and the underflow flag (ENCA_nUDF) is set.
- (7) Because ENCA_nLDE = 1, if an underflow occurs, the ENCA_nCCR0 value is loaded to ENCA_nCNT.
- (8) After the ENCA_nCCR0 value is set to ENCA_nCNT, a compare match is detected according to the count clock. If the ENCA_nCNT value matches with the ENCA_nCCR0 value, a compare match interrupt (INTENCA_nI0) is output.

28.6.12 Up-count after Conflict between ENCA_nLDE Function (Loading Counter Value) and Clear Operation by Encoder Clear Input

Figure 28.23 Up-count after Conflict between ENCA_nLDE Function and Encoder Clear Input

- (1) The values are set as follows: ENCA_nCTS = 0, ENCA_nECS1 and ENCA_nECS0 = 01_B, ENCA_nLDE = 1, and ENCA_nCCR0 = 5555_H.
- (2) A down-count is performed: 0002_H → 0001_H → 0000_H
- (3) When the count value becomes 0000_H, the rising edge of ENCA_nEC is detected, and clear operation by the encoder clear input is performed.
- (4) Because a count clear is performed when the count value reaches 0000_H, a counter clear interrupt (INTENCA_nIEC) by the encoder clear input is output. An underflow does not occur because a down-count is not performed when the count value is 0000_H. Therefore, an underflow interrupt (INTENCA_nIUD) is not output, and the underflow flag (ENCA_nUDF) is not set.
- (5) After the count value is cleared to 0000_H by clear operation by the encoder clear input, an up-count is performed.
- (6) An underflow interrupt (INTENCA_nIUD) is not output, and the underflow flag (ENCA_nUDF) is not set.

28.6.13 Capture Operation between Count Clocks (ENCAnCCR1)

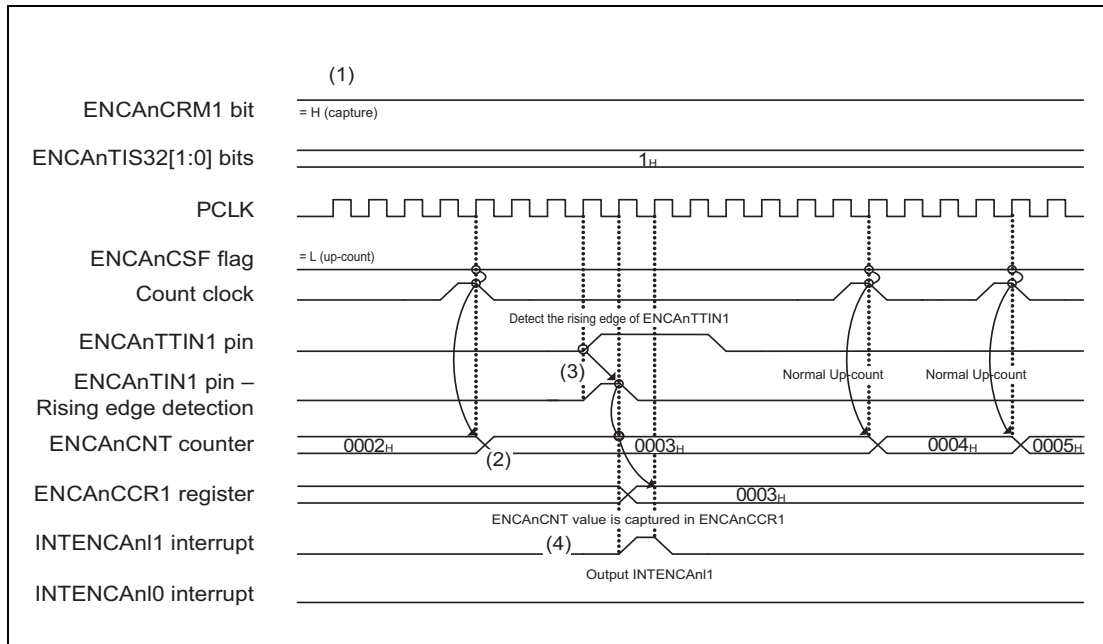

Figure 28.24 Capture Operation between Count Clocks (ENCAnCCR1)

- (1) The values are set as follows: ENCAAnCRM1 = 1 and ENCAAnTIS32[1:0] = 01_B.
- (2) An up-count is performed.
- (3) The rising edge of the ENCAAnTTIN1 input is detected, and the count value is captured in ENCAAnCCR1.
- (4) An interrupt request signal (INTENCAAn1) corresponding to the capture to the ENCAAnCCR1 register is output.

28.6.14 Capture Operation between Count Clocks (ENCA_nCCR0)

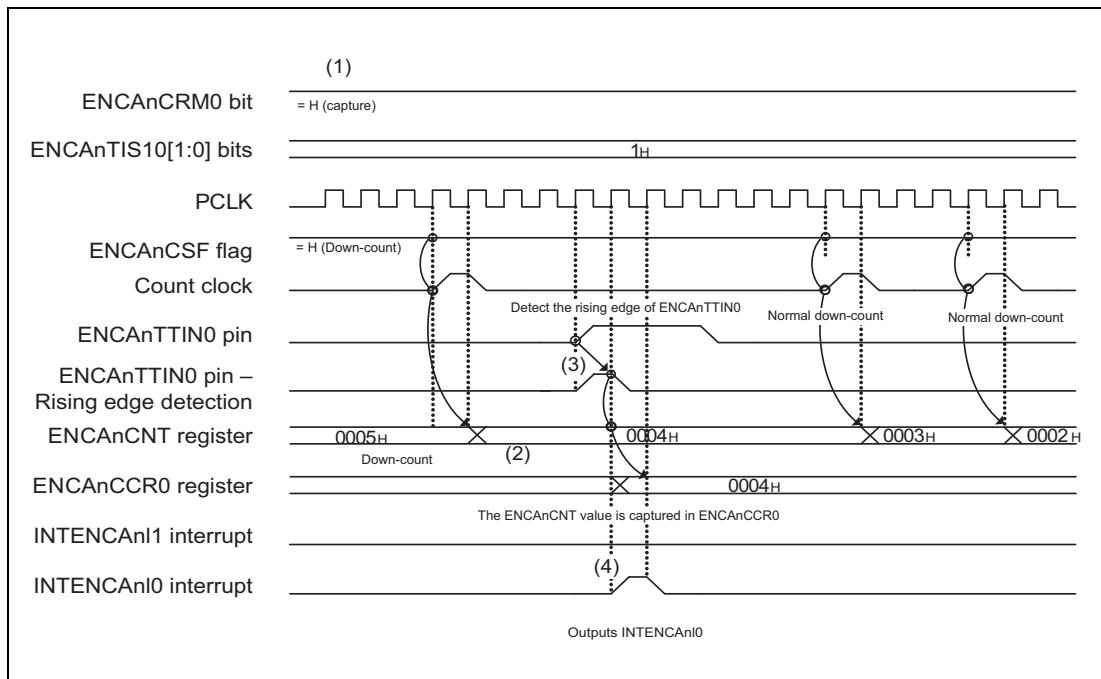

Figure 28.25 Capture Operation between Count Clocks (ENCA_nCCR0)

- (1) The values are set as follows: ENCA_nCRM0 = 1, and ENCA_nTIS10[1:0] = 01_B.
- (2) A down-count is performed.
- (3) The rising edge of the ENCA_nTTIN0 input is detected, and the count value is captured in ENCA_nCCR0.
- (4) An interrupt request signal (INTENCA_n0) corresponding to the capture to the ENCA_nCCR0 register is output.

28.6.15 Encoder operation when compare match clear control is enabled and ENCA_nCTS = 0

Figure 28.26 Encoder Operation when ENCA_nECM[1:0] = 01_B and ENCA_nCTS = 0

- (1) The values are set as follows: ENCA_nCCR0 = 4444_H, ENCA_nCRM0 = 0, ENCA_nCRM1 = 1, ENCA_nECM[1:0] = 01_B, and ENCA_nCTS = 0.
- (2) A down-count is performed.
- (3) The rising edge of the ENCA_nTTIN1 input is detected, and the ENCA_nCNT value (4444_H) is captured in the ENCA_nCCR1 register.
- (4) An interrupt signal (INTENCA_n1) corresponding to the capture to the ENCA_nCCR1 register is output.
- (5) When a compare match occurs between ENCA_nCNT (counted down from 4445_H to 4444_H) and ENCA_nCCR0 (4444_H), a compare match interrupt (INTENCA_n0) with ENCA_nCCR0 is output.
- (6) The count operation changes to up-count.
- (7) When ENCA_nCNT is counted up from 4443_H to 4444_H, a compare match with ENCA_nCCR0 occurs again. Because the count operation is up-count when the compare match occurs, the count value is cleared according to the setting of ENCA_nECM1 and ENCA_nECM0 (01_B), and the ENCA_nCNT value changes to 0000_H.
- (8) When ENCA_nCNT changes to 4444_H, a compare match interrupt (INTENCA_n0) with ENCA_nCCR0 is output.

28.6.16 Encoder operation when compare match clear control is enabled and ENCA_nCTS = 1

Figure 28.27 Encoder Operation when ENCA_nECM[1:0] = 01_B and ENCA_nCTS = 1

- (1) The values are set as follows: ENCA_nCCR0 = 4444_H, ENCA_nCRM0 = 0, ENCA_nCRM1 = 1, ENCA_nECM[1:0] = 01_B, and ENCA_nCTS = 1.
- (2) A down-count is performed.
- (3) When a compare match occurs between ENCA_nCNT (counted down from 4445_H to 4444_H) and ENCA_nCCR0 (4444_H), an interrupt request signal (INTENCA_nI0) is output.
- (4) The count operation changes to up-count.
- (5) When ENCA_nCNT is counted up from 4443_H to 4444_H, a compare match with ENCA_nCCR0 occurs again. Because the count operation is up-count when the compare match occurs, the count value is cleared according to the setting of ENCA_nECM1 and ENCA_nECM0 (01_B), and the ENCA_nCNT value changes to 0000_H.
- (6) When ENCA_nCNT changes to 4444_H, a compare match interrupt (INTENCA_nI0) with ENCA_nCCR0 is output.
- (7) After the count value is cleared, an up-count is performed, and the count value changes to 0001_H. At this point, the ENCA_nCNT value (0001_H) is captured in ENCA_nCCR1 by detecting the rising edge of the ENCA_nEC signal, and the counter is cleared to 0000_H.
- (8) An interrupt (INTENCA_nI1) corresponding to the capture to the ENCA_nCCR1 register and a clear interrupt (INTENCA_nIEC) by ENCA_nEC are output.

28.6.17 Encoder operation when compare match clear control is disabled

Figure 28.28 Encoder Operation when ENCA nECM[1:0] = 00_B

- (1) The values are set as follows: ENCA nCCR1 = 4446_H, ENCA nCRM0 = 1, ENCA nCRM1 = 0, ENCA nECM[1:0] = 00_B, and ENCA nCTS = 0.
- (2) A down-count is performed.
- (3) When the rising edge of ENCA nTTIN0 is detected, the ENCA nCNT value (4444_H) is captured in ENCA nCCR0.
- (4) An interrupt signal (INTENCA nI0) corresponding to the capture to the ENCA nCCR0 register is output.
- (5) The count operation changes to up-count.
- (6) When ENCA nCNT changes to 4446_H, a compare match with ENCA nCCR1 is detected.
- (7) A compare match interrupt (INTENCA nI1) with ENCA nCCR1 is output.

28.6.18 Capture Operation Performed upon Clearing by ENCA_nEC, ENCA_nE0, and ENCA_nE1 when ENCA_nSCE = 1

28.6.18.1 Accompanying Capture Operation

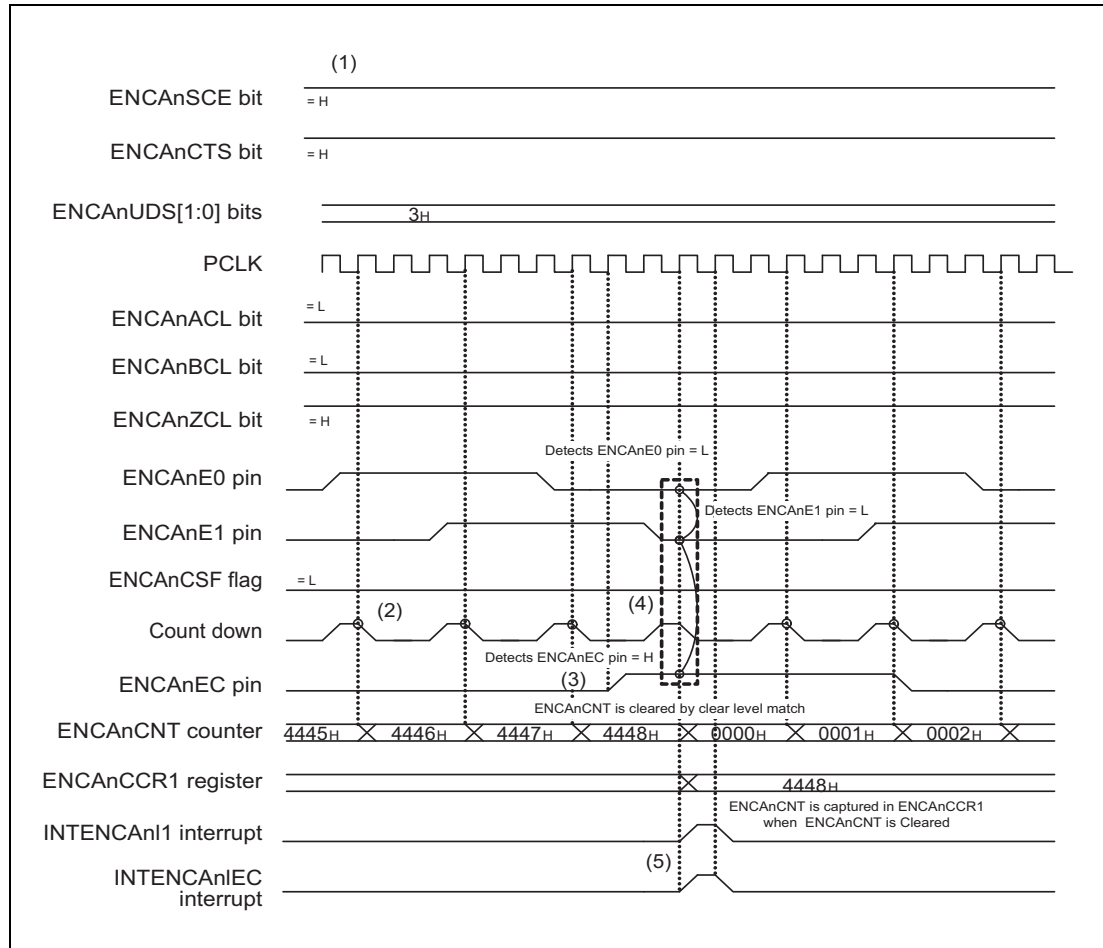

Figure 28.29 Capture Operation Performed upon Clearing by ENCA_nEC, ENCA_nE0, and ENCA_nE1 when ENCA_nSCE = 1

- (1) The values are set as follows: ENCA_nSCE = 1, ENCA_nCTS = 1, ENCA_nUDS[1:0] = 11_B, ENCA_nACL = 0, ENCA_nBCL = 0, and ENCA_nZCL = 1.
- (2) An up-count is performed.
- (3) The count value is not cleared upon the rising edge of ENCA_nEC.
- (4) When ENCA_nE0, ENCA_nE1, and ENCA_nEC reach the set clear level, the count value is cleared. The count value is captured in ENCA_nCCR1 at the time of the clearing.
- (5) At the time of the clearing, an interrupt (INTENCA_n1) corresponding to the capture to the ENCA_nCCR1 register and a clear interrupt (INTENCA_nIEC) by ENCA_nEC are output.

28.6.18.2 When the Timing of the ENCA_nEC Input is Later than that of the ENCA_nE1 Input during Up-count

(When ENCA_nACL = 1, ENCA_nBCL = 0, ENCA_nZCL = 1, and ENCA_nUDS[1:0] = 11_B)

Figure 28.30 Clearing Timing for when the Timing of the ENCA_nEC Input is Later than that of the ENCA_nE1 Input during Up-count

28.6.18.3 When the Timing of the ENCA_nEC Input is the Same as that of the ENCA_nE1 Input during Up-count

(When ENCA_nACL = 1, ENCA_nBCL = 0, ENCA_nZCL = 1, and ENCA_nUDS[1:0] = 11_B)

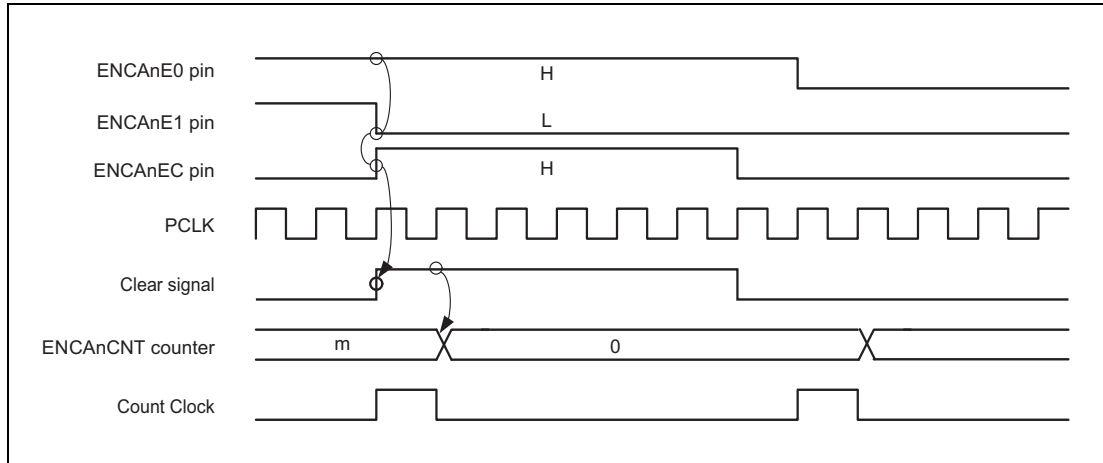

Figure 28.31 Clearing Timing for when the Timing of the ENCA_nEC Input is the Same as that of the ENCA_nE1 Input During Up-count

28.6.18.4 When the Timing of the ENCA_nEC Input is Earlier than that of the ENCA_nE1 Input during Up-count

(When ENCA_nACL = 1, ENCA_nBCL = 0, ENCA_nZCL = 1, and ENCA_nUDS[1:0] = 11_B)

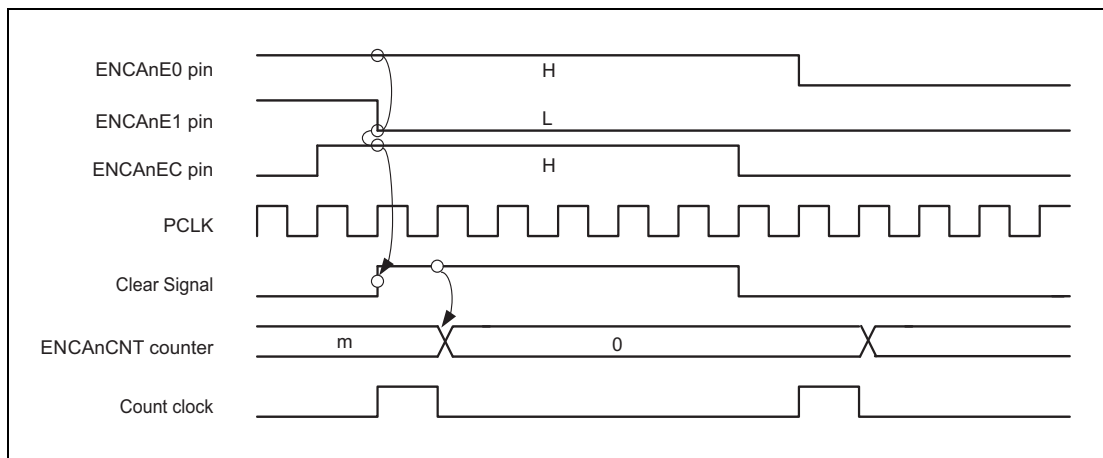

Figure 28.32 Clearing Timing for when the Timing of the ENCA_nEC Input is Earlier than that of the ENCA_nE1 Input during Up-count

28.6.18.5 When the Timing of the ENCA_nEC Input is Later than that of the ENCA_nE1 Input during Down-count

(When ENCA_nACL = 1, ENCA_nBCL = 0, ENCA_nZCL = 1, ENCA_nUDS[1:0] = 11_B)

Figure 28.33 Clearing Timing for when the Timing of the ENCA_nEC Input is Later than that of the ENCA_nE1 Input during Down-count

28.6.19 Capture Operation Performed upon Clearing by ENCA_nEC when ENCA_nSCE = 0

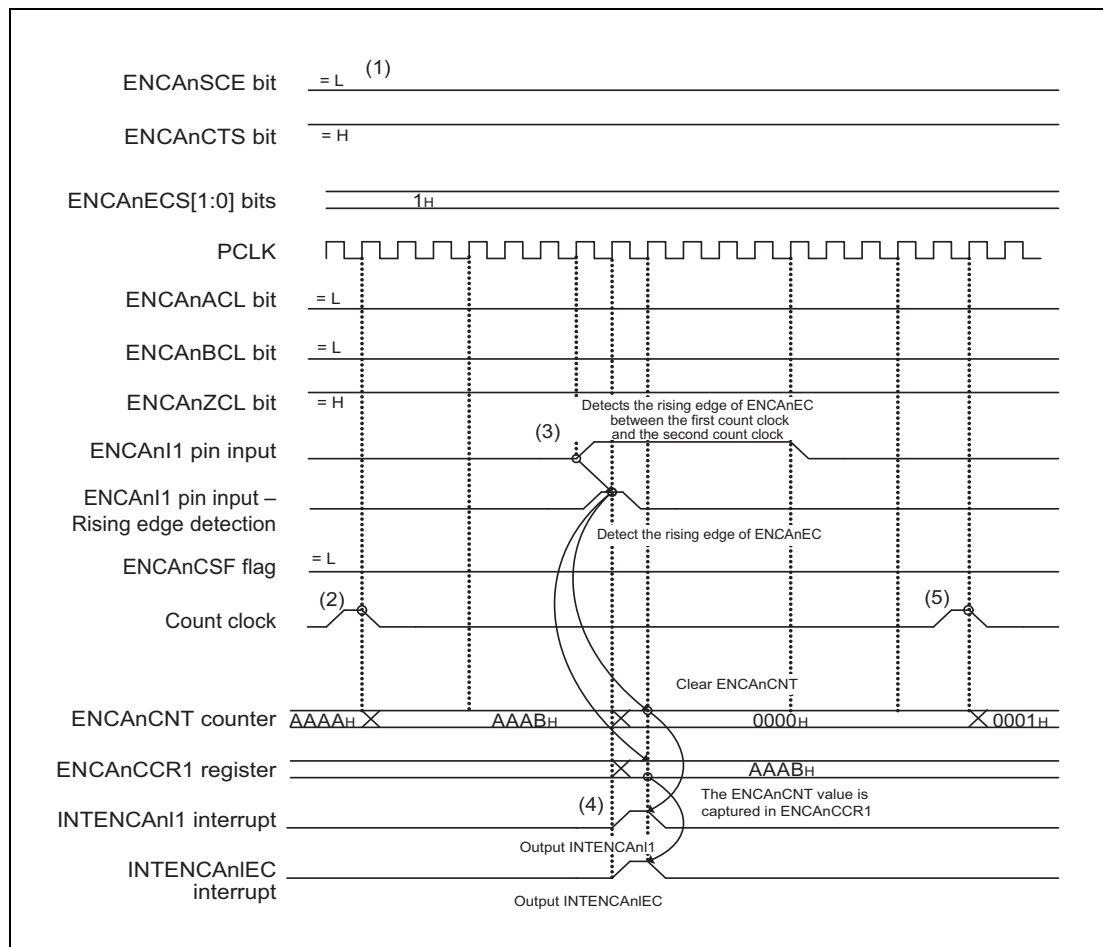

Figure 28.34 Capture Operation Performed upon Clearing by ENCA_nEC when ENCA_nSCE = 0

- (1) The values are set as follows: ENCA_nSCE = 0, ENCA_nCTS = 1, and ENCA_nECS[1:0] = 01_B.
- (2) An up-count is performed.
- (3) The rising edge of the ENCA_nEC input is detected, and the ENCA_nCNT value (AAAB_H) is captured in the ENCA_nCCR1 register. Concurrently, clear operation by ENCA_nEC is performed, and ENCA_nCNT is reset to 0000_H.
- (4) An interrupt (INTENCA_n1) corresponding to the capture to the ENCA_nCCR1 register and an encoder clear interrupt (INTENCA_nIEC) by ENCA_nEC are output.
- (5) After the count value is cleared, an up-count is performed, and the count value changes to 0001_H.

Section 29 Peripheral Interconnection (PIC)

29.1 Features of RH850/P1M-E PIC

Peripheral interconnect (PIC) connects some peripherals with each other in order to achieve enhanced stand-alone functionality. This product includes two PIC units: PIC1A and PIC1B.

29.1.1 Number of Units

This microcontroller has the following number of PIC units.

Table 29.1 Number of Units (PIC1A)

Products	RH850/P1M-E
Number of Units	1
Name	PIC1A

Table 29.2 Number of Units (PIC2B)

Products	RH850/P1M-E
Number of Units	1
Name	PIC2B

Table 29.3 Index

Index	Meaning
n	The individual unit of each timer and A/D converter is identified by the index "n".
m	The individual channel of each timer and A/D converter is identified by the index "m".
x	The scan group number of A/D converter is indicated by the index "x".
i	The variable used for description is indicated by the index "i".

29.1.2 Register Base Address

PIC base addresses are listed in the following table.

PIC register addresses are given as offsets from the base addresses.

Table 29.4 Register Base Address

Base Address Name	Base Address
<PIC1A_base>	FFDD 0000 _H
<PIC2B_base>	FFDD 1000 _H

29.1.3 Clock Supply

Clock supplies by and to PIC are listed in the following table.

Table 29.5 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
PIC1A	PCLK	High-speed peripheral clock (CLK_HSB)
PIC2B	PCLK	High-speed peripheral clock (CLK_HSB)

29.1.4 Reset Sources

Please refer to **Section 8, Reset Controller**.

29.1.5 Input/Output Signals

Table 29.6 PIC Input/Output Signals (1/2)

Signal Name	I/O	Function	Connected to
ENCA0TSST	O	ENCA0 simultaneous start trigger signal	ENCA0
ENCAT0AIN	O	ENCA0 encoder input signal (A phase)	
ENCAT0BIN	O	ENCA0 encoder input signal (B phase)	
ENCAT0ZIN	O	ENCA0 encoder input signal (Z phase)	
INTENCA0I1	O	ENCA0 capture trigger	
INTENCA0IEC	I	Clear interrupt signal by the ENCA0 encoder input (Z phase)	
ENCAT0EQ0	I	ENCA0 match detection signal 0	
ENCAT0EQ1	I	ENCA0 match detection signal 1	
ENCA1TSST	O	ENCA1 simultaneous start trigger signal	ENCA1
ENCAT1AIN	O	ENCA1 encoder input signal (A phase)	
ENCAT1BIN	O	ENCA1 encoder input signal (B phase)	
ENCAT1ZIN	O	ENCA1 encoder input signal (Z phase)	
INTENCA1I1	O	ENCA1 capture trigger	
INTENCA1IEC	I	Clear interrupt signal by the ENCA1 encoder input (Z phase)	
ENCAT1EQ0	I	ENCA1 match detection signal 0	
ENCAT1EQ1	I	ENCA1 match detection signal 1	
TOP0TAPATHASIN	O	Hi-Z asynchronous signal	TAPA0
TOP1TAPATHASIN	O	Hi-Z asynchronous signal	TAPA1
TOP2TAPATHASIN	O	Hi-Z asynchronous signal	TAPA2
TOP3TAPATHASIN	O	Hi-Z asynchronous signal	TAPA3
TAUD0TSSTm (m = 0 to 15)	O	TAUD0 simultaneous start trigger signal	TAUD0
TAUD0TOUTm (m = 0 to 15)	I	TAUD0 channel output signal	
TAUD0TINm (m = 0 to 15)	O	TAUD0 channel input signal	
INTTAUD0Im (m = 0 to 15)	I	TAUD0 interrupt signal	
TAUD1TSSTm (m = 0 to 15)	O	TAUD1 simultaneous start trigger signal	TAUD1
TAUD1TOUTm (m = 0 to 15)	I	TAUD1 channel output signal	
TAUD1TINm (m = 0 to 15)	O	TAUD1 channel input signal	
INTTAUD1Im (m = 0 to 15)	I	TAUD1 interrupt signal	

Table 29.6 PIC Input/Output Signals (2/2)

Signal Name	I/O	Function	Connected to
TAUJ0TSST _m (m = 0 to 3)	O	TAUJ0 simultaneous start trigger signal	TAUJ0
TAUJ0TIN _m (m = 0 to 3)	O	TAUJ0 channel input signal	
TAUJ1TSST _m (m = 0 to 3)	O	TAUJ1 simultaneous start trigger signal	TAUJ1
TPBA0TSST	O	TPBA0 simultaneous start trigger signal	TPBA0
TPBA1TSST	O	TPBA1 simultaneous start trigger signal	TPBA1
TSG30TSST	O	TSG30 simultaneous start trigger signal	TSG30
TSG30TSTOPC0	O	Timer output pattern control 0 signal	
TSG30TSTOPC1	O	Timer output pattern control 1 signal

29.1.6 External Input/Output Signals

External input/output signals of PIC are listed in the following table.

Table 29.7 PIC1A External Input/Output Signals (1/2)

Unit Signal Name	Description	Alternative Port Pin Signal Name
ENCA0I1	ENCA0 capture trigger input 1	ENCA0TIN1
ENCA1I1	ENCA1 capture trigger input 1	ENCA1TIN1
ENCA0E0	ENCA0 encoder input (count pulse 0)	ENCA0E0
ENCA1E0	ENCA1 encoder input (count pulse 0)	ENCA1E0
ENCA0E1	ENCA0 encoder input (count pulse 1)	ENCA0E1
ENCA1E1	ENCA1 encoder input (count pulse 1)	ENCA1E1
ENCA0EC	ENCA0 encoder input (clear pulse)	ENCA0EC
ENCA1EC	ENCA1 encoder input (clear pulse)	ENCA1EC
TAUD0TINm (m = 0 to 15)	TAUD0 channel input m (m = 0 to 15)	TAUD0Im (m = 0 to 15)
TAUD1TINm (m = 0 to 15)	TAUD1 channel input m (m = 0 to 15)	TAUD1Im (m = 0 to 15)
TAUD2TINm (m = 0 to 15)	TAUD2 channel input m (m = 0 to 15)	TAUD2Im (m = 0 to 15)
ESOn	Hi-Z control	TAPAnESO
TOP0U	Motor control output U phase	TAUD0O10
TOP0UB	Motor control output UB phase	TAUD0O11
TOP0V	Motor control output V phase	TAUD0O12
TOP0VB	Motor control output VB phase	TAUD0O13
TOP0W	Motor control output W phase	TAUD0O14
TOP0WB	Motor control output WB phase	TAUD0O15
TOP1U	Motor control output U phase	TAUD1O10
TOP1UB	Motor control output UB phase	TAUD1O11
TOP1V	Motor control output V phase	TAUD1O12
TOP1VB	Motor control output VB phase	TAUD1O13
TOP1W	Motor control output W phase	TAUD1O14
TOP1WB	Motor control output WB phase	TAUD1O15
TOP2U	Motor control output U phase	TSG3001
TOP2UB	Motor control output UB phase	TSG3002
TOP2V	Motor control output V phase	TSG3003
TOP2VB	Motor control output VB phase	TSG3004
TOP2W	Motor control output W phase	TSG3005
TOP2WB	Motor control output WB phase	TSG3006
TOP3U	Motor control output U phase	TSG3101
TOP3UB	Motor control output UB phase	TSG3102
TOP3V	Motor control output V phase	TSG3103
TOP3VB	Motor control output VB phase	TSG3104
TOP3W	Motor control output W phase	TSG3105
TOP3WB	Motor control output WB phase	TSG3106

Table 29.7 PIC1A External Input/Output Signals (2/2)

Unit Signal Name	Description	Alternative Port Pin Signal Name
TAUJ0TINm (m = 0 to 3)	TAUJ input	TAUJ0Im (m = 0 to 3)
TAUJ1TINm (m = 0 to 3)	TAUJ input	TAUJ1Im (m = 0 to 3)
TAUJ2TINm (m = 0 to 3)	TAUJ input	TAUJ2Im (m = 0 to 3)

Table 29.8 PIC2B External Input/Output Signals

Unit Signal Name	Description	Alternative Port Pin Signal Name
ADTRG0Z	ADCG0 trigger	ADCGTRG0
ADTRG1Z	ADCG1 trigger	ADCGTRG1

29.2 Peripheral Interconnection — 1 (PIC1A)

29.2.1 Overview

29.2.1.1 Functional Overview

The peripheral interconnection-1 (PIC1A) realizes various functions by synchronous operation using multiple timers and by connecting the timer internal I/O signals between the timers.

CAUTION

The signal names used in the following descriptions are abbreviations. The actual signal names corresponding to each abbreviation are as follows:

INTm → TAUDnTINTm

TINm → TAUDnTTINm

TOUTm → TAUDnTTOUTm

CDRm → TAUDnCDRm

CNTm → TAUDnCNTm

The PIC1A has the following functions.

- Simultaneous start trigger function
- PWM output function with dead time
- High accuracy triangle wave PWM output function with dead time
- Delay pulse output function with dead time
- Trigger pulse width measurement function
- Encoder capture trigger select function
- Two-phase encoder control function (control method 1)
- Two-phase encoder control function (control method 2)
- Three-phase pulse input control function
- Three-phase encoder control function
- TAUD input select function
- Hi-Z control function
- Timer output monitor function (PWM-Diag)
- Timer input monitor function
- TSG3 Synchronous Clear Function

29.2.2 Registers

29.2.2.1 List of Registers

The registers are listed in the following table.

The bits can be accessed only in 32-bit units. Access in 16-bits or 8-bits is operated as 32-bit access.

Table 29.9 Registers

Register Function	Symbol	Address
Simultaneous start trigger control register	PIC1ASST	<PIC1A_base> + 04 _H
Simultaneous start control register 0	PIC1ASSER0	<PIC1A_base> + 10 _H
Simultaneous start control register 1	PIC1ASSER1	<PIC1A_base> + 14 _H
Simultaneous start control register 2	PIC1ASSER2	<PIC1A_base> + 18 _H
Simultaneous start control register 3	PIC1ASSER3	<PIC1A_base> + 1C _H
RS flip-flop circuit initialization register 00	PIC1AINI00	<PIC1A_base> + 20 _H
DT initialization register 01	PIC1AINI01	<PIC1A_base> + 24 _H
RS flip-flop circuit initialization register 10	PIC1AINI10	<PIC1A_base> + 2C _H
DT initialization register 11	PIC1AINI11	<PIC1A_base> + 30 _H
Hall sensor input select register	PIC1ATSGHALLSEL	<PIC1A_base> + 74 _H
TAUD0 input select register	PIC1ATAUD0SEL	<PIC1A_base> + 78 _H
TAUD1 input select register	PIC1ATAUD1SEL	<PIC1A_base> + 7C _H
Hi-Z control register 0	PIC1AHIZCEN0	<PIC1A_base> + 80 _H
Hi-Z control register 1	PIC1AHIZCEN1	<PIC1A_base> + 84 _H
Hi-Z control register 2	PIC1AHIZCEN2	<PIC1A_base> + 88 _H
Hi-Z control register 3	PIC1AHIZCEN3	<PIC1A_base> + 8C _H
ENCATIN1 input select register 400	PIC1AENCSEL400	<PIC1A_base> + B8 _H
ENCATIN1 input select register 410	PIC1AENCSEL410	<PIC1A_base> + BC _H
Timer input/output control register 200	PIC1AREG200	<PIC1A_base> + C0 _H
Timer input/output control register 201	PIC1AREG201	<PIC1A_base> + C4 _H
Timer input/output control register 202	PIC1AREG202	<PIC1A_base> + C8 _H
Timer input/output control register 203	PIC1AREG203	<PIC1A_base> + CC _H
Timer input/output control register 210	PIC1AREG210	<PIC1A_base> + D4 _H
Timer input/output control register 211	PIC1AREG211	<PIC1A_base> + D8 _H
Timer input/output control register 212	PIC1AREG212	<PIC1A_base> + DC _H
Timer input/output control register 213	PIC1AREG213	<PIC1A_base> + E0 _H
Timer input/output control register 30	PIC1AREG30	<PIC1A_base> + E8 _H
Timer input/output control register 31	PIC1AREG31	<PIC1A_base> + EC _H
Timer input/output control register 50	PIC1AREG50	<PIC1A_base> + F8 _H
Timer input/output control register 51	PIC1AREG51	<PIC1A_base> + FC _H
Synchronous clear enable register	SELBSSER	FFDD 2000 _H
Port output monitor select register	POMONSEL	FFDD 7400 _H
Port input monitor select register	PIMONSEL	FFDD 7000 _H

Combinations of registers used for each function are listed in the following table.

Table 29.10 Registers Used by Each Function

Section Number	Function Name	PIC1ASST				PIC1ASSER				PIC1AINI				PIC1ATSGHALLSEL	PIC1ATAUD0SEL	PIC1ATAUD1SEL	PIC1AHIZCE				PIC1AENCSEL4				PIC1AREG												POMONSEL	PIMONSEL	SELSSER	
		0	1	2	3	0	1	2	3	00	01	10	11	—	—	—	0	1	2	3	00	10	200	201	202	203	210	211	212	213	30	31	50	51	—	—	—

29.2.2.2 PIC1ASST — Simultaneous Start Trigger Control Register

The PIC1ASST register is an 8-bit register that selects the simultaneous start trigger.

Access: This register can be read/written in 8-bit units.

Address: FFDD 0004_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	PIC1ASYNCTR G
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 29.11 PIC1ASST Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	PIC1ASYNCTR G	Generates a start trigger for the timer for which simultaneous start is enabled. 0: Disabled 1: Simultaneous start trigger (pulse with a width of 1PCLK is output).

Note: PIC1ASYNCTR_G always reads 0 when read.

29.2.2.3 PIC1ASSER0 — Simultaneous Start Control Register 0

The PIC1ASSER0 register enables a start trigger for each channel of TAUD0.

Access: This register can be read/written in 16-bit units.

Address: FFDD 0010_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIC1AS SER015	PIC1AS SER014	PIC1AS SER013	PIC1AS SER012	PIC1AS SER011	PIC1AS SER010	PIC1AS SER009	PIC1AS SER008	PIC1AS SER007	PIC1AS SER006	PIC1AS SER005	PIC1AS SER004	PIC1AS SER003	PIC1AS SER002	PIC1AS SER001	PIC1AS SER000
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 29.12 PIC1ASSER0 Register Contents

Bit Position	Bit Name	Function
15 to 0	PIC1ASSER0m	Enables or disables a simultaneous start trigger for CHm of TAUD0. 0: Disabled 1: Enabled

29.2.2.4 PIC1ASSER1 — Simultaneous Start Control Register 1

The PIC1ASSER1 register enables a start trigger for each channel of TAUD1.

Access: This register can be read/written in 16-bit units.

Address: FFDD 0014_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIC1AS SER115	PIC1AS SER114	PIC1AS SER113	PIC1AS SER112	PIC1AS SER111	PIC1AS SER110	PIC1AS SER109	PIC1AS SER108	PIC1AS SER107	PIC1AS SER106	PIC1AS SER105	PIC1AS SER104	PIC1AS SER103	PIC1AS SER102	PIC1AS SER101	PIC1AS SER100
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.13 PIC1ASSER1 Register Contents

Bit Position	Bit Name	Function
15 to 0	PIC1ASSER1m	Enables or disables a simultaneous start trigger for CHm of TAUD1. 0: Disabled 1: Enabled

29.2.2.5 PIC1ASSER2 — Simultaneous Start Control Register 2

The PIC1ASSER2 register enables a start trigger of TAUJ_n, TSG3_n, TPBA_n, and ENCA_n.

Access: This register can be read/written in 16-bit units.

Address: FFDD 0018_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.14 PIC1ASSER2 Register Contents (1/2)

Bit Position	Bit Name	Function
15, 14	Reserved	When read, the value after reset is read. When writing, write the value after reset.
13	PIC1ASSER213	Enables or disables a simultaneous start trigger for the ENCA1. 0: Disabled 1: Enabled
12	PIC1ASSER212	Enables or disables a simultaneous start trigger for the ENCA0. 0: Disabled 1: Enabled
11	PIC1ASSER211	Enables or disables a simultaneous start trigger for the TPBA1. 0: Disabled 1: Enabled
10	PIC1ASSER210	Enables or disables a simultaneous start trigger for the TPBA0. 0: Disabled 1: Enabled
9	PIC1ASSER209	Enables or disables a simultaneous start trigger for the TSG31. 0: Disabled 1: Enabled
8	PIC1ASSER208	Enables or disables a simultaneous start trigger for the TSG30. 0: Disabled 1: Enabled
7	PIC1ASSER207	Enables or disables a simultaneous start trigger for CH03 of TAUJ1. 0: Disabled 1: Enabled
6	PIC1ASSER206	Enables or disables a simultaneous start trigger for CH02 of TAUJ1. 0: Disabled 1: Enabled
5	PIC1ASSER205	Enables or disables a simultaneous start trigger for CH01 of TAUJ1. 0: Disabled 1: Enabled
4	PIC1ASSER204	Enables or disables a simultaneous start trigger for CH00 of TAUJ1. 0: Disabled 1: Enabled
3	PIC1ASSER203	Enables or disables a simultaneous start trigger for CH03 of TAUJ0. 0: Disabled 1: Enabled
2	PIC1ASSER202	Enables or disables a simultaneous start trigger for CH02 of TAUJ0. 0: Disabled 1: Enabled
1	PIC1ASSER201	Enables or disables a simultaneous start trigger for CH01 of TAUJ0. 0: Disabled 1: Enabled

Table 29.14 PIC1ASSER2 Register Contents (2/2)

Bit Position	Bit Name	Function
0	PIC1ASSER200	Enables or disables a simultaneous start trigger for CH00 of TAUJ0. 0: Disabled 1: Enabled

29.2.2.6 PIC1ASSER3 — Simultaneous Start Control Register 3

The PIC1ASSER3 register enables a start trigger for each channel of OSTMn.

Access: This register can be read/written in 16-bit units.

Address: FFDD 001C_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PIC1ASSER301	PIC1ASSER300
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 29.15 PIC1ASSER3 Register Contents

Bit Position	Bit Name	Function
15 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	PIC1ASSER301	Enables or disables a simultaneous start trigger for OSTM1. 0: Disabled 1: Enabled
0	PIC1ASSER300	Enables or disables a simultaneous start trigger for OSTM0. 0: Disabled 1: Enabled

29.2.2.7 PIC1AINn0 — Flip-Flop Circuit Initialization Register n0

The PIC1AINn0 register enables initialization of the RS flip-flop circuits 4 to 2 (RSn4 to 2).

Access: This register can be read/written in 8-bit units.

Address: FFDD 0020_H (n=0), FFDD 002C_H (n=1)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	PIC1AINn04	PIC1AINn03	PIC1AINn02	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R	R

Table 29.16 PIC1AINn0 Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4 to 2	PIC1AINn0[4:2]	Enables or disables initialization of the RS flip-flop circuits 4 to 2 (RSn4 to RSn2) used for the PWM output function with dead time. These bits are always read as 0. 0: Disabled 1: Initialized
1, 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

29.2.2.8 PIC1AINn1 — DT Initialization Register n1

The PIC1AINn1 register enables initialization of the latch & toggle (DT) circuit.

Access: This register can be read/written in 8-bit units.

Address: FFDD 0024_H (n=0), FFDD 0030_H (n=1)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	PIC1AINn12	PIC1AINn11	PIC1AINn10
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 29.17 PIC1AINn1 Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2 to 0	PIC1AINn1[2:0]	Enables or disables initialization of the DT circuit to be used for the trigger pulse width measurement function. These bits are always read as 0. 0: Disabled 1: Initialized

29.2.2.9 PIC1ATSGHALLSEL — Hall Sensor Input Select Register

The PIC1ATSGHALLSEL register sets the pin conditions to input the external hall sensor signal.

Access: This register can be read/written in 8-bit units.

Address: FFDD 0074_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG1HALLSEL	TSG0HALLSEL
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 29.18 PIC1ATSGHALLSEL Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	TSG1HALLSEL	Sets pin condition to input the external hall sensor signal.* ¹ 0: Separate input 1: Alternative input with ENCA
0	TSG0HALLSEL	Sets pin condition to input the external hall sensor signal.* ¹ 0: Separate input 1: Alternative input with ENCA

Note 1. When TSG3nPTS12 to TSG3nPTS10 are used for input pattern to the TSG3, always set this bit to 1. In addition, set bit0 in the PIC1AREG50 register and bit0 in the PIC1AREG51 register as described below. When those bits are not used, do not change the setting from the value after reset.

TSG1HALLSEL	PIC1AREG5100	Function
1	1	Select input pin ENCA1E0, ENCA1E1, and ENCA1EC.
Other than above		Setting prohibited.

TSG0HALLSEL	PIC1AREG5000	Function
1	0	Select input pin ENCA0E0, ENCA0E1 and ENCA0EC
Other than above		Setting prohibited

29.2.2.10 PIC1ATAUD0SEL — TAUD0 Input Select Register

The PIC1ATAUD0SEL register is a 32-bit register that selects TAUDTIN input signals.

Access: This register can be read/written in 32-bit units.

Address: FFDD 0078_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.19 PIC1ATAUD0SEL Register Contents

Bit Position	Bit Name	Function
2m+3 2m+2	PIC1ATAUD0IN m[3:2]	Selects the signal to output to TAUD0TIN (m+1) output pin. 00: TAUD0TIN (m+1) is selected. 01: TAUD0TIN (m) is selected. 10: TAUD1TIN (m+1) is selected. 11: TAUD1TIN (m) is selected.
2m+1 2m	PIC1ATAUD0IN m[1:0]	Selects the signal to output to TAUD0TIN (m) output pin. 00: TAUD0TIN (m) is selected. 01: TAUD0TIN (m+1) is selected. 10: TAUD1TIN (m) is selected. 11: TAUD1TIN (m+1) is selected.

Note: m is an even channel number of TAUD0 (CHm_even)

29.2.2.11 PIC1ATAUD1SEL — TAUD1 Input Select Register

The PIC1ATAUD1SEL register is a 32-bit register that selects TAUDTIN input signals.

Access: This register can be read/written in 32-bit units.

Address: FFDD 007C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.20 PIC1ATAUD1SEL Register Contents

Bit Position	Bit Name	Function
2m+3 2m+2	PIC1ATAUD1IN m[3:2]	Selects the signal to output to TAUD1TIN (m+1) output pin 00: TAUD1TIN (m+1) is selected. 01: TAUD1TIN (m) is selected. 10: TAUD0TIN (m+1) is selected. 11: TAUD0TIN (m) is selected.
2m+1 2m	PIC1ATAUD1IN m[1:0]	Selects the signal to output to TAUD1TIN (m) output pin 00: TAUD1TIN (m) is selected. 01: TAUD1TIN (m+1) is selected. 10: TAUD0TIN (m) is selected. 11: TAUD0TIN (m+1) is selected.

Note: m is an even channel number of TAUD1 (CH_{m_even})

29.2.2.12 PIC1AHIZCEN0 — Hi-Z Control Register 0

The PIC1AHIZCEN0 register selects Hi-Z control input signals of TAUD0.

Access: This register can be read/written in 8-bit units.

Address: FFDD 0080_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	PIC1AHIZCEN 07	PIC1AHIZCEN 06	PIC1AHIZCEN 05	—	—	—	—	PIC1AHIZCEN 00
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R	R	R/W

Table 29.21 PIC1AHIZCEN0 Register Contents

Bit Position	Bit Name	Function
7	PIC1AHIZCEN 07	Enables or disables Hi-Z control by AD CG1 error interrupt (INTADCG1ERR). 0: Disabled 1: Enabled
6	PIC1AHIZCEN 06	Enables or disables Hi-Z control by AD CG0 error interrupt (INTADCG0ERR). 0: Disabled 1: Enabled
5	PIC1AHIZCEN 05	Enables or disables Hi-Z control by ERROROUT signal. 0: Disabled 1: Enabled
4 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	PIC1AHIZCEN 00	Enables or disables Hi-Z control by TAPA0ESO pin input. 0: Disabled 1: Enabled

CAUTIONS

1. Set this register before starting U/V/W outputs or UB/VB/WB outputs of TAUD0.
2. Set TAPA0CTL0.TAPA0DCN = 0 and TAPA0CTL0.TAPA0DCP = 1 when performing Hi-Z control by AD CG error signal and ERROROUT signal.

29.2.2.13 PIC1AHIZCEN1 — Hi-Z Control Register 1

The PIC1AHIZCEN1 register selects Hi-Z control input signals of TAUD1.

Access: This register can be read/written in 8-bit units.

Address: FFDD 0084_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	PIC1AHIZCEN 17	PIC1AHIZCEN 16	PIC1AHIZCEN 15	—	—	—	—	PIC1AHIZCEN 10
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R	R	R/W

Table 29.22 PIC1AHIZCEN1 Register Contents

Bit Position	Bit Name	Function
7	PIC1AHIZCEN 17	Enables or disables Hi-Z control by AD CG1 error interrupt (INTADCG1ERR). 0: Disabled 1: Enabled
6	PIC1AHIZCEN 16	Enables or disables Hi-Z control by AD CG0 error interrupt (INTADCG0ERR). 0: Disabled 1: Enabled
5	PIC1AHIZCEN 15	Enables or disables Hi-Z control by ERROROUT signal. 0: Disabled 1: Enabled
4 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	PIC1AHIZCEN 10	Enables or disables Hi-Z control by TAPA1ESO pin input. 0: Disabled 1: Enabled

CAUTIONS

1. Set this register before starting U/V/W outputs or UB/VB/WB outputs of TAUD1.
2. Set TAPA1CTL0.TAPA1DCN = 0 and TAPA1CTL0.TAPA1DCP = 1 when performing Hi-Z control by AD CG error signal and ERROROUT signal.

29.2.2.14 PIC1AHIZCEN2 — Hi-Z Control Register 2

The PIC1AHIZCEN2 register selects Hi-Z control input signals of TSG30.

Access: This register can be read/written in 8-bit units.

Address: FFDD 0088_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	PIC1AHIZCEN 27	PIC1AHIZCEN 26	PIC1AHIZCEN 25	—	PIC1AHIZCEN 23	—	—	PIC1AHIZCEN 20
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R/W	R	R	R/W

Table 29.23 PIC1AHIZCEN2 Register Contents

Bit Position	Bit Name	Function
7	PIC1AHIZCEN 27	Enables or disables Hi-Z control by AD CG1 error interrupt (INTADCG1ERR). 0: Disabled 1: Enabled
6	PIC1AHIZCEN 26	Enables or disables Hi-Z control by AD CG0 error interrupt (INTADCG0ERR). 0: Disabled 1: Enabled
5	PIC1AHIZCEN 25	Enables or disables Hi-Z control by ERROROUT signal. 0: Disabled 1: Enabled
4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3	PIC1AHIZCEN 23	Enables or disables Hi-Z control by INTTSG30IER interrupt signal. 0: Disabled 1: Enabled
2, 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	PIC1AHIZCEN 20	Enables or disables Hi-Z control by TAPA0ESO pin input. 0: Disabled 1: Enabled

CAUTIONS

1. Set this register before starting TSG30 output.
2. Set TAPA2CTL0.TAPA2DCN = 0 and TAPA2CTL0.TAPA2DCP = 1 when performing Hi-Z control by AD CG error signal, ERROROUT signal, and TSG30 error signal.

29.2.2.15 PIC1AHIZCEN3 — Hi-Z Control Register 3

The PIC1AHIZCEN3 register selects Hi-Z control input signals of TSG31.

Access: This register can be read/written in 8-bit units.

Address: FFDD 008C_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	PIC1AHIZCEN 37	PIC1AHIZCEN 36	PIC1AHIZCEN 35	PIC1AHIZCEN 34	—	—	—	PIC1AHIZCEN 30

Table 29.24 PIC1AHIZCEN3 Register Contents

Bit Position	Bit Name	Function
7	PIC1AHIZCEN 37	Enables or disables Hi-Z control by AD CG1 error interrupt (INTADCG1ERR) 0: Disabled 1: Enabled
6	PIC1AHIZCEN 36	Enables or disables Hi-Z control by AD CG0 error interrupt (INTADCG0ERR). 0: Disabled 1: Enabled
5	PIC1AHIZCEN 35	Enables or disables Hi-Z control by ERROROUT signal 0: Disabled 1: Enabled
4	PIC1AHIZCEN 34	Enables or disables Hi-Z control by INTTSG31IER interrupt signal. 0: Disabled 1: Enabled
3 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	PIC1AHIZCEN 30	Enables or disables Hi-Z control by TAPA1ESO pin input. 0: Disabled 1: Enabled

CAUTION

Set this register before starting TSG31 output.

Set TAPA3CTL0.TAPA3DCN = 0 and TAPA3CTL0.TAPA3DCP = 1 when performing Hi-Z control by AD CG error signal, ERROROUT signal, and TSG31 error signal.

29.2.2.16 PIC1AENCSEL400 — ENCATIN1 Input Select Register 400

The PIC1AENCSEL400 register is used for encoder capture trigger select function.

Access: This register can be read/written in 8-bit units.

Address: FFDD 00B8_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	PIC1AENCSEL 4007	—	—	—	PIC1AENCSEL 4003	PIC1AENCSEL 4002	PIC1AENCSEL 4001	PIC1AENCSEL 4000

Table 29.27 PIC1AREG200 Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is read. When writing, write the value after reset.
18	PIC1AREG20018	Selects the signal for input as TAUD0TIN10, TAUD0TIN12, and TAUD0TIN14 signals of TAUD0. 1: Select TOUT of TAUD0 CH02. Settings other than above are prohibited.*1
17 to 12	Reserved	When read, the value after reset is read. When writing, write the value after reset.
11, 10	PIC1AREG200 [11:10]	Selects the signal to be input as TAUD0TIN6, TAUD0TIN7 signals of TAUD0. 10: TS0PTE signal of TSG3. Settings other than above are prohibited.*1
9, 8	PIC1AREG200 [09:08]	Selects the signal to be input as TAUD0TIN4, TAUD0TIN5 signals of TAUD0. 10: TS0PTE signal of TSG3. Settings other than above are prohibited.*1
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3	PIC1AREG20003	Selects the signal to be input as TAUD0TIN7 signal of TAUD0. 0: TIN pin input 1: Input signal selected by PIC1AREG20011, PIC1AREG20010 bits (TS0PTE signal).
2	PIC1AREG20002	Selects the signal to be input as TAUD0TIN6 signal of TAUD0. 0: TIN pin input 1: Input signal selected by PIC1AREG20011 and PIC1AREG20010 bits (TS0PTE signal).
1	PIC1AREG20001	Selects the signal to be input as TAUD0TIN5 signal of TAUD0. 0: TIN pin input 1: Input signal selected by PIC1AREG20009, PIC1AREG20008 bits (TS0PTE signal).
0	PIC1AREG20000	Selects the signal to be input as TAUD0TIN4 signal of TAUD0. 0: TIN pin input 1: Input signal selected by PIC1AREG20009 and PIC1AREG20008 bits (TS0PTE signal).

Note 1. Make sure to set an appropriate value when a selectable signal is used. Do not change the value from the value after reset when not used.

29.2.2.19 PIC1AREG210 — Timer Input/Output Control Register 210

The PIC1AREG210 register selects TAUD1 input signals.

Access: This register can be read/written in 32-bit units.

Address: FFDD 00D4_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.28 PIC1AREG210 Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is read. When writing, write the value after reset.
18	PIC1AREG21018	Selects the signal for input as TAUD1TIN10, TAUD1TIN12, and TAUD1TIN14 signals of TAUD1. 1: Select TOUT of TAUD1 CH02. Settings other than above are prohibited.*1
17 to 12	Reserved	When read, the value after reset is read. When writing, write the value after reset.
11, 10	PIC1AREG210 [11:10]	Selects the signal to be input as TAUD1TIN6 and TAUD1TIN7 signals of TAUD1. 10: TS0PTE signal of TSG31 Settings other than above are prohibited.*1
9, 8	PIC1AREG210 [09:08]	Selects the signal to be input as TAUD1TIN4 and TAUD1TIN5 signals of TAUD1. 10: TS0PTE signal of TSG31 Settings other than above are prohibited.*1
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3	PIC1AREG21003	Selects the signal to be input as TAUD1TIN7 signal of TAUD1. 0: TIN pin input 1: Input signal selected by PIC1AREG21011 and PIC1AREG21010 bits (TS0PTE signal).
2	PIC1AREG21002	Selects the signal to be input as TAUD1TIN6 signal of TAUD1. 0: TIN pin input 1: Input signal selected by PIC1AREG21011 and PIC1AREG21010 bits (TS0PTE signal).
1	PIC1AREG21001	Selects the signal to be input as TAUD1TIN5 signal of TAUD1. 0: TIN pin input 1: Input signal selected by PIC1AREG21009 and PIC1AREG21008 bits (TS0PTE signal).
0	PIC1AREG21000	Selects the signal to be input as TAUD1TIN4 signal of TAUD1. 0: TIN pin input 1: Input signal selected by PIC1AREG21009 and PIC1AREG21008 bits (TS0PTE signal).

Note 1. Make sure to set an appropriate value when a selectable signal is used. Do not change the value from the

value after reset when not used.

29.2.2.20 PIC1AREG2n1 — Timer Input/Output Control Register 2n1

The PIC1AREG2n1 register selects the logical operation for the combination circuit PFN0xx.

Access: This register can be read/written in 32-bit units.

Address: FFDD 00C4_H(n = 0), FFDD 00D8_H(n = 1)

Value after reset: 0000 0000_H

Table 29.29 PIC1AREG2n1 Register Contents

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is read. When writing, write the value after reset.
27, 26	PIC1AREG2n1 [27:26]	Selects PFN045 WO2 output.* ¹ 10: Combination circuit output. 11: Inverted combination circuit output. Settings other than above are prohibited.* ²
25, 24	PIC1AREG2n1 [25:24]	Selects PFN045 WO1 output.* ¹ 10: Combination circuit output. 11: Inverted combination circuit output. Settings other than above are prohibited.* ²
23, 22	PIC1AREG2n1 [23:22]	Selects PFCN023 VO2 output.* ¹ 10: Combination circuit output. 11: Inverted combination circuit output. Settings other than above are prohibited.* ²
21, 20	PIC1AREG2n1 [21:20]	Selects PFN023 VO1 output.* ¹ 10: Combination circuit output. 11: Inverted combination circuit output. Settings other than above are prohibited.* ²
19, 18	PIC1AREG2n1 [19:18]	Selects PFN001 UO2 output.* ¹ 10: Combination circuit output. 11: Inverted combination circuit output. Settings other than above are prohibited.* ²
17, 16	PIC1AREG2n1 [17:16]	Selects PFN001 UO1 output.* ¹ 10: Combination circuit output. 11: Inverted combination circuit output. Settings other than above are prohibited.* ²
15 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

Note 1. The register value for some functions needs to be set depending on the value of TAUD. For the setting values, see **Section 29.2.3, Function**.

Note 2. Make sure to set an appropriate value when a selectable signal is used. Do not change the value from the value after reset when not used.

Block diagram of PFN001 is shown in the following figure.

PFN023 and PFN045 are operated under the same logic with different input signals and select registers.

For connection of PFN0xx with peripheral circuits, see **Figure 29.11**.

Figure 29.1 Block Diagram of PFN001

29.2.2.21 PIC1AREG2n2 — Timer Input/Output Control Register 2n2

The PIC1AREG2n2 register selects input signals of TAUDn CHm.

Access: This register can be read/written in 32-bit units.

Address: FFDD 00C8_H (n=0), FFDD 00DC_H (n=1)

Value after reset: 0000 0000_H

Table 29.30 PIC1AREG2n2 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is read. When writing, write the value after reset.
27, 26	PIC1AREG2n2 [27:26]	Selects the TIN input signal of TAUDnCH15. 00: TIN pin input. 10: Signal selected by PIC1AREG2n204 bit (TOUT of TAUDnCH09). Settings other than above are prohibited.
25, 24	PIC1AREG2n2 [25:24]	Selects the TIN input signal of TAUDnCH14. 00: TIN pin input 10: Signal selected by PIC1AREG2n018 register bit (TOUT of TAUDnCH02). Settings other than above are prohibited.
23, 22	PIC1AREG2n2 [23:22]	Selects the TIN input signal of TAUDnCH13. 00: TIN pin input 10: Signal selected by PIC1AREG2n203 bit (TOUT of TAUDnCH07). Settings other than above are prohibited.
21, 20	PIC1AREG2n2 [21:20]	Selects the TIN input signal of TAUDnCH12. 00: TIN pin input 10: Signal selected by PIC1AREG2n018 register bit (TOUT of TAUDnCH02). Settings other than above are prohibited.
19, 18	PIC1AREG2n2 [19:18]	Selects the TIN input signal of TAUDnCH11. 00: TIN pin input 10: Signal selected by PIC1AREG2n202 bit (TOUT of TAUDnCH05). Settings other than above are prohibited.
17, 16	PIC1AREG2n2 [17:16]	Selects the TIN input signal of TAUDnCH10. 00: TIN pin input 10: Signal selected by PIC1AREG2n018 register bit (TOUT of TAUDnCH02). Settings other than above are prohibited.
15 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	PIC1AREG2n2 04	Selects the signal to be supplied to TIN of TAUDnCH15. 0: TOUT of TAUDnCH09. 1: Set/clear output by INTTAUDnI8 and INTTAUDnI9.
3	PIC1AREG2n2 03	Selects the signal to be supplied to TIN of TAUDnCH13. 0: TOUT of TAUDnCH07. 1: Set/clear output by INTTAUDnI6 and INTTAUDnI7.

Table 29.30 PIC1AREG2n2 Register Contents (2/2)

Bit Position	Bit Name	Function
2	PIC1AREG2n2 02	Selects the signal to be supplied to TIN of TAUDnCH11. 0: TOUT of TAUDnCH05. 1: Set/clear output by INTTAUDnI4 and INTTAUDnI5.
1, 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

29.2.2.22 PIC1AREG2n3 — Timer Input/Output Control Register 2n3

The PIC1AREG2n3 register selects logical operation for the combination circuit FN0i.

Access: This register can be read/written in 32-bit units.

Address: FFDD 00CC_H (n = 0), FFDD 00E0_H (n = 1)

Value after reset: 0000 0000_H

Table 29.32 PIC1AREG30 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22	PIC1AREG3022	Selects the input pins (ENCA0E0, ENCA0E1, ENCA0EC internal inputs) of ENCA0 timer. 0: The signal selected by PIC1AREG3000 (ENCA0E0), PIC1AREG3001 (ENCA0E1), and PIC1AREG3017-16 (ENCA0EC) 1: The signal selected by PIC1AREG3020 and PIC1AREG3019
21	PIC1AREG3021	Selects the signal to be supplied to PIC1AREG3012-15. 0: ENCA111 (signal 1 of the ENCA1 external pin) 1: The signal selected by the PIC1AENCSEL4107 bit of the PIC1AENCSEL410 register.
20,19	PIC1AREG30 [20:19]	Selects the input pins (ENCA1E0, ENCA1E1, ENCA1EC internal inputs) of ENCA1 timer. 00: The ENCA1E0, ENCA1E1, ENCA1EC input pins of ENCA1 timer. Settings other than above are prohibited.
18	PIC1AREG3018	Selects the signal to be supplied to PIC1AREG3002 to 05. 0: ENCA011 (signal 1 of ENCA0 external pin) 1: The signal selected by the PIC1AENCSEL4007 bit of the PIC1AENCSEL400 register.
17, 16	PIC1AREG30 [17:16]	Selects the input pins (ENCA0E0, ENCA0E1, ENCA0EC internal inputs) of ENCA0 timer. 00: The ENCA0E0, ENCA0E1, ENCA0EC input pins of ENCA0 timer. Settings other than above are prohibited.
15 to 12	PIC1AREG30 [15:12]	Selects the signal to be input as the ENCA1TIN1 signal. 0: The signal selected by PIC1AREG3021. 1: The signal selected by PIC1AREG3018. 2: ADG0TRG4 3: ADG0TRG3 4: ADG0TRG2 5: ADG0TRG1 6: ADG0TRG0 7: ADG1TRG4 8: ADG1TRG3 9: ADG1TRG2 10: ADG1TRG1 11: ADG1TRG0 Settings other than above are prohibited.

Table 29.32 PIC1AREG30 Register Contents (2/2)

Bit Position	Bit Name	Function
11, 10	PIC1AREG30 [11:10]	Selects the ENCAEC pin input of timer ENCA1. 00: The signal selected by the PIC1AREG3019 and PIC1AREG3020 bits. 10: The signal selected by the PIC1AREG3016 and PIC1AREG3017 bits. 11: ENCA0EQ1 signal (ENCA0 timer) Settings other than above are prohibited
9, 8	PIC1AREG30 [09:08]	Selects the ENCA1E1 pin input of timer ENCA1. 00: Signal selected by the PIC1AREG3019 and PIC1AREG3020 bits. 01: The signal selected by the PIC1AREG3016 and PIC1AREG3017 bits. 10: TS1PUD signal of TSG31. Settings other than above are prohibited.
7, 6	PIC1AREG30 [07:06]	Selects the ENCA1E0 pin input of timer ENCA1. 00: The signal selected by the PIC1AREG3019 and PIC1AREG3020 bits. 01: The signal selected by the PIC1AREG3016 and PIC1AREG3017 bits. 10: TS1PEC signal of TSG31. Settings other than above are prohibited
5 to 2	PIC1AREG30 [05:02]	Selects the signal to be input as the ENCAT0TIN1 signal. 0: The signal selected by the PIC1AREG3018 bit. 1: The signal selected by the PIC1AREG3021 bit. 2: ADCG0TRG4 3: ADCG0TRG3 4: ADCG0TRG2 5: ADCG0TRG1 6: ADCG0TRG0 7: ADCG1TRG4 8: ADCG1TRG3 9: ADCG1TRG2 10: ADCG1TRG1 11 : ADCG1TRG0 Settings other than above are prohibited.
1	PIC1AREG3001	Selects the signal to input as the ENCA0E1 internal signal. 0: Signal selected by PIC1AREG3017 and PIC1AREG3016. 1: TS0PUD signal of TSG30.
0	PIC1AREG3000	Selects the signal to input as the ENCA0E0 internal signal. 0: Signal selected by PIC1AREG3017 and PIC1AREG3016. 1: TS0PEC signal of TSG30.

29.2.2.24 PIC1AREG31 — Timer Input/Output Control Register 31

The PIC1AREG31 register selects TAUDn and TAUJ0 input signals.

Access: This register can be read/written in 32-bit units.

Address: FFDD 00EC_H

Value after reset: 0000 0000_H

Table 29.33 PIC1AREG31 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22, 21	PIC1AREG31 [22:21]	Selects the TIN input signal of TAUD1CH02. 00: TIN pin input 01: DT output signal of ENCAT1EQ0 Settings other than above are prohibited.
20	PIC1AREG3120	Selects the TIN input signal of TAUD1CH01. 0: TIN pin input 1: The signal selected by PIC1AREG3115 to PIC1AREG3117.
19, 18	PIC1AREG31 [19:18]	Selects the TIN input signal of TAUD1CH00. 00: The signal selected by PIC1AREG3115 to PIC1AREG3117. 10: DT output signal of ENCAT1EQ0 Settings other than above are prohibited.
17 to 15	PIC1AREG31 [17:15]	Selects the TIN input signal of TAUD1CH00 and TAUD1CH01. 000: TIN pin input. 001: DT output signal of ENCAT1EQ1 Settings other than above are prohibited.
14	Reserved	When read, the value after reset is read. When writing, write the value after reset.
13, 12	PIC1AREG31 [13:12]	Selects the TIN input signal of TAUD0CH02. 00: TIN pin input. 10: DT output signal of ENCAT0EQ0 Settings other than above are prohibited.
11	PIC1AREG3111	Selects the TIN input signal of TAUD0CH01. 0: TIN pin input. 1: The signal selected by PIC1AREG3106 to PIC1AREG3108.
10, 9	PIC1AREG31 [10:09]	Selects the TIN input signal of TAUD0CH00. 00: The signal selected by PIC1AREG3106 to PIC1AREG3108. 10: DT output signal of ENCAT0EQ0 Settings other than above are prohibited.
8 to 6	PIC1AREG31 [08:06]	Selects the TIN input signal of TAUD0CH00 and TAUD0CH01. 000: TIN pin input 001: DT output signal of ENCAT0EQ1 Settings other than above are prohibited.

Table 29.33 PIC1AREG31 Register Contents (2/2)

Bit Position	Bit Name	Function
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	PIC1AREG3104	Selects the TIN input signal of TAUJ0CH03. 0: TIN pin input. 1: DT output signal of ENCAT1IEC.
3	PIC1AREG3103	Selects the TIN input signal of TAUJ0CH02. 0: TIN pin input. 1: DT output signal of ENCAT1IEC
2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	PIC1AREG3101	Selects the TIN input signal of TAUJ0CH01. 0: TIN pin input. 1: DT output signal of ENCAT0IEC
0	PIC1AREG3100	Selects the TIN input signal of TAUJ0CH00. 0: TIN pin input. 1: DT output signal of ENCAT0IEC

29.2.2.25 PIC1AREG50 — Timer Input/Output Control Register 50

The PIC1AREG50 register selects TSG30 input signals.

Access: This register can be read/written in 16-bit units.

Address: FFDD 00F8_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 29.34 PIC1AREG50 Register Contents

Bit Position	Bit Name	Function
15 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10	PIC1AREG5010	Selects the signal to be input as the TSG30TSTOPC0 signal of the TSG30 timer. 0: INTENCA111 input of the ENCA1 timer 1: Setting prohibited.
9	Reserved	When read, the value after reset is read. When writing, write the value after reset.
8	PIC1AREG5008	Selects the signal to be input as the TSG30TSTOPC0 signal of the TSG30 timer. 0: INTENCA011 input of the ENCA0 timer 1: Setting prohibited.
7	PIC1AREG5007	Selects the signal to be input as the TS0OPCI1 signal of the TSG30 timer. 0: INTTAUD017 input of the TAUD 1: Setting prohibited.
6, 5	PIC1AREG50 [06:05]	Selects the signal to be input as the TSG30TSTOPS (TS0OPCI0) signal of the TSG30 timer. 01: The signal selected by the PIC1AREG5008 bit 10: The signal selected by the PIC1AREG5010 bit 11: INTTAUD015 output signal of TAUD0. Settings other than above are prohibited. ¹
4 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	PIC1AREG5000	Switches the ENCA signal and external hall sensor signal. For the note on selection of the signals, see Note 1 of Section 29.2.2.9, PIC1ATSGHALLSEL — Hall Sensor Input Select Register . 0: Select the pin input ENCA0E0, ENCA0E1, ENCA0EC. 1: Setting prohibited.

Note 1. Make sure to set an appropriate value when a selectable signal is used. Do not change the value from the value after reset when not used

29.2.2.26 PIC1AREG51 — Timer Input/Output Control Register 51

The PIC1AREG51 register selects TSG31 input signals.

Access: This register can be read/written in 16-bit units.

Address: FFDD 00FC_H

Value after reset: 0000_H

Table 29.35 PIC1AREG51 Register Contents

Bit Position	Bit Name	Function
15 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10	PIC1AREG5110	Selects the signal to be input as the TSG31TSTOPC0 signal from the TSG31 timer. 0: INTENCA111 input signal of the ENCA1 timer 1: Setting prohibited.
9	Reserved	When read, the value after reset is read. When writing, write the value after reset.
8	PIC1AREG5108	Selects the signal to be input as the TSG31TSTOPC0 signal from TSG31 timer. 0: INTENCA011 input signal of the ENCA0 timer 1: Setting prohibited.
7	PIC1AREG5107	Selects the signal to be input as the TS0OPC11 signal from TSG31 timer. 0: The INTTAUD117 signal input of the TAUD1 timer. 1: Setting prohibited.
6, 5	PIC1AREG51 [06:05]	Selects the signal to be input as the TSG31TSTOPS (TS1OPC10) signal from TSG31 timer. 01: The signal selected by the PIC1AREG5108 bit. 10: The signal selected by the PIC1AREG5110 bit. 11: The INTTAUD115 output of the TAUD1. Settings other than above are prohibited.*1
4 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	PIC1AREG5100	Switches the ENCA signal and external hall sensor signal. For the note on selection of the signals, see Note 1 of Section 29.2.2.9, PIC1ATSGHALLSEL — Hall Sensor Input Select Register . 1: Select the pin input ENCA1E0, ENCA1E1, ENCA1EC. Settings other than above are prohibited.*1

Note 1. Make sure to set an appropriate value when a selectable signal is used. Do not change the value from the value after reset when not used

29.2.2.27 POMONSEL — Port Output Monitor Select Register

The POMONSEL register selects the channels to monitor output of TAUD0, TAUD1, TSG30, TSG31, OSTM0, and OSTM1 timers using TAUD2.

Access: This register can be read/written in 8-bit units.

Address: FFDD 7400_H

Value after reset: 00_H

CAUTIONS

- Using the synchronous clearing and simultaneous starting trigger functions for TSG3 at the same time is prohibited. If you are using synchronous clearing of TSG3, only use the simultaneous start trigger function at the start of counting. After counting has started, set the bits of the simultaneous start control register listed below to 0.
 - PIC1SSER0.PIC1ASSER014 (TAUD0 channel 14)
 - PIC1SSER0.PIC1ASSER015 (TAUD0 channel 15)
 - PIC1SSER2.PIC1ASSER208 (TSG30)
 - PIC1SSER2.PIC1ASSER209 (TSG31)

To start TSG30 and TSG31, and TAUD0 channels 14 and 15 simultaneously while synchronous clearing of TSG3 is in use, disable synchronous clearing of TSG3 before using the simultaneous start trigger function.

Switching of the above setting while the trigger for synchronous clearing or simultaneous starting of TSG3 is active is prohibited.
- Writing in the following ways to SSER during counter operation is prohibited.
 - Writing a value other than 000_B or the setting at the start of operation.
 - Writing at a timing that coincides with the occurrence of an interrupt for TAUD0 channel 14 or 15.

29.2.3 Function

29.2.3.1 Simultaneous Start Trigger Function

(1) Overview

This function allows any combination of timers (TAUDn, TAUJn, TSG3n, TPBA_n, OSTM_n, and ENCA_n) to be started simultaneously.

(2) Configuration

The timers which support simultaneous start trigger function are as follows.

- TAUD_n
- TAUJ_n
- TSG3_n
- TPBA_n
- OSTM_n
- ENCA_n

Figure 29.3 Block Diagram of Simultaneous Start Trigger Function

Set 1 to the PIC1ASYNCTRГ bit of the simultaneous start trigger control register (PIC1ASST) after unmasking the target timers. The timer operations start by active signal input to the start trigger of each timer.

(3) Registers

The PIC1A registers set by this function are as follows. For setting value of the registers, see **Section 29.2.2.2** to **Section 29.2.2.6**.

- PIC1A registers to be set
PIC1ASST
PIC1ASSER0
PIC1ASSER1
PIC1ASSER2
PIC1ASSER3

(4) Function

This function allows any combination of timers (TAUDn, TAUJn, TSG3n, TPBA n, OSTMn, and ENCA n) to be started simultaneously.

(5) Flow Chart

The following figure shows the setting flow of this function.

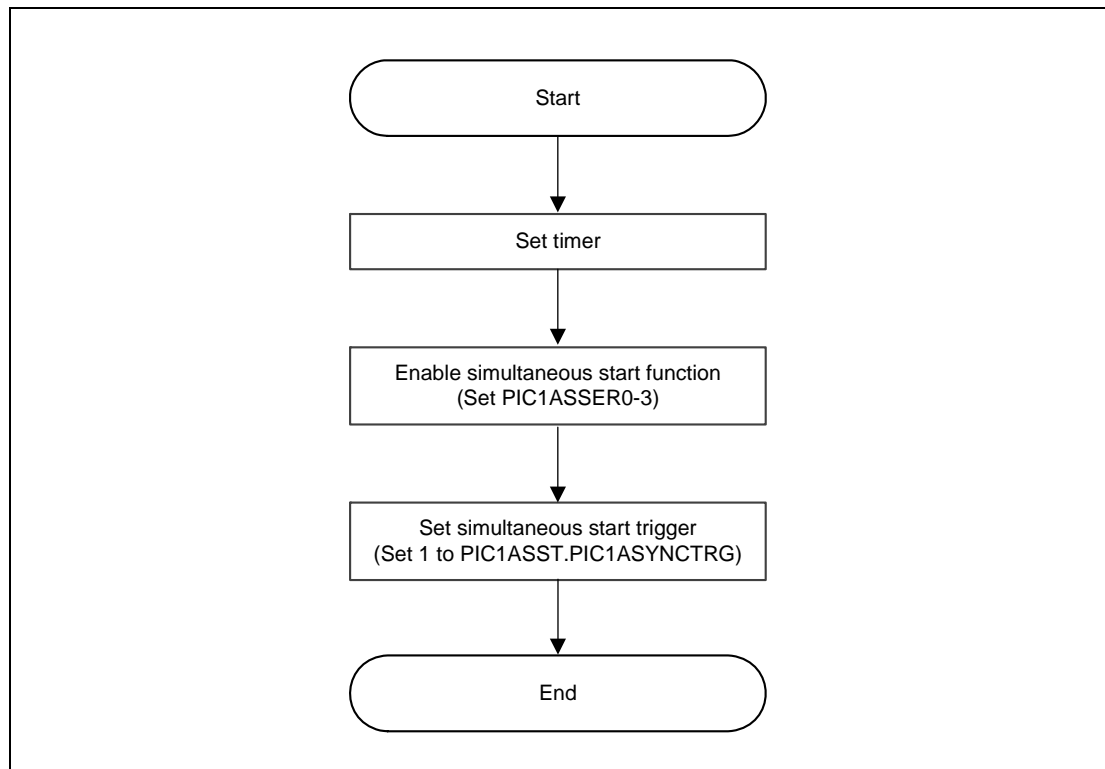

Figure 29.4 Setting Flow

Setting procedures are as follows.

- Set timer
Set the timers to start simultaneously.
- Enable simultaneous start function
Set 1 to the applicable bits of the PIC1ASSER0, PIC1ASSER1, PIC1ASSER2, and PIC1ASSER3 registers to enable simultaneous start of the corresponding timers.
- Set simultaneous start trigger
Setting 1 to the PIC1ASYNCTRG bit of the simultaneous start trigger control register (PIC1ASST) simultaneously starts the timers.

29.2.3.2 PWM Output Function with Dead Time

(1) Overview

This function generates and outputs PWM waveforms with the dead time from one phase to three phases using TAUDn.

The PWM output function of TAUD sets only the clear timing in a period under the duty ratio specification. This function enables the set timing to be specified in addition to the clear timing to output more flexible PWM waveforms with the dead time.

The following table lists the number of TAUDn channels used.

PWM Output with Dead Time	Number of TAUDn Channels
One-phase PWM output (U phase/UB phase)	5 channels (master channel: 1, slave channel: 4)
Two-phase PWM output (U phase/UB phase, V phase/VB phase)	9 channels (master channel: 1, slave channel: 8)
Three-phase PWM output (U phase/UB phase, V phase/VB phase, W phase/WB phase)	13 channels (master channel: 1, slave channel: 12)

Note: Above are examples of PWM output combinations.

Usages of each TAUDn channel are listed in the following table. CH2 is used as the master channel.

TAUDn Channel	U phase/ UB phase	V phase/ VB phase	W phase/ WB phase	Usage
CH0	—	—	—	Not used
CH1	—	—	—	Not used
CH2	√	√	√	Carrier period (common to each phase)
CH3	—	—	—	Not used
CH4	√	—	—	Duty (U phase setting)
CH5	√	—	—	Duty (U phase clearing)
CH6	—	√	—	Duty (V phase setting)
CH7	—	√	—	Duty (V phase clearing)
CH8	—	—	√	Duty (W phase setting)
CH9	—	—	√	Duty (W phase clearing)
CH10	√	—	—	U phase output (TOUT10)
CH11	√	—	—	UB phase output (TOUT11)
CH12	—	√	—	V phase output (TOUT12)
CH13	—	√	—	VB phase output (TOUT13)
CH14	—	—	√	W phase output (TOUT14)
CH15	—	—	√	WB phase output (TOUT15)

Note: √: Used; —: Not used

(2) Configuration

The PWM output function with the dead time is realized by using the PWM output function/one-phase output PWM function of TAUDn and PIC1A in combination. The following figure shows the block diagram of the PWM output function with the dead time.

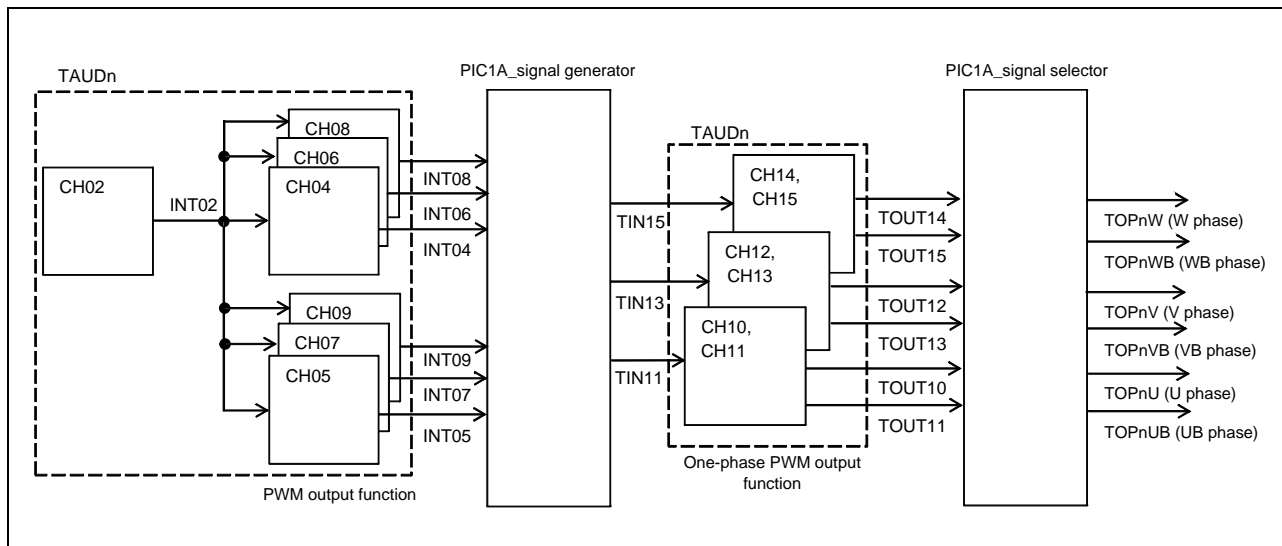

Figure 29.5 Block Diagram of PWM Output Function with Dead Time

The configuration of this function is described below using the PWM output of U phase/UB phase as an example.

- [TAUDn] PWM output function
CH02, CH04, and CH05 are used in combination. Setting the period, U phase set value, and U phase clear value to CDR02, CDR04, and CDR05, respectively, generates the set and clear PWM signals (INT04 and INT05).
- [PIC1A_signal generator] RS flip-flop circuit (RSn2)
The INT04 and INT05 inputs are selected and TIN11 (PWM signal) is generated.
- [TAUDn] One-phase PWM output function
CH10 and CH11 are used in combination. A dead time value is set to CDR11, dead time is inserted in the PWM signal to be input to TIN11, and TOUT10 (U phase PWM signal) and TOUT11 (UB phase PWM signal) are output.
- [PIC1A_signal selector]
TOUT10 and TOUT11 inputs are selected and output to TOPnU and TOPnUB pins, respectively.

A similar process occurs for V phase/VB phase and W phase/WB phase.

(3) Registers

The block diagram of PIC1A is shown in the following figure.

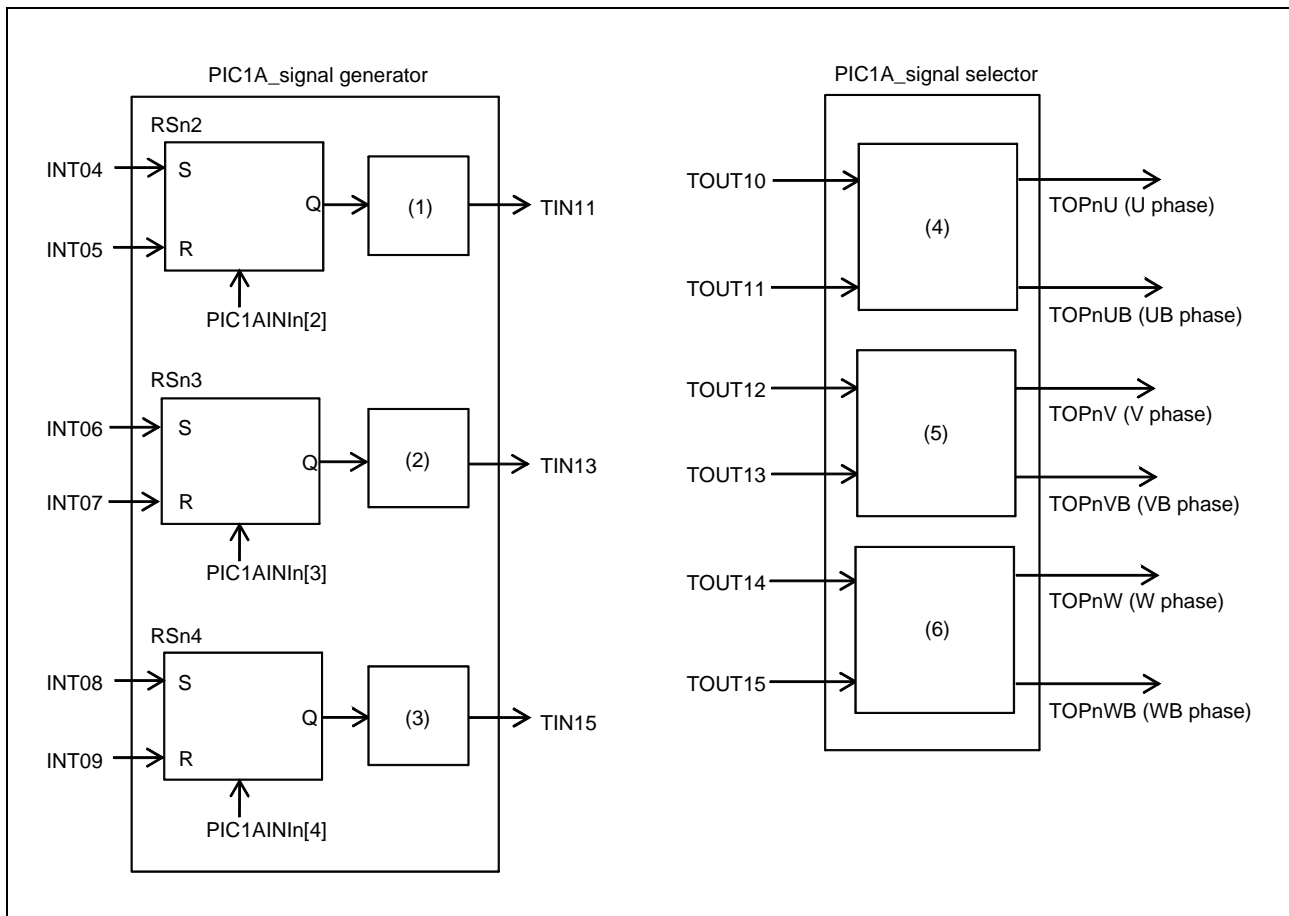

Figure 29.6 Block Diagram of PIC1A

The values of PIC1A registers used in this function are as follows.

U phase/ UB phase

The values to output the signal Q from RSn2 as TIN11. (**Figure 29.6**, unit (1))

$$\text{PIC1AREG2n2}[19:18] = 10_{\text{B}}$$

$$\text{PIC1AREG2n2}[2] = 1_{\text{B}}$$

$$\text{PIC1ATAUDnSEL}[23:22] = 00_{\text{B}}$$

The values to output TOUT10 and TOUT11 as TOPnU and TOPnUB, respectively (**Figure 29.6**, unit (4))

$$\text{PIC1AREG2n1}[19:16] = 0000_{\text{B}}$$

$$\text{PIC1AREG2n3}[2:0] = 000_{\text{B}}$$

$$\text{PIC1AREG2n3}[6:4] = 000_{\text{B}}$$

V phase/ VB phase

The values to output the signal Q from RSn3 as TIN13. (**Figure 29.6**, unit (2))

$$\text{PIC1AREG2n2}[23:22] = 10_{\text{B}}$$

$$\text{PIC1AREG2n2}[3] = 1_{\text{B}}$$

$$\text{PIC1ATAUDnSEL}[27:26] = 00_{\text{B}}$$

The values to output TOUT12 and TOUT13 as TOPnV and TOPnVB, respectively (**Figure 29.6**, unit (5))

$$\text{PIC1AREG2n1}[23:20] = 0000_{\text{B}}$$

$$\text{PIC1AREG2n3}[10:8] = 000_{\text{B}}$$

$$\text{PIC1AREG2n3}[14:12] = 000_{\text{B}}$$

W phase/ WB phase

The values to output the signal Q from RSn4 as TIN15. (**Figure 29.6**, unit (3))

$$\text{PIC1AREG2n2}[27:26] = 10_{\text{B}}$$

$$\text{PIC1AREG2n2}[4] = 1_{\text{B}}$$

$$\text{PIC1ATAUDnSEL}[31:30] = 00_{\text{B}}$$

The values to output TOUT14 and TOUT15 as TOPnW and TOPnWB, respectively (**Figure 29.6**, unit (6))

$$\text{PIC1AREG2n1}[27:24] = 0000_{\text{B}}$$

$$\text{PIC1AREG2n3}[18:16] = 000_{\text{B}}$$

$$\text{PIC1AREG2n3}[22:20] = 000_{\text{B}}$$

Enables initialization of RSn2 to RSn4

The values to enable initialization of RSn2 to RSn4

$$\text{PIC1AINIn0}[4] = 1_{\text{B}} \text{ (initialized)}$$

$$\text{PIC1AINIn0}[3] = 1_{\text{B}} \text{ (initialized)}$$

$$\text{PIC1AINIn0}[2] = 1_{\text{B}} \text{ (initialized)}$$

(4) Function

Details of this function are described using the one-phase PWM output (U phase/UB phase) with dead time as an example.

The following figure shows the timing diagram.

Figure 29.7 Timing Diagram of One-Phase PWM Output with Dead Time (U phase/UB phase)

- (1) Using the simultaneous start trigger function, the timers to be used are started simultaneously.*¹
- (2) For CH04 and CH05, the values set to CDR04 and CDR05 are reloaded to CNT04 and CNT05, respectively, upon the occurrence of a CH02 underflow.
- (3) INT04 is generated and TIN11 becomes high level upon the occurrence of a CH04 underflow, and INT05 is generated and TIN11 becomes low level upon the occurrence of a CH05 underflow. This process generates a PWM waveform.
- (4) The set values are reloaded to CNT11 at both edges of TIN11.*²
- (5) INT11 is generated and TAUDnO10 becomes high level upon the occurrence of a CH11 underflow, and INT05 is generated and TAUDnO10 becomes low level upon the occurrence of a CH05 underflow. This process generates a U-phase PWM waveform, which is output to TOPnU.
- (6) TAUDnO11 becomes low level at the rising edge of TIN11, and INT11 is generated and TAUDnO11 becomes high level upon the occurrence of a CH11 underflow. This process generates a UB-phase PWM waveform, which is output to TOPnUB.

A similar process occurs for V phase/VB phase and W phase/WB phase.

Note 1. Select the count clock signal of the same clock for TAUDn.

Note 2. Set both edges (rising and falling) as the valid edge of TIN11 of TAUDn to be detected.

Details of this function when setting a clear timing longer than the carrier period are described below using V phase/VB phase as an example.

The following figure shows the timing diagram.

Figure 29.8 Clear Timing Value > Carrier Period Value (V phase/VB phase)

Setting a clear timing longer than the carrier period allows the waveform output to be extended over the carrier period.

An operation example of one-phase PWM output (V phase/VB phase) is shown below. The operation flow from timer operation start to one-phase PWM output by one-phase PWM output function, refer to the description for one-phase PWM output with dead time (U phase/UB phase).

When the value set in CH07 is larger than the value set in CH02 (**Figure 29.8 (1)**), underflow of the carrier period timer is generated before generation of V phase clear timing signal (INT07), and the value is reloaded (**Figure 29.8 (2)**).

As a result, the V phase clear timing signal (INT07) that should be generated is not generated, and instead the V phase set timing signal (INT06) is generated again (**Figure 29.8 (3)**).

At this time, the PWM waveform is not affected because V phase set timing signal is ignored in the PIC circuit (**Figure 29.8 (4)**). Therefore, the PWM waveform is output extended over the carrier period (**Figure 29.8 (5)**)

The following figure shows the timing diagram of three-phase PWM output with the dead time.

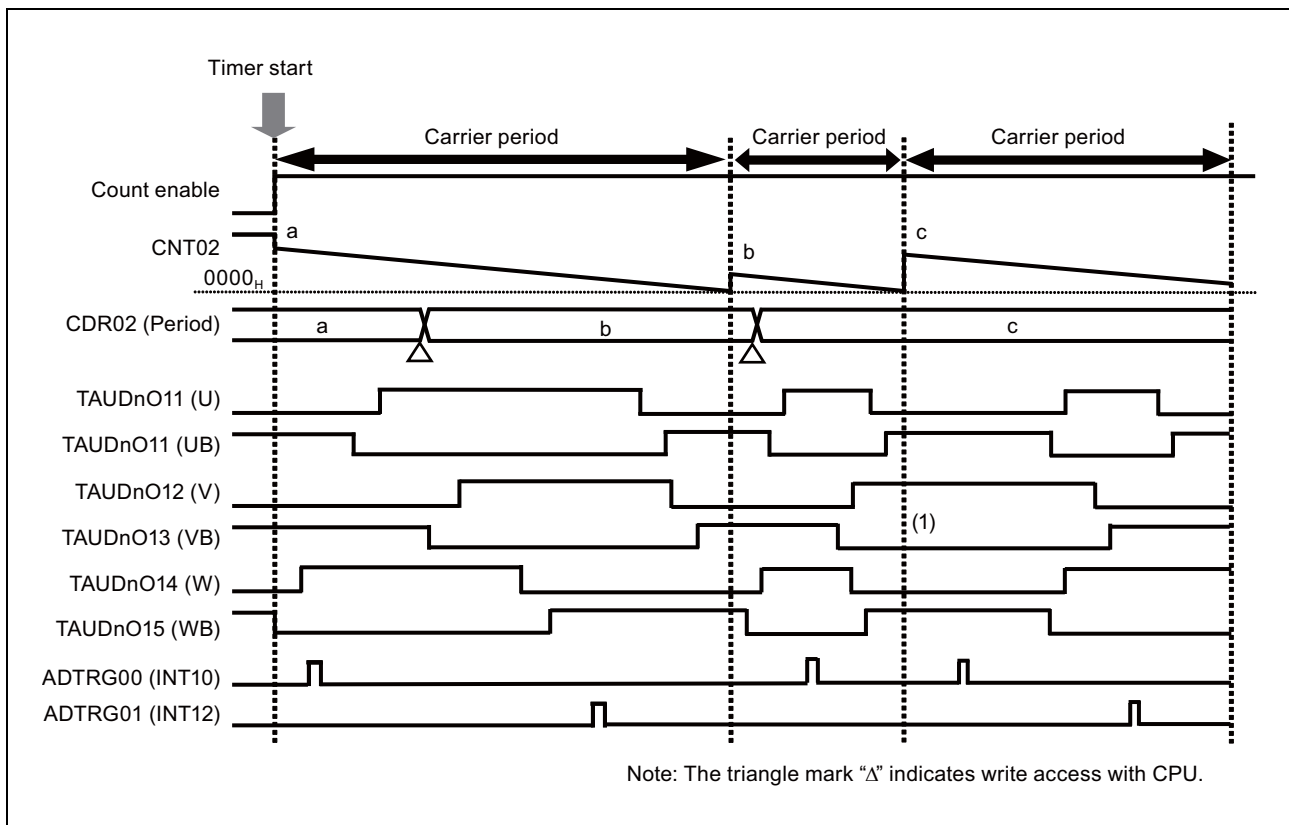

Figure 29.9 Timing Diagram of Three-Phase PWM Output with Dead Time

(5) Flow Chart

The following flow chart shows the PMW output function with the dead time.

29.2.3.3 High Accuracy Triangle Wave PWM Output Function with Dead Time

(1) Overview

This function generates triangle wave PWM output with dead time from one-phase to three-phases. Compared to the triangle wave PWM output function with dead time of TAUDn, this function enables a control of the variable dead time range, where duty cycle is close to 100% and 0%.

The TAUDn channels used in this function and the numbers of channels are listed in the following table.

High Accuracy Triangle Wave PWM Output with Dead Time	Number of TAUDn Channels
One-phase PWM output (U phase/UB phase)	5 channels (master channel: 1, slave channel: 4)
Two-phase PWM output (U phase/UB phase, V phase/VB phase)	9 channels (master channel: 1, slave channel: 8)
Three-phase PWM output (U phase/UB phase, V phase/VB phase, W phase/WB phase)	13 channels (master channel: 1, slave channel: 12)

Note: Above are examples of PWM output combinations.

Usages of each TAUDn channel are listed in the following table. CH2 is used as the master channel of CH3 to 9.

CHm is used as the master channel of CHm+1 (m = 10, 12, 14).

TAUDn Channel	U phase/ UB phase	V phase/ VB phase	W phase/ WB phase	Usage
CH0	—	—	—	Not used
CH1	—	—	—	Not used
CH2	√	√	√	Carrier period (common to each phase)
CH3	—	—	—	Not used
CH4	√	—	—	Triangle PWM output with dead time (U phase/UB phase)
CH5	√	—	—	
CH6	—	√	—	Triangle PWM output with dead time (V phase/VB phase)
CH7	—	√	—	
CH8	—	—	√	Triangle PWM output with dead time (W phase/WB phase)
CH9	—	—	√	
CH10	√	—	—	Reduced dead time pulse (U phase/UB phase)
CH11	√	—	—	
CH12	—	√	—	Reduced dead time pulse (V phase/VB phase)
CH13	—	√	—	
CH14	—	—	√	Reduced dead time pulse (W phase/WB phase)
CH15	—	—	√	

Note: √: Used; —: Not used

(2) Configuration

The high accuracy triangle wave PWM output function with the dead time is realized by using the triangle wave PWM output function/one-shot pulse output function of TAUDn and PIC1A in combination. The following figure shows the block diagram of the high accuracy triangle wave PWM output function with the dead time.

Figure 29.10 Block Diagram of High Accuracy Triangle Wave Three-Phase PWM Output With Dead Time

The configuration of this function is described below using the PWM output of U phase/UB phase as an example.

- [PIC1A_TAUD input selector]
TOUT02 is selected and output to TIN10.
- [TAUDn] One-shot pulse output function
CH10 and CH11 are used in combination. The delay value and the pulse width are set to CDR10 and CDR11, respectively, and the one-shot pulse output signal (TOUT11) is generated.
- [TAUDn] Triangle wave PWM output function with dead time
CH02, CH04, and CH05 are used in combination. The period, duty, and dead time are set to CDR02, CDR04, and CDR05, respectively, and a triangle wave PWM output signal with dead time (TOUT04 and TOUT05) is generated.
- [PIC1A_signal generator]
The reduced dead time pulses (UO1 and UO2) are generated at PFN001 from the one-shot pulse output signal.
UO1 and UO2 are synthesized with TOUT04 and TOUT05 at FN00 and FN01, respectively, a dead time variable range pulse is added, and TOPnU (U phase PWM signal) and TOPnUB (UB phase PWM signal) are generated.

A similar process occurs for V phase/VB phase and W phase/WB phase.

(3) Registers

The following figure shows the block diagram of PIC1A.

Figure 29.11 Block Diagram of PIC1A

The values of PIC1A registers used in this function are as follows.

- (1) PIC1A_TAUD input selector (U phase/ UB phase)
 The values to output TOUT02 as TIN10 (common to active high/low)
 $PIC1AREG2n0[18] = 1_B$
 $PIC1AREG2n2[17:16] = 10_B$
 $PIC1ATAUDnSEL[21:20] = 00_B$
- (2) PIC1A_TAUD input selector (V phase/ VB phase)
 The values to output TOUT02 as TIN12 (common to active high/low)
 $PIC1AREG2n0[18] = 1_B$
 $PIC1AREG2n2[21:20] = 10_B$
 $PIC1ATAUDnSEL[25:24] = 00_B$
- (3) PIC1A_TAUD input selector (W phase/ WB phase)
 The values to output TOUT02 as TIN14 (common to active high/low)
 $PIC1AREG2n0[18] = 1_B$
 $PIC1AREG2n2[25:24] = 10_B$
 $PIC1ATAUDnSEL[29:28] = 00_B$
- (4) PIC1A_ signal generator (U phase/ UB phase)
 The values to output one-phase PWM (active high/low) from TAUDnO10 and TAUDnO11
 $PIC1AREG2n1[19:16] = 1010_B$ (active high), 1111_B (active low)
 $PIC1AREG2n3 [06:04] = 100_B$ (active high), 101_B (active low)
 $PIC1AREG2n3[02:00] = 100_B$ (active high), 101_B (active low)
- (5) PIC1A_ signal generator (V phase/ VB phase)
 The values to output one-phase PWM (active high/low) from TAUDnO12 and TAUDnO13
 $PIC1AREG2n1[23:20] = 1010_B$ (active high), 1111_B (active low)
 $PIC1AREG2n3 [14:12] = 100_B$ (active high), 101_B (active low)
 $PIC1AREG2n3[10:08] = 100_B$ (active high), 101_B (active low)
- (6) PIC1A_ signal generator (W phase/ WB phase)
 The values to output one-phase PWM (active high/low) from TAUDnO14 and TAUDnO15
 $PIC1AREG2n1[27:24] = 1010_B$ (active high), 1111_B (active low)
 $PIC1AREG2n3 [22:20] = 100_B$ (active high), 101_B (active low)
 $PIC1AREG2n3[18:16] = 100_B$ (active high), 101_B (active low)

(4) Function

Details of this function are described using U phase/UB phase as an example. The function with V phase/VB phase and W phase/WB phase are operated under the same logic as that of U phase/UB phase with different input signals and register settings.

- U phase combination circuit (PFN001)
This circuit generates reduced dead time pulses*¹ (FN00A and FN01A) that are used to insert the pulse generated by the one-shot pulse output function into the triangle wave PWM generated by the triangle wave PWM output function with the dead time. For the block diagram, see **Figure 29.1, Block Diagram of PFN001**.

Note 1. Reduced dead time pulses are the pseudo pulses that are inserted into the PWM output provided by the triangle wave PWM output function with dead time of TAUDn and that are modeled on the dead time pulses that are generated in the range where duty cycle is close to 100% or 0% in PWM output in HT-PWM mode of TSG3n.

- Logical operation circuits (FN0i) (i = 0, 1)
This circuit synthesizes the triangle wave PWM output (TOUT04 and TOUT05) from the triangle wave PWM output function with the dead time and the outputs from the combinational circuit PFN001 (UO0 and UO1) to generate PWM with variable dead time range pulse inserted. The synthesizing logic of this circuit is selected with PIC1AREG2n3k (k = 00 to 02, 04 to 06). For the block diagram, see **Figure 29.2, Block Diagram of FN00**.

Details of this function are described using high accuracy triangle wave PWM output function (U phase/UB phase) as an example.

The following figure shows the timing diagram when U phase duty cycle = 0% and UB phase duty cycle = 100% at active high.

Figure 29.12 Timing Diagram of High Accuracy Triangle Wave PWM (U phase duty cycle = 0%, UB phase duty cycle = 100%) Output with Dead Time (Active High)

- (1) Using the simultaneous start trigger function, the timers to be used are started simultaneously.
- (2) TOUT04 and TOUT05 are generated by the triangle wave PWM output function with dead time.
- (3) A 0% duty cycle value is set in CDR04 for U phase output.
- (4) The setting described in step (3) sets the TOUT04 output to the inactive level and the TOUT05 output to the active level.
- (5) To generate the variable dead time range pulse, a value for the reduced dead time pulse width is set in CDR11 when a 0% duty cycle value for U phase output is set in step (3).
- (6) CH10 count starts with the effective edge of TOUT02 and INT10 is generated when the counter underflows. CH11 count starts by generation of INT10 and the reduced dead time pulse (TOUT11) of the width set in CDR11 is output.
- (7) The reduced dead time pulse (UO1 and UO2) are generated from TOUT02 and TOUT11 in PFN001.
- (8) UO1 and UO2 are synthesized with TOUT04 and TOUT05 in FN00 and FN01, and are output as TOPnU (U phase PWM signal) and TOPnUB (UB phase PWM signal).

CAUTION

Since the reduced dead time pulses are sawtooth waves, they expand and contract on one side, unlike the triangle wave pulses, which expand and contract on both sides. Since one-side expansion and contraction applies to the reduced dead time pulses, a one-phase PWM output period in the variable dead time range is longer by half the width of the inserted reduced dead time pulse.

The following figure shows the timing diagram when U phase duty cycle = 100% and UB phase duty cycle = 0% at active high.

Figure 29.13 Timing Diagram of High Accuracy Triangle Wave PWM (U phase duty cycle = 100%, UB phase duty cycle = 0%) Output with Dead Time (Active High)

- (1) Using the simultaneous start trigger function, the timers to be used are started simultaneously.
- (2) TOUT04 and TOUT05 are generated by the triangle wave PWM output function with dead time.
- (3) A 100% duty cycle value ($CDR4 = 0000_H$) is set in CDR04 for U phase output.
- (4) TOUT04 outputs the active level and TOUT05 outputs the inactive level.
- (5) A value for the reduced dead time pulse width is set in CDR11 one period after setting 100% duty cycle for U phase output.
- (6) CH10 count starts with the effective edge of TOUT02 and INT10 is generated when the counter underflows. CH11 count starts by generation of INT10 and the reduced dead time pulse (TOUT11) of the width set in CDR11 is output.
- (7) The reduced dead time pulse (UO1 and UO2) are generated from TOUT02 and TOUT11 in PFN001.
- (8) UO1 and UO2 are synthesized with TOUT04 and TOUT05 in FN00 and FN01, and are output as TOPnU (U phase PWM signal) and TOPnUB (UB phase PWM signal).

CAUTION

As shown in Figure 29.14, if a value is set for the variable dead time range pulse width in CDR11 at the same time as a 100% duty cycle value is set for U phase output in CDR04, the variable dead time range pulse affects the last PWM output from TOUT04 (indicated by Figure 29.14, (1)) by the amount of time indicated by Figure 29.14, (2). CDR11 must be set one period after setting CDR04.

Figure 29.14 Timing Diagram of Variable Dead Time Range Pulse Affecting Triangle Wave PWM Output with Dead Time

The following figure shows the timing diagram when U phase duty cycle = 100% and UB phase duty cycle = 0% at active low.

Figure 29.15 Timing Diagram of High Accuracy Triangle Wave PWM (U phase duty cycle = 100%, UB phase duty cycle = 0%) Output with Dead Time (Active Low)

The operation flow from timer operation start to triangle wave PWM output with dead time is same as **Figure 29.13, Timing Diagram of High Accuracy Triangle Wave PWM (U phase duty cycle = 100%, UB phase duty cycle = 0%) Output with Dead Time (Active High)**, with the difference of the PWM output signal from TOUT04 and TOUT05 are active low.

CAUTION

Set each CDR for the one-shot pulse output function so that the following condition is satisfied.

$$\text{CDR05} \geq (\text{CDR10} + \text{CDR11})$$

If the condition above is not satisfied, the output waveform may be influenced. To minimize the influence, satisfy the condition above, and also fix the value of CDR11 to 0000_H until the reduced dead time pulse is required.

Set the both edges to be detected of TIN10 (TOUT02) as effective, and set TAUDnTOL11 to 1 (active low).

Select the count clock signal (CK0 to 3) of the same clock for TAUDn.

After high accuracy triangle wave PWM output with dead time is started, do not set the value of variable dead time pulse width at the same time as setting a 100% duty cycle value for U phase, V phase, and W phase.

(5) Flow Chart

The flow chart of this function is shown in the following figure.

29.2.3.4 Delay Pulse Output Function with Dead Time

(1) Overview

This function allows generation of PWM output with the dead time, that is, delayed as specified from the period timing using TAUDn.

With this function, PWM output can be reset in the next period unlike with the function described in **Section 29.2.3.2, PWM Output Function with Dead Time**.

The following table lists the number of channels used.

PWM Output with Dead Time	Number of TAUDn Channels
One-phase PWM output (U phase/UB phase)	5 channels (master channel: 1, slave channel: 4)
Two-phase PWM output (U phase/UB phase, V phase/VB phase)	9 channels (master channel: 1, slave channel: 8)
Three-phase PWM output (U phase/UB phase, V phase/VB phase, W phase/WB phase)	13 channels (master channel: 1, slave channel: 12)

Note: Above are examples of PWM output combinations.

Usages of each TAUDn channel are listed in the following table. CH2 is used as the master channel of CH3 to 9.

TAUDn Channel	U phase / UB phase	V phase / VB phase	W phase / WB phase	Usage
CH0	—	—	—	Not used
CH1	—	—	—	Not used
CH2	√	√	√	Carrier period (common to each phase)
CH3	√	√	√	Reserved
CH4	√	—	—	Delay pulse input (U phase/UB phase)
CH5	√	—	—	
CH6	—	√	—	Delay pulse input (V phase/VB phase)
CH7	—	√	—	
CH8	—	—	√	Delay pulse input (W phase/WB phase)
CH9	—	—	√	
CH10	√	—	—	U phase output (TOUT10)
CH11	√	—	—	UB phase output (TOUT11)
CH12	—	√	—	V phase output (TOUT12)
CH13	—	√	—	VB phase output (TOUT13)
CH14	—	—	√	W phase output (TOUT14)
CH15	—	—	√	WB phase output (TOUT15)

Note: √: Used; —: Not used

(2) Configuration

The delay pulse output function with the dead time is realized by using the delay pulse output function/one-phase PWM output function of TAUDn and PIC1A in combination. The following figure shows the block diagram of the delay pulse output function with the dead time.

Figure 29.16 Block Diagram of Delay Pulse Output Function with Dead Time

The configuration of this function is described as follows using the PWM output of U phase/UB phase as an example.

- [TAUDn] Delay pulse output function
CH02, CH04, and CH05 are used in combination. The period, delay value, and the pulse width are set to CDR02, CDR04, and CDR05, respectively, and the delay pulse output signal (TOUT05) is generated.
- [PIC1A_TAUD input selector]
TOUT05 is selected for output as TIN11.
- [TAUDn] One-phase PWM output function
CH10 and CH11 are used in combination. The dead time value is set to CDR11, dead time is inserted in the PWM signal to be input to TIN11, and TOUT10 (U phase PWM signal) and TOUT11 (UB phase PWM signal) are output.
- [PIC1A_signal selector]
TOUT10 and TOUT11 inputs are selected and output to TOPnU and TOPnUB pins, respectively.

A similar process occurs for V phase/VB phase and W phase/WB phase.

(3) Registers

A block diagram of PIC1A is shown in the following figure.

Figure 29.17 Block Diagram of PIC1A

The values of PIC1A registers used in this function are as follows.

U phase/ UB phase

The values to output TOUT05 as TIN11 (Figure 29.17, unit (1))

$$\text{PIC1AREG2n2}[19:18] = 10_{\text{B}}$$

$$\text{PIC1AREG2n2}[2] = 0_{\text{B}}$$

$$\text{PIC1ATAUDnSEL}[23:22] = 00_{\text{B}}$$

The values to output the TOUT10 and TOUT11 as TOPnU and TOPnUB, respectively (Figure 29.17, unit (4))

$$\text{PIC1AREG2n1}[19:16] = 0000_{\text{B}}$$

$$\text{PIC1AREG2n3}[2:0] = 000_{\text{B}}$$

$$\text{PIC1AREG2n3}[6:4] = 000_{\text{B}}$$

V phase/ VB phase

The values to output TOUT07 as TIN13 (**Figure 29.17**, unit (2))

$$\text{PIC1AREG2n2}[23:22] = 10_{\text{B}}$$

$$\text{PIC1AREG2n2}[3] = 0_{\text{B}}$$

$$\text{PIC1ATAUDnSEL}[27:26] = 00_{\text{B}}$$

The values to output TOUT12 and TOUT13 as TOPnV and TOPnVB, respectively (**Figure 29.17**, unit (5))

$$\text{PIC1AREG2n1}[23:20] = 0000_{\text{B}}$$

$$\text{PIC1AREG2n3}[10:8] = 000_{\text{B}}$$

$$\text{PIC1AREG2n3}[14:12] = 000_{\text{B}}$$

W phase/ WB phase

The values to output TOUT09 as TIN15 (**Figure 29.17**, unit (3))

$$\text{PIC1AREG2n2}[27:26] = 10_{\text{B}}$$

$$\text{PIC1AREG2n2}[4] = 0_{\text{B}}$$

$$\text{PIC1ATAUDnSEL}[31:30] = 00_{\text{B}}$$

The values to output TOUT14 and TOUT15 as TOPnW and TOPnWB, respectively (**Figure 29.17**, unit (6))

$$\text{PIC1AREG2n1}[27:24] = 0000_{\text{B}}$$

$$\text{PIC1AREG2n3}[18:16] = 000_{\text{B}}$$

$$\text{PIC1AREG2n3}[22:20] = 000_{\text{B}}$$

(4) Function

Details of this function are described using the delay pulse output with dead time (U phase/UB phase) as an example.

The following figure shows the timing diagram.

Figure 29.18 Timing Diagram of Delay Pulse Output with Dead Time (U phase/ UB phase)

- (1) Using the simultaneous start trigger function, the timers to be used are started simultaneously.
- (2) For CH04, the set value is reloaded to CNT04 upon the occurrence of a CH02 underflow.
- (3) INT04 is generated upon the occurrence of a CH04 underflow.
- (4) The set value is reloaded to CDR05 upon the generation of INT04, causing CH05 to start operating.
- (5) When CH05 starts operating, INT05 is generated and the TOUT05 output level changes to the active level.
- (6) Upon CH05 underflow, INT05 is generated again and the TOUT05 output level changes to the inactive level. TOUT05 is supplied to TIN11.
- (7) The U phase PWM signal (TOUT10) and UB phase PWM signal (TOUT11) with the dead time are generated and output at the detection of the TIN11 edge, and output to TOPnU and TOPnUB.

A similar process occurs for V phase/VB phase and W phase/WB phase.

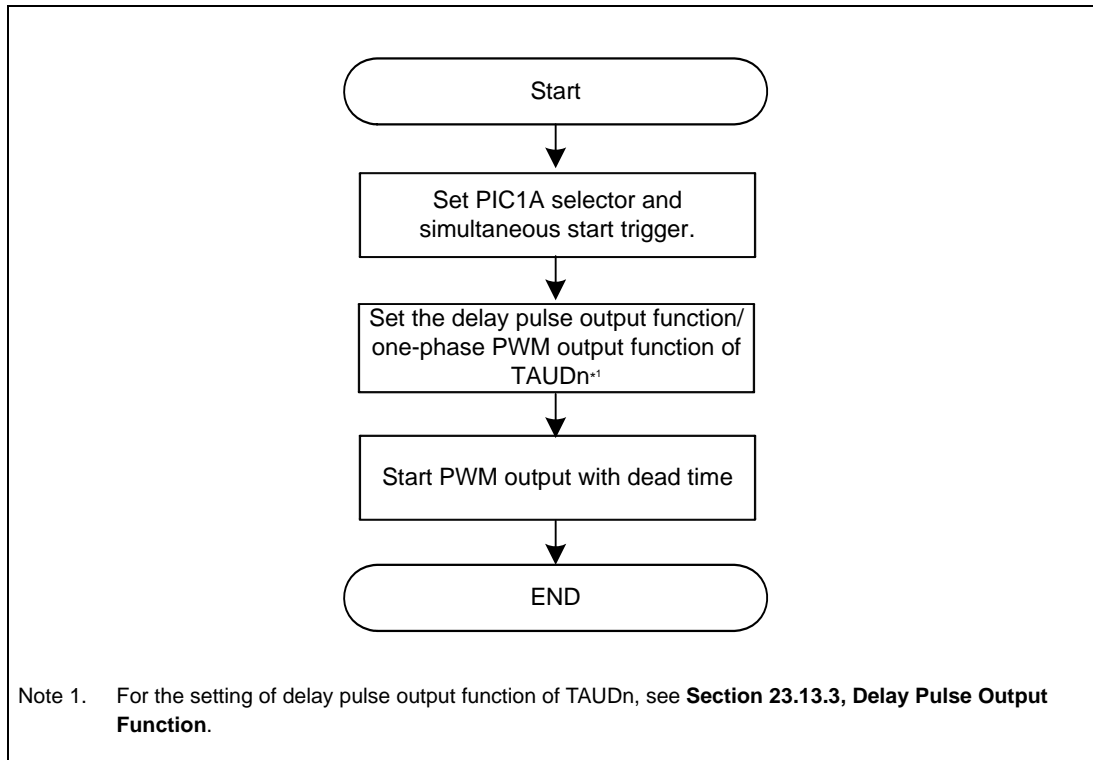

CAUTION

Do not set the delay value which extends over carrier period.

Select the count clock signal of the same clock for TAUDn.

(5) Flow Chart

The following flow chart shows the PMW output function with the dead time.

29.2.3.5 Trigger Pulse Interval Measurement Function

(1) Overview

This function allows measurement of trigger periods by inputting the trigger signal output from ENCA_n to TAUJ₀ and TAUD_n.

The following table lists the ENCA_n interrupt trigger signals to be measured by each timer and channel.

Timer	Channel	Interrupt Signal to be Measured
TAUJ0	CH0	ENCAT0IEC
	CH1	ENCAT0IEC
	CH2	ENCAT1IEC
	CH3	ENCAT1IEC
TAUD0	CH0	ENCAT0EQ0 or ENCAT0EQ1
	CH1	ENCAT0EQ1
	CH2	ENCAT0EQ0
TAUD1	CH0	ENCAT0EQ0 or ENCAT0EQ1
	CH1	ENCAT0EQ1
	CH2	ENCAT0EQ0

(2) Configuration

The trigger and pulse width measurement function is realized by using the TINm input pulse interval measurement functions of TAUJ0 and TAUDn, and PIC1A in combination. The following figure shows the block diagram of the trigger and pulse width measurement function.

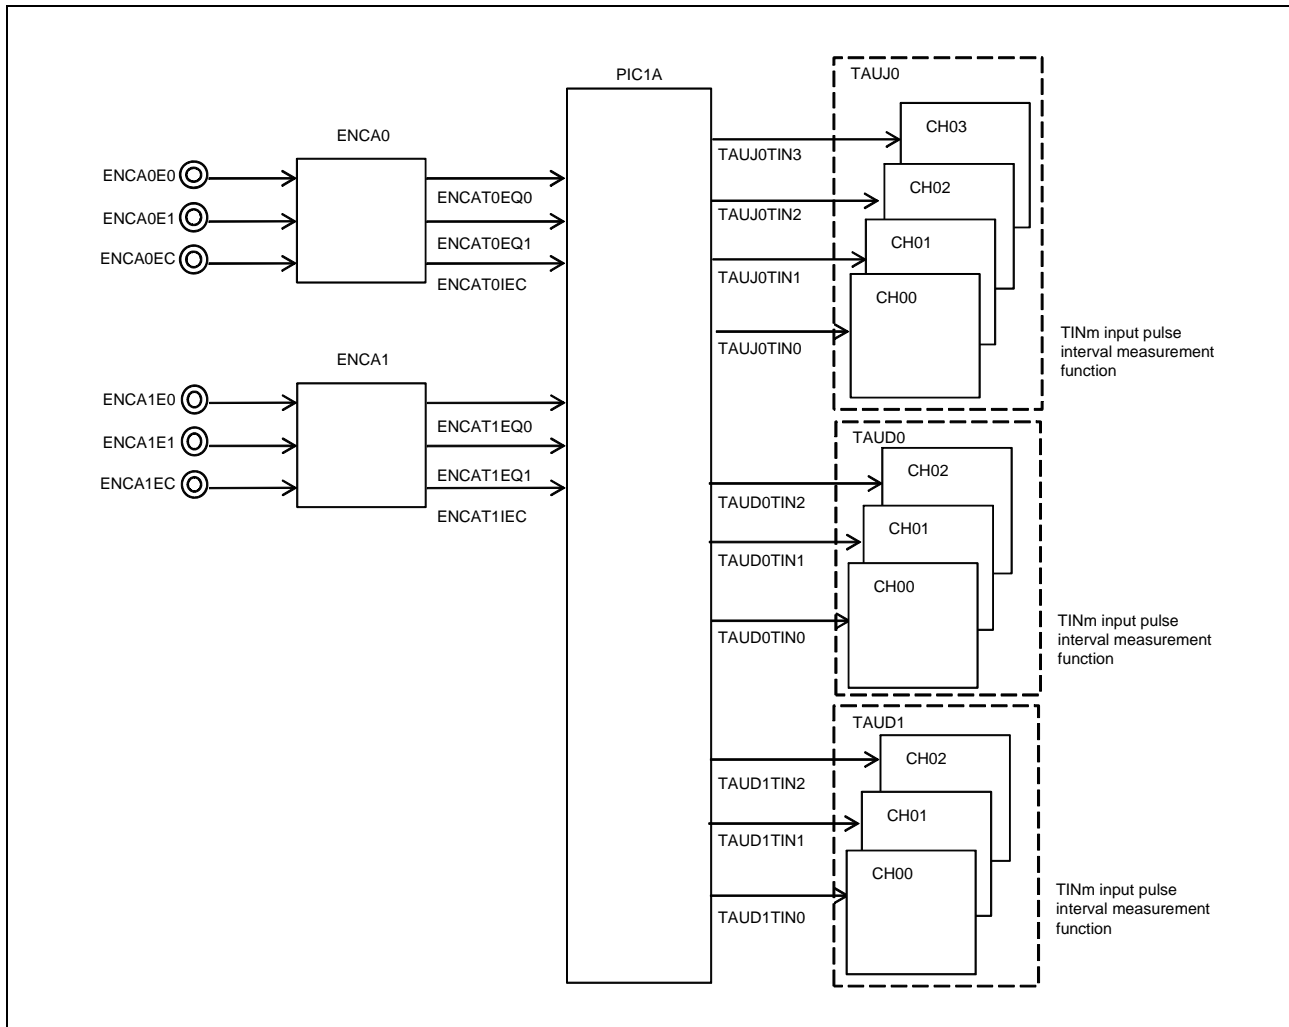

Figure 29.19 Block Diagram of Trigger and Pulse Width Measurement Function

The configuration of this function is described below using TAUJ0 CH0 as an example.

- [ENCA0]
ENCAT0IEC interrupt signal is generated each time ENCA0 timer counter is cleared by input from ENCA0EC pin.
- [PIC1A] Latch and toggle output (DT) circuit
ENCA0IEC interrupt trigger signal selected by the DT circuit is converted into a level-sensitive toggle signal and output to TAUJ0TIN0.
- [TAUJ0] TINm input pulse interval measurement function
TAUJ0 CH0 is used. TAUJ0CNT0 is captured each time input signal is toggled. The counter is cleared and restarted.

Similar configuration is applied for trigger and pulse width measurement of TAUD0 and TAUD1.

(3) Registers

Block diagram of PIC1A is shown in the following figure.

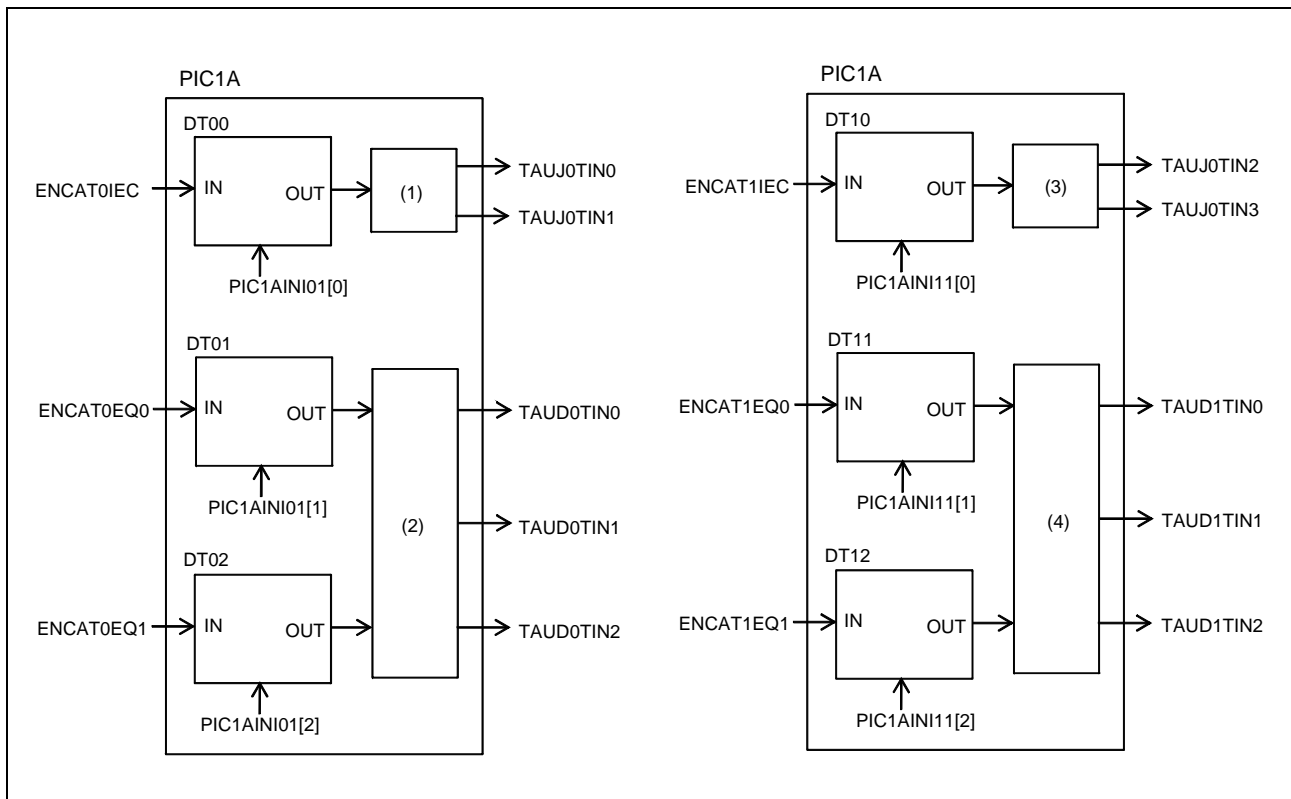

Figure 29.20 Block Diagram of PIC1A

The values of PIC1A registers used in this function are as follows.

ENCA0

- ENCAT0EC trigger and pulse width measurement
The register values to select the timer which performs ENCAT0EC trigger and pulse width measurement. (**Figure 29.20**, unit (1))

Register Value		TAUJ0.TIN00	TAUJ0.TIN01
PIC1AREG31			
1	0		
0	0	Not selected.	
0	1	ENCAT0IEC	—
1	0	—	ENCAT0IEC
1	1	ENCAT0IEC	ENCAT0IEC

Note: Write 0 (value after reset) to PIC1AREG30[22,17:16]

- ENCAT0EQ0 and ENCAT0EQ1 trigger and pulse width measurement

The register values to select the timer which performs ENCAT0EQ0 and ENCAT0EQ1 trigger and pulse width measurement. (Figure 29.20, unit (2))

Register Value								TAUD0.TIN00	TAUD0.TIN01	TAUD0.TIN02
PIC1AREG31										
13	12	11	10	9	8	7	6			
0	0	0	0	0	0	0	0	Not selected.		
0	0	1	1	0	0	0	1	ENCAT0EQ0	ENCAT0EQ1	—
0	1	0	0	0	0	0	1	ENCAT0EQ1	—	ENCAT0EQ0
0	1	1	0	0	0	0	1	ENCAT0EQ1	ENCAT0EQ1	ENCAT0EQ0
0	1	1	1	0	0	0	1	ENCAT0EQ0	ENCAT0EQ1	ENCAT0EQ0

Note: Do not set the values other than those listed above for this function. Write 0 (value after reset) to PIC1ATAUD0SEL[5:0] and PIC1AREG30[22,17:16,1:0].

- Enable initialization of the DT02 to DT00 circuits

The register values to enable initialization of the DT02 to DT00 circuits.

PIC1AINI01[2:0] = 111_B (initialized)

ENCA1

ENCAT1EC trigger and pulse width measurement

The register values to select the timer which performs ENCAT1EC trigger and pulse width measurement. (Figure 29.20, unit (3))

Register Value				TAUJ0.TIN02	TAUJ0.TIN03
PIC1AREG31					
4		3			
0		0		Not selected.	
0		1		ENCAT1IEC	—
1		0		—	ENCAT1IEC
1		1		ENCAT1IEC	ENCAT1IEC

Note: Write 0 (value after reset) to PIC1AREG30[20:19,11:10]

- ENCAT1EQ0 and ENCAT1EQ1 trigger and pulse width measurement

The register values to select the timer which performs ENCAT1EQ0 and ENCAT1EQ1 trigger and pulse width measurement. (Figure 29.20, unit (4))

Register Value								TAUD1.TIN00	TAUD1.TIN01	TAUD1.TIN02
PIC1AREG31										
22	21	20	19	18	17	16	15			
0	0	0	0	0	0	0	0	Not selected.		
0	0	1	1	0	0	0	1	ENCAT1EQ0	ENCAT1EQ1	—
0	1	0	0	0	0	0	1	ENCAT1EQ1	—	ENCAT1EQ0
0	1	1	0	0	0	0	1	ENCAT1EQ1	ENCAT1EQ1	ENCAT1EQ0
0	1	1	1	0	0	0	1	ENCAT1EQ0	ENCAT1EQ1	ENCAT1EQ0

Note: Do not set the values other than those listed above for this function. Write 0 (value after reset) to PIC1ATAUD1SEL[5:0] and PIC1AREG30[20:19,9:6].

- Enable initialization of DT12 to DT10 circuits

The register values to enable initialization of the DT12 to DT10 circuits.

PIC1AINI11[2:0] = 111_B (initialized)

(4) Function

Details of this function are described here.

The following figure shows the timing diagram.

Figure 29.21 Timing Diagram of Trigger and Pulse Width Measurement

- (1) Using the simultaneous start trigger function, the timers to be used are started simultaneously.
- (2) The interrupt trigger signal output from ENCA_n is converted to the level-sensitive toggle signal by the DT circuit and is output to TIN_m of TAUJ₀ and TIN_m of TAUD_n.
- (3) The CNT_m value is captured into CDR_m on the TIN_m toggle timing and the counter is cleared at the same time.
- (4) When an overflow occurs, the greatest count value (FFFF_H for TAUD_n and FFFF FFFF_H for TAUJ₀) is captured and the counter is cleared at the same time. The CNT_m value is not captured on the first trigger after the overflow. (When TAUD_nCMOR_m.TAUD_nCOS[1] = 1_B)

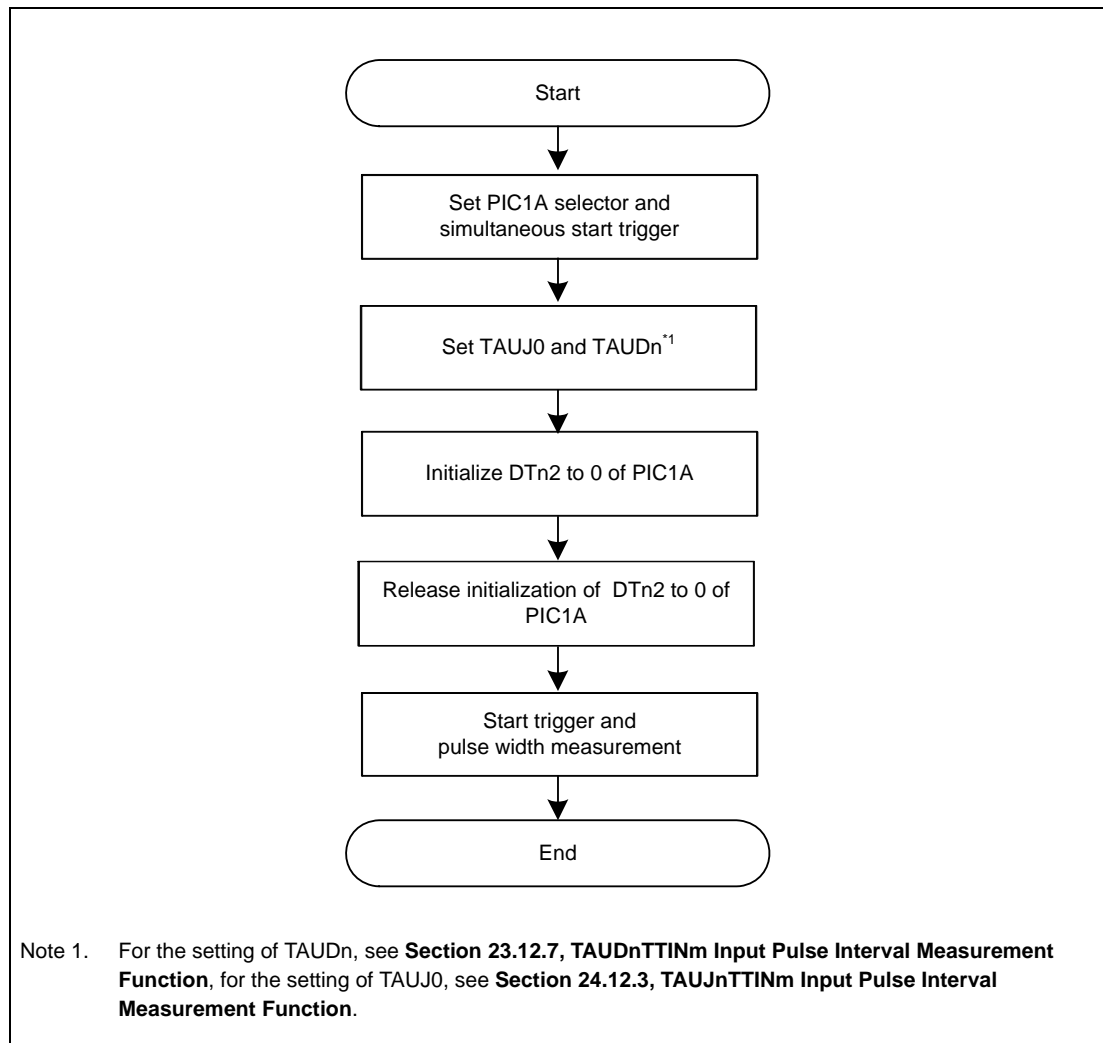

CAUTION

Operation at an overflow varies depending on the setting of TAUJ and TAUD. For details of the TAUJ setting, see Section 24.12.3, TAUJ_nTTIN_m Input Pulse Interval Measurement Function, see Section 23.12.7, TAUD_nTTIN_m Input Pulse Interval Measurement Function. In this function, set both edges (rising and falling) as the valid edge of TIN_m of TAUJ₀ and TAUD_n to be detected.

(5) Flow Chart

The following figure shows the setting flow of this function.

These settings can be performed while ENCA_n is operating as well as while waiting for the simultaneous start trigger.

The ENCA_n settings to use this function are as follows.

ENCA_nCTL[15:0] = xx00 0000 x00x xxxx_B

ENCA_nIOC0[7:0] = 0000 0000_B

ENCA_nIOC1[7:0] = (set any value)

“x” can be set arbitrarily. For the registers specifications, see **Section 28, Encoder Timer (ENCA)**.

29.2.3.6 Encoder Capture Trigger Select Function

(1) Overview

This function selects either ADcGnTRGm (ADcGn conversion start trigger signal m), TAUDnTINTm (TAUDn-CHm interrupt signal), or ENcAnI1 (ENcAn external pin input signal) as the ENcAn capture trigger signal.

(2) Configuration

The encoder capture trigger select function is realized by using ADcGnTRGm (ADcGn conversion start trigger signal m), TAUDnTINTm (TAUDn CHm interrupt signal), ENcAnI1 (ENcAn external pin input 1 signal), and PIC1A in combination.

Block diagram of this function is shown in the following figure.

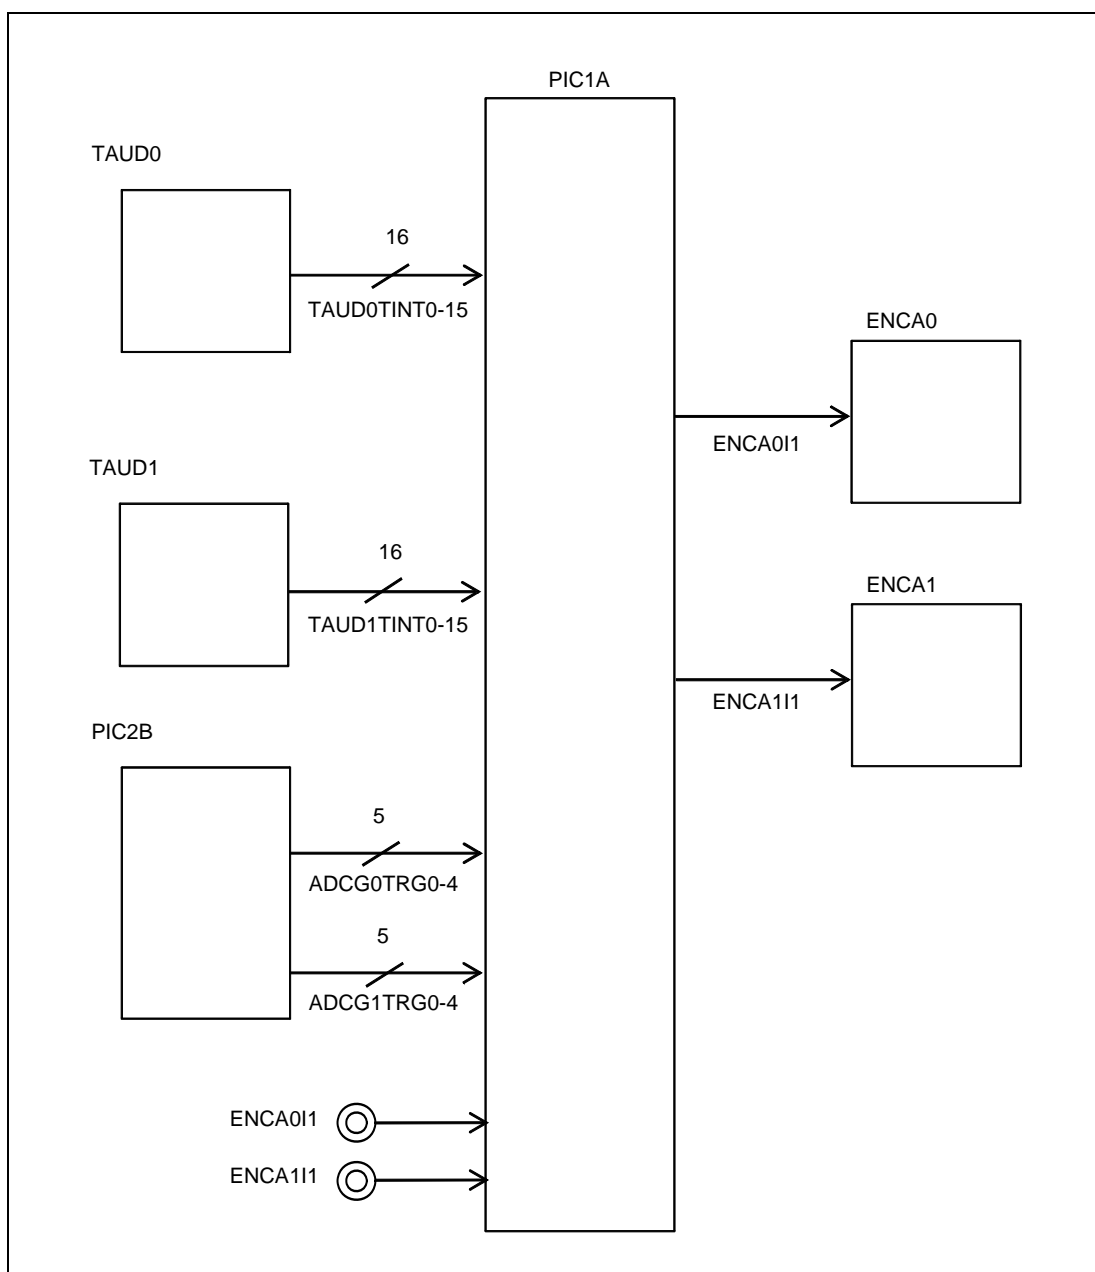

Figure 29.22 Block Diagram of Encoder Capture Trigger Select Function

An example of selecting CH0 of TAUD0 as a capture trigger input of ENCA0 is described below.

$$\text{PIC1AENCSEL400}[7] = 1_B$$

$$\text{PIC1AENCSEL400}[3:0] = 0000_B$$

$$\text{PIC1AREG30}[18] = 1_B$$

$$\text{PIC1AREG30}[5:2] = 0000_B$$

(3) Registers

Block diagram of PIC1A is shown in the following figure.

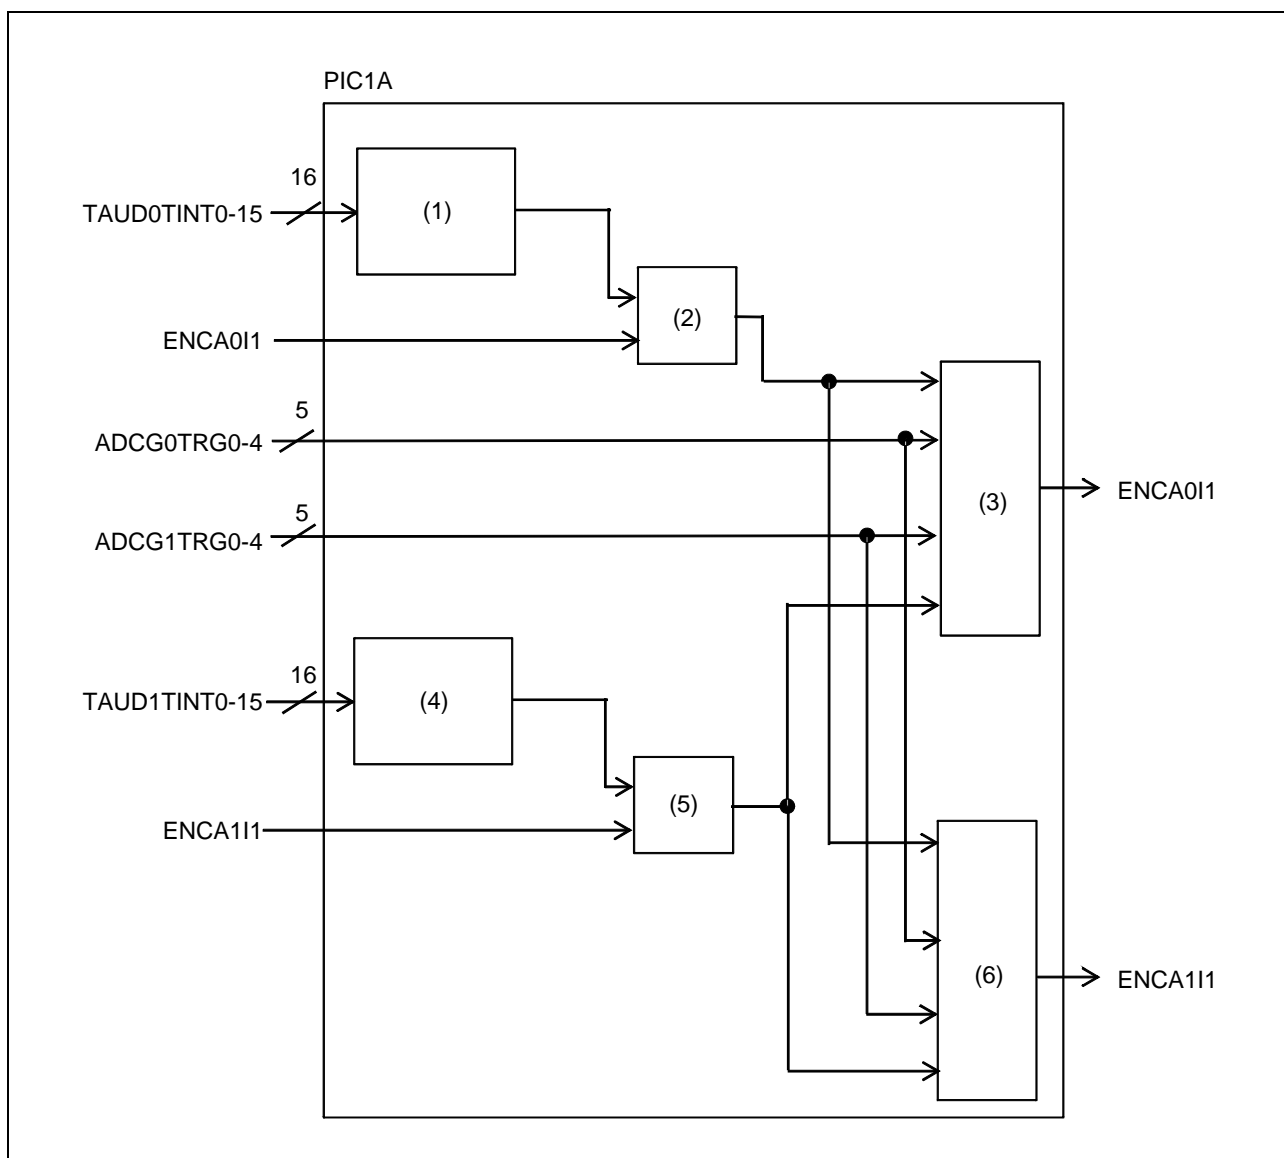

Figure 29.23 Block Diagram of PIC1A

The values of PIC1A registers used in this function are as follows.

ENCA0

(1) TAUD0TINTm selection

The register values to select TAUD0TINTm. Set 1 to the PIC1AENCSEL400[7] to select TAUD0TINTm.

Register Values					Output of (1)
PIC1AENCSEL400					
7	3	2	1	0	
1	0	0	0	0	INTTAUD0I0
1	0	0	0	1	INTTAUD0I1
1	0	0	1	0	INTTAUD0I2
1	0	0	1	1	INTTAUD0I3
1	0	1	0	0	INTTAUD0I4
1	0	1	0	1	INTTAUD0I5
1	0	1	1	0	INTTAUD0I6
1	0	1	1	1	INTTAUD0I7
1	1	0	0	0	INTTAUD0I8
1	1	0	0	1	INTTAUD0I9
1	1	0	1	0	INTTAUD0I10
1	1	0	1	1	INTTAUD0I11
1	1	1	0	0	INTTAUD0I12
1	1	1	0	1	INTTAUD0I13
1	1	1	1	0	INTTAUD0I14
1	1	1	1	1	INTTAUD0I15

(2) TAUD0TINTm and ENCA0I1 pins selection

The register values to select either the output (1) or ENCA0I1.

Register Values		Output (2)
PIC1AREG30		
18		
1		Output (1)
0		ENCA0I1

(3) ENCA0I1 selection

The register values to select any of the output (2), output (5), ADCG0TRG0-4, or ADCG1TRG0-4.

Register Values				ENCA0I1
PIC1AREG30				
5	4	3	2	
0	0	0	0	Output (2)
0	0	0	1	Output (5)
0	0	1	0	ADCG0TRG4
0	0	1	1	ADCG0TRG3
0	1	0	0	ADCG0TRG2
0	1	0	1	ADCG0TRG1
0	1	1	0	ADCG0TRG0
0	1	1	1	ADCG1TRG4
1	0	0	0	ADCG1TRG3
1	0	0	1	ADCG1TRG2
1	0	1	0	ADCG1TRG1
1	0	1	1	ADCG1TRG0

Note: Do not set the values other than those listed above for this function.

ENCA1

(4) TAUD1TINTm selection

The register values to select TAUD1TINTm. Set 1 to the PIC1AENCSEL410[7] to select TAUD1TINTm.

Register Values					Output (4)
PIC1AENCSEL410					
7	3	2	1	0	
1	0	0	0	0	INTTAUD110
1	0	0	0	1	INTTAUD111
1	0	0	1	0	INTTAUD112
1	0	0	1	1	INTTAUD113
1	0	1	0	0	INTTAUD114
1	0	1	0	1	INTTAUD115
1	0	1	1	0	INTTAUD116
1	0	1	1	1	INTTAUD117
1	1	0	0	0	INTTAUD118
1	1	0	0	1	INTTAUD119
1	1	0	1	0	INTTAUD1110
1	1	0	1	1	INTTAUD1111
1	1	1	0	0	INTTAUD1112
1	1	1	0	1	INTTAUD1113
1	1	1	1	0	INTTAUD1114
1	1	1	1	1	INTTAUD1115

(5) TAUD1TINTm and ENCA1I1 pins selection

The register values to select either the output (4) or ENCA1I1.

Register Values		Output (5)
PIC1AREG30		
21		
1		Output (4)
0		ENCA1I1

(6) ENCA1I1 selection

The register values to select any of the output (2), output (5), ADCG0TRG0-4, or ADCG1TRG0-4.

Register Values				ENCA1I1
PIC1AREG30				
15	14	13	12	
0	0	0	0	Output (5)
0	0	0	1	Output (2)
0	0	1	0	ADCG0TRG4
0	0	1	1	ADCG0TRG3
0	1	0	0	ADCG0TRG2
0	1	0	1	ADCG0TRG1
0	1	1	0	ADCG0TRG0
0	1	1	1	ADCG1TRG4
1	0	0	0	ADCG1TRG3
1	0	0	1	ADCG1TRG2
1	0	1	0	ADCG1TRG1
1	0	1	1	ADCG1TRG0

Note: Do not set the values other than those listed above for this function.

(4) Function

Function

Details of this function are described with an example of selecting TAUDnTINTm as a capture trigger signal.

The following figure shows the timing diagram.

Figure 29.24 Timing Diagram of Encoder Capture Trigger Select Function (TAUDnTINTm)

- (1) Using the simultaneous start trigger function, the timers to be used are started simultaneously.
- (2) On generation of an effective edge of TAUDnTINTm, ENCAAn captures ENCAAnCNT.

Do not select ENCAAn interrupt trigger signal (INTENCAAnI1) as the ADCGn trigger described in **Section 29.3.3.1, ADCGn Trigger Select Function**. If it is selected, the correct operation cannot be performed because the following loop occurs: ADCGnTRG1 generation → ENCAAn capture operation → INTENCAAnI1 generation by capture operation → ADCGnTRG1 generation.

The following figure shows the loop paths of PIC1A, PIC2B, and ENCA_n.

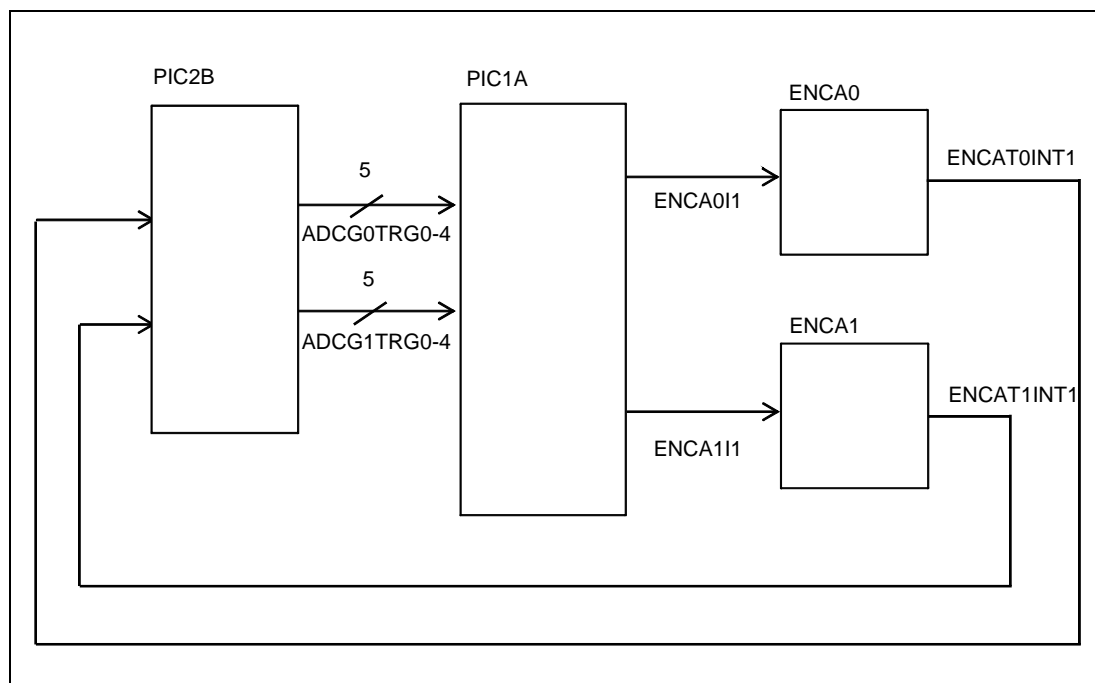

Figure 29.25 Timing Chart of Loop Paths of PIC1A, PIC2B, and ENCA_n

(5) Flow Chart

Select the encoder capture trigger before starting the encoder timer.

ENCA_n settings to use this function are as follows.

$$\text{ENCA}_n\text{CTL}[15:0] = 0000\ 001x\ 0\ 00x\ \text{xxxx}_B$$

$$\text{ENCA}_n\text{IOC0}[7:0] = 0000\ 01x_x_B$$

$$\text{ENCA}_n\text{IOC1}[7:0] = (\text{set any value})$$

“x” can be set arbitrarily. For the registers specifications, see **Section 28, Encoder Timer (ENCA)**.

29.2.3.7 Two-Phase Encoder Control Function (Control Method 1)

(1) Overview

This function allows switching of the output patterns of the motor control function (TSG3n) in 120-DC mode using the two-phase encoder control function (ENCA_n).

(2) Configuration

Switching of output pattern in 120-DC mode by encoder result is realized by using ENCA_n and TSG3n, and PIC1A in combination. The following figure describes the block diagram of two-phase encoder control function (control method 1).

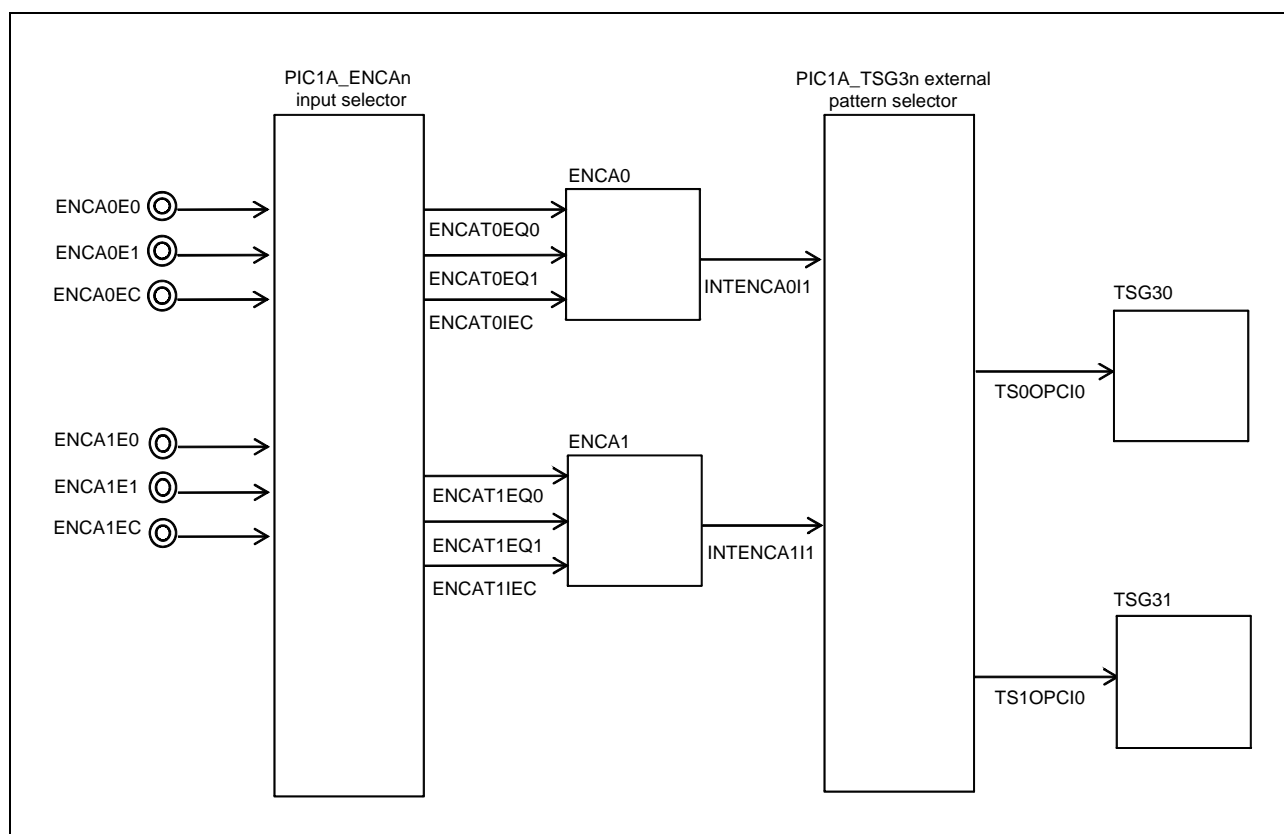

Figure 29.26 Block Diagram of Two-Phase Encoder Control Function (Control Method 1)

The configuration of two-phase encoder control function (control method 1) is described below.

- [PIC1A_ENCODn input selector]
ENCA_nE0, ENCA_nE1, and ENCA_nEC pin inputs are selected and output as ENCA_nEQ0, ENCA_nEQ1, and ENCA_nIEC.
- [ENCA_n]
INTENCA_nI1 is output by two-phase encoder processing.
- [PIC1A_TSG3n external pattern selector]
INTENCA_nI1 is selected and output to TS0OPCI0 or TS1OPCI0.
- [TSG3n]
Output pattern in 120-DC mode is switched by TSG3nOPCI0.

(3) Registers

The values of PIC1A registers used in this function are as follows.

PIC1A_ENCA_n input selector

The register values to output ENCA_n pin inputs (ENCA_nE0, ENCA_nE1, and ENCA_nEC) as ENCA_nEQ0, ENCA_nEQ1, and ENCA_nIEC.

$$\text{PIC1AREG30}[22] = 0_{\text{B}}$$

$$\text{PIC1AREG30}[20:19] = 00_{\text{B}}$$

$$\text{PIC1AREG30}[17:16] = 00_{\text{B}}$$

$$\text{PIC1AREG30}[11:6] = 000000_{\text{B}}$$

$$\text{PIC1AREG30}[1:0] = 00_{\text{B}}$$

PIC1A_TSG3_n external pattern selection

The register values to select the interrupt signal to be input as TSG30 external pattern.

Register Values				TS0OPCI0
PIC1AREG50				
10	8	6	5	
X	0	0	1	INTENCA011
0	X	1	0	INTENCA111

Note: Do not set the values other than those listed above for this function.

The register values to select the interrupt signal to be input as TSG31 external pattern.

Register Values				TS1OPCI0
PIC1AREG51				
10	8	6	5	
X	0	0	1	INTENCA011
0	X	1	0	INTENCA111

Note: Do not set the values other than those listed above for this function.

(4) Function

Details of this function are described using the two-phase encoder control function (method 1) at up count (normal rotation) as an example.

The following figure shows the timing diagram.

Figure 29.27 Timing Diagram of Two-Phase Encoder Control Function (Control Method 1) at Up Count (Normal Rotation)

- (1) The encoder counter value matches the ENCAAnCCR1, INTENCAAnI1 is generated, and the set pattern is output from the TSG3nO1 to TSG3nO6 pins.
- (2) CPU calculates the next timing to switch output patterns by an interrupt processing and sets the value to ENCAAnCCR1.
- (3) Upon a match of the encoder counter value and ENCAAnCCR0, the encoder counter is cleared.

CAUTION

It is necessary to set ENCA_nCCR1 at each pattern switch (each INTENCA_n1 interrupt). It is necessary to match the initial output pattern of timer TSG3_n to the set value of ENCA_nCCR1 before starting, because this value is not cleared by the encoder clear input.

Switching between normal and reverse rotations of output patterns is set with the TSG3_nPSC bit of the TSG3_nOPT0 register.

The following figure shows the timing diagram at down count (reverse rotation).

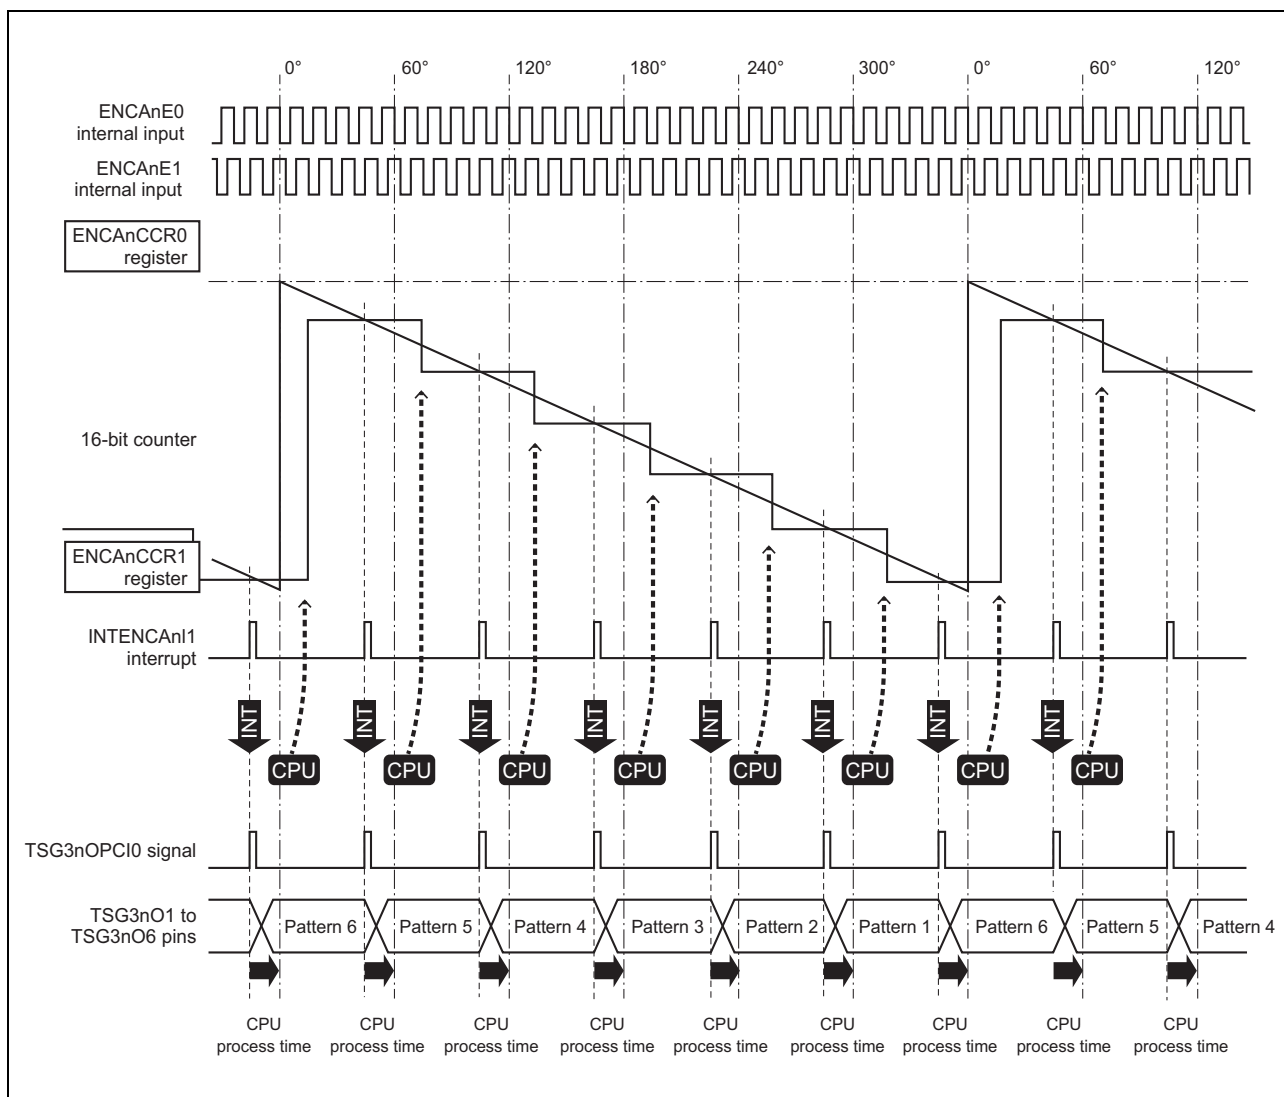

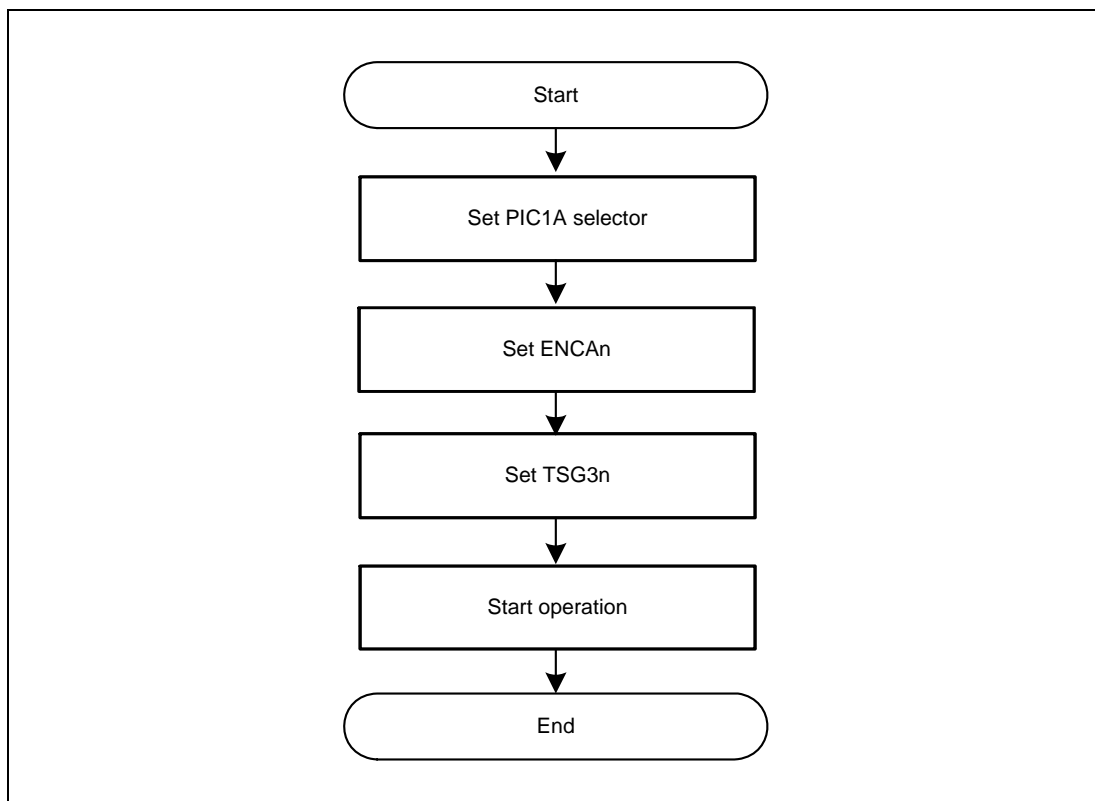

Figure 29.28 Timing Diagram of Two-Phase Encoder Control Function (Control Method 1) at Down Count (Reverse Rotation)

(5) Flow Chart

The following figure shows the setting flow of this function.

The following figure shows the flow chart after interrupt processing.

The values of ENCA_n registers used in this function are as follows.

ENCA_nCTL[15:0] = 1000 0000 000x 01xx_B

ENCA_nIOC1[7:0] = 0000 00xx_B

ENCA_nCCR0 = (set any value)

ENCA_nCCR1 = (set any value)

ENCA_nCNT = (set any value)

“x” can be set arbitrarily. For the registers specifications, see **Section 28, Encoder Timer (ENCA)**.

The values of TSG3_n registers used in this function are as follows.

TSG3_nCTL0[7:0] = 000x 0011_B

TSG3_nCTL3[7:0] = 0000 00xx_B

TSG3_nCTL4[15:0] = 0000 0001 xxx0 0000_B

TSG3_nIOC0[7:0] = 0111 1110_B

TSG3_nIOC2[15:0] = 0xxx xxx0 0000 0000_B

TSG3_nOPT0[7:0] = 0011 1xx0_B

TSG3_nOPT1[7:0] = 0000 0xxx_B

TSG3_nCMP0 = (set any value)

TSG3_nCMP1W,5W,9W = (set any value)

TSG3_nCMP1,5,9 = (set any value)

TSG3_nPAT0W,1W = (set any value)

TSG3_nDTC0W,1W = (set any value)

“x” can be set arbitrarily. For the registers specifications, see **Section 25, Motor Control Timer (TSG3)**.

29.2.3.8 Two-Phase Encoder Control Function (Control Method 2)

(1) Overview

This function allows switching the phase lead and phase lag control of the motor control function (TSG3n) output patterns in 120-DC mode using the two-phase encoder control function (ENCAn).

(2) Configuration

The same configuration as the **Section 29.2.3.7, Two-Phase Encoder Control Function (Control Method 1)** applies to this function. See **(2) Configuration** of **Section 29.2.3.7, Two-Phase Encoder Control Function (Control Method 1)**.

(3) Registers

The same register values as the **Section 29.2.3.7, Two-Phase Encoder Control Function (Control Method 1)** applies to this function. See **(3) Registers** in **Section 29.2.3.7, Two-Phase Encoder Control Function (Control Method 1)**.

(4) Function

Details of this function are described using **Section 29.2.3.8, Two-Phase Encoder Control Function (Control Method 2)** with phase lead (normal rotation) as an example.

The following figure shows the timing diagram.

Figure 29.29 Timing Diagram of Two-Phase Encoder Control Function (Method 2) with Phase Lead (Normal Rotation)

- (1) Upon a match of the encoder counter value and ENCAnCCR1 (corresponds to the output pattern switch position for TSG3n), INTENCAnI1 is generated, and the set pattern is output from the TSG3nO1 to 6 pins.
- (2) Upon a match of the encoder counter value and ENCAnCCR0 (corresponds to the phase lead or lag of the switch position), INTENCAnI0 is generated and the encoder counter is cleared.

CAUTION

It is necessary to set ENCA_nCCR1 at each pattern switch (each INTENCA_n1 interrupt). It is necessary to match the initial output pattern of timer TSG3_n to the set value of ENCA_nCCR0 before starting, because this value is not cleared by the encoder clear input.

Switching between normal and reverse rotations of output patterns is set with the TSG3_nPSC bit of the TSG3_nOPT0 register.

The following figure shows the timing diagram with phase lag (normal rotation).

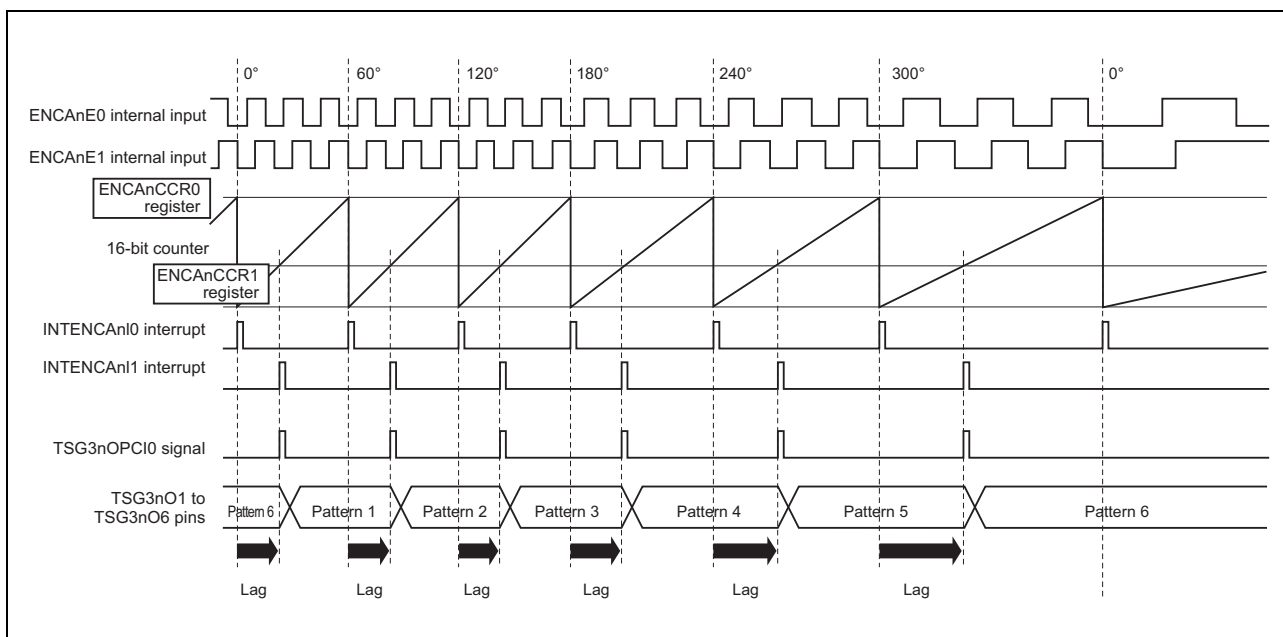

Figure 29.30 Timing Diagram of Two-Phase Encoder Control Function (Method 2) with Phase Lag (Normal Rotation)

By setting greater value to ENCA_nCCR1 than that of ENCA_nCCR0, TSG3_n output pattern phase can be made to lag.

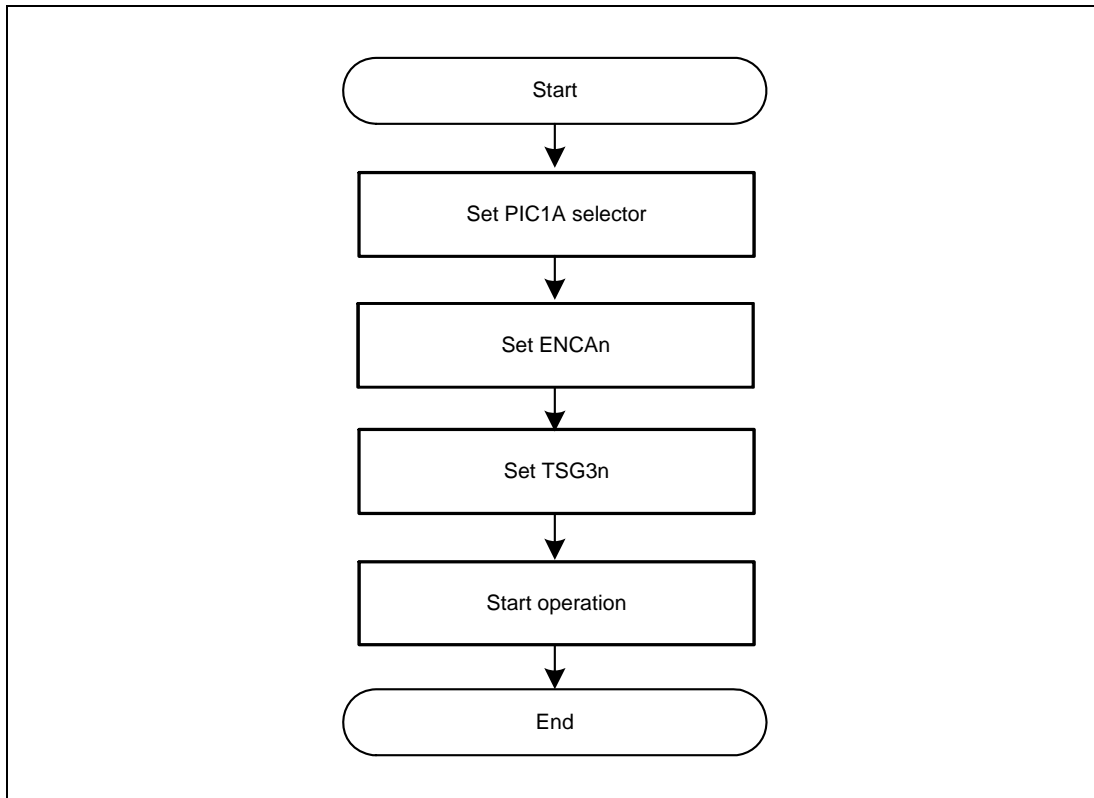

NOTE

This function can be used for phase lead and phase lag control both at up count and down count.

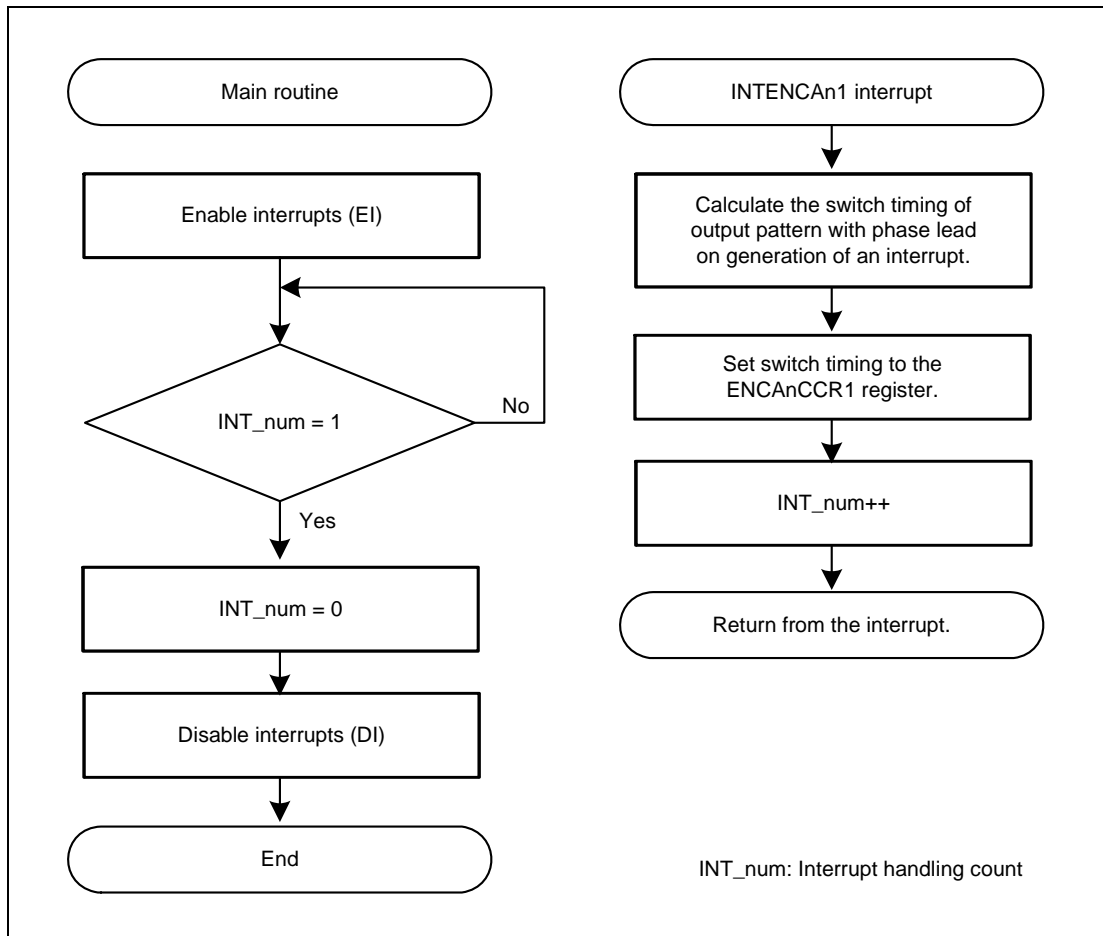

(5) Flow Chart

The flow charts for this function are shown below.

Flow chart of main routine.

Flow chart of ENCANCCR1 rewrite processing with phase lead.

Flow chart of ENCANCCR1 rewrite processing with phase lag.

The register settings for ENCA_n to use this function are as follows.

ENCA_nCTL[15:0] = 1000 0000 000x 01xx_B

ENCA_nIOC1[7:0] = 0000 00xx_B

ENCA_nCCR0 = (set any value)

ENCA_nCCR1 = (set any value)

ENCA_nCNT = (set any value)

“x” can be set arbitrarily. For the registers specifications, **Section 28, Encoder Timer (ENCA)**.

The register settings for TSG3_n to use this function are as follows.

TSG3_nCTL0[7:0] = 000x 0011_B

TSG3_nCTL3[7:0] = 0000 00xx_B

TSG3_nCTL4[15:0] = 0000 0001 xxx0 0000_B

TSG3_nIOC0[7:0] = 0111 1110_B

TSG3_nIOC2[15:0] = 0xxx xxx0 0000 0000_B

TSG3_nOPT0[7:0] = 0011 1xx0_B

TSG3_nOPT1[7:0] = 0000 0xxx_B

TSG3_nCMP0 = (set any value)

TSG3_nCMP1W, 5W, 9W = (set any value)

TSG3_nCMP1, 5, 9 = (set any value)

TSG3_nPAT0W, 1W = (set any value)

TSG3_nDTC0W, 1W = (set any value)

“x” can be set arbitrarily. For the registers specifications, **Section 25, Motor Control Timer (TSG3)**.

29.2.3.9 Three-Phase Pulse Input Control Function

(1) Overview

This function allows variable phase control of TSG3n pattern output in 120-DC mode using TSG3n and TAUDn.

The following diagram shows the method of three-phase pulse input control.

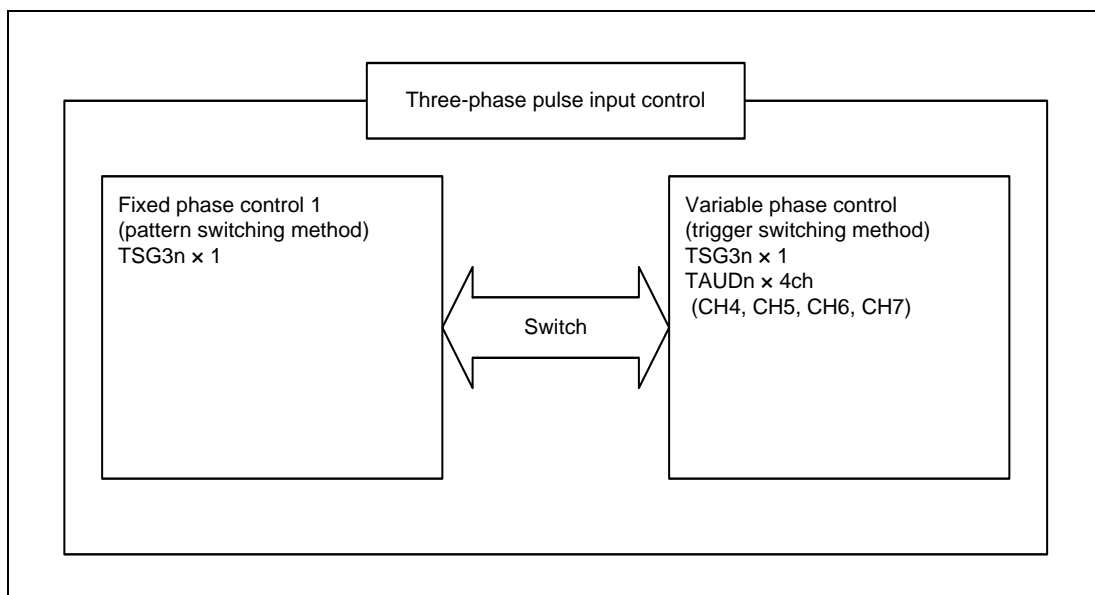

Figure 29.31 Control Method of Three-Phase Pulse Input Control Function

Control Method	Function
Fixed phase control 1 (pattern switching method)	Outputs a fixed pattern at constant rotation angle.
Variable phase control (trigger switching method)	Varies the phase by arbitrary angle (or time) up to ± 60 degrees with reference to the rotation angle and outputs the pattern.

(2) Configuration

Three-phase pulse input control function is realized by using three-phase pulse input and TAUDn offset trigger mode, and PIC1A in combination.

The following figure shows the block diagram of three-phase pulse input control function.

Figure 29.32 Block Diagram of Three-Phase Pulse Input Control

The configuration of this function is described below.

- [PIC1A_TSG3n input selector 1]
ENCA nE0, ENCA nE1, and ENCA nEC pin inputs are selected and output to TSG3nPTSIO to TSG3nPTSIO2.
- [TSG3n]
Patterns set in TSGnTO1 to TSGnTO6 are output in response to the input of TSG3nPTSIO to TSG3nPTSIO2 signals. TSG3nPTE is toggled each time the output patterns are switched.
- [PIC1A_TAUDn connection selector]
TSG3nPTE input is selected and output to TAUDnTTIN4 to TAUDnTTIN7.
- [TAUDn]
Interrupt signals INTTAUDnI5 and INTTAUDnI7 for output pattern phase generation are output with the offset trigger mode.
- [PIC1A_TSG3n input selector 2]
INTTAUDnI5 and INTTAUDnI7 inputs are selected and output as TSG3nOPCI0 and TSG3nOPCI1.

(3) Registers

Block diagram of PIC1A is shown in the following figure.

Figure 29.33 Block Diagram of PIC1A

The values of PIC1A registers used in this function are as follows.

Unit (1): PIC1A_TSG3n input selector 1

The values to output ENCA0E0, ENCA0E1, and ENCA0EC as TSG30PTSIO to TSG30PTS12

$$\text{PIC1ATSGHALLSEL}[0] = 1_{\text{B}}$$

$$\text{PIC1AREG50}[0] = 0_{\text{B}}$$

The values to output ENCA1E0, ENCA1E1, and ENCA1EC as TSG31PTSIO to TSG31PTS12

$$\text{PIC1ATSGHALLSEL}[1] = 1_{\text{B}}$$

$$\text{PIC1AREG51}[0] = 1_{\text{B}}$$

Unit (2): PIC1A_TAUDn connection selector

The values to output TSG3nPTE to TAUDnTTIN4 to TAUDnTTIN7.

$$\text{PIC1AREG2n0}[11:8] = 1010_{\text{B}}$$

$$\text{PIC1AREG2n0}[3:0] = 1111_{\text{B}}$$

$$\text{PIC1ATAUDnSEL}[15:8] = 00_{\text{H}}$$

Unit (3): PIC1A_ENCAn input selector 2

The values to output INTTAUDnI5 and INTTAUDnI7 to TSG3nOPCI0 and TSG3nOPCI1.

$$\text{PIC1AREG5n}[7:5] = 011_{\text{B}}$$

(4) Function

Details of the three-phase pulse input control function are described here.

The following figure shows the timing diagram.

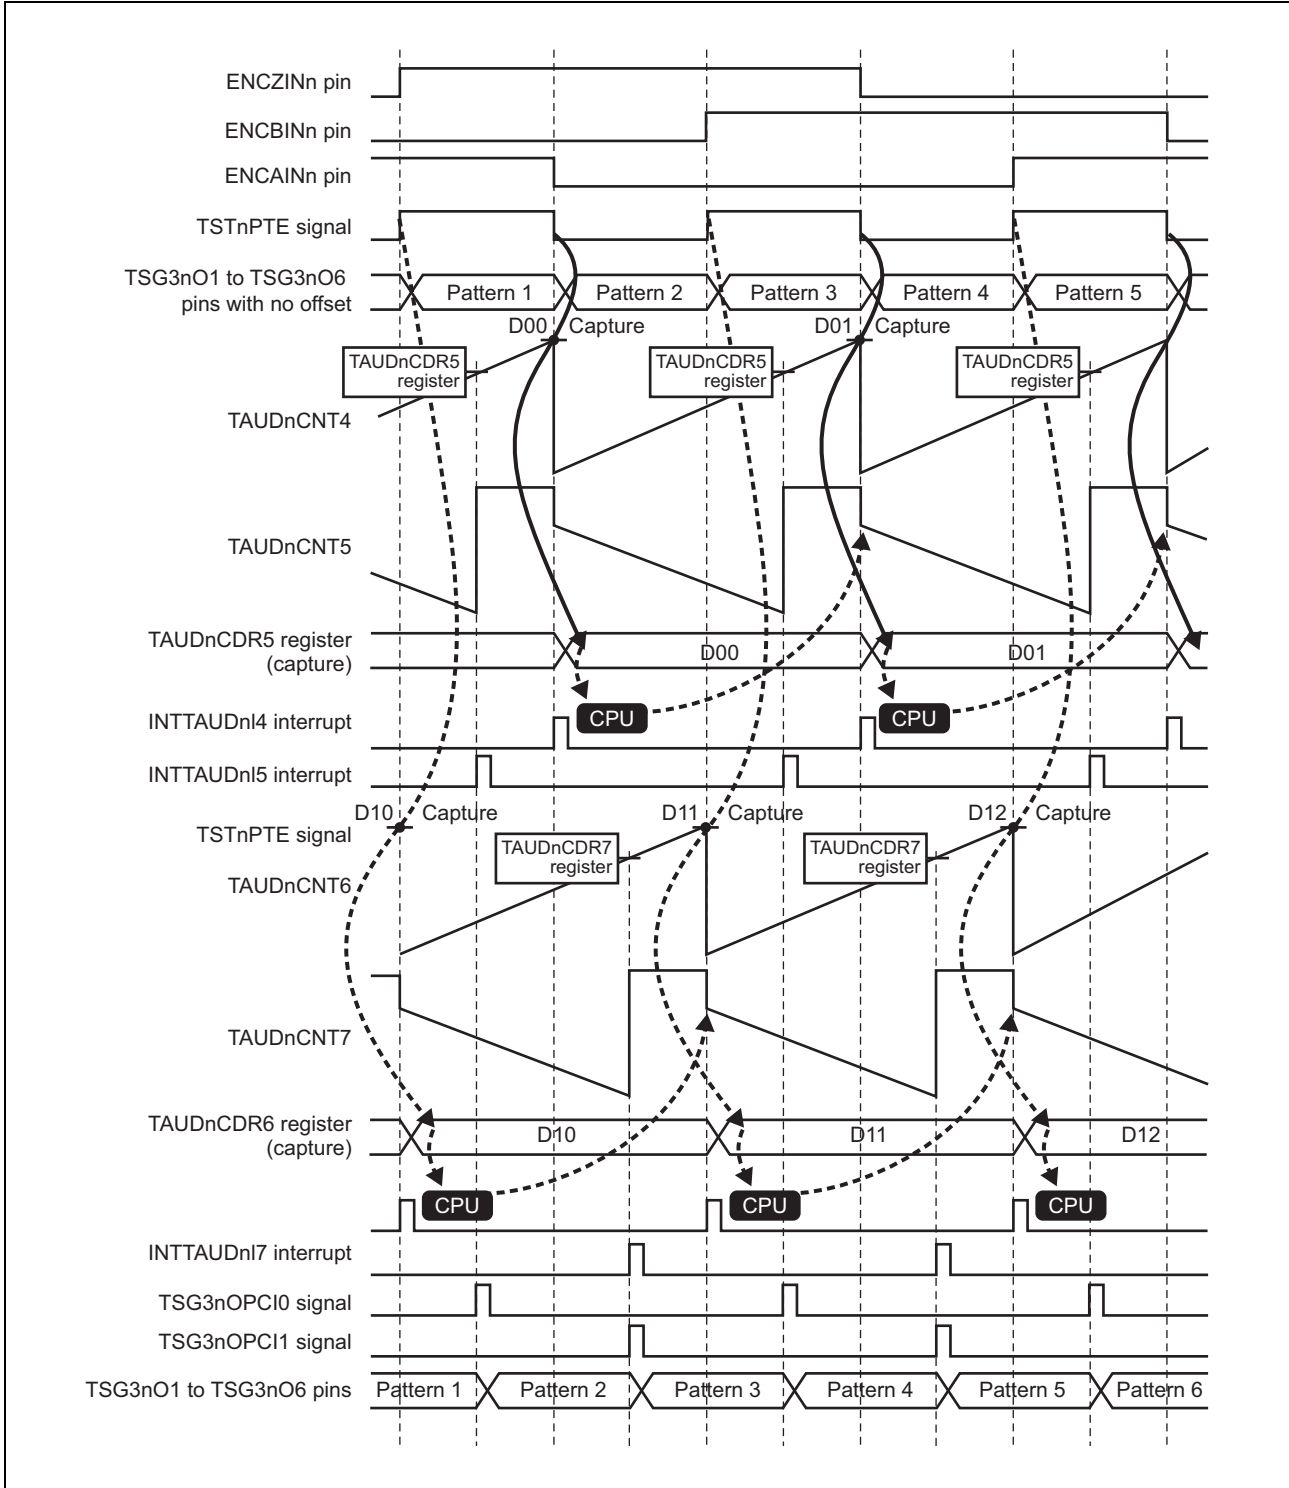

Figure 29.34 Three-Phase Pulse Input Control Function

- (1) The output patterns are switched by the TSG pattern switching method on detection of ENCAIn pin signal. The TSTnPTE signal toggles each time the patterns are switched.

- (2) TAUDnCNT6 and TAUDnCNT4 are captured at the rising edge and falling edge of the TSTnPTE signal. The interval to switch patterns is calculated according to the captured value.
- (3) CPU calculates the phase of the next output pattern and set the values to TAUDnCNT5 and TAUDnCNT7. The signals corresponding to the values are output as TSG3nOPCI0 and TSG3nOPCI1. At this time, the patterns delayed for the set phase are output by switching the output patterns by the trigger switching method.

The following table lists the relation between the value set to TAUDnCNT_m and the captured value in TAUDnCDR (m-1) (m = 5, 7).

TAUDnCNT _m Register Setting	TSG3n Pattern Output Switch Timing
TAUDnCNT _m = 0000 _H	Patterns are switched upon detection of the TSTnPTE signal edge (delayed by up to one TAUDn count clock cycle).
TAUDnCNT _m = Captured value	Patterns are switched upon detection of the TSTnPTE signal edge.
TAUDnCNT _m < Captured value	The patterns are switched after a delay of one phase from detection of the TSTnPTE signal edge.
TAUDnCNT _m > Captured value	Setting prohibited

An example of switch operation from fixed phase control 1 to variable phase control

The following figure shows an example of switch operation from fixed phase control 1 to variable phase control.

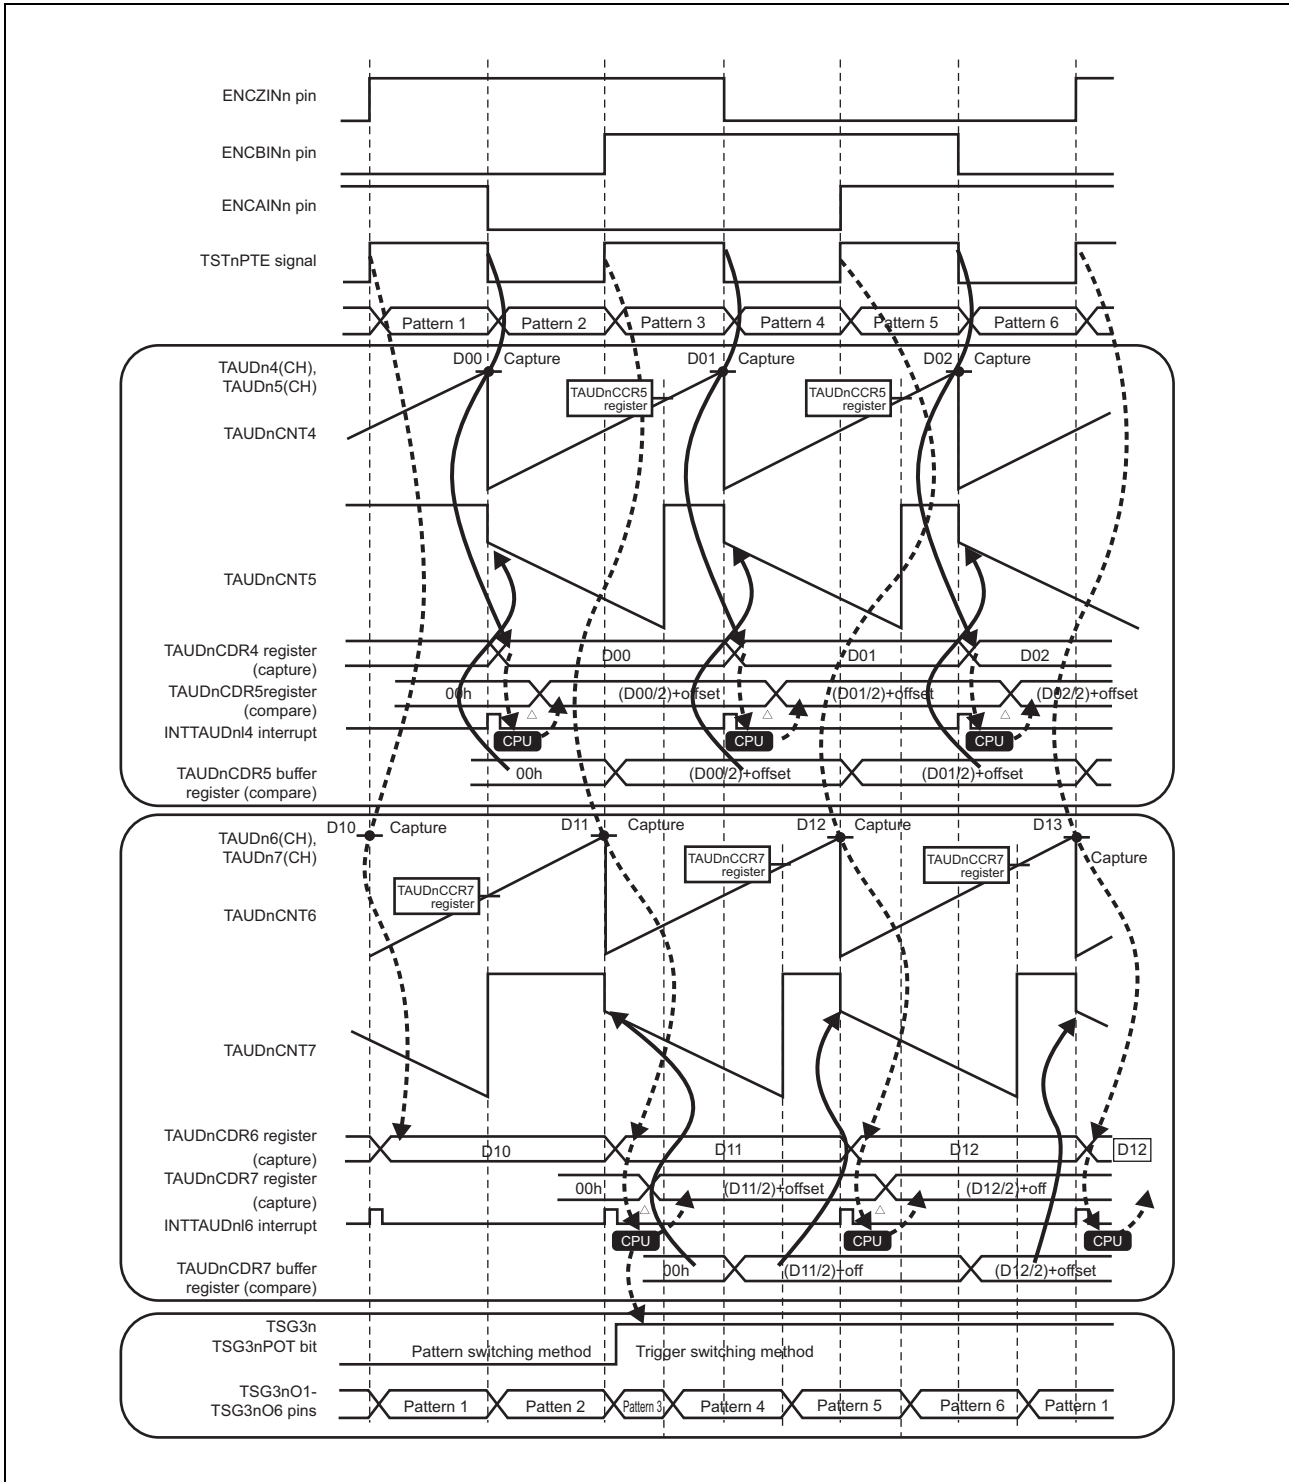

Figure 29.35 An Example of Switch Operation from Fixed Phase Control 1 to Variable Phase Control

By changing the TSG3nPOT bit from low level to high level, the output pattern switching method is changed to the trigger switching method, and the variable phase control is enabled.

An example of switch operation from variable phase control to fixed phase control 1

The following figure shows an example of switch operation from variable phase control to fixed phase control 1.

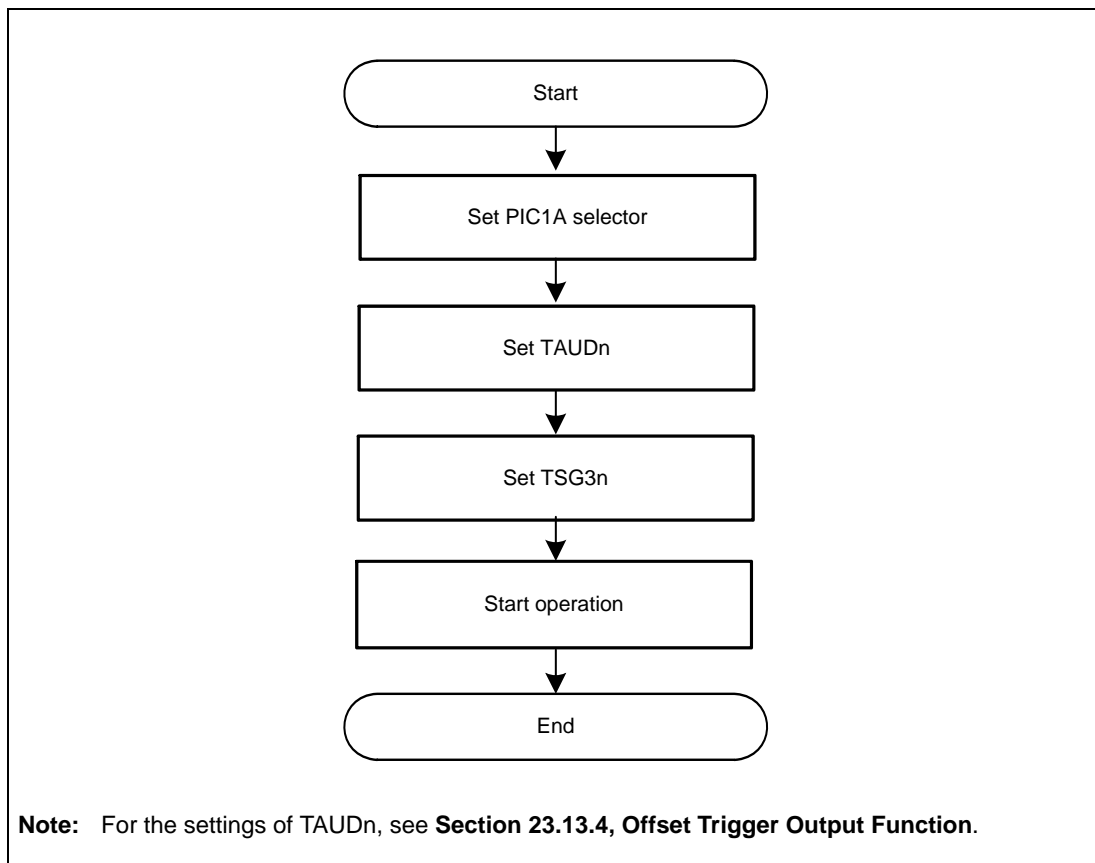

Figure 29.36 Example of Switch Operation from Variable Phase Control to Fixed Phase Control 1

By changing the TSG3nPOT bit from high level to low level, the output pattern switching method is changed to the pattern switching method, and the fixed phase control 1 is enabled.

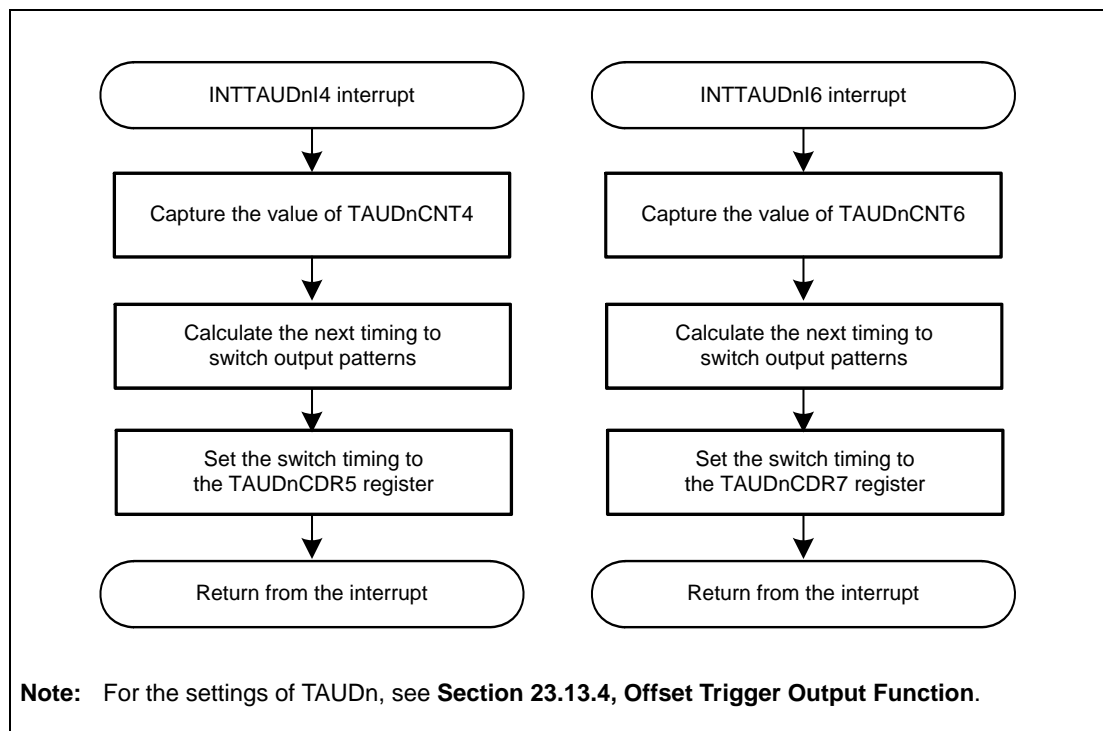

(5) Flow Chart

The flow charts for this function are shown below.

Flow chart of main routine

Flow chart for rewriting of TAUDnCDR5 and TAUDnCDR7 during operation

The values of TSG3n registers used in this function are as follows.

$TSG3nCTL0[7:0] = 0000\ 0011_B$

$TSG3nCTL3[7:0] = 0000\ 00xx_B$

$TSG3nCTL4[15:0] = 0000\ 0001\ xxx0\ 0000_B$

$TSG3nIOC0[7:0] = 0111\ 1110_B$

$TSG3nIOC1[7:0] = 0001\ xxxx_B$

$TSG3nIOC2[15:0] = 0xxx\ xxx0\ 0000\ 0000_B$

$TSG3nOPT0[7:0] = 0011\ 1xx0_B$

$TSG3nOPT1[7:0] = 0000\ 0xxx_B$

$TSG3nCMP0 = (\text{set any value})$

$TSG3nCMP1W,5W,9W = (\text{set any value})$

$TSG3nCMP1,5,9 = (\text{set any value})$

$TSG3nPAT0W,1W = (\text{set any value})$

$TSG3nDTC0W,1W = (\text{set any value})$

“x” can be set arbitrarily. For the registers specifications, see **Section 25, Motor Control Timer (TSG3)**.

29.2.3.10 Three-Phase Encoder Control Function

(1) Overview

The function allows three-phase external pattern inputs (TSG3nPTSIO to TSG3nPTSIO2) to be encoded using ENCA_n.

(2) Configuration

The three-phase encoder control function is realized by using TSG3_n, ENCA_n, and PIC1A in combination. The following figure shows the block diagram of three-phase encoder control function.

Figure 29.37 Block Diagram of Three-Phase Encoder Control Function

The configuration of this function is described below.

- [PIC1A_input pattern selector]
ENCA_nE0, ENCA_nE1, and ENCA_nEC pin inputs are selected and output to TSG3_nPTSIO to TSG3_nPTSIO2.
- [TSG3_n]
Patterns set in TSG3_nPEC are output in response to the input of the TSG3_nPTSIO to TSG3_nPTSIO2 signals. TSG3_nPUD is output depending on the rotation (normal or reverse).
- [PIC1A_ENCA_n input selector]
TSG3_nPEC is selected and output to ENCA_nE0. TSG3_nPUD is selected and output to ENCA_nE1.
- [ENCA_n]
ENCA_nE0 and ENCA_nE1 are encoded.

(3) Registers

Block diagram of PIC1A is shown in the following figure.

Figure 29.38 Block Diagram of PIC1A

The register settings for PIC1A to use this function are as follows.

Unit (1): PIC1A_ input pattern selector

The values to output ENCA0E0, ENCA0E1, and ENCA0EC as TSG30PTSIO to TSG30PTS2

$$\text{PIC1ATSGHALLSEL}[0] = 1_{\text{B}}$$

$$\text{PIC1AREG50}[0] = 0_{\text{B}}$$

The value to output ENCA1E0, ENCA1E1, and ENCA1EC as TSG31PTSIO to TSG31PTS2

$$\text{PIC1ATSGHALLSEL}[1] = 1_{\text{B}}$$

$$\text{PIC1AREG51}[0] = 1_{\text{B}}$$

Unit (2): PIC1A_ENCA_n input selector

The values to output the TS0PEC and TS0PUD as ENCA0E0 and ENCA0E1, respectively

$$\text{PIC1AREG30}[22] = 0_{\text{B}}$$

$$\text{PIC1AREG30}[1:0] = 11_{\text{B}}$$

The values to output the TS1PEC and TS1PUD as ENCA1E0 and ENCA1E1, respectively

$$\text{PIC1AREG30}[9:8] = 10_{\text{B}}$$

$$\text{PIC1AREG30}[7:6] = 10_{\text{B}}$$

(4) Function

Details of the three-phase encoder control function are described below.

The following figure shows the timing diagram.

Figure 29.39 Timing Diagram of Three-Phase Encoder Control Function_ENCAnUDS1 and ENCAAnUDS0 = 00_B

- (1) When the low level is input to ENCAAnE1, the count is incremented each time an active edge is input to ENCAAnE0.

Figure 29.40 Timing Diagram of Three-Phase Encoder Control Function_Normal Rotation/Reverse Rotation

(5) Flow Chart

Set PIC before using the three-phase encoder control function.

The values of ENCA_n registers used in this function are as follows.

$$\text{ENCA}_n\text{CTL}[15:0] = \text{xx}00\ 00\text{xx}\ 000\text{x}\ \text{xx}00_{\text{B}}$$

$$\text{ENCA}_n\text{IOC1}[7:0] = 0000\ 00\text{xx}_{\text{B}}^{*1}$$

$$\text{ENCA}_n\text{CCR0} = (\text{set any value})$$

$$\text{ENCA}_n\text{CCR1} = (\text{set any value})$$

$$\text{ENCA}_n\text{CNT} = (\text{set any value})$$

“x” can be set arbitrarily. For the registers specifications, **Section 28, Encoder Timer (ENCA)**.

Note 1. Except for ENCA_nIOC1[1:0] = 00_B (no edge detected) because edge detection is necessary.

The values of TSG3_n registers used in this function are as follows.

$$\text{TSG3}_n\text{CTL0}[7:0] = 0000\ 0001_{\text{B}}$$

$$\text{TSG3}_n\text{CTL3}[7:0] = 0000\ 00\text{xx}_{\text{B}}$$

$$\text{TSG3}_n\text{CTL4}[15:0] = 0000\ 000\text{x}\ \text{xxxx}\ \text{xxxx}_{\text{B}}$$

$$\text{TSG3}_n\text{IOC0}[7:0] = 0\text{xxx}\ \text{xxx}0_{\text{B}}$$

$$\text{TSG3}_n\text{IOC1}[7:0] = 0001\ \text{xxxx}_{\text{B}}$$

$$\text{TSG3}_n\text{IOC2}[15:0] = 0\text{xxx}\ \text{xxx}0\ 0000\ 0000_{\text{B}}$$

$$\text{TSG3}_n\text{OPT0}[7:0] = 0\text{xxx}\ \text{xxx}0_{\text{B}}$$

$$\text{TSG3}_n\text{OPT1}[7:0] = 0000\ 0\text{xxx}_{\text{B}}$$

$$\text{TSG3}_n\text{CMP0} = (\text{set any value})$$

$$\text{TSG3}_n\text{CMP1W,5W,9W} = (\text{set any value})$$

$$\text{TSG3}_n\text{CMP1,5,9} = (\text{set any value})$$

$$\text{TSG3}_n\text{PAT0W,1W} = (\text{set any value})$$

$$\text{TSG3}_n\text{DTC0W,1W} = (\text{set any value})$$

“x” can be set arbitrarily. For the registers specifications, **Section 25, Motor Control Timer (TSG3)**.

29.2.3.11 TAUD Input Select Function

(1) Overview

The function selects TAUDn input signal to be input as TAUDnTINm/m+1 signal from either TAUD0TINm/m+1 signal or TAUD1TINm/m+1 signal (m is an even number between 0 and 15).

(2) Configuration

The TAUD input select function is realized by using TAUDn input signals and PIC1A in combination.

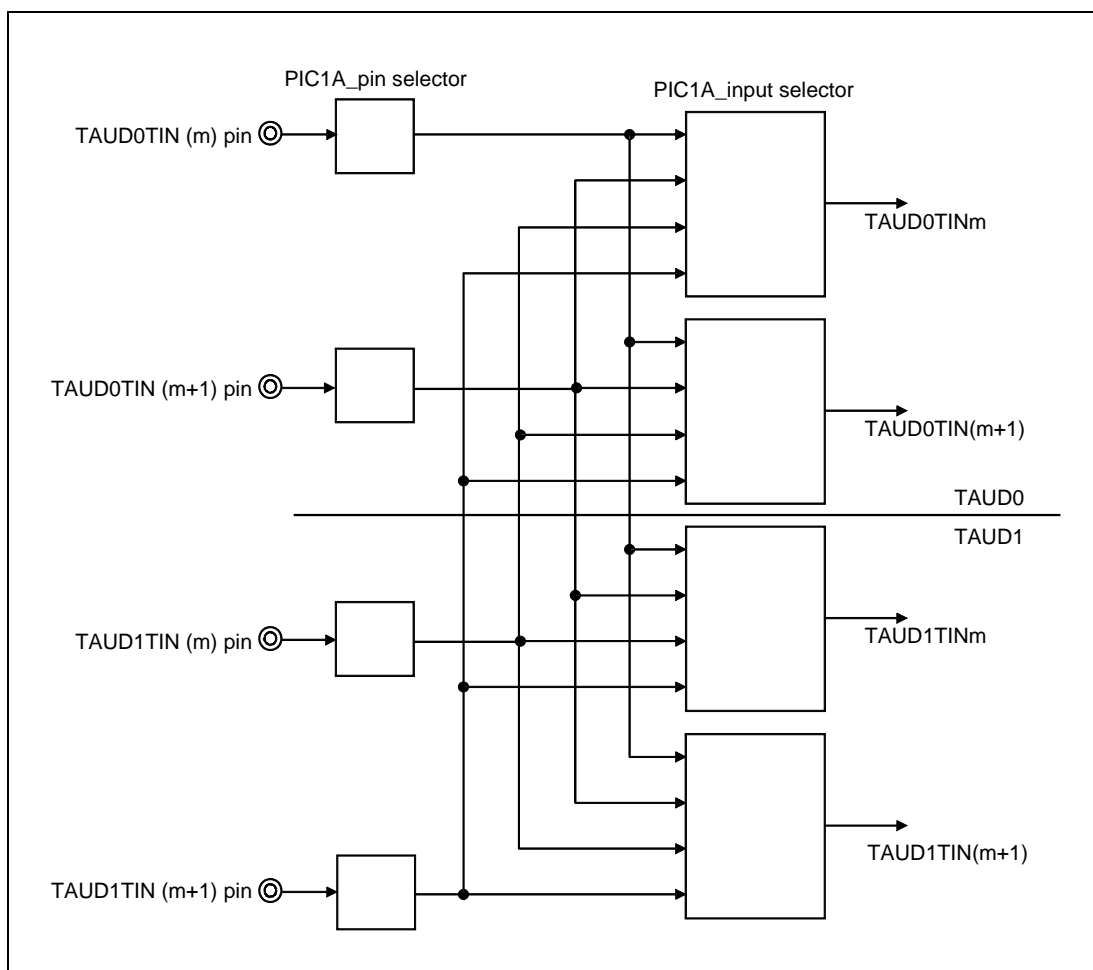

Figure 29.41 Block Diagram of TAUD Input Select Function

(3) Registers

The register settings for PIC1A to use this function are as follows.

PIC1A_pin selector

Select TAUDn external channel input pin for output from PIC1A pin selector.

PIC1A_input selector

Select the input signal using the following registers.

PIC1ATAUD0SEL

PIC1ATAUD1SEL

For the details of the register settings, **Section 29.2.2.10**, **Section 29.2.2.11**, **Section 29.2.2.18**, **Section 29.2.2.19**, **Section 29.2.2.21**, and **Section 29.2.2.24** .

(4) Function

Details of this function are described using selection of the TAUD0TIN[1:0] signal as an example.

The following table lists the selection of the TAUD0TIN[1:0] signals as an example. Setting 000000 to PIC1AREG31[11:6], and setting 01 to PIC1ATAUD0SEL[3:2] and PIC1ATAUD0SEL[1:0] causes the TAUD0TIN0 and TAUD0TIN1 signals to be input to TAUD0TIN1 and TAUD0TIN0 input pins of the TAUD0 timer. Setting 1 to PIC1ATAUD0SEL[3] and PIC1ATAUD0SEL[1] selects TIN pin signal of TAUD1.

Register Setting	
PIC1ATAUD0SEL	
[1:0]	TAUD0TIN0
00 _B	TAUD0TIN0 pin
01 _B	TAUD0TIN1 pin
10 _B	TAUD1TIN0 pin
11 _B	TAUD1TIN1 pin

Register Setting	
PIC1ATAUD0SEL	
[3:2]	TAUD0TIN1
00 _B	TAUD0TIN1 pin
01 _B	TAUD0TIN0 pin
10 _B	TAUD1TIN1 pin
11 _B	TAUD1TIN0 pin

(5) Flow Chart

Set PIC1A before starting the TAUDn timer.

29.2.3.12 Hi-Z Control Function

(1) Overview

The function disconnects three-phase output signal and changes to Hi-Z state.

For details of the purpose and operation of the Hi-Z control function, see **Section 26.4.1, Asynchronous Hi-Z Control Function.**

(2) Configuration

The ESO_n, ERROROUT, INTTSG30IER, INTTSG31IER, INTADCG0ERR, and INTADCG1ERR signals are masked and OR'ed in PIC1A, and output to TAPAn as the signal for Hi-Z control.

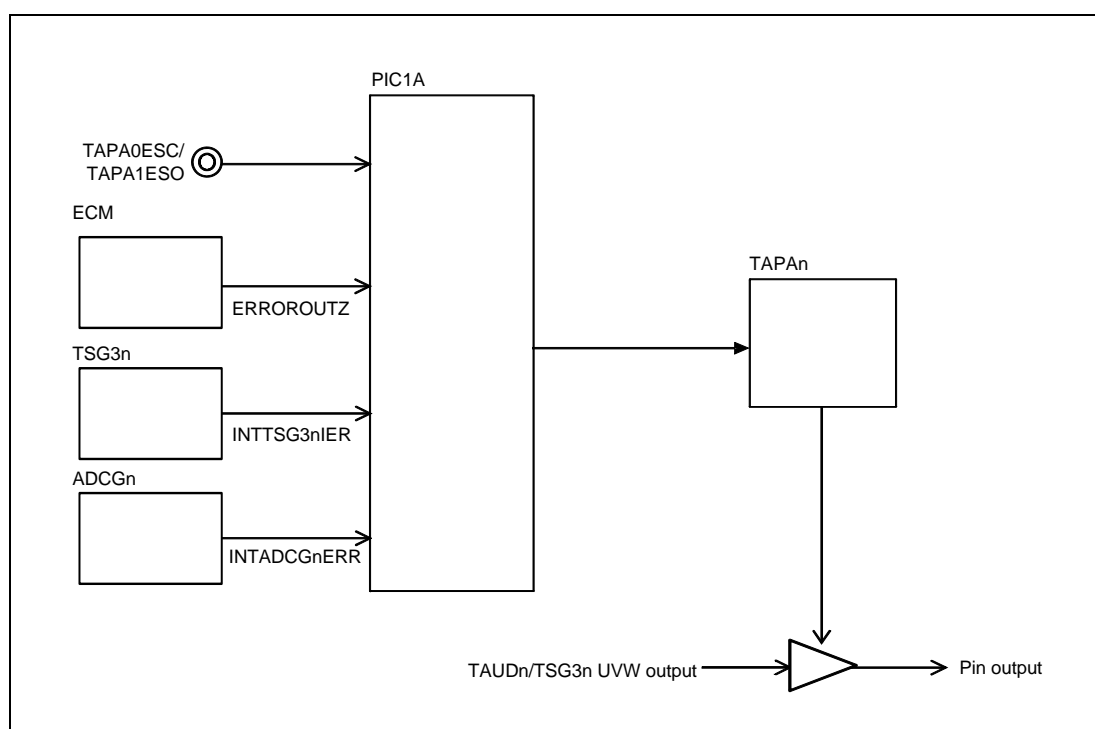

Figure 29.42 Block Diagram of Hi-Z Control

(3) Registers

The block diagram of PIC1A is shown in the following figure.

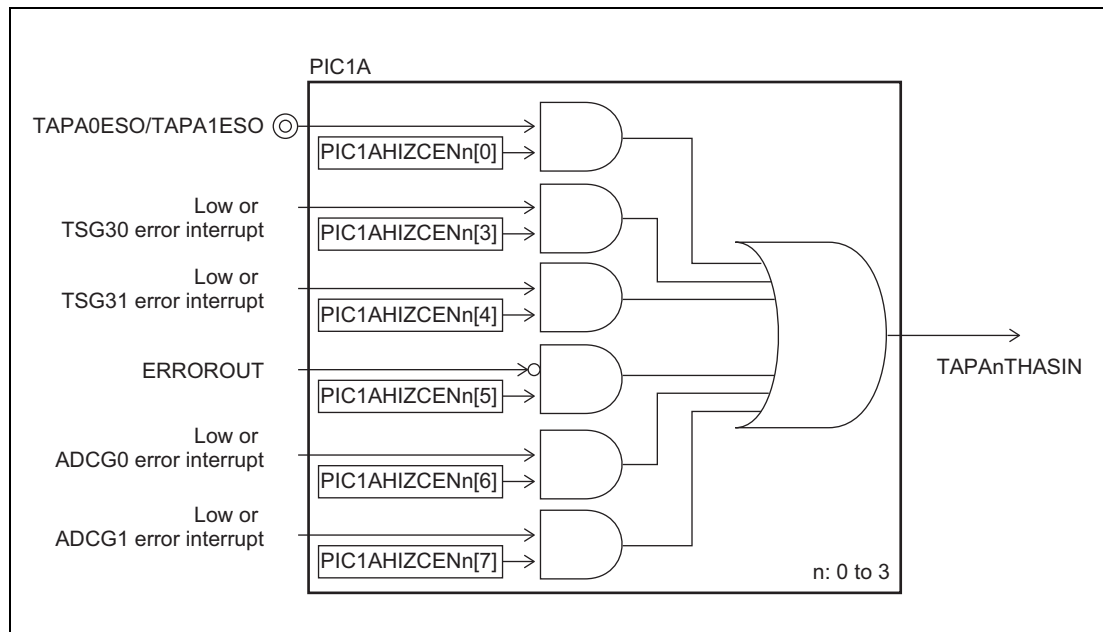

Figure 29.43 Block Diagram of PIC1A

The register settings for PIC1A to use this function are as follows.

PIC1AHIZCENn[5] = 1 (enabled), 0 (disabled): ERROROUT

PIC1AHIZCENn[0] = 1 (enabled), 0 (disabled): TAPA0ESO or TAPA1ESO

PIC1AHIZCENn[3] = 1 (enabled), 0 (disabled): INTTSG30IER

PIC1AHIZCENn[4] = 1 (enabled), 0 (disabled): INTTSG31IER

PIC1AHIZCENn[6] = 1 (enabled), 0 (disabled): INTADCG0ERR

PIC1AHIZCENn[7] = 1 (enabled), 0 (disabled): INTADCG1ERR

n = 0, 1 is available for TAUD0/TAUD1 and not available for PIC1AHIZCENn[3] and PIC1AHIZCENn[4].

n = 2 is available for TSG30 and not available for PIC1AHIZCENn[4].

n = 3 is available for TSG31 and not available for PIC1AHIZCENn[3].

Table 29.41 Correspondence between the Hi-Z Control Function Input Pins and Control Pins

Input Pin Name	Control Register	TAPA Unit Number	Target Timers for Hi-Z Control
TAPA0ESO	PIC1AHIZCEN0	TAPA0	TAUD0
TAPA1ESO	PIC1AHIZCEN1	TAPA1	TAUD1
TAPA0ESO	PIC1AHIZCEN2	TAPA2	TSG30
TAPA1ESO	PIC1AHIZCEN3	TAPA3	TSG31

(4) Function

The TAPA0ESO/TAPA1ESO pins, ERROROUT, INTTSG30IER, INTTSG31IER, INTADCG0ERR, and INTADCG1ERR for Hi-Z control are masked and OR'ed in PIC1A, and output to TAPAn. For Hi-Z control by TAPA, see **Section 26.4.1.3, Basic Operation**.

(5) Flow Chart

Set PIC1A before starting Hi-Z control.

For the operation flow of TAPA, see **Section 26.4.1, Asynchronous Hi-Z Control Function**.

29.2.3.13 Timer Output Monitor Function (PWM-Diag)

(1) Overview

With this function, output signals of TAUD0, TAUD1, TSG30, TSG31, OSTM0, and OSTM1 are monitored using TAUD2.

(2) Configuration

Monitoring of output signals of TAUD0, TAUD1, TSG30, TSG31, OSTM0, and OSTM1 is realized using TAUD2 and PIC1A in combination.

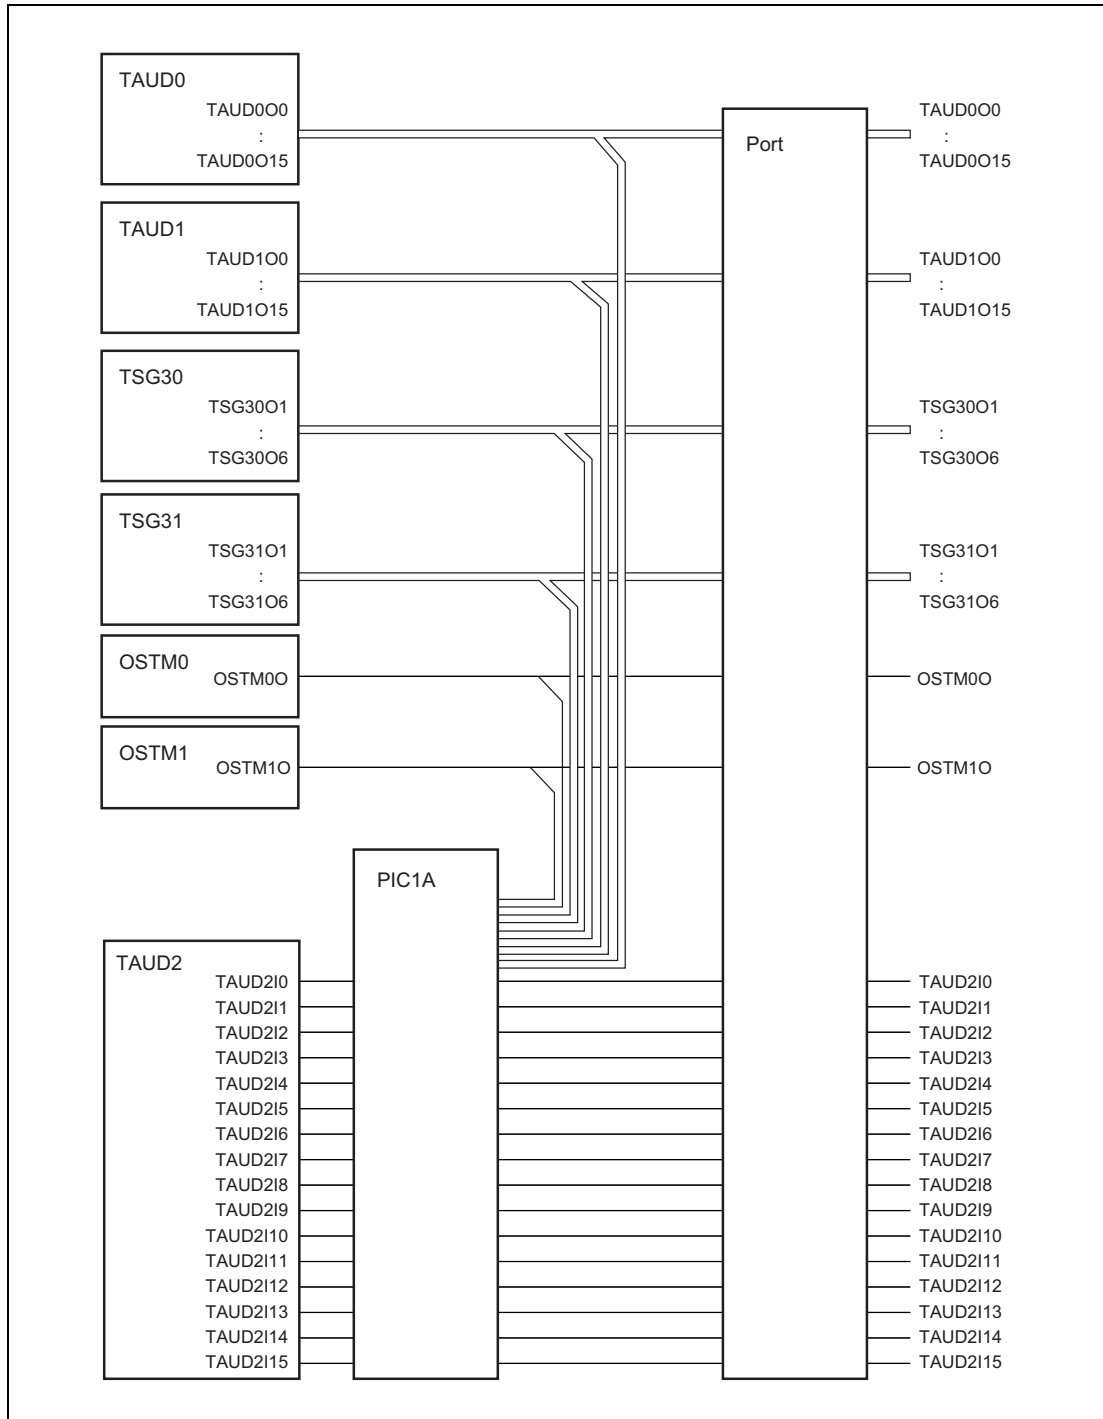

Figure 29.44 Block Diagram of Timer Output Monitor Function

(3) Registers

- The POMONSEL register selects the output signal to be monitored.
- Set the alternative output level loopback function for the port of the output signal to be monitored.
For details, see **Section 2.3.4.3, (1) PBDCn/JPBDC0 — Port Bi-Direction Control Register**.

29.2.3.14 Timer Input Monitor Function**(1) Overview**

With this function, input signals of TAUJ0 and TAUJ1 are monitored using TAUJ2.

(2) Configuration

Monitoring of input signals of TAUJ0 and TAUJ1 is realized using TAUJ2 and PIC1A in combination.

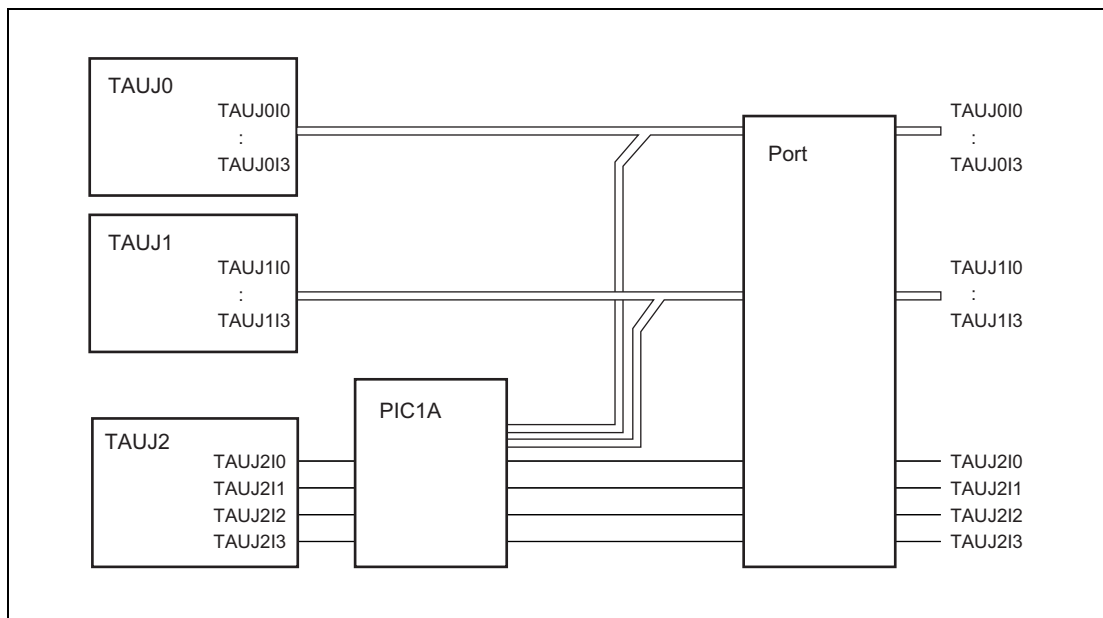

Figure 29.45 Block Diagram of Timer Input Monitor Function

(3) Registers

The PIMONSEL register selects the input signals to be monitored.

29.2.3.15 TSG3 Synchronous Clear Function

(1) Overview

This function allows synchronous starting and clearing of TAUD0, TSG30 and TSG31.

(2) Configuration

The interrupt signals from TAUD0 channels 14 and 15 are used as synchronous start triggers to initiate synchronous starting or clearing of TSG30 and TSG31.

Figure 29.46 Block Diagram of TSG3 Synchronous Clear Function

29.3 Peripheral Interconnection — 2 (PIC2B)

29.3.1 Overview

29.3.1.1 Functional Overview

The peripheral interconnection-2 (PIC2B) allows ADCG hardware trigger signal to be generated using the internal and external trigger signals output from individual IPs.

29.3.2 Registers

29.3.2.1 List of Registers

PIC2B registers are listed in the following table.

Table 29.42 List of Registers

Register Name	Symbol	Address
A/D converter 0 trigger select control register 0	PIC2BADCG0TSEL0	<PIC2B_base> + 00 _H
A/D converter 0 trigger select control register 1	PIC2BADCG0TSEL1	<PIC2B_base> + 04 _H
A/D converter 0 trigger select control register 2	PIC2BADCG0TSEL2	<PIC2B_base> + 08 _H
A/D converter 0 trigger select control register 3	PIC2BADCG0TSEL3	<PIC2B_base> + 0C _H
A/D converter 0 trigger select control register 4	PIC2BADCG0TSEL4	<PIC2B_base> + 10 _H
A/D converter 0 trigger edge select control register	PIC2BADCG0EDGSEL	<PIC2B_base> + 1C _H
A/D converter 1 trigger select control register 0	PIC2BADCG1TSEL0	<PIC2B_base> + 20 _H
A/D converter 1 trigger select control register 1	PIC2BADCG1TSEL1	<PIC2B_base> + 24 _H
A/D converter 1 trigger select control register 2	PIC2BADCG1TSEL2	<PIC2B_base> + 28 _H
A/D converter 1 trigger select control register 3	PIC2BADCG1TSEL3	<PIC2B_base> + 2C _H
A/D converter 1 trigger select control register 4	PIC2BADCG1TSEL4	<PIC2B_base> + 30 _H
A/D converter 1 trigger edge select control register	PIC2BADCG1EDGSEL	<PIC2B_base> + 3C _H
Common to ADCG0, 1		
A/D converter trigger output control register 400	PIC2BADTEN400	<PIC2B_base> + 40 _H
A/D converter trigger output control register 401	PIC2BADTEN401	<PIC2B_base> + 44 _H
A/D converter trigger output control register 402	PIC2BADTEN402	<PIC2B_base> + 48 _H
A/D converter trigger output control register 403	PIC2BADTEN403	<PIC2B_base> + 4C _H
A/D converter trigger output control register 404	PIC2BADTEN404	<PIC2B_base> + 50 _H
A/D converter trigger output control register 410	PIC2BADTEN410	<PIC2B_base> + 60 _H
A/D converter trigger output control register 411	PIC2BADTEN411	<PIC2B_base> + 64 _H
A/D converter trigger output control register 412	PIC2BADTEN412	<PIC2B_base> + 68 _H
A/D converter trigger output control register 413	PIC2BADTEN413	<PIC2B_base> + 6C _H
A/D converter trigger output control register 414	PIC2BADTEN414	<PIC2B_base> + 70 _H
A/D converter synchronized start trigger register	ADSYNCTRG	FFF9 1C00 _H

29.3.2.2 PIC2BADCGnTSELx — A/D Converter n Trigger Select Control Register x

The PIC2BADCGnTSELx register selects triggers for ADCGn scan group x (n = 0, 1; x = 0 to 4).

Access: This register can be read/written in 32-bit units.

Address: Base= FFDD 1000_H
 Base + 00_H (n = 0, x = 0), Base + 04_H (n = 0, x = 1), Base + 08_H (n = 0, x = 2),
 Base + 0C_H (n = 0, x = 3), Base + 10_H (n = 0, x = 4),
 Base + 20_H (n = 1, x = 0), Base + 24_H (n = 1, x = 1), Base + 28_H (n = 1, x = 2),
 Base + 2C_H (n = 1, x = 3), Base + 30_H (n = 1, x = 4)

Value after reset: 0000 0000_H

Table 29.43 PIC2BADCGnTSELx Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is read. When writing, write the value after reset.
29	ADCGn TSELx29	Selects INTTSG3112 interrupt of TSG31 as the trigger source for ADCGn SGx. 0: INTTSG3112 is not selected. 1: INTTSG3112 is selected.
28	ADCGn TSELx28	Selects INTTSG3111 interrupt of TSG31 as the trigger source for ADCGn SGx. 0: INTTSG3111 is not selected. 1: INTTSG3111 is selected.
27	ADCGn TSELx27	Selects INTTSG3118 interrupt of TSG31 as the trigger source for ADCGn SGx. 0: INTTSG3118 is not selected. 1: INTTSG3118 is selected.
26	ADCGn TSELx26	Selects INTTSG3117 interrupt of TSG31 as the trigger source for ADCGn SGx. 0: INTTSG3117 is not selected. 1: INTTSG3117 is selected.
25	ADCGn TSELx25	Selects INTTSG3114 interrupt of TSG31 as the trigger source for ADCGn SGx. 0: INTTSG3114 is not selected. 1: INTTSG3114 is selected.
24	ADCGn TSELx24	Selects INTTSG3113 interrupt of TSG31 as the trigger source for ADCGn SGx. 0: INTTSG3113 is not selected. 1: INTTSG3113 is selected.
23, 22	Reserved	When read, the value after reset is read. When writing, write the value after reset.
21	ADCGn TSELx21	Selects INTTSG3012 interrupt of TSG30 as the trigger source for ADCGn SGx. 0: INTTSG3012 is not selected. 1: INTTSG3012 is selected.
20	ADCGn TSELx20	Selects INTTSG3011 interrupt of TSG30 as the trigger source for ADCGn SGx. 0: INTTSG3011 is not selected. 1: INTTSG3011 is selected.
19	ADCGn TSELx19	Selects INTTSG3018 interrupt of TSG30 as the trigger source for ADCGn SGx. 0: INTTSG3018 is not selected. 1: INTTSG3018 is selected.

Table 29.43 PIC2BADCGnTSELx Register Contents (2/2)

Bit Position	Bit Name	Function
18	ADCGn TSELx18	Selects INTTSG30I7 interrupt of TSG30 as the trigger source for ADCGn SGx. 0: INTTSG30I7 is not selected. 1: INTTSG30I7 is selected.
17	ADCGn TSELx17	Selects INTTSG30I4 interrupt of TSG30 as the trigger source for ADCGn SGx. 0: INTTSG30I4 is not selected. 1: INTTSG30I4 is selected.
16	ADCGn TSELx16	Selects INTTSG30I3 interrupt of TSG30 as the trigger source for ADCGn SGx. 0: INTTSG30I3 is not selected. 1: INTTSG30I3 is selected.
15 to 9	Reserved	When read, the value after reset is read. When writing, write the value after reset.
8	ADCGn TSELx08	Selects ADTRGn as the trigger source for ADCGn SGx. 0: ADTRGn is not selected. 1: ADTRGn is selected.
7	ADCGn TSELx07	Selects the TSG3nADTRG1 signal of TSG31 as the trigger source for ADCGn SGx. 0: TSG3nADTRG1 is not selected. 1: TSG3nADTRG1 is selected.
6	ADCGn TSELx06	Selects the TSG3nADTRG0 signal of TSG31 as the trigger source for ADCGn SGx. 0: TSG3nADTRG0 is not selected. 1: TSG3nADTRG0 is selected.
5	ADCGn TSELx05	Selects the TSG3nADTRG1 signal of TSG30 as the trigger source for ADCGn SGx. 0: TSG3nADTRG1 is not selected. 1: TSG3nADTRG1 is selected.
4	ADCGn TSELx04	Selects the TSG3nADTRG0 signal of TSG30 as the trigger source for ADCGn SGx. 0: TSG3nADTRG0 is not selected. 1: TSG3nADTRG0 is selected.
3	ADCGn TSELx03	Selects the INTENCA1I1 interrupt signal of ENCA1 as the trigger source for ADCGn SGx. 0: INTENCA1I1 is not selected. 1: INTENCA1I1 is selected.
2	ADCGn TSELx02	Selects the INTENCA0I1 interrupt signal of ENCA0 as the trigger source for ADCGn SGx. 0: INTENCA0I1 is not selected. 1: INTENCA0I1 is selected.
1	ADCGn TSELx01	Selects the TAUD1 interrupt signal selected by the PIC2BADTEN41x register as the trigger source for ADCGn SGx. 0: TAUD1 interrupt is not selected. 1: TAUD1 interrupt is selected.
0	ADCGn TSELx00	Selects the TAUD0 interrupt signal selected by the PIC2BADTEN40x register as the trigger source for ADCGn SGx. 0: TAUD0 interrupt is not selected. 1: TAUD0 interrupt is selected.

29.3.2.3 PIC2BADCGnEDGSEL — A/D Converter Trigger Edge Control Register

The PIC2BADCGnEDGSEL register selects an effective edge for the one-shot pulse generation circuit which generates an ADCG trigger.

Access: This register can be read/written in 16-bit units.

Address: Base = FFDD 1000_H
Base + 1C_H (n = 0), Base + 3C_H (n = 1)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PIC2BADCGnEDGSEL[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.44 PIC2BADCGnEDGSEL Register Contents

Bit Position	Bit Name	Function
15 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9, 8	PIC2BADCGnEDGSEL[9:8]	Selects an effective edge of ADCGn scan group 4. 00: Rising edge is selected. 01: Falling edge is selected. 10: Both edges are selected. 11: — (setting prohibited.)
7, 6	PIC2BADCGnEDGSEL[7:6]	Selects an effective edge of ADCGn scan group 3. 00: Rising edge is selected. 01: Falling edge is selected. 10: Both edges are selected. 11: — (setting prohibited.)
5, 4	PIC2BADCGnEDGSEL[5:4]	Selects an effective edge of ADCGn scan group 2. 00: Rising edge is selected. 01: Falling edge is selected. 10: Both edges are selected. 11: — (setting prohibited.)
3, 2	PIC2BADCGnEDGSEL[3:2]	Selects an effective edge of ADCGn scan group 1. 00: Rising edge is selected. 01: Falling edge is selected. 10: Both edges are selected. 11: — (setting prohibited.)
1, 0	PIC2BADCGnEDGSEL[1:0]	Selects an effective edge of ADCGn scan group 0. 00: Rising edge is selected. 01: Falling edge is selected. 10: Both edges are selected. 11: — (setting prohibited.)

29.3.2.4 PIC2BADTEN4nx — A/D Converter Trigger Output Select Control Register

The PIC2BADTEN4nx register enables selecting a trigger source from TAUDn channel m as the ADCG trigger. (n = 0, 1; x = 0 to 4). This register is common to ADCG0 and ADCG1.

Access: This register can be read/written in 16-bit units.

Address: Base = FFDD 1000_H
 Base + 40_H (n = 0, x = 0), Base + 44_H (n = 0, x = 1), Base + 48_H (n = 0, x = 2),
 Base + 4C_H (n = 0, x = 3), Base + 50_H (n = 0, x = 4),
 Base + 60_H (n = 1, x = 0), Base + 64_H (n = 1, x = 1), Base + 68_H (n = 1, x = 2),
 Base + 6C_H (n = 1, x = 3), Base + 70_H (n = 1, x = 4)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIC2BADTEN4nx[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.45 PIC2BADTEN4nx Register Contents

Bit Position	Bit Name	Function
15 to 0	PIC2BADTEN4nxm (m = 0 to 15)	Set a trigger source from TAUDn channel m. 0: Trigger source of TAUDn channel m cannot be selected as the ADCG trigger. 1: Trigger source of TAUDn channel m can be selected as the ADCG trigger.

29.3.2.5 ADSYNCTRГ — A/D Converter Synchronized Start Trigger Register

The ADSYNCTRГ register controls synchronized start trigger for ADCG0 and ADCG1.

Access: This register can be read/written in 8-bit units.

Address: FFF9 1C00_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	ADSYNCTRГ4	ADSYNCTRГ3	ADSYNCTRГ2	ADSYNCTRГ1	ADSYNCTRГ0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 29.46 ADSYNCTRГ Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	ADSYNCTRГ4	Synchronously converts the SG of ADCG1 with the conversion start trigger selected by the individual SG of ADCG0.
3	ADSYNCTRГ3	0: Synchronized start is disabled.
2	ADSYNCTRГ2	1: Synchronized start is enabled.
1	ADSYNCTRГ1	The function only applies to normal A/D conversion of ADCG0 and ADCG1.
0	ADSYNCTRГ0	

29.3.3 Function

29.3.3.1 ADCG Trigger Select Function

(1) Overview

The function allows generation of ADCG hardware trigger signal for individual scan groups by the signals from each IP. The IPs can be selected from TAUD0, TAUD1, ENCA0, ENCA1, TSG30, and TSG31.

(2) Configuration

The ADCG trigger select function is realized by using individual IPs and PIC2B in combination. The following figure shows the block diagram of ADCG trigger select function.

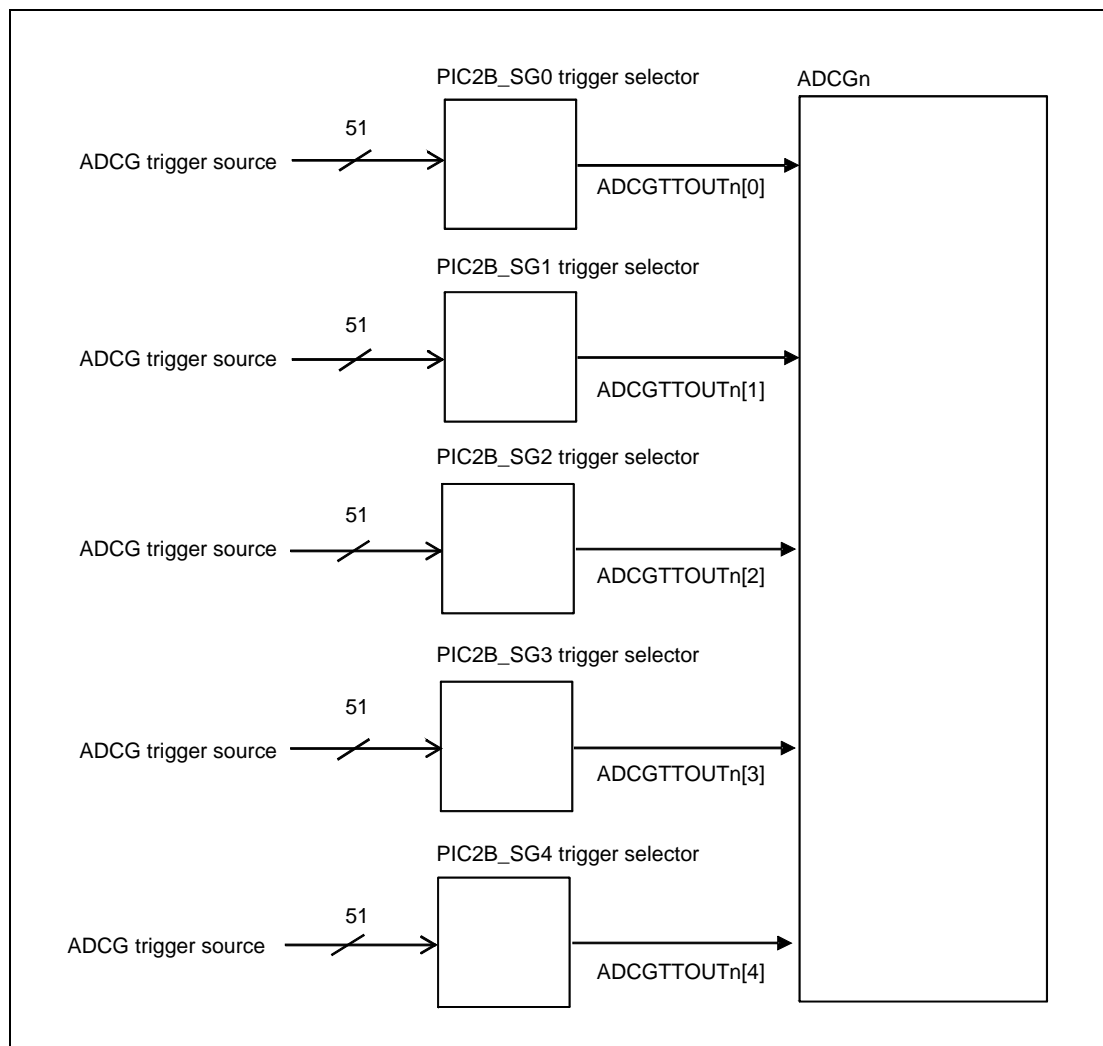

Figure 29.47 Block Diagram of ADCG Trigger Select Function

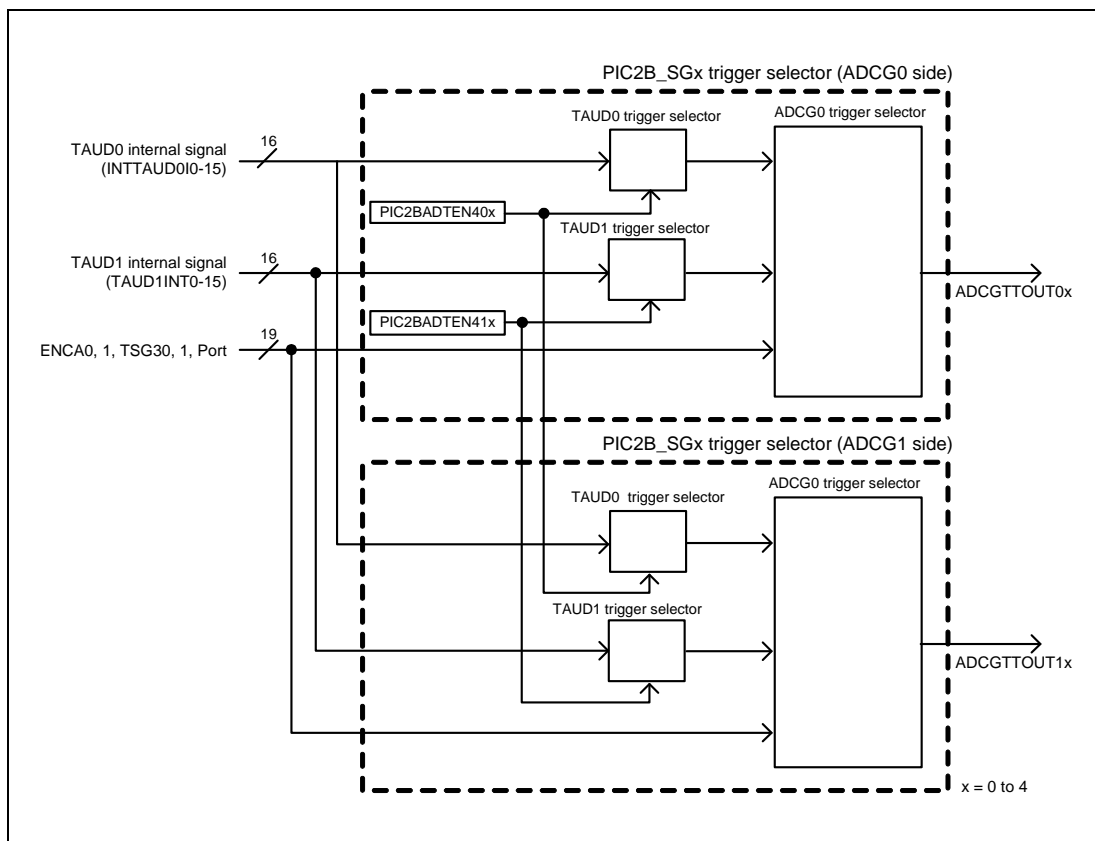

Figure 29.48 Block Diagram of PIC2B_SGx Trigger Selection

(3) Registers

For the settings of the registers used in this function, see **Figure 29.49, Block Diagram of PIC2B**, and from **Section 29.3.2.2** to **Section 29.3.2.4**.

Figure 29.49 Block Diagram of PIC2B

(4) Function

A/D trigger signal can be selected for individual ADCGn scan groups and output can be selected from rising edge, falling edge, and both edges. The TAUD trigger for the scan group with the same number is shared between ADCG0 and ADCG1.

(5) Flow Chart

Set this function before starting A/D converter.

Section 30 A/D Converter (ADCG)

The A/D Converter (ADCG) is advanced A/D converter of successive approximation method. ADCG has two units implemented.

30.1 Features of RH850/P1M-E ADCG

30.1.1 Number of Units

This microcontroller has the following number of ADCG units.

Table 30.1 Number of Units

Products	RH850/P1M-E
Number of units	2
Name	ADCGn (n = 0, 1)

Table 30.2 Index

Index	Meaning
n	Throughout this section, the individual ADCG units are identified by the index “n” (n = 0, 1).
m	Throughout this section, the number of each ADCG physical channel is indicated by the index “m” (see Table 30.6 for physical channel number m).
j	Throughout this section, the number of data registers and virtual channels are identified by the index “j” (j = 0 to 23), for example, ADCGnDRj for the data register j.
k	Throughout this section, the T&H channel number is indicated by the letter “k” (k = 0 to 5 for ADCG0; k = 0 to 3 for ADCG1).
x	Throughout this section, the scan group is indicated by the letter “x” (x = 0 to 4).
y	Throughout this section, the number of A/D timers are indicated by the letter “y” (y = 3, 4).
z	Throughout this section, A/D conversion monitor virtual channel pointer is indicated by the index “z” (z = 0 to 4).

30.1.2 Register Base Address

ADCG base addresses are listed in the following table.

ADCG register addresses are given as offsets from the individual base address.

Table 30.3 Register Base Address

Base Address Name	Base Address
<ADCG0_base>	FFF9 1000 _H
<ADCG1_base>	FFF9 2000 _H

30.1.3 Clock Supply

Clock supply by and to ADCG is listed in the following table.

Table 30.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
ADCGn	PCLK	Low-speed peripheral clock CLK_LSB
	ADC clock	ADCG clock CLK_ADC

30.1.4 Interrupt Requests

ADCG interrupt requests are listed in the following table.

Table 30.5 Interrupt Requests

Unit Interrupt Name	Description	Interrupt Code	DMA/DTS Trigger	ECM
ADCG0				
INTADCG0I0	ADCG0 scan group 0 end interrupt	√	√	—
INTADCG0I1	ADCG0 scan group 1 end interrupt	√	√	—
INTADCG0I2	ADCG0 scan group 2 end interrupt	√	√	—
INTADCG0I3	ADCG0 scan group 3 end interrupt	√	√	—
INTADCG0I4	ADCG0 scan group 4 end interrupt	√	√	—
INTADCG0ERR	ADCG0 A/D error interrupt	√	—	—
INTADCG0MPX	ADCG0 MPX request interrupt	√	√	—
INTADCG0PE	ADCG0 parity error interrupt	—	—	√
ADCG1				
INTADCG1I0	ADCG1 scan group 0 end interrupt	√	√	—
INTADCG1I1	ADCG1 scan group 1 end interrupt	√	√	—
INTADCG1I2	ADCG1 scan group 2 end interrupt	√	√	—
INTADCG1I3	ADCG1 scan group 3 end interrupt	√	√	—
INTADCG1I4	ADCG1 scan group 4 end interrupt	√	√	—
INTADCG1ERR	ADCG1 A/D error interrupt	√	—	—
INTADCG1MPX	ADCG1 MPX request interrupt	√	√	—
INTADCG1PE	ADCG1 parity error interrupt	—	—	√

30.1.5 Reset Sources

Please refer to **Section 8, Reset Controller**.

30.1.6 External Input/Output Signals

External input/output signals of ADCG are listed in the following table.

Table 30.6 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Signal Name
AVcc0	—	Power supply pin for the input analog part	A0VCC
AVss0	—	Ground pin for the input analog part	A0VSS
AVcc1	—	Power supply pin for the input analog part	A1VCC
AVss1	—	Ground pin for the input analog part	A1VSS
AVREFH0	I	Reference voltage pin for the input analog part	A0VREFH
AVREFH1	I	Reference voltage pin for the input analog part	A1VREFH
AN000	I	12-bit resolution analog input pin (for T&H)	ADCG0I0
AN001	I	12-bit resolution analog input pin (for T&H)	ADCG0I1
AN002	I	12-bit resolution analog input pin (for T&H)	ADCG0I2
AN003	I	12-bit resolution analog input pin (for T&H)	ADCG0I3
AN004	I	12-bit resolution analog input pin (for T&H)	ADCG0I4
AN005	I	12-bit resolution analog input pin (for T&H)	ADCG0I5
AN006	I	12-bit resolution analog input pin (for MPX)	ADCG0I6
AN007	I	12-bit resolution analog input pin	ADCG0I7
AN008	I	12-bit resolution analog input pin	ADCG0I8
AN009	I	12-bit resolution analog input pin	ADCG0I9*1
AN010	I	12-bit resolution analog input pin	ADCG0I10*1
AN011	I	12-bit resolution analog input pin	ADCG0I11*1
AN100	I	12-bit resolution analog input pin (for T&H and MPX)	ADCG1I0
AN101	I	12-bit resolution analog input pin (for T&H)	ADCG1I1
AN102	I	12-bit resolution analog input pin (for T&H)	ADCG1I2
AN103	I	12-bit resolution analog input pin (for T&H)	ADCG1I3
AN104	I	12-bit resolution analog input pin	ADCG1I4
AN105	I	12-bit resolution analog input pin	ADCG1I5
AN106	I	12-bit resolution analog input pin	ADCG1I6
AN107	I	12-bit resolution analog input pin	ADCG1I7
AN108	I	12-bit resolution analog input pin	ADCG1I8

ADCG1CNV4	O	A/D converter status monitor pin	ADCG1CNV4

Note 1. This channel is not supported in this product (100 pin).

30.1.7 Analog Channels and Track and Hold Function

A/D conversion is available for 12 ADCG0 channels and 13 ADCG1 channels (including the temperature sensor dedicated channel), 25 channels in total. For corresponding channel numbers for each product, see **Table 30.6**.

ADCG0 and ADCG1 have an internal track and hold circuit that enables A/D conversion with simultaneous sampling of the voltages on different channels.

ADCG0 has a track and hold circuit for six channels that enables simultaneous track and hold for up to six channels.

ADCG1 has a track and hold circuit for four channels that enables simultaneous track and hold for up to four channels.

30.1.8 Virtual Channel

Each ADCG has 24 virtual channels. Analog channels for which A/D conversion is to be made and other accompanying information are configured for each virtual channel. By sequentially performing the processing for the virtual channels indicated by the start virtual channel pointer and the end virtual channel pointer in each scan group, scans (which can perform A/D conversion for any analog channels in any order) can be executed.

30.2 Overview

30.2.1 Functional Overview

ADCG has the following features.

Advanced A/D converter

Resolution: 12 bits

A/D conversion method: Successive approximation method

A/D conversion time: Selectable as 1.0 μ s and 11.3 μ s.

(The A/D conversion time is the sum of the sampling time of the sample-and-hold circuits and the time for conversion by successive approximation.)

- Supports five scan groups
Each ADCG has five scan groups. Scan settings can be made independently for each scan group.
- Two scan modes
Each ADCG has two scan modes.
Multicycle scan mode: Specified number of scans are executed.
Continuous scan mode: Scans are repeatedly executed without limit.
- Interval function
The ADCG can start scan groups in any cycle by using the A/D timer equipped in the scan groups 3 and 4. This enables scans with intervals inserted.
- A/D-converted value adding function
The ADCG performs A/D conversion sequentially twice or four times for a channel, and stores the addition result in the data register. The addition count setting is common to all virtual channels. The effect of the moving average filter can be gained by using this result. However, this function does not always ensure that A/D conversion accuracy is improved.
- Extended physical channels
Each ADCG can extend physical channels by using an external analog multiplexer. (Available channels are AN006 and AN100.)
- Data registers
Data registers corresponding to virtual channels are provided.
- Start trigger for each scan group
Hardware triggers and software triggers can start processing of each scan group. Only scan groups 3 and 4 can start processing by an A/D timer trigger.
- Asynchronous/synchronous suspend and resume function
A processing for a scan group can interrupt an ongoing processing for another scan group. The priority is as follows:

Low	High
SG0 < SG1 < SG2 < SG3 < SG4	(SG: Scan group)

If a request for a higher-priority SG is made while a lower-priority SG is being processed, the lower-priority SG is suspended after the ongoing virtual channel processing is stopped (synchronous suspend) or after the ongoing virtual channel processing is immediately stopped (asynchronous suspend), and then the processing for the higher-priority SG is performed. After the processing for the higher-priority SG is completed, the suspended virtual channel processing of the lower-priority SG resumes (synchronous suspend is available only when T&H function is not used.)

The following configuration is also available: when a higher-priority SG interrupts an SG0 processing, asynchronous suspend occurs, but when a higher-priority SG interrupts a lower-priority SG other than SG0, synchronous suspend occurs (only when T&H function is not used).

- Supports scan end interrupt and DMA transfer
Each scan group can generate an interrupt request to the INTC and activate the DMAC each time a processing for the virtual channel indicated by the end virtual channel pointer ends or a virtual channel ends.
- An analog conversion voltage can be specified
The A0VREFH pin and the A1VREFH pin can be used to set the voltage range for analog conversion.
- A variety of safety functions
The ADCG is equipped with various safety functions, including A/D conversion circuit selfdiagnostic function, pin-level self-diagnostic function, wiring-break detection, ID error check, upper-limit/lower-limit check for data registers, parity check for data registers, overwrite check for data registers, and read and clear function for data registers.

30.2.2 Block Diagram

Figure 30.1 and Figure 30.2 show the ADCG block diagram.

Figure 30.1 Block Diagram of ADCG0

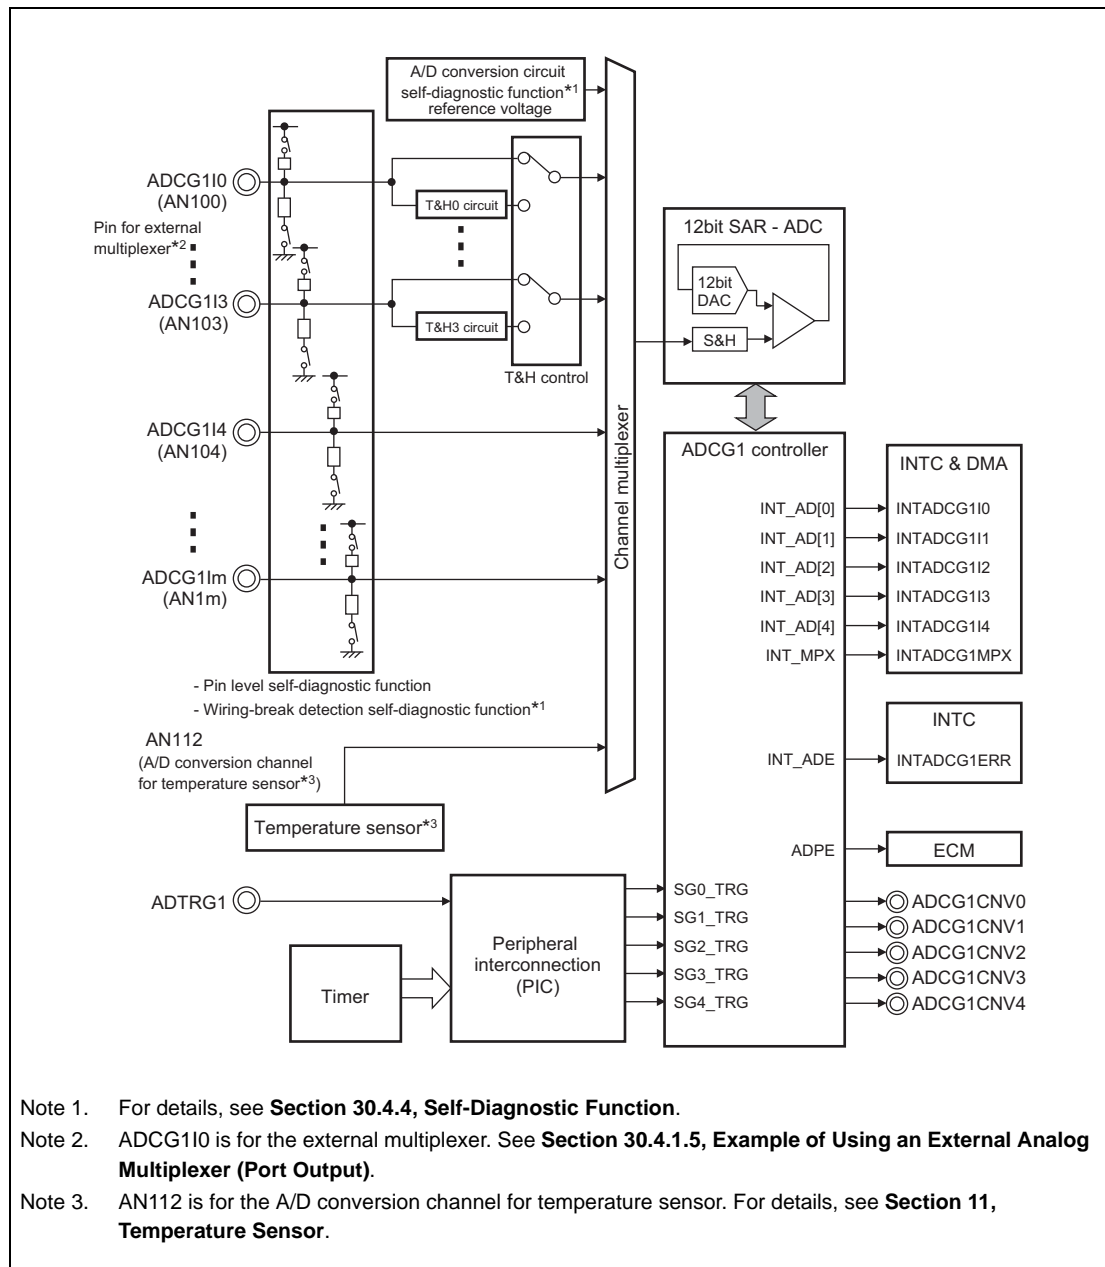

Figure 30.2 Block Diagram of ADCG1

30.2.3 Scan Group (SG)

A scan group is a group of multiple virtual channels.

ADCG has 5 scan groups and the order of priority for A/D conversion is as follows: SG4 > SG3 > SG2 > SG1 > SG0.

SGx can group consecutive virtual channels. Grouping is set up by using a start pointer (ADCGnSGVCSPx register) and an end pointer (ADCGnSGVCEPx register). Disable the A/D conversion trigger input for any unused scan groups.

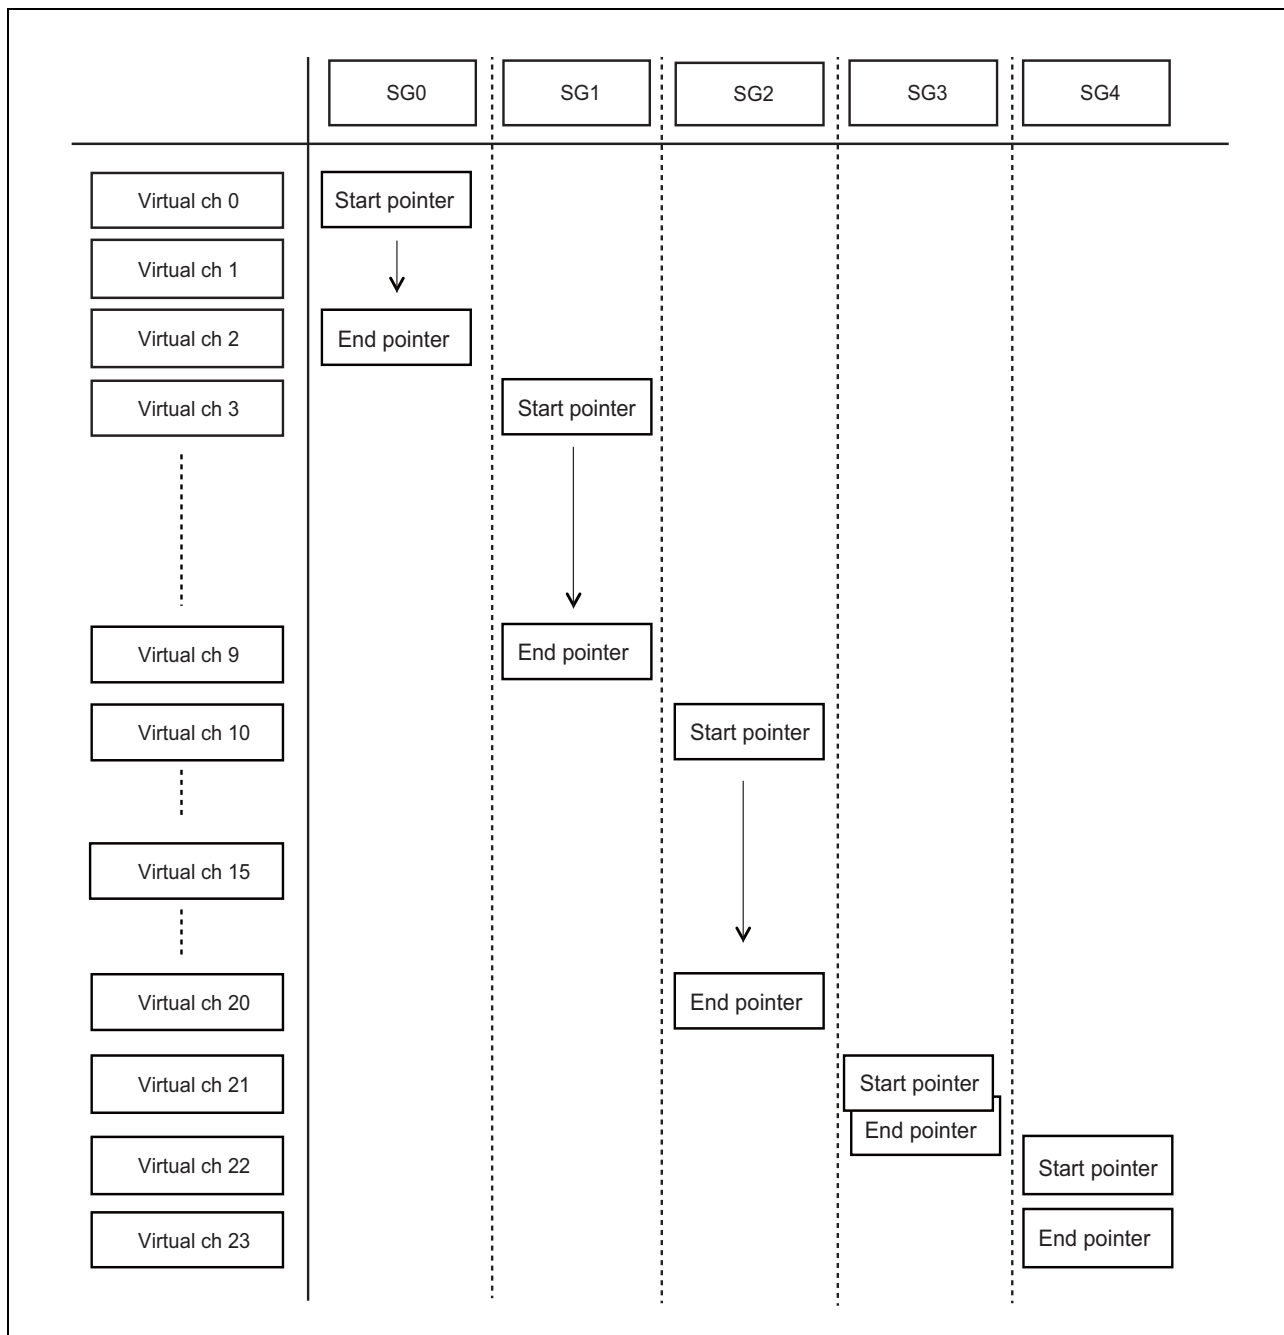

Figure 30.3 Example of SG Assignment

30.3 Registers

30.3.1 List of Registers

ADCG registers are listed in the following table.

Table 30.7 List of Registers (1/2)

Register Name	Symbol	Address
ADC common registers		
A/D synchronization start control register	ADCG0ADSYNSTCR	<ADCG0_base> + 300 _H
A/D timer synchronization start control register	ADCG0ADTSYNSTCR	<ADCG0_base> + 304 _H
ADC specific registers (virtual channel)		
Virtual channel register j	ADCGnVCRj	<ADCGn_base> + j × 4 _H
Data register j (j = only even numbers)	ADCGnDRj	<ADCGn_base> + 100 _H + j × 2 _H
Data supplementary information register j	ADCGnDIRj	<ADCGn_base> + 200 _H + j × 4 _H
ADC specific registers (control)		
A/D conversion time control register	ADCGnSMPCR	<ADCGn_base> + 340 _H
A/D halt register	ADCGnADHALTR	<ADCGn_base> + 380 _H
A/D control register 1	ADCGnADCR1	<ADCGn_base> + 384 _H
MPX current control register	ADCGnMPXCURCR	<ADCGn_base> + 388 _H
MPX current register	ADCGnMPXCURR	<ADCGn_base> + 38C _H
MPX optional wait register	ADCGnMPXOWR	<ADCGn_base> + 390 _H
A/D control register 2	ADCGnADCR2	<ADCGn_base> + 398 _H
A/D conversion monitor virtual channel pointer 0	ADCGnADENDP0	<ADCGn_base> + 3A0 _H
A/D conversion monitor virtual channel pointer 1	ADCGnADENDP1	<ADCGn_base> + 3A4 _H
A/D conversion monitor virtual channel pointer 2	ADCGnADENDP2	<ADCGn_base> + 3A8 _H
A/D conversion monitor virtual channel pointer 3	ADCGnADENDP3	<ADCGn_base> + 3AC _H
A/D conversion monitor virtual channel pointer 4	ADCGnADENDP4	<ADCGn_base> + 3B0 _H
T&H sampling start control register	ADCGnTHSMPSTCR	<ADCGn_base> + 400 _H
T&H stop control register	ADCGnTHSTPCR	<ADCGn_base> + 404 _H
T&H control register	ADCGnTHCR	<ADCGn_base> + 408 _H
T&H group A hold start control register	ADCGnTHAHLSTCR	<ADCGn_base> + 410 _H
T&H group B hold start control register	ADCGnTHBHLSTCR	<ADCGn_base> + 414 _H
T&H group A control register	ADCGnTHACR	<ADCGn_base> + 420 _H
T&H group B control register	ADCGnTHBCR	<ADCGn_base> + 424 _H
T&H enable register	ADCGnTHER	<ADCGn_base> + 430 _H
T&H group select register	ADCGnTHGSR	<ADCGn_base> + 434 _H
ADC specific registers (safety-related)		
Safety control register	ADCGnSFTCR	<ADCGn_base> + 3C0 _H
Pin level self-diagnostic control register	ADCGnTDCR	<ADCGn_base> + 3C4 _H
Wiring-break detection control register	ADCGnODCR	<ADCGn_base> + 3C8 _H
Wiring-break detection pin setting register 0	ADOPDIG0	FFF9 1800 _H
Wiring-break detection pin setting register 1	ADOPDIG1	FFF9 2800 _H
Upper-limit/lower-limit table register 0	ADCGnULLMTBR0	<ADCGn_base> + 3CC _H
Upper-limit/lower-limit table register 1	ADCGnULLMTBR1	<ADCGn_base> + 3D0 _H
Upper-limit/lower-limit table register 2	ADCGnULLMTBR2	<ADCGn_base> + 3D4 _H
Error clear register	ADCGnECR	<ADCGn_base> + 3D8 _H
Upper-limit/lower-limit error register	ADCGnULER	<ADCGn_base> + 3DC _H
Overwrite error register	ADCGnOWER	<ADCGn_base> + 3E0 _H
Parity error register	ADCGnPER	<ADCGn_base> + 3E4 _H

Table 30.7 List of Registers (2/2)

Register Name	Symbol	Address
ID error register	ADCGnIDER	<ADCGn_base> + 3E8 _H
Scan group specific registers		
Scan group x start control register 0	ADCGnSGSTCR0	<ADCGn_base> + 480 _H
Scan group x start control register 1	ADCGnSGSTCR1	<ADCGn_base> + 500 _H
Scan group x start control register 2	ADCGnSGSTCR2	<ADCGn_base> + 580 _H
Scan group x start control register 3	ADCGnSGSTCR3	<ADCGn_base> + 600 _H
Scan group x start control register 4	ADCGnSGSTCR4	<ADCGn_base> + 680 _H
A/D timer y start control register 3	ADCGnADTSTCR3	<ADCGn_base> + 608 _H
A/D timer y start control register 4	ADCGnADTSTCR4	<ADCGn_base> + 688 _H

Scan group x upper-limit/lower-limit table select register 1	ADCGnULLMSR1	<ADCGn_base> + 530 _H
Scan group x upper-limit/lower-limit table select register 2	ADCGnULLMSR2	<ADCGn_base> + 5B0 _H
Scan group x upper-limit/lower-limit table select register 3	ADCGnULLMSR3	<ADCGn_base> + 630 _H
Scan group x upper-limit/lower-limit table select register 4	ADCGnULLMSR4	<ADCGn_base> + 6B0 _H

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.2 ADCG0ADSYNSTCR — A/D Synchronization Start Control Register

ADCG0ADSYNSTCR is an 8-bit write-only register that controls simultaneous start of A/D conversion for each scan group of ADCG0 and ADCG1. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: <ADCG0_base> + 300_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADSTART
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 30.8 ADCG0ADSYNSTCR Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	ADSTART	Starts simultaneous A/D conversion for scan groups of ADCG0 and ADCG1. 0: No function. (Writing 0 is ignored.) 1: A/D conversion is started simultaneously. Enable the SG synchronization start enable bit (ADCGnSGCRx.ADSTARTE) for the scan group which is to have A/D conversion simultaneously started.

30.3.3 ADCG0ADTSYNSTCR — A/D Timer Synchronization Start Control Register

ADCG0ADTSYNSTCR is an 8-bit write-only register that controls simultaneous start of count operation for each A/D timer of ADCG0 and ADCG1. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: <ADCG0_base> + 304_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADTSTART
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	ADTSTART	Starts count operation of the A/D timer of ADCG0 and ADCG1 simultaneously. 0: No function. (Writing 0 is ignored.) 1: A/D timer count is started. Enable the A/D timer synchronization start enable bit (the ADCGnSGCRx.ADTSTARTE) for the A/D timer which is to have count operation simultaneously started.

30.3.4 ADCGnVCRj — Virtual Channel Register j

ADCGnVCRj is a 32-bit readable/writable register configured for each virtual channel.

Access: This register can be read/written in 32-bit units.

Address: <ADCGn_base> + j × 4_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

6 _H : Normal A/D conversion (with the external MPX in addition mode)	GCTRL[4:0]: Set physical channel number m of MPX supported pin.																	
Other than above: Setting prohibited	—																	

Write 0 to the bits in GCTRL[5:0] which are not used.

Note 1. Specify a physical channel ANNm listed in **Table 29.7, PIC1A External Input/Output Signals**. Setting any of physical channels ANNm not incorporated is prohibited.

CAUTION

To prevent malfunctions, make ADCGnVCRj settings after making or confirming the following settings in the order shown:

- (1) HLDTE of T&H group A and B are 0.
- (2) ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
- (3) SGACT of all scan groups are 0 (before scan groups are started).

However, if the above are for scan groups where ADCGnVCRj.PUE and ADCGnVCRj.PDE are being used to detect wiring breaks, the ADCGnVCRj.GCTRL[5:0] bits can be set even when not all of the SGACT bits are 0 (0 indicating that conversion by the scan groups has not started yet). Only the SGACT bits for the scan groups to be set need to be 0.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.5 ADCGnDRj — Data Register j

ADCGnDRj is a 32-bit read-only register that stores the A/D conversion results corresponding to ADCGnVCRj and ADCGnVCR(j+1). As the A/D conversion results, the conversion result for ADCGnVCR(j+1) is stored in the upper bits (ADCGnDR(j+1)), and the conversion result for ADCGnVCRj is stored in the lower bits (ADCGnDRj). The format of ADCGnDRj depends on the setting of ADDNT when DFMT and CNVCLS[2:0] in ADCGnVCRj = 4H, 6H. ADCGnDRj is cleared to 0000_H when ADCGnDRj or ADCGnDIRj is read while RDCLRE is set to 1.

Access: This register can be read in 32-bit units.

Address: <ADCGn_base> + 100_H + j × 2_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DRj+1[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DRj[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 30.11 ADCGnDRj Register Contents

Bit Position	Bit Name	Function
31 to 16	DRj+1[15:0]	Stores the A/D conversion result data of DR(j+1)[15:0]. (The A/D conversion result for the channel set in ADCGnVCR(j+1) is transferred.)
15 to 0	DRj [15:0]	Stores the A/D conversion result data of DRj[15:0]. (The A/D conversion result for the channel set in ADCGnVCRj is transferred.)

Note: j = 00, 02, 04 ... only even numbers

For signed fixed-point format (DFMT = 0)

Number of addition	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Convert once	S													0	0	0
Convert twice	S														0	0
Convert 4 timers	S															0

↑ Position of decimal point

For signed integer format (DFMT = 1)

Number of addition	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Convert once	S	S	S	S												
Convert twice	S	S	S													
Convert 4 timers	S	S														

↗
Position of decimal point

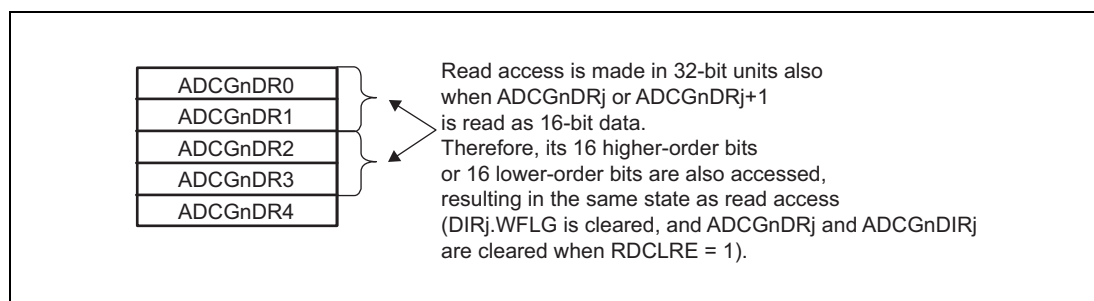

- | |
|---|
| S |
|---|

 : Sign bit (always 0)
- | |
|---|
| 0 |
|---|

 : Zero extension

The format setting in ADDNT is valid when CNVCLS[2:0] = 4_H or 6_H.

If CNVCLS[2:0] is neither 4_H nor 6_H, the format is “convert once.”

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units.**

30.3.6 ADCGnDIRj — Data Supplementary Information Register j

ADCGnDIRj is a 32-bit read-only register that stores supplementary information on ADCGnDRj and the A/D converted value. ADCGnDIRj is provided for each virtual channel. ADCGnDIRj is cleared to 0000 0000_H when ADCGnDRj or ADCGnDIRj is read while RDCLRE is set to 1. WFLG is cleared when ADCGnDRj or ADCGnDIRj is read regardless of the RDCLRE setting. This register must always be read as 32-bit data. ADCGnDRj is read from the 16 lower-order bits.

Access: This register can be read in 32-bit units.

Address: <ADCGn_base> + 200_H + j × 4_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15 to 0	DRj[15:0]	Data Register The same data as that in the ADCGnDRj register is stored as an A/D conversion result.																

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.7 ADCGnSMPCR — A/D Conversion Time Control Register

ADCGnSMPCR is a 16-bit readable/writable register that controls the A/D conversion time.

ADCGn supports 1- μ s conversion and 11.3- μ s conversion.

Access: This register can be read/written in 16-bit units.

Address: <ADCGn_base> + 340_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SMPCR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.13 ADCGnSMPCR Register Contents

Bit Position	Bit Name	Function
15 to 0	SMPCR[15:0]	Sets the A/D conversion time. 0000 _H : 1- μ s conversion 90CC _H : 11.3- μ s conversion Settings other than the above are prohibited.
CAUTION		
For 1- μ s conversion, set the CLK_ADC frequency to 40 MHz. If you wish to use 11.3- μ s conversion, be sure to set the CLK_ADC frequency to 20 MHz.		

Settings other than the above are prohibited. Use register CKSC8C to set the CLK_ADC frequency. For details, see **Section 12.3.11, CKSC8C — Clock Selector 8 Control Register**.

CAUTION

If ADCGnSMPCR is changed, the unit for counting of the wait time to be inserted when waiting for MPX will change accordingly. For details, see **Section 30.3.12, ADCGnMPXOWR — MPX Optional Wait Register**.

To prevent malfunctions, make ADCGnSMPCR settings after making or confirming the following settings in the order shown:

- (1) HLDTE of T&H group A and B are 0.
- (2) ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
- (3) SGACT of all scan groups are 0 (before scan groups are started).

30.3.8 ADCGnADHALTR — A/D Halt Register

ADCGnADHALTR is an 8-bit write-only register that halts the ADC. The register bits are always read as 0.

Access: This register can be written only in 8-bit units.

Address: <ADCGn_base> + 380_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	HALT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 30.14 ADCGnADHALTR Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	HALT	All scan group conversions and A/D timers are halted forcibly. 0: No function (Writing 0 is ignored.) 1: Halted

30.3.9 ADCGnADCR1 — A/D Control Register 1

ADCGnADCR1 is an 8-bit readable/writable register for ADC common control.

Access: This register can be read/written in 8-bit units.

Address: <ADCGn_base> + 384_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	SUSMTD[1:0]	
Value after reset	0	0	0	0	0	0	0	0

Table 30.15 ADCGnADCR1 Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	SUSMTD [1:0]	<p>Suspend Method</p> <p>These bits select the suspend method used when a higher-priority scan group interrupts a lower-priority scan group.</p> <p>Synchronous suspend: If a request from a higher-priority SG is made while a lower-priority SG is being processed, processing for the lower-priority SG is suspended after the ongoing virtual channel processing is completed, and then processing for the higher-priority SG is executed. After processing for the higher-priority SG is completed, the suspended virtual channel processing for the lower-priority SG is resumed.</p> <p>Asynchronous suspend: If a request from a higher-priority SG is made while a lower-priority SG is being processed, the ongoing virtual channel processing is immediately suspended, and then processing for the higher-priority SG is executed. After processing for the higher-priority SG is completed, the suspended virtual channel processing for the lower-priority SG is resumed.</p> <ul style="list-style-type: none"> When ADCGnTHACR.HLDCTE = 0 and ADCGnTHBCR.HLDCTE = 0 <ul style="list-style-type: none"> 0_H: Synchronous suspend 1_H: Asynchronous suspend when a higher-priority SG interrupts SG0 Synchronous suspend when a higher-priority SG interrupts a lower-priority SG (except for SG0) 2_H: Asynchronous suspend 3_H: Setting prohibited When ADCGnTHACR.HLDCTE = 1 or ADCGnTHBCR.HLDCTE = 1 <ul style="list-style-type: none"> 2_H: Asynchronous suspend Other than above: Setting prohibited

For details, see **Figure 30.13, Example of Synchronous Suspend and Resume Operation** and **Figure 30.14, Example of Asynchronous Suspend and Resume Operation**.

CAUTION

- To prevent malfunctions, make ADCGnADCR1 settings after making or confirming the following settings in the order shown:
 - HLDTTE of T&H group A and B are 0.
 - ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
 - SGACT of all scan groups are 0 (before scan groups are started).
- When SGx hold trigger is selected for the trigger input to SGx, only asynchronous suspend can be specified (SUMTD[1:0] = 2_H).

30.3.10 ADCGnMPXCURCR — MPX Current Control Register

ADCGnMPXCURCR is a register that controls the ADCGnMPXCURR format.

Access: This register can be read/written in 8-bit units.

Address: <ADCGn_base> + 388_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MSKCFMT[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 30.16 ADCGnMPXCURCR Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	MSKCFMT[3:0]	MSKC Format Specification Specifies the format for MSKC[15:0] of ADCGnMPXCURR MSKCFMT[3] 0: MSKC[15:12] = 0000 1: MSKC[15:12] = 1111 MSKCFMT[2] 0: MSKC[11:8] = 0000 1: MSKC[11:8] = 1111 MSKCFMT[1] 0: MSKC[7:4] = 0000 1: MSKC[7:4] = 1111 MSKCFMT[0] 0: MSKC[3:0] = 0000 1: MSKC[3:0] = 1111

CAUTION

To prevent malfunctions, make ADCGnMPXCURCR settings after making or confirming the following settings in the order shown:

- (1) HLDTE of T&H group A and B are 0.
- (2) ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
- (3) SGACTION of all scan groups are 0 (before scan groups are started).

30.3.11 ADCGnMPXCURR — MPX Current Register

ADCGnMPXCURR is a 32-bit read-only register that stores the MPX value for an external analog multiplexer.

Access: This register can be read in 32-bit units.

Address: <ADCGn_base> + 38C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MSKC[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—											MPXCUR[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 30.17 ADCGnMPXCURR Register Contents

Bit Position	Bit Name	Function
31 to 16	MSKC[15:0]	Mask Control The format depends on the MSKCFMT[3:0] setting of ADCGnMPXCURCR. For details, see Section 30.3.10, ADCGnMPXCURCR — MPX Current Control Register .
15 to 5	Reserved	When read, the value after reset is read.
4 to 0	MPXCUR[4:0]	Current MPX value When a virtual channel for which CNVCLS[2:0] in ADCGnVCRj is set to 5 _H or 6 _H is started, GCTRL[4:0] in ADCGnVCRj is transferred to MPXCUR[4:0]. At this time, an interrupt request to the INTC or a DMA transfer request is generated. The DMAC transfers ADCGnMPXCURR to PSRn of the I/O port, enabling the MPX value to be sent to an external analog multiplexer. When PSRn is used, transfer the MPX value as a 32-bit value. This enables rewriting of only the necessary ports using the format control in MSKC[15:0]. For details, see Section 30.4.1.5, Example of Using an External Analog Multiplexer (Port Output) .

CAUTION

For a DMA transfer to the PSRn register, the MSKC bit is specified in 4-bit units (register ADCGnMPXCURCR). When MSKCFMT[1]=1(MSKC[7:4]=1111B), the Pn[7:4] bits are updated. Do not use the 3 higher-order bits of the Pn register as output port since they are overwritten unexpectedly.

NOTE

For the indices of ADCG, see **Section 30.1.1, Number of Units**.

30.3.12 ADCGnMPXOWR — MPX Optional Wait Register

ADCGnMPXOWR is a register that specifies the wait time to be inserted for an external analog multiplexer.

Access: This register can be read/written in 8-bit units.

Address: <ADCGn_base> + 390_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MPXOW[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 30.18 ADCGnMPXOWR Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	MPXOW[3:0]	<p>MPX Optional Wait</p> <p>These bits specify the wait time to be inserted before A/D conversion is started after a virtual channel for which CNVCLS[2:0] in ADCGnVCRj is 5_H or 6_H is started.</p> <p>1_H: A/D conversion time × 1 2_H: A/D conversion time × 2 3_H: A/D conversion time × 3 4_H: A/D conversion time × 4 5_H: A/D conversion time × 5 6_H: A/D conversion time × 6 7_H: A/D conversion time × 7 8_H: A/D conversion time × 8 9_H: A/D conversion time × 9 A_H: A/D conversion time × 10 B_H to F_H: Setting prohibited</p> <p>For the A/D conversion time, see Section 30.3.7, ADCGnSMPCR — A/D Conversion Time Control Register.</p>

CAUTION

To prevent malfunctions, make ADCGnMPXOWR settings after making or confirming the following settings.

- (1) HLDTE of T&H group A and B are 0.
- (2) ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
- (3) SGACT of all scan groups are 0 (before scan groups are started).

30.3.13 ADCGnADCR2 — A/D Control Register 2

ADCGnADCR2 is an 8-bit readable/writable register for ADCG common control.

Access: This register can be read/written in 8-bit units.

Address: <ADCGn_base> + 398_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	DFMT	—	—	—	ADDNT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R	R	R/W

Table 30.19 ADCGnADCR2 Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	DFMT	Data Format 0: Signed fixed-point format 1: Signed integer format This bit specifies the format of data to be transferred to ADCGnDRj. For details of data format, see Section 30.3.5, ADCGnDRj — Data Register j .
3 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ADDNT	Addition Count Select 0: Add twice 1: Add 4 times This bit is valid only when CNVCLS[2:0] is 4 _H ,6 _H

CAUTION

To prevent malfunctions, make ADCGnADCR2 settings after making or confirming the following settings.

- (1) HLDTE of T&H group A and B are 0.
- (2) ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
- (3) SGACTION of all scan groups are 0 (before scan groups are started).

30.3.14 ADCGnADENDPz — A/D Conversion Monitor Virtual Channel Pointer z

ADCGnADENDPz is an 8-bit readable/writable register which selects the virtual channel which outputs the A/D conversion timing to ADCGnCNVx.

Access: This register can be read/written in 8-bit units.

Address: ADCGnADENDP0: <ADCGn_base> + 3A0_H
 ADCGnADENDP1: <ADCGn_base> + 3A4_H
 ADCGnADENDP2: <ADCGn_base> + 3A8_H
 ADCGnADENDP3: <ADCGn_base> + 3AC_H
 ADCGnADENDP4: <ADCGn_base> + 3B0_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	ENDP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.20 ADCGnADENDPz Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is read. When writing, write the value after reset.
5 to 0	ENDP[5:0]	A/D Conversion Monitor Virtual Channel Pointer When the virtual channel selected by ADCGnADENDPz is started, a high level is output from the ADCGnCNVz pin. When the virtual channel selected by ADCGnADENDPz ends, a low level is output.

CAUTION

To prevent malfunctions, make ADCGnADENDPz settings after making or confirming the following settings.

- (1) HLDTE of T&H group A and B are 0.
- (2) ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
- (3) SGACT of all scan groups are 0 (before scan groups are started).

30.3.15 ADCGnTHSMPSTCR — T&H Sampling Start Control Register

ADCGnTHSMPSTCR is an 8-bit write-only register that control starting of all T&H sampling. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: <ADCGn_base> + 400_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SMPST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 30.21 ADCGnTHSMPSTCR Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	SMPST	Starts T&H sampling. 0: No function. (Writing 0 is ignored.) 1: Sampling is started. Conditions for T&Hk to transit to the sampling state: 1 is written to SMPST while THkE = 1 At completion of A/D conversion of the value held by T&Hz while THkE = 1 and ASMPMSK = 0

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.16 ADCGnTHSTPCR — T&H Stop Control Register

ADCGnTHSTPCR is an 8-bit write-only register that controls stopping of all T&H. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: <ADCGn_base> + 404_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	THSTP
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 30.22 ADCGnTHSTPCR Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	THSTP	Stops T&H. 0: No function. (Writing 0 is ignored.) 1: T&H is stopped.

CAUTION

Set THSTP after all scan groups are stopped by ADCGnADHALTR.HALT.

After T&H are forcibly terminated by THSTP, set all THzE (z = 0 to 5) of ADCGnTHER to 0 to prevent resampling by auto sampling function (ADCGnTHCR.ASMPMASK).

30.3.17 ADCGnTHCR — T&H Control Register

ADCG0THCR in an 8-bit readable/writable register that controls T&H.

Access: This register can be read/written in 8-bit units.

Address: <ADCGn_base> + 408_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ASMPMSK
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 30.23 ADCGnTHCR Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ASMPMSK	Controls whether to start auto sampling of the T&H when A/D conversion of the relevant held value is complete. 0: Automatic sampling is performed. 1: Automatic sampling is not performed.

CAUTION

To prevent malfunctions, make ADCGnTHCR settings after making or confirming the following settings.

- (1) HLDTE of T&H group A and B are 0.
- (2) SGACT of the scan group x specified by SGS[1:0] of T&H group A and B are 0 (before scan groups are started).
- (3) THkE of all T&H are 0 (All T&H are stopped).

30.3.18 ADCGnTHAHLDDSTCR — T&H Group A Hold Start Control Register

ADCGnTHAHLDDSTCR is an 8-bit write-only register that controls the start of the hold for T&H group A. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: <ADCGn_base> + 410_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	HLDST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 30.24 ADCGnTHAHLDDSTCR Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	HLDST	Starts the hold of T&H group A. 0: No function (Writing 0 is ignored.) 1: The hold is started.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.19 ADCGnTHBHLDDSTCR — T&H Group B Hold Start Control Register

ADCGnTHBHLDDSTCR is an 8-bit write-only register that controls the start of the hold for T&H group B. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: <ADCGn_base> + 414_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	HLDST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 30.25 ADCGnTHAHLDDSTCR Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	HLDST	Starts the hold of T&H group B. 0: No function (Writing 0 is ignored.) 1: The hold is started.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.20 ADCGnTHACR — T&H Group A Control Register

ADCGnTHACR is an 8-bit readable/writable register that controls T&H group A.

Access: This register can be read/written in 8-bit units.

Address: <ADCGn_base> + 420_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	HLDCTE	HLDTTE	—	—	SGS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R/W	R/W

1	0	The software trigger by the ADCGnTHAHLDTSTCR.HLDST is selected as the hold trigger for the SG selected in SGS[1:0]. Hardware trigger is disabled. Note															
1	1	SGx_TRG hardware trigger is selected as the hold trigger for the SG selected in SGS[1:0]. Note															
		<p>Note: A/D conversion is forcibly suspended during the period from hold trigger to hold completion. SUSMTD[1:0] should be 2_H. (Setting of SUSMTD[1:0] = 0_H or 1_H is prohibited.) The setting of TRGMD of the scan group selected in SGS[1:0] should be 1_H (Setting of TRGMD = 0_H, 2_H, or 3_H is prohibited.)</p> <p>When modifying HLDTTE from 1 to 0 (SGx_TRG hardware trigger is disabled) when HLDCTE = 1 and during operation, follow the procedure below: (1) Change HLDTTE from 1 to 0 (2) Change TRGMD of the scan group x selected in SGS[1:0] from 1 to 0 When modifying HLDTTE from 0 to 1 (SGx_TRG hardware trigger is selected): (1) Change TRGMD of the scan group x selected in SGS[1:0] from 0 to 1 (2) Change HLDTTE from 0 to 1.</p>															
3, 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.															
1, 0	SGS[1:0]	<p>Scan Group Select Selects the scan group for T&H group A.</p> <p>0_H: SG1 1_H: SG2 2_H: SG3 3_H: SG4</p> <p>For details, see Section 30.4.1.3, Simultaneous Track and Hold Operation (THC Control).</p> <p>CAUTION</p> <p>This bit is enabled when HLDCTE = 1. Designate a scan group which include the virtual channel subject to T&H conversion.</p>															

CAUTION

To prevent malfunctions, make settings for ADCGnTHACR.HLDCTE and ADCG0THACR.SGS[1:0] after making or confirming the following settings.

- (1) HLDTE of T&H group A and B are 0.
- (2) ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
- (3) SGACTION of all scan groups are 0 (before scan groups are started).
- (4) THkE of all T&H are 0 (all T&H are stopped).

Do not set the SGS[1:0] bit of ADCGnTHACR and ADCGnTHBCR to the same scan group when both T&H group A and B are used.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.21 ADCGnTHBCR — T&H Group B Control Register

ADCGnTHBCR is an 8-bit readable/writable register that controls T&H group B.

Access: This register can be read/written in 8-bit units.

Address: <ADCGn_base> + 424_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0

1, 0	SGS[1:0]	<p>Scan Group Select</p> <p>Selects the scan group for T&H group B.</p> <p>0_H: SG1</p> <p>1_H: SG2</p> <p>2_H: SG3</p> <p>3_H: SG4</p> <p>For details, see Section 30.4.1.3, Simultaneous Track and Hold Operation (THC Control).</p> <p>CAUTION</p> <p>This bit is enabled when HLDCTE = 1. Designate a scan group which include the virtual channel subject to T&H conversion.</p>															

CAUTION

To prevent malfunctions, make settings for ADCGnTHBCR.HLDCTE and ADCG0THBCR.SGS[1:0] after making or confirming the following settings.

- (1) HLDTE of T&H group A and B are 0.
- (2) ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
- (3) SGACT of all scan groups are 0 (before scan groups are started).
- (4) THkE of all T&H are 0 (all T&H are stopped).

Do not set the SGS[1:0] bit of ADCGnTHACR and ADCGnTHBCR to the same scan group when both T&H group A and B are used.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.22 ADCGnTHER — T&H Enable Register

ADCGnTHER is an 8-bit readable/writable register that controls enabling and disabling of each T&H.

Access: This register can be read/written in 8-bit units.

Address: <ADCGn_base> + 430_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	TH5E	TH4E	TH3E	TH2E	TH1E	TH0E
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.28 ADCGnTHER Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is read. When writing, write the value after reset.
5 to 0	THkE	Enables or disables track and hold operation of T&Hk circuit. 0: Disabled 1: Enabled For details, see Section 30.4.1.3, Simultaneous Track and Hold Operation (THC Control) .

CAUTION

To prevent malfunctions, make ADCGnTHER settings after making or confirming the following settings.

- (1) HLDTE of T&H group A and B are 0.
- (2) SGACT of the scan group x specified in SGS[1:0] of the T&H group A and B are 0 (before scan groups are started).

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.23 ADCGnTHGSR — T&H Group Select Register

ADCGnTHGSR is a 16-bit readable/writable register that selects the T&H group of each T&H.

Access: This register can be read/written in 16-bit units.

Address: <ADCGn_base> + 434_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	TH5GS	—	TH4GS	—	TH3GS	—	TH2GS	—	TH1GS	—	TH0GS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R	R/W	R	R/W	R	R/W	R	R/W	R	R/W

Table 30.29 ADCGnTHGSR Register Contents

Bit Position	Bit Name	Function
15 to 11, 9, 7, 5, 3, 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10, 8, 6, 4, 2, 0	THkGS	Selects the T&H group for T&Hk. 0: T&H group A is selected. 1: T&H group B is selected. For details, see Section 30.4.1.3, Simultaneous Track and Hold Operation (THC Control) .

CAUTION

To prevent malfunctions, make settings for ADCGnTHGSR after making or confirming the following settings.

- (1) HLDTE of T&H group A and B are 0.
- (2) SGACT of the scan group x specified in SGS[1:0] of the T&H group A and B are 0 (before scan groups are started).
- (3) THkE of all T&H are 0 (all T&H are stopped).

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.24 ADCGnSFTCR — Safety Control Register

ADCGnSFTCR is an 8-bit readable/writable register for safety control.

Access: This register can be read/written in 8-bit units.

Address: <ADCGn_base> + 3C0_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	RDCLRE	ULEIE	OWEIE	PEIE	IDEIE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 30.30 ADCGnSFTCR Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	RDCLRE	Read and Clear Enable/Disable This bit sets whether to clear (ALL 0) the ADCGnDRj and ADCGnDIRj registers when reading the ADCGnDRj or ADCGnDIRj. 0: Do not perform read and clear 1: Perform read and clear CAUTION ADCGnDIRj.WFLG is cleared by reading ADCGnDRj or ADCGnDIRj regardless of the RDCLRE setting.
3	ULEIE	Enables or disables upper-limit/lower-limit error interrupt. 0: Disabled 1: Enabled
2	OWEIE	Enables or disables overwrite error interrupt. 0: Disabled 1: Enabled
1	PEIE	Enables or disables parity error interrupt. 0: Disabled 1: Enabled
0	IDEIE	Enables or disables ID error interrupt. 0: Disabled 1: Enabled

CAUTION

To prevent malfunctions, make ADCGnSFTCR settings after making of confirming the following settings.

- (1) HLDTE of T&H group A and B are 0.
- (2) ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
- (3) SGACTION of all scan groups are 0 (before the scan group is started).

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.25 ADCGnTDCR — Pin Level Self-Diagnostic Control Register

ADCGnTDCR is an 8-bit readable/writable register that controls the pin level self-diagnosis.

Access: This register can be read/written in 8-bit units.

Address: <ADCGn_base> + 3C4_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	TDE	—	—	—	—	—	TDLV[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R/W	R/W

Table 30.31 ADCGnTDCR Register Contents

Bit Position	Bit Name	Function
7	TDE	<p>Enables or disables pin level self-diagnosis.</p> <p>0: Pin level self-diagnosis is disabled.</p> <p>1: Pin level self-diagnosis is enabled.</p> <p>When TDE is set to 1, all analog pins are disconnected from the input buffer. When TDE is set to 0, all analog pins are connected to the input buffer. When TDE is set to 1, the voltage is fixed to the level specified by TDLV[1:0]. Performing A/D conversion in this state and checking the A/D converted value allows diagnosis of the path from an analog pin to the ADCG.</p>
<p>CAUTION</p> <ol style="list-style-type: none"> When TDE = 1, be sure to set both the PUE and PDE bits of ADCGnVCRj to 0. Set ADCGnTDCR.TDE to 0 before setting the PUE and PDE bits of ADCGnVCRj to 1. Similarly, when setting ADCGnTDCR.TDE to 1, set the PUE and PDE bits of ADCGnVCRj targeted for A/D conversion to 0 while ADCGnTDCR.TDE = 1 (the recommended setting is 0 for the PUE and PDE bits of all ADCGnVCRj registers). 		
6 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TDLV[1:0]	<p>Sets pin level self-diagnosis voltage level.</p> <p>0: Apply AnVSS to even-numbered physical channel groups and AnVCC to odd-numbered physical channel groups.</p> <p>1: Apply AnVCC to even-numbered physical channel groups and AnVSS to odd-numbered physical channel groups.</p> <p>2: Apply AnVSS to even-numbered physical channel groups and 1/2 × AnVCC to odd-numbered physical channel groups.</p> <p>3: Apply 1/2 × AnVCC to even-numbered physical channel groups and 1/2 × AnVSS to odd-numbered physical channel groups.</p>

CAUTION

To prevent malfunctions, make ADCGnTDCR settings after making or confirming the following settings.

- (1) HLDTE of T&H group A and B are 0.
- (2) ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
- (3) SGACTION of all scan groups are 0 (before scan groups are started).

When **Section 30.4.4.5, Pin-Level Self-Diagnosis of T&H Paths** is used, however, settings of ADCGnTDCR of the scan group in progress is possible only if the procedure is followed correctly.

30.3.26 ADcGnODcR — Wiring Break Detection Control Register

ADcGnODcR is a 32-bit readable/writable register that controls wiring-break detection.

Access: This register can be read/written in 32-bit units.

Address: <ADcGn_base> + 3C8_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ODDE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	ODE	—	ODPW[5:0]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.32 ADcGnODcR Register Contents

Bit Position	Bit Name	Function
31	ODDE	Enables or disables diagnosis of wiring-break detection. 0: Wiring-break detection is not diagnosed. 1: Wiring-break detection is diagnosed. When the ODDE bit is set to 1, diagnosis of wiring-break detection is enabled for all analog pins. CAUTION Do not set the ODE and ODDE bits at the same time.
30 to 8	Reserved	When read, the value after reset is read. When writing, write the value after reset.
7	ODE	Sets the mode for wiring-break detection. 0: Wiring-break detection mode 2 1: Wiring-break detection mode 1 For details, see Section 30.4.4.3, Wiring-Break Detection .
6	Reserved	When read, the value after reset is read. When writing, write the value after reset.
5 to 0	ODPW[5:0]	Sets the width of pull-down pulse to be generated in wiring-break detection mode 1. 04 _H : 1 clock 05 _H : 2 clocks : 13 _H : 16 clocks 14 _H : 17 clocks A value larger than 03 _H and less than 15 _H is required.

CAUTIONS

1. To prevent malfunctions, make ADCGnODCR settings after making or confirming the following settings.
 - (1) HLDTE of T&H group A and B are 0.
 - (2) ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
 - (3) SGACT of all scan groups are 0 (before scan groups are started).
 2. Do not perform A/D conversion of the held value (ADCGnVCRj.CNVCLS = 1_H) with wiring-break detection enabled.
 3. When Wiring-break Detection mode 1 (ADCGnODCR.ODE = 1_H) is used, to prevent malfunctions, use the wiring-break detection function after setting all THkE (k = 0 to 5) of ADCGnTHER to 0 or stopping all T&H by THSTPCR.THSTP.
-

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.27 ADOPDIGn — Wiring-break Detection Pin Setting Register n (n = 0, 1)

ADOPDIGn is a register that controls the pull-down/pull-up switch for I/O buffer of each analog input.

Access: This register can be read/written in 32-bit units.

Address: ADOPDIG0: FFF9 1800_H
ADOPDIG1: FFF9 2800_H

Value after reset: 0000 0000_H

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset is read. When writing, write the value after reset.
11 to 0	ADOPDIGnm	Controls the pull-down/pull-up settings for the wiring-break detection pin. Specify an analog pin for wiring-break detection. 0: Wiring-break Detection is not performed. 1: Wiring-break Detection is performed. When Wiring-break Detection mode 1 is used, wiring-break detection for the analog pin which has this bit set to 1 is performed. When Wiring-break Detection mode 2 is used, the pull-up/pull-down setting (ADCGnVCRj.PDE/ADCGnVCRj.PUE) of the analog pin which has this bit set to 1 is enabled.

CAUTIONS

- To prevent malfunctions, make ADOPDIGn settings after making or confirming the following settings.
 - HLDTTE of T&H group A and B are 0.
 - ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
 - SGACT of all scan groups are 0 (before scan groups are started).
- Do not perform A/D conversion of the held value (ADCGnVCRj.CNVCLS = 1_H) with wiring-break detection enabled.
- When Wiring-break Detection mode 1 (ADCGnODCR.ODE = 1_H) is used, to prevent malfunctions, use the wiring-break detection function after setting all THkE (k = 0 to 5) of ADCGnTHER to 0 or stopping all T&H by THSTPCR.THSTP.

30.3.28 ADCGnULLMTBR0 to 2 — Upper-limit/Lower-limit Table Registers 0 to 2

ADCGnULLMTBR0-2 are 32-bit readable/writable registers that set the upper-limit and lower-limit values of an A/D converted value. Specify any of ADCGnULLMTBR0 to 2 by ULS[1:0] in ADCGnULLMSRx.

Access: This register can be read/written in 32-bit units.

Address: ADCGmULLMTBR0: <ADCGn_base> + 3CC_H
 ADCGmULLMTBR1: <ADCGn_base> + 3D0_H
 ADCGmULLMTBR2: <ADCGn_base> + 3D4_H

Value after reset: 7FFE 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ULMTB[15:0]															
Value after reset	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LLMTB[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 30.34 ADCGnULLMTBR Register Contents

Bit Position	Bit Name	Function
31 to 16	ULMTB[15:0]	Upper Limit Table These bits specify the upper-limit value of an A/D converted value. ULE (upper limit/lower limit error) is set when the following condition is met. $ULMTB[15:0] < A/D \text{ converted value}$ The ULMTB[15:0] format is the signed fixed-point format regardless of the format of ADCGnDRj. If the signed integer format is selected for the ADCGnDRj format, the ADCGnDRj format is converted to the signed fixed-point format, and then the values are compared. Note that ULMTB[15] and ULMTB[0] are always fixed to 0.
15 to 0	LLMTB[15:0]	Lower Limit Table These bits specify the lower-limit value of an A/D converted value. ULE (upper limit/lower limit error) is set when the following condition is met. $LLMTB[15:0] > A/D \text{ converted value}$ The LLMTB[15:0] format is the signed fixed-point format regardless of the format of ADCGnDRj. If the signed integer format is selected for the ADCGnDRj format, the ADCGnDRj format is converted to the signed fixed-point format, and then the values are compared. Note that LLMTB[15] and LLMTB[0] are always fixed to 0.

CAUTION

- To prevent malfunctions, make settings for ADCGnULLMTBR0 to 2 after making or confirming the following settings.
 - HLDTE of T&H group A and B are 0.
 - ADSTARTE of all scan groups are 0 and TRGMD of all scan groups are 0_H.
 - SGACT of all scan groups are 0 (before scan groups are started).
- The upper table (ULMTB[15:0]) must be set greater than the lower table (LLMTB[15:0]).

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.29 ADCGnECR — Error Clear Register

ADCGnECR is an 8-bit write-only register that controls error clear. The register bits are always read as 0.

Access: This register can be written only in 8-bit units.

Address: <ADCGn_base> + 3D8_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	ULEC	OWEC	PEC	IDEC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	W	W	W	W

Table 30.35 ADCGnECR Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When writing, write the value after reset.
3	ULEC	Upper Limit/Lower Limit Error Clear Clears the upper limit or lower limit errors (ADCGnULER.ULE) and the upper limit or lower limit error capture (ADCGnULER.ULECAP[5:0]). 0: Not cleared 1: Cleared
2	OWEC	Overwrite Error Clear Clears over write errors (ADCGnOWER.OWE) and over write error capture (ADCGnOWER.OWECAP[5:0]). 0: Not cleared 1: Cleared
1	PEC	Parity Error Clear Clears parity errors (ADCGnPER.PE) and parity error capture (ADCGnPER.PECAP[5:0]). 0: Not cleared 1: Cleared
0	IDEC	ID Error Clear Clears ID errors (ADCGnIER.IDE) and ID error capture (ADCGnIER.IDECAP[5:0]). 0: Not cleared 1: Cleared

30.3.30 ADCGnULER — Upper-limit/Lower-limit Error Register

ADCGnULER is an 8-bit read-only register that indicates upper limit/lower limit errors.

Access: This register can be read only in 8-bit units.

Address: <ADCGn_base> + 3DC_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	ULE	—	ULECAP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 30.36 ADCGnULER Register Contents

Bit Position	Bit Name	Function
7	ULE	Upper Limit/Lower Limit Error 0: No error 1: An error is present. Setting condition The A/D converted value exceeds the range of the specified upper limit/lower limit table Clearing condition A value of 1 is written to ULEC.
6	Reserved	When read, the value after reset is read.
5 to 0	ULECAP[5:0]	Upper Limit/Lower Limit Error Capture The virtual channel at the time when an upper limit/lower limit error occurred is captured. Capturing condition ULE = 0 and the A/D converted value exceeds the range of the specified upper limit/lower limit table. Clearing condition A value of 1 is written to ULEC

CAUTION

ADCGnULER is updated when the A/D converted value is written to ADCGnDRj.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.31 ADCGnOWER — Overwrite Error Register

ADCGnOWER is an 8-bit read-only register that indicates an overwrite error.

Access: This register can be read only in 8-bit units.

Address: <ADCGn_base> + 3E0_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0	
	OWE	—	OWECAP[5:0]						
Value after reset	0	0	0	0	0	0	0	0	
R/W	R	R	R	R	R	R	R	R	

Table 30.37 ADCGnOWER Register Contents

Bit Position	Bit Name	Function
7	OWE	Overwrite Error 0: No error 1: An error is present. Setting condition The A/D converted value is written to ADCGnDRj when WFLG = 1 Clearing condition A value of 1 is written to OWEC
6	Reserved	When read, the value after reset is read.
5 to 0	OWECAP[5:0]	Overwrite Error Capture The virtual channel at the time when an overwrite error occurred is captured. Capturing condition The A/D converted value is written to ADCGnDRj when OWE = 0 and WFLG = 1. Clearing condition A value of 1 is written to OWEC

CAUTION

ADCGnOWER is updated when the A/D converted value is written to ADCGnDRj.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.32 ADCGnPER — Parity Error Register

ADCGnPER is an 8-bit read-only register that indicates a parity error.

Access: This register can be read only in 8-bit units.

Address: <ADCGn_base> + 3E4_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0	
	PE	—	PECAP[5:0]						
Value after reset	0	0	0	0	0	0	0	0	
R/W	R	R	R	R	R	R	R	R	

Table 30.38 ADCGnPER Register Contents

Bit Position	Bit Name	Function
7	PE	Parity Error 0: No error 1: An error is present. Setting condition A parity error is detected. Clearing condition A value of 1 is written to PEC.
6	Reserved	When read, the value after reset is read.
5 to 0	PECAP[5:0]	Parity Error Capture The virtual channel at the time when a parity error occurred is captured. Capturing condition A parity error is detected when PE = 0. Clearing condition A value of 1 is written to PEC.

CAUTION

ADCGnPER is updated when ADCGnDRj or ADCGnDIRj is read.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.33 ADCGnIDER — ID Error Register

ADCGnIDER is an 8-bit read-only register that indicates an ID error.

Access: This register can be read only in 8-bit units.

Address: <ADCGn_base> + 3E8_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0	
	IDE	—	IDECAP[5:0]						
Value after reset	0	0	0	0	0	0	0	0	
R/W	R	R	R	R	R	R	R	R	

Table 30.39 ADCGnIDER Register Contents

Bit Position	Bit Name	Function
7	IDE	ID Error 0: No error 1: An error is present. Setting condition The physical channel specified in ADCGnVCRj does not match the physical channel actually converted. Clearing condition A value of 1 is written to IDEC.
6	Reserved	When read, the value after reset is read.
5 to 0	IDECAP[5:0]	ID Error Capture The virtual channel at the time when an ID error occurred is captured. Capturing condition The physical channel specified in ADCGnVCRj does not match the physical channel actually converted when IDE = 0. Clearing condition A value of 1 is written to IDEC.

CAUTION

ADCGnIDER is updated when the A/D converted value is written to ADCGnDRj.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.34 ADCGnSGSTCRx — Scan Group x Start Control Register

ADCGnSGSTCRx is an 8-bit write-only register that controls the start of scan group x. The register bits are always read as 0.

Access: This register can be written only in 8-bit units.

Address: ADCGnSGSTCR0: <ADCGn_base> + 480_H
 ADCGnSGSTCR1: <ADCGn_base> + 500_H
 ADCGnSGSTCR2: <ADCGn_base> + 580_H
 ADCGnSGSTCR3: <ADCGn_base> + 600_H
 ADCGnSGSTCR4: <ADCGn_base> + 680_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SGST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 30.40 ADCGnSGSTCRx Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	SGST	Starts A/D Conversion of Scan Group x 0: No function (Writing 0 is ignored.) 1: Start A/D conversion while A/D conversion start scan group status (ADCGnSGSRx.SGACT) is 0.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.35 ADCGnADTSTCRy — A/D Timer y Start Control Register

ADCGnADTSTCRy is an 8-bit write-only register that controls the start of A/D timer y. The register bits are always read as 0.

Access: This register can be written only in 8-bit units.

Address: ADCGnADTSTCR3: <ADCGn_base> + 608_H
ADCGnADTSTCR4: <ADCGn_base> + 688_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADTST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 30.41 ADCGnADTSTCRy Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	ADTST	Starts A/D timer y. 0: No function (Writing 0 is ignored.) 1: A/D timer is started. Start A/D timer while A/D timer status (ADCGnSGSRx.ADTACT) is 0.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.36 ADCGnADTENDCRy — A/D Timer y End Control Register

ADCGnADTENDCRy is an 8-bit write-only register that controls the end of the A/D timer y. The register bits are always read as 0.

Access: This register can be written only in 8-bit units.

Address: ADCGnADTENDCR3: <ADCGn_base> + 60C_H
ADCGnADTENDCR4: <ADCGn_base> + 68C_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADTEND
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 30.42 ADCGnADTENDCRy Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	ADTEND	Ends A/D timer. 0: No function (Writing 0 is ignored.) 1: End A/D timer.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.37 ADCGnSGCRx — Scan Group x Control Register

ADCGnSGCRx is an 8-bit readable/writable register that controls scan group x.

Access: This register can be read/written in 8-bit units.

Address: ADCGnSGCR0: <ADCGn_base> + 490_H
 ADCGnSGCR1: <ADCGn_base> + 510_H
 ADCGnSGCR2: <ADCGn_base> + 590_H
 ADCGnSGCR3: <ADCGn_base> + 610_H
 ADCGnSGCR4: <ADCGn_base> + 690_H

Value after reset: 00_H

- When x = 0 to 2

Bit	7	6	5	4	3	2	1	0

7	ADTSTARTE	A/D Timer Synchronization Start Enable 0: ADTSTART is disabled. 1: ADTSTART is enabled.
6	ADSTARTE	Scan Group Synchronization Start Enable 0: ADSTART is disabled. 1: ADSTART is enabled.
5	SCANMD	Scan Mode 0: Multicycle scan mode 1: Continuous scan mode In multicycle scan mode, scans are repeated as many times as specified in ADCGnSGMCCRx. In continuous scan mode, scans are repeated unlimited of times.
4	ADIE	Scan End Interrupt Enable 0: INTADCGnIx is not output at the end of scan for SGx. 1: INTADCGnIx is output at the end of scan for SGx. ADIE of ADCGnSGCRx is independent of ADIE of ADCGnVCRj. For details, see Section 30.4.5.1, Scan End Interrupt Request .
3, 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TRGMD[1:0]	Enables or disables trigger input to Scan Group x.

TRGMD [1:0]	Hardware trigger			Software trigger		
	Trigger input to SGx	Trigger input to timer x	Hold trigger to SGx	Trigger input to SGx	Trigger input to timer x	Hold trigger to SGx
0	Disabled	Disabled	Disabled	Enabled	Disabled	Disabled
1	Enabled	Disabled	Enabled	Enabled	Disabled	Enabled
2	Disabled	Disabled	Disabled	Enabled	Enabled	Disabled
3	Disabled	Enabled	Disabled	Enabled	Enabled	Disabled

CAUTIONS

- To prevent malfunctions, make settings for SCANMD and ADIE of ADCGnSGCRx after making or confirming the following settings.
 - HLDTTE of the T&H group A is 0 when scan group x is selected in SGS[1:0] of the T&H group A.
 - HLDTTE of the T&H group B is 0 when scan group x is selected in SGS[1:0] of the T&H group B.
 - ADTSTARTE of scan group x is 0 and TRGMD of scan group x is 0_H.
 - SGACT of scan group x is 0 (before the scan group is started).
- If a trigger of lower-priority scan group is input to a scan group for which continuous scan mode is set (SCANMD = 1_H), the trigger is not accepted. Therefore, it is assumed that continuous scan mode is specified for scan group 0.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.38 ADCGnSGVCSPx — Scan Group x Start Virtual Channel Pointer

ADCGnSGVCSPx is an 8-bit readable/writable register that specifies the start pointer of a virtual channel.

Access: This register can be read/written in 8-bit units.

Address: ADCGnSGVCSP0: <ADCGn_base> + 494_H
 ADCGnSGVCSP1: <ADCGn_base> + 514_H
 ADCGnSGVCSP2: <ADCGn_base> + 594_H
 ADCGnSGVCSP3: <ADCGn_base> + 614_H
 ADCGnSGVCSP4: <ADCGn_base> + 694_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	VCSP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.45 ADCGnSGVCSPx Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is read. When writing, write the value after reset.
5 to 0	VCSP[5:0]	Start Virtual Channel Pointer These bits select the virtual channel from which the scan is to be started. When SGx is started, processing for the virtual channels from ADCGnSGVCSPx to ADCGnSGVCEPx is executed.

CAUTIONS

- ADCGnSGVCSPx must be equal to or smaller than ADCGnSGVCEPx.
- To prevent malfunctions, make ADCGnSGVCSPx settings after making or confirming the following settings.
 - HLDTE of the T&H group A is 0 when scan group x is selected in SGS[1:0] of the T&H group A.
 - HLDTE of the T&H group B is 0 when scan group x is selected in SGS[1:0] of the T&H group B.
 - ADSTARTE of scan group x is 0 and TRGMD of scan group x is 0_H.
 - SGACT of scan group x is 0 (before the scan group is started).
- Do not set a value greater than the number of virtual channels provided.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.39 ADCGnSGVCEPx — Scan Group x End Virtual Channel Pointer

ADCGnSGVCEPx is an 8-bit readable/writable register that specifies the end pointer of a virtual channel.

Access: This register can be read/written in 8-bit units.

Address: ADCGnSGVCEP0: <ADCGn_base> + 498_H
 ADCGnSGVCEP1: <ADCGn_base> + 518_H
 ADCGnSGVCEP2: <ADCGn_base> + 598_H
 ADCGnSGVCEP3: <ADCGn_base> + 618_H
 ADCGnSGVCEP4: <ADCGn_base> + 698_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	VCEP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.46 ADCGnSGVCEPx Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is read. When writing, write the value after reset.
5 to 0	VCEP[5:0]	End Virtual Channel Pointer These bits select the virtual channel at which the scan is to end. When SGx is started, processing for the virtual channels from ADCGnSGVCSPx to ADCGnSGVCEPx is executed.

CAUTION

To prevent malfunctions, make ADCGnSGVCEPx settings after making or confirming the following settings.

- (1) HLDTE of the T&H group A is 0 when scan group x is selected in SGS[1:0] of the T&H group A.
- (2) HLDTE of the T&H group B is 0 when scan group x is selected in SGS[1:0] of the T&H group B.
- (3) ADSTARTE of scan group x is 0 and TRGMD of scan group x is 0_H.
- (4) SGACTION of scan group x is 0 (before the scan group is started).

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.40 ADCGnSGMICYCRx — Scan Group x Multicycle Register

ADCGnSGMICYCRx is an 8-bit readable/writable register that specifies the number of scan modes.

Access: This register can be read/written in 8-bit units.

Address: ADCGnSGMICYCR0: <ADCGn_base> + 49C_H
 ADCGnSGMICYCR1: <ADCGn_base> + 51C_H
 ADCGnSGMICYCR2: <ADCGn_base> + 59C_H
 ADCGnSGMICYCR3: <ADCGn_base> + 61C_H
 ADCGnSGMICYCR4: <ADCGn_base> + 69C_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	MCYC[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 30.47 ADCGnSGMICYCRx Register Contents

Bit Position	Bit Name	Function
7 to 0	MCYC[7:0]	Multicycle These bits specify the number of scan times in multicycle scan mode. Number of scan times = MCYC[7:0] + 1 When SGx is started, scans are repeated for virtual channels from ADCGnSGVCSPx to ADCGnSGVCEPx as many times as specified in ADCGnSGMICYCRx.

CAUTION

To prevent malfunctions, make ADCGnSGMICYCRx settings after making or confirming the following settings.

- (1) HLDTE of the T&H group A is 0 when scan group x is selected in SGS[1:0] of the T&H group A.
- (2) HLDTE of the T&H group B is 0 when scan group x is selected in SGS[1:0] of the T&H group B.
- (3) ADSTARTE of scan group x is 0 and TRGMD of scan group x is 0_H.
- (4) SGACT of scan group x is 0 (before the scan group is started).

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.41 ADCGnSGSRx — Scan Group x Status Register

ADCGnSGSRx is an 8-bit read-only register that indicates the status of scan group x.

Access: This register can be read only in 8-bit units.

Address: ADCGnSGSR0: <ADCGn_base> + 4A4_H
 ADCGnSGSR1: <ADCGn_base> + 524_H
 ADCGnSGSR2: <ADCGn_base> + 5A4_H
 ADCGnSGSR3: <ADCGn_base> + 624_H
 ADCGnSGSR4: <ADCGn_base> + 6A4_H

Value after reset: 00_H

- x = 0 to 2

Bit	7	6	5	4	3	2	1	0

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.42 ADCGnADTIPRy — A/D Timer Initial Phase Register y

ADCGnADTIPRy is a 32-bit readable/writable register that sets the initial phase of A/D timer y.

Access: This register can be read/written in 32-bit units.

Address: ADCGnADTIPR3: <ADCGn_base> + 628_H
ADCGnADTIPR4: <ADCGn_base> + 6A8_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

20 to 0	ADTIP[20:0]	A/D Timer Initial Phase These bits set the initial phase of A/D timer y. (1) After A/D timer y is started, ADCGnADTIPRy is loaded to A/D timer y and the timer counts down. (2) After A/D timer y becomes 0, A/D timer y trigger is output for one cycle, ADCGnADTPRRy is loaded to A/D timer y, and the timer counts down again. After that, (2) is repeated. For details, see Section 30.4.2.3, Starting A/D Timer by Using a Hardware Trigger .

CAUTION

To prevent malfunctions, make ADCGnADTIPRy settings when ADTACT of scan group y is 0 (before A/D timer is started), ADTSTARTE of scan group y is 0, and TRGM[1:0] of scan group y is not 3_H.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.43 ADCGnADTPRRy — A/D Timer Period Register y

ADCGnADTPRRy is a 32-bit readable/writable register that sets the cycle of A/D timer y.

Access: This register can be read/written in 32-bit units.

Address: ADCGnADTPRR3: <ADCGn_base> + 62C_H
ADCGnADTPRR4: <ADCGn_base> + 6AC_H

Value after reset: 001F FFFF_H

CAUTION

To prevent malfunctions, make ADCGnADTPRRy settings when ADTACT of scan group y is 0 (before A/D timer is started), ADTSTARTE of scan group y is 0, and TRGMD[1:0] of scan group y is not 3_H.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.3.44 ADCGnULLMSRx — Scan Group x Upper-limit/Lower-limit Table Select Register

ADCGnULLMSRx is an 8-bit readable/writable register that controls scan group x.

Access: This register can be read/written in 8-bit units.

Address: ADCGnULLMSR0: <ADCGn_base> + 4B0_H
 ADCGnULLMSR1: <ADCGn_base> + 530_H
 ADCGnULLMSR2: <ADCGn_base> + 5B0_H
 ADCGnULLMSR3: <ADCGn_base> + 630_H
 ADCGnULLMSR4: <ADCGn_base> + 6B0_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	ULS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 30.52 ADCGnULLMSRx Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	ULS[1:0]	Upper Limit/Lower Limit Table Select 0 _H : Neither upper limit nor lower limit is checked. 1 _H : Upper limit and lower limit are checked in ADCGnULLMTBR0. 2 _H : Upper limit and lower limit are checked in ADCGnULLMTBR1. 3 _H : Upper limit and lower limit are checked in ADCGnULLMTBR2. Upper limit and lower limit are checked by using the upper limit/lower limit table selected by ULS[1:0] when storing the A/D converted value in ADCGnDRj.

CAUTION

To prevent malfunctions, make ADCGnULLMSRx settings after making or confirming the following settings.

- (1) HLDTE of the T&H group A is 0 when scan group x is selected in SGS[1:0] of the T&H group A.
- (2) HLDTE of the T&H group B is 0 when scan group x is selected in SGS[1:0] of the T&H group B.
- (3) ADSTARTE of scan group x is 0 and TRGMD of scan group x is 0_H.
- (4) SGACT of scan group x is 0 (before the scan group is started).

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.4 Function

30.4.1 A/D Conversion Function

A/D Conversion is performed in scan group units. All scan groups have A/D conversion trigger signals. When a trigger signal (SG_x_TRG) is input, the signals on the virtual channels assigned to the scan group are A/D converted in ascending order. An A/D complete interrupt (INTADCGnIx) is generated on completion of A/D conversion for each virtual channel or for all virtual channels assigned to a scan group.

In multi-scan mode, A/D conversion is repeated the specified number of times in response to the input of a trigger signal. In continuous scan mode, A/D conversion is repeated until it is stopped.

The A/D conversion data format can be selected between signed fixed-point format and signed integer format. For the bit sequence of the data formats, see **Section 30.3.5, ADCGnDRj — Data Register j**.

30.4.1.1 Example of Multicycle Scan Mode Operation

The following figure shows an example of operation when converting four virtual channels by 2-cycle scan for scan group 0 in multicycle scan mode by using normal A/D conversion mode (CNVCLS[2:0] = 0_H).

Figure 30.4 Example of Operation in Multicycle Scan Mode

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.4.1.2 Example of Continuous Scan Mode Operation

Figure 30.5 shows an example of operation when converting four virtual channels for scan group 0 in continuous scan mode by using normal A/D conversion mode (CNVCLS[2:0] = 0_H).

In this mode, if a trigger of a lower-priority scan group is input to a scan group for which continuous scan mode is set (SCANMD = 1_H), the trigger is not accepted. Therefore, it is assumed that continuous scan mode is set for scan group 0.

Figure 30.5 Example of Operation in Continuous Scan Mode

30.4.1.3 Simultaneous Track and Hold Operation (THC Control)

The following figures show examples of simultaneous track and hold operation with T&H control, A/D conversion of the held value (CNVCLS[2:0] = 1_H), self-diagnosis (CNVCLS[2:0] = 3_H), and normal A/D conversion in addition mode (CNVCLS[2:0] = 4_H) by THC.

If a hold trigger is input from T&H group A or B, on-going conversion of the virtual channel is suspended regardless of the priority of the scan group and the hold operation is started. When the hold operation is completed, the virtual channel operation is executed in order of priority of the scan groups. The virtual channel suspended by the hold trigger is restarted from the beginning.

The following figures (**Figure 30.6**, **Figure 30.7**, **Figure 30.8**, and **Figure 30.9**) show the operations when a hold trigger is generated during A/D conversion.

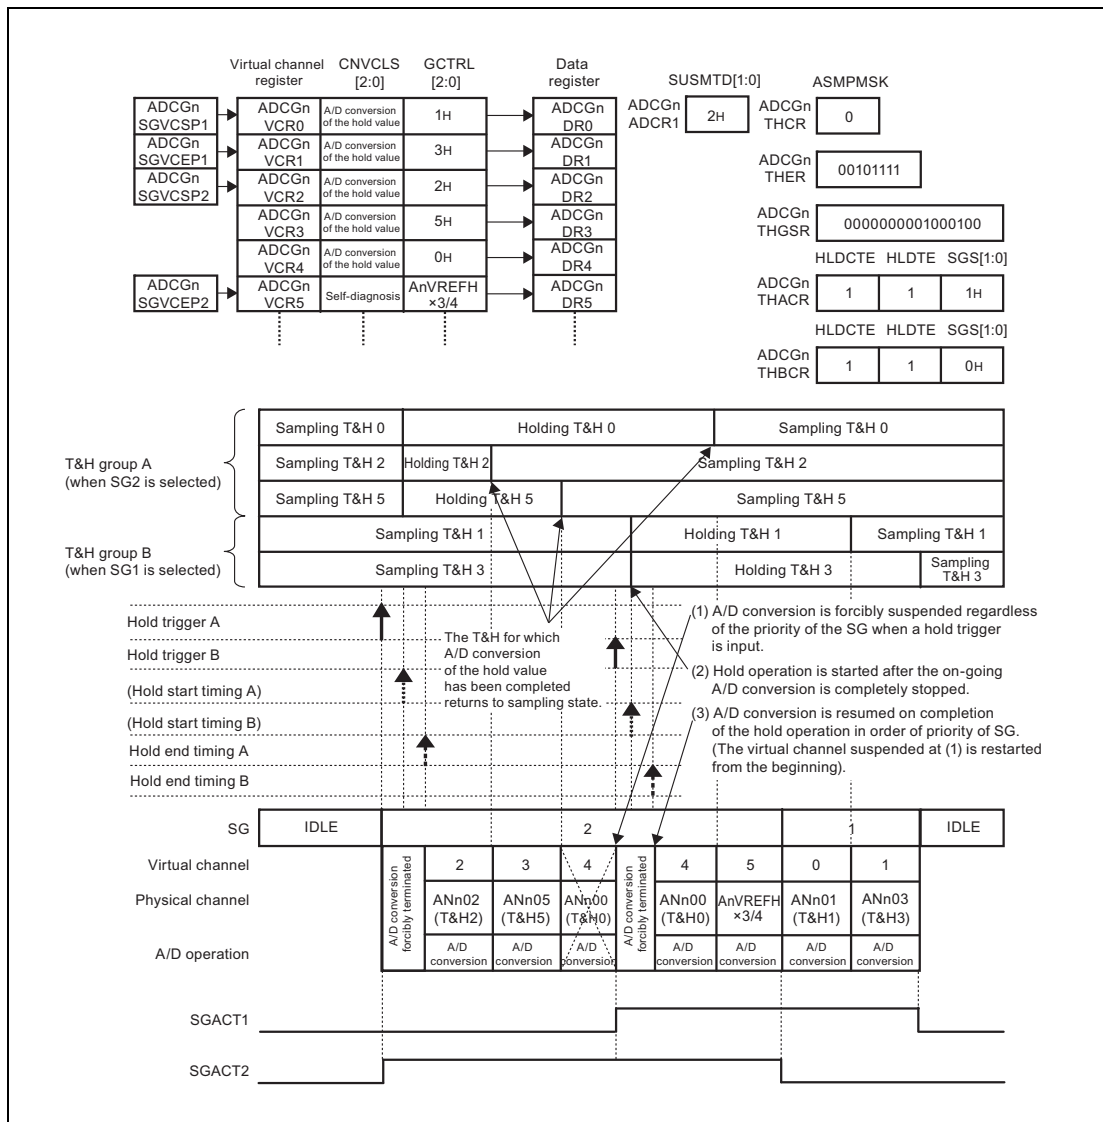

Figure 30.6 Simultaneous Track and Hold Operation (THC Control/Case 1)

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

Figure 30.7 Simultaneous Track and Hold Operation (THC Control/Case 2)

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

Figure 30.8 Simultaneous Track and Hold Operation (THC Control/Case 3)

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

Figure 30.9 Simultaneous Track and Hold Operation (THC Control/Case 4)

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units.**

30.4.1.4 Example of Normal A/D Conversion Operation in Addition Mode

Figure 30.10 shows an example of operation when converting four virtual channels for scan group 0 by using normal A/D conversion (CNVCLS[2:0] = 4_H) in addition mode.

Figure 30.10 Example of Normal A/D Conversion Operation in Addition Mode

30.4.1.5 Example of Using an External Analog Multiplexer (Port Output)

Figure 30.11 shows an example of port output using an external analog multiplexer.

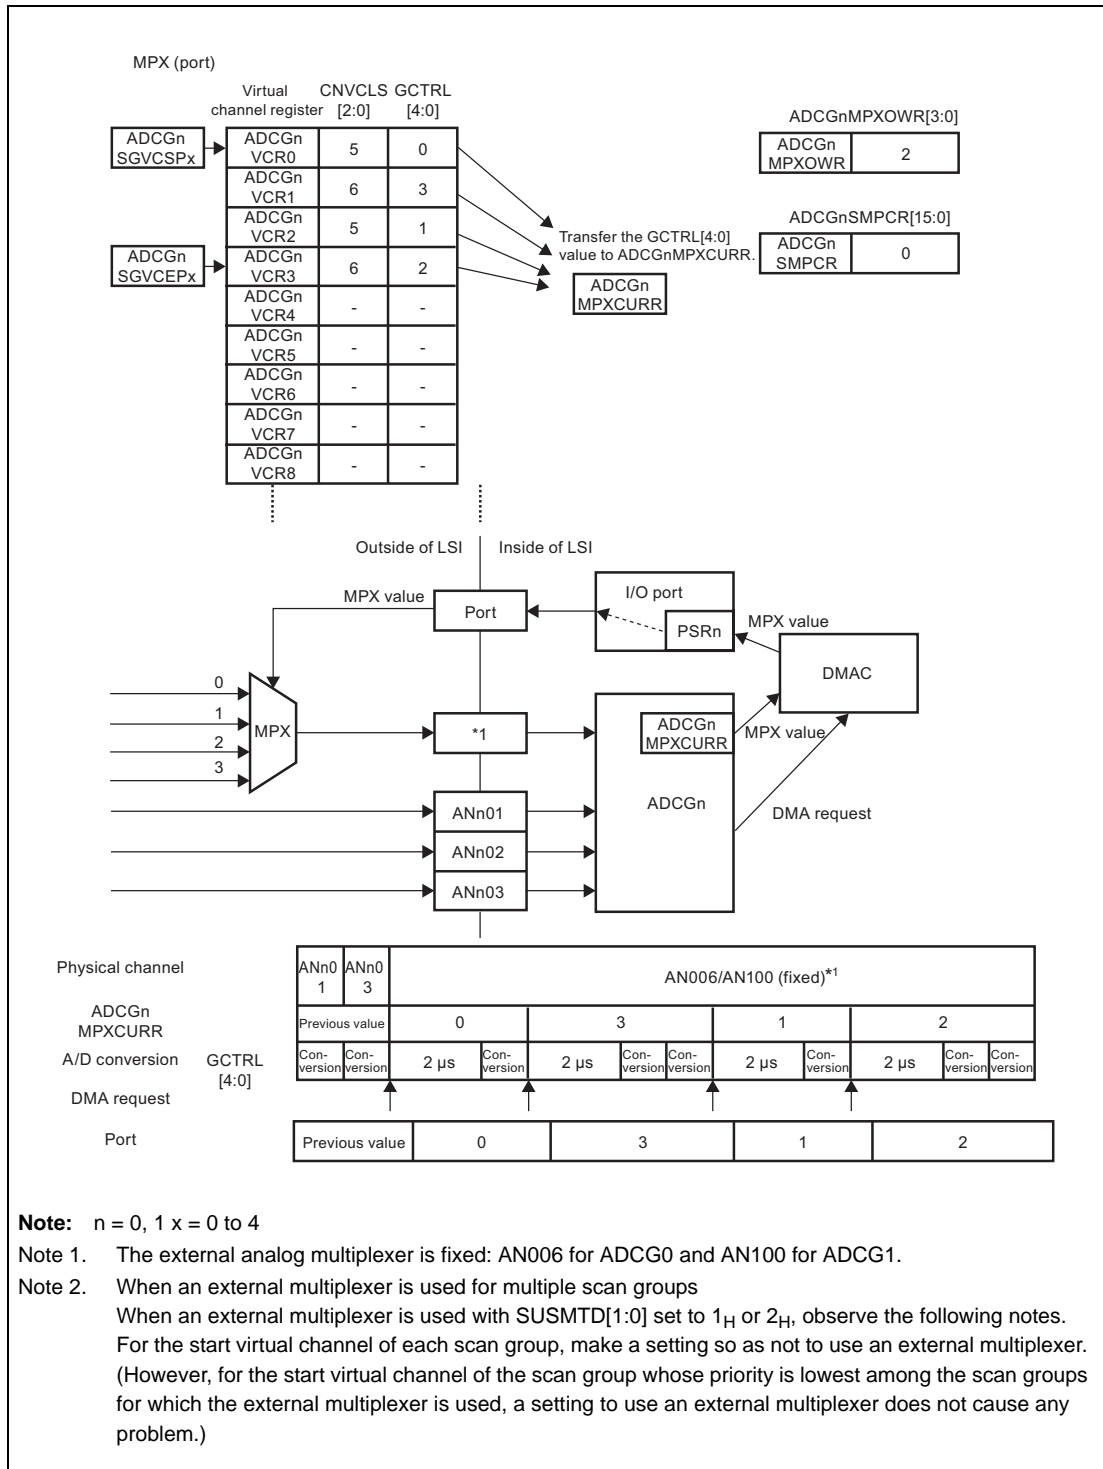

Figure 30.11 Example of Using an External Analog Multiplexer (Port Output)

30.4.2 Trigger Function

The following triggers are selectable as an A/D conversion start trigger of each scan group.

- Hardware (SG_x_TRG)*¹
- A/D timer
- Software (by setting the ADCGnSGSTCR_x)

The following triggers are selectable for activating A/D timer.

- Hardware (SG_x_TRG)*¹
- Software (by setting the ADCGnADTSTCR_y)

Triggering of a scan group which is the same as the scan group being A/D converted is invalid.

Triggering of a scan group which has a lower-priority than the scan group being A/D converted is put on hold; the conversion is started after the conversion of higher-priority scan groups are completed.

For triggering of a scan group which has a higher-priority than the scan group being A/D converted, see **Section 30.4.3, Suspend Function**.

Note 1. For details on SG_x_TRG, see **Section 29.3, Peripheral Interconnection — 2 (PIC2B)**.

30.4.2.1 Starting a Scan Group by Using a Hardware Trigger

Scan group *x* can be started by using an input from hardware trigger SG_x_TRG. To start scan group *x* by an input from hardware trigger SG_x_TRG, set TRGMD in ADCGnSGCR_x to 1_H. When the selected hardware trigger SG_x_TRG is input in this state, SGACT is set to 1. The timing since SGACT is set to 1 until scan group *x* is started is the same as the timing when SGST is set to 1 by a software trigger.

NOTES

1. For the number of units and indices, see **Section 30.1.1, Number of Units**.
2. When a hardware trigger SG_x_TRG is generated during A/D conversion (ADCGnSGSR_x.SGACT=1) for same scan group *x*, the hardware trigger SG_x_TRG is ignored.

30.4.2.2 Starting a Scan Group by Using an A/D Timer Trigger

Scan group 3 or 4 can be started by using a trigger from A/D timer 3 or 4. To start scan group 3 or 4 by using a trigger from A/D timer 3 or 4, set TRGMD in ADCGnSGCR3 or ADCGnSGCR4 to 2_H. Furthermore, set ADTST of scan group 3 or 4 to 1 to start A/D timer 3 or 4.

When a timer trigger is input in this state, SGACT is set to 1. The timing since SGACT is set to 1 until scan group 3 or 4 is started is the same as the timing when SGST is set to 1 by a software trigger.

30.4.2.3 Starting A/D Timer by Using a Hardware Trigger

A/D timer 3 or 4 can be started by using a hardware trigger SG3_TRG or SG4_TRG input. To start A/D timer 3 or 4 by using a hardware trigger SG3_TRG or SG4_TRG input, set TRGMMD in ADCGnSGCR3 or ADCGnSGCR4 to 3_H. When the selected external trigger is input in this state, A/D timer 3 or 4 starts. Furthermore, a trigger from A/D timer 3 or 4 starts scan group 3 or 4.

Figure 30.12 shows an example of A/D timer operation.

The A/D timer counts in synchronization with the CLK_ADC clock.

Figure 30.12 Example of A/D Timer Operation

- (1) A/D timer y is loaded with ADCGnADTIPRy at the start of counting.
- (2) If the A/D timer y is 0, an A/D timer trigger is output for one cycle and the A/D timer y is loaded with ADCGnADTPRRy.

If the A/D timer y is not 0, the timer counts down. After that, (2) is repeated.

CAUTION

If 0 is set to the A/D timer initial phase register y (ADCGnADTIPRy), an A/D timer trigger is output simultaneously with the start of the A/D timer.

If 0 is set to the A/D timer period register y (ADCGnADTPRRy), an A/D timer trigger is output at each clock cycle.

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.4.3 Suspend Function

In suspend function, when a scan group request with higher priority is issued during lower-priority scan group processing, A/D conversion of the lower priority level is suspended and A/D conversion with higher priority level is performed. There are three types in the suspend operation.

30.4.3.1 Example of Synchronous Suspend and Resume Operation

When the A/D conversion trigger is generated for a scan group with higher priority than one on which A/D conversion is in progress, A/D conversion for the scan group with higher priority does not proceed until A/D conversion of the virtual channel for which conversion was in progress is completed. A/D conversion for the suspended scan group is resumed from the virtual channel after the one that was being converted on completion of A/D conversion for the scan group with higher priority.

Figure 30.13 shows an example of synchronous suspend and resume operation when a higher-priority SG interrupts a lower-priority SG.

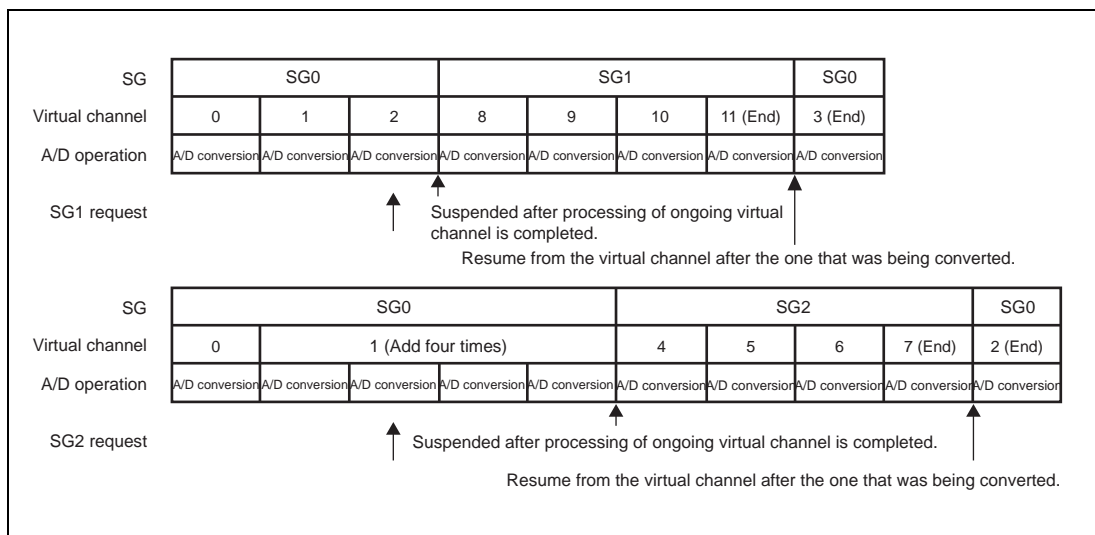

Figure 30.13 Example of Synchronous Suspend and Resume Operation

CAUTION

Priority of scan groups:
Low **High**
SG0 < SG1 < SG2 < SG3 < SG4

30.4.3.2 Example of Asynchronous Suspend and Resume Operation

When the A/D conversion trigger is generated for a scan group with higher priority than one on which A/D conversion is in progress, A/D conversion of the virtual channel for which conversion was in progress is suspended immediately and A/D conversion for the scan group with higher priority proceeds. A/D conversion for the suspended scan group is resumed on completion of A/D conversion for the scan group with higher priority.

Figure 30.14 shows an example of asynchronous suspend and resume operation when a higher priority SG interrupts a lower-priority SG.

Figure 30.14 Example of Asynchronous Suspend and Resume Operation

CAUTION

Priority of scan groups:
Low High
SG0 < SG1 < SG2 < SG3 < SG4

30.4.3.3 Mixed Synchronous and Asynchronous Suspend Operations

If scan group 0 is interrupted by a higher priority scan group, an asynchronous suspend operation is performed. If a scan group other than scan group 0 is interrupted by a higher priority scan group, a synchronous suspend operation is performed.

An example of mixed synchronous and asynchronous suspend operations is shown below.

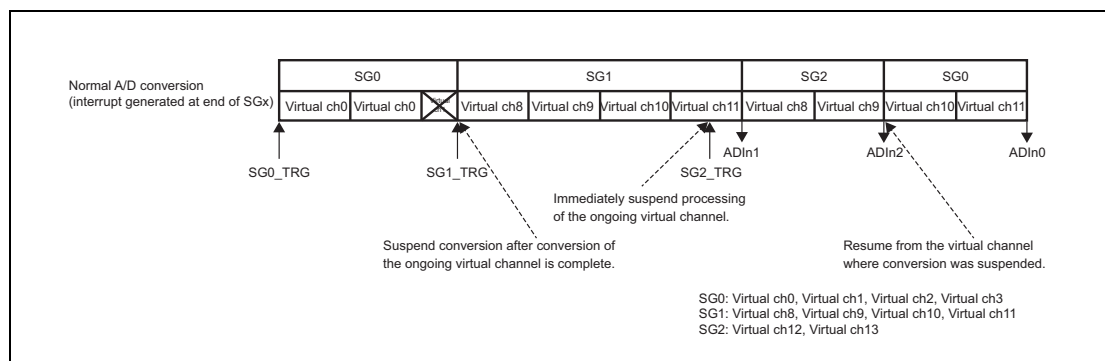

Figure 30.15 Example of Mixed Synchronous and Asynchronous Suspend Operations

30.4.4 Self-Diagnostic Function

The ADCG is equipped with the following self-diagnostic functions.

- Pin level self-diagnostic function
- A/D conversion circuit self-diagnostic function
- Wiring-break detection function

30.4.4.1 Pin Level Self-Diagnostic Function

Figure 30.16 is a flowchart of pin-level self-diagnosis.

The pin-level self-diagnosis flowchart below illustrates an example where pin-level self-diagnosis proceeds after assigning all ADCG0 pins to virtual channels and switching the applied voltage to even and odd numbered physical channel groups. This flowchart assumes that pin-level self-diagnosis proceeds before the start of A/D conversion.

[Features]

1. Physical channels for diagnosis can be arbitrarily selected.
2. The voltage level of pin-level self-diagnosis (AnVSS, AnVCC, or $1/2 \times \text{AnVCC}$) can be selected for each even- or odd-numbered physical channel.
3. Pin-level self-diagnosis function is available by performing A/D conversion for SG0 to SG4.

[Settings]

1. Make initial settings according to **Figure 30.24, Initial Settings**.
2. In the virtual channel register ADCGnVCRj (j = 0 to 23), set normal A/D conversion ($\text{CNVCLS}[2:0] = 0_H$) and set the desired physical channel for pin-level self-diagnosis in $\text{GCTRL}[5:0]$.
3. In pin-level self-diagnosis control register ADCGnTDCR, set diagnosis voltage ($\text{TDLV}[1:0]$) and set pin-level self-diagnosis ($\text{TDE} = 1$).
4. Configure other necessary settings for A/D conversion according to **Figure 30.24, Initial Settings**.
5. Assert the trigger for SG0 to SG4 to start A/D conversion.

NOTE

The results of conversion of diagnosis voltage at self-diagnosis include the total errors at selfdiagnosis (TESH0SN). For the values of TESH0SN, see **Section 37.14, A/D Converter Characteristics**.

CAUTION

The accuracy of conversion at a pin-level self-diagnosis is affected by the current injected. For details, see Section 37.14, A/D Converter Characteristics.

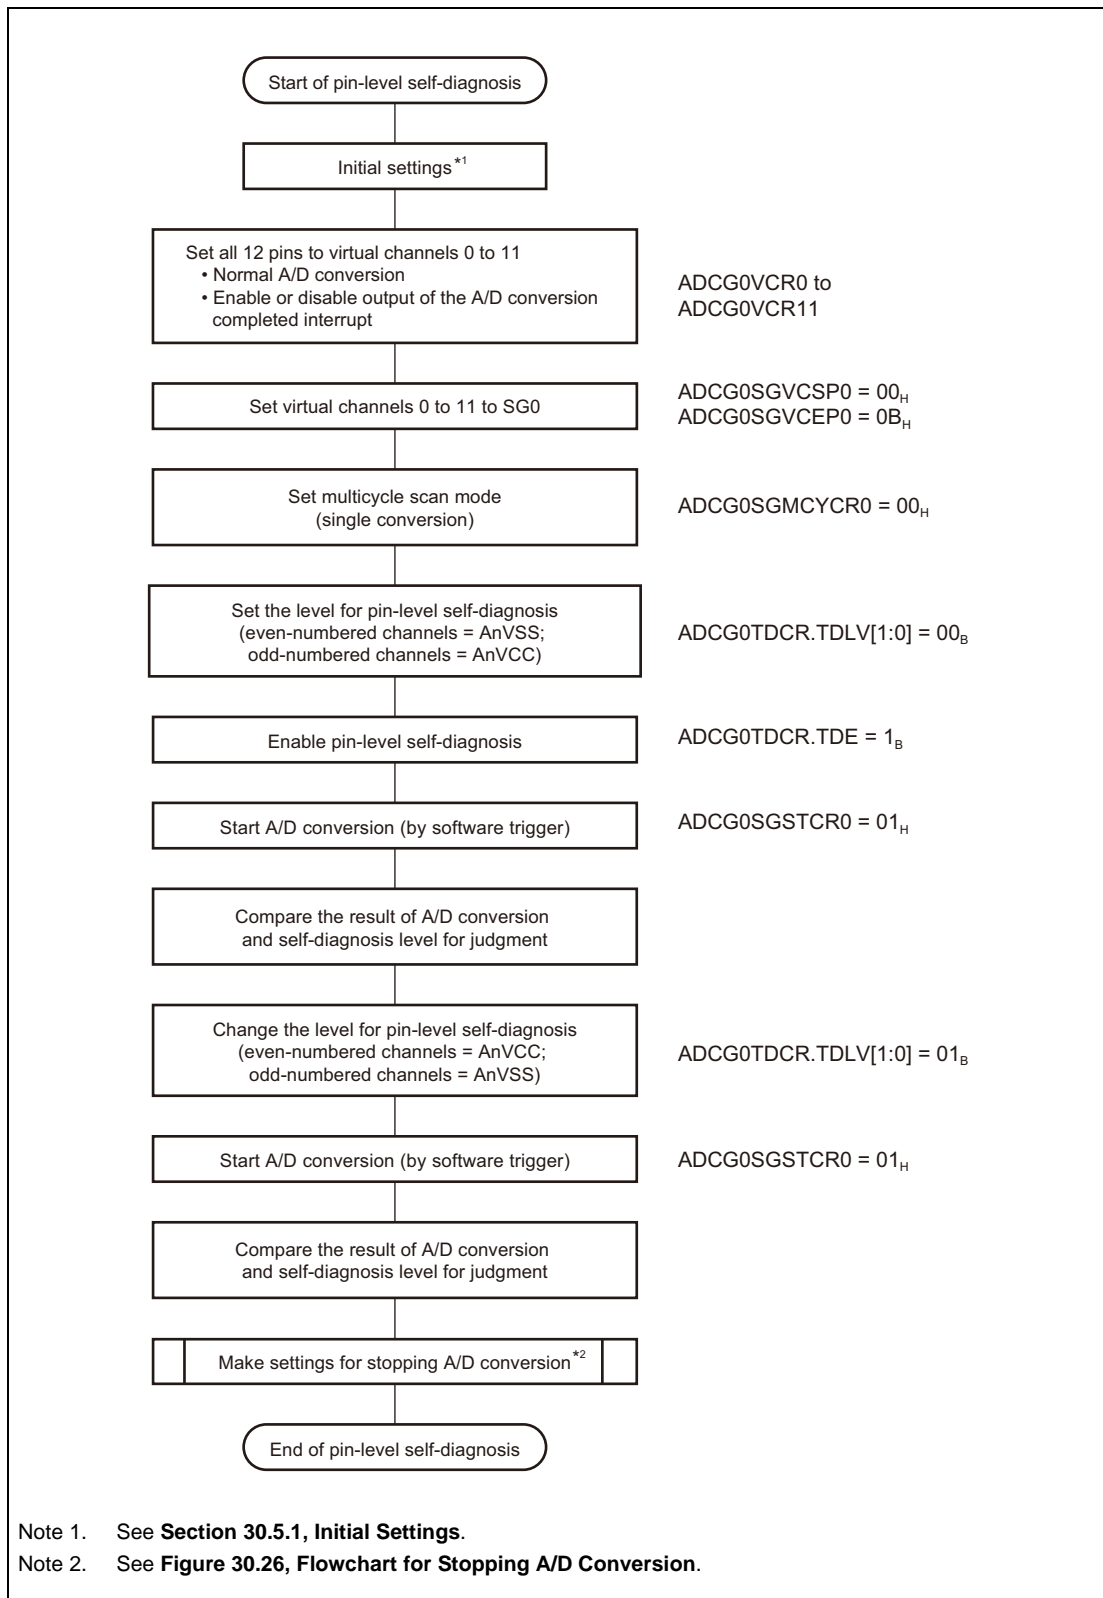

Figure 30.16 Flowchart of Pin-Level Self-Diagnosis (Example of ADCG0 144-pin Package)

30.4.4.2 A/D Conversion Circuit Self-Diagnostic Function

The A/D conversion circuit self-diagnostic function is used to verify that A/D conversion operates correctly.

The voltage value setting is made in GCTRL[4:0] when CNVCLS[2:0] = 3_H, and can be converted for AnVREFH×1, AnVREFH×3/4, AnVREFH×1/2, AnVREFH×1/4, and AnVSS.

Features and settings of the A/D conversion circuit self-diagnostic function of the ADCG are described below.

[Features]

1. AnVREFH×1, AnVREFH×3/4, AnVREFH×1/2, AnVREFH×1/4, or AnVSS can be selected as a self-diagnosis voltage level.
2. Performing A/D conversion for SG0 to SG4 makes the A/D conversion circuit self-diagnostic function available.

[Settings]

1. Make initial settings according to **Figure 30.24, Initial Settings**.
2. Set self-diagnosis mode (CNVCLS[2:0] = 3_H) and any self-diagnosis voltage level with GCTRL[5:0] in the virtual channel register ADCGnVCRj (j = 0 to 23).
3. Make other settings required for A/D conversion according to **Figure 30.24, Initial Settings**.
4. Assert triggers of SG0 to SG4 to start A/D conversion.

NOTE

The results of conversion of diagnosis voltage at self-diagnosis include the total errors at selfdiagnosis (TESH0SN). For the values of TESH0SN, see **Section 37.14, A/D Converter Characteristics**.

CAUTION

Do not use the temperature sensor when A/D conversion circuit self-diagnostic function is used. Set TSN0CR.TSNEN = 0.

30.4.4.3 Wiring-Break Detection

Wiring-break detection is a facility for detecting wiring breaks in AN_{nm}. If a wiring break exists the result of A/D conversion converges approximately to AnVSS or AnVCC due to pull-down or pull-up resistor. Therefore, the existence of wiring-breaks can be determined from the conversion result.

ADCG_n supports two wiring-break detection modes.

- Mode 1: A wiring-break detection for each physical channel can be performed at the same time as normal conversion (wiring-break detection by pull-down resistor).
- Mode 2: A wiring-break detection for each virtual channel can be performed by using the function dedicated to wiring-break (wiring-break detection by pull-down or pull-up resistor).

(1) Wiring-break detection mode 1 (ADCG_nODCR.ODE = 1)

In wiring-break detection mode 1, the desired width of pull-down pulse (1 to 17 states) can be set and a pull-down resistor is connected for conversion by successive approximation (A pull-up resistor cannot be used in wiring-break detection mode 1). Enabling or disabling of wiring-break detection is specified for each analog pin.

[Settings]

1. Make initial settings according to **Figure 30.24, Initial Settings**.
2. In virtual channel register ADCG_nVCR_j (j = 0 to 23), set normal A/D conversion (CNVCLS[2:0] = 0_H), set a pull-up/-down resistor off (ADCG_nVCR_j.PDE = 0_H, and ADCG_nVCR_j.PUE = 0_H), and set the desired channel in GCTRL[5:0].
3. Set wiring-break detection mode 1 (ADCG_nODCR.ODE = 1), the physical channel for wiring-break detection (ADOPDIG_{nm} = 1), and the desired width of pull-down pulse in ADCG_nODCR.ODPW[5:0].
4. Assert the trigger signal for SG0 to SG4 to start A/D conversion.
5. Repeat A/D conversion several times to check that the result voltage of A/D conversion has not been converged approximately to AnVSS.

(2) Wiring-break detection mode 2 (ADCG_nODCR.ODE = 0)

In wiring-break detection mode 2, a pull-down or pull-up resistor is connected for sampling of the sample-and-hold circuits when the width of pulse is fixed (18 states). Enabling or disabling of wiring-break detection can be set for each virtual channel.

[Settings]

1. Make initial settings according to **Figure 30.24, Initial Settings**.
2. In virtual channel register ADCG_nVCR_j (j = 0 to 23) for the virtual channel where wiring-break is to be detected, set normal A/D conversion mode (CNVCLS[2:0] = 0_H), set a pull-down or pull-up resistor on (ADCG_nVCR_j.PDE = 1_H, or ADCG_nVCR_j.PUE = 1_H) and set the desired channel in GCTRL[5:0].
3. Set wiring-break detection mode 2 (ADCG_nODCR.ODE = 0) and the physical channel for wiring-break detection (ADOPDIG_{nm} = 1).
4. Assert the trigger signal for SG0 to SG4 to start A/D conversion.

- Repeat A/D conversion several times to check that the result voltage of A/D conversion with the pull-down resistor has not been converged approximately to AnVSS and the voltage of the result of A/D conversion with the pull-up resistor has not been converged approximately to AnVCC.

30.4.4.4 Diagnosis of Wiring-Break Detection

Diagnosis of wiring-break detection is a self-diagnosis facility to check that wiring-break detection is working properly.

Start by performing A/D conversion in pin-level self-diagnosis mode, and then calculate the voltage which will be used as a baseline for comparison.

Next, pseudo-disconnect ANnm and repeat A/D conversion from several to a few dozen times using wire-break detection mode 2. If the result of A/D conversion in this disconnected state converged approximately to AnVSS or AnVCC, you can determine that wiring-break detection is working properly.

[Features]

- Physical channels for diagnosis of wiring-break detection can be arbitrarily selected.

[Settings]

- Make initial settings according to **Figure 30.24, Initial Settings**.
- In the virtual channel register ADCGnVCRj, set normal A/D conversion mode (CNVCLS[2:0] = 0_H), and the desired physical channel for wiring-break detection in GCTRL[5:0].
- In the pin-level self-diagnosis control register ADCGnTDCR, set pin-level self-diagnosis (TDE = 1_H) and the desired level for pin-level self-diagnosis in TDLV[1:0].
- Assert the trigger signal for SG0 to SG4 to start A/D conversion.
- After A/D conversion, enable wiring-break detection diagnosis (ODDE = 1_H) in ADCGnODCR (ADCGn automatically turns off pin-level self-diagnosis).
- In ADCGnVCRj, set a pull-down resistor on (PDE = 1_H) or pull-up resistor on (PUE = 1_H), set wire-break detection mode 2 (ADCGnODCR.ODE = 0), and set the desired physical channel for wiring-break detection (ADOPDIGnm = 1).
- Assert the trigger signal for SG0 to SG4 to start A/D conversion.
- Repeat A/D conversion from several to a few dozen times in wiring-break detection diagnosis mode to check that the result of A/D conversion has converged approximately to AnVSS for the pull-down resistor and AnVCC for the pull-up resistor.

30.4.4.5 Pin-Level Self-Diagnosis of T&H Paths

A facility for pin-level self-diagnosis is used for self-diagnostic testing of T&H paths.

This checks that the results of pin-level self-diagnosis for both the voltage held by the T&H circuit and the voltage when the T&H circuit is not used match the diagnostic voltages. If this test is run for all values (0_H , 1_H , 2_H , and 3_H) of the pin-level self-diagnosis level specification bits (TDLV) of the pin-level self-diagnosis control register (ADCGnTDCR) and the results match the respective diagnostic voltages, the T&H paths can be considered normal.

The following describes the procedures for configuration and evaluation when **(1)** pin-level self-diagnosis proceeds with the voltages held by the T&H circuits being used and when **(2)** pin-level self-diagnosis proceeds with the voltages held by the T&H circuits not being used.

NOTE

The settings in (1) and (2) below assume that the even- and odd-numbered physical channel groups are connected as follows.

- Even-numbered physical channel group = ANn00, ANn02, ANn04, ANn06, ...
- Odd-numbered physical channel group = ANn01, ANn03, ANn05, ANn07, ...

(1) Pin-level self-diagnosis of T&H paths (the voltage held by the T&H circuits used)

[Settings]

1. Make initial settings as shown in **Figure 30.18**.
2. Write 1 to the sampling start bit (SMPST) of the T&H sampling start control register (ADCGnTHSMPSTCR) to start sampling by the T&H circuits.
3. Write 1 to the scan group start bit (SGST) of the scan group 2 start control register (ADCGnSGSTCR2) to start A/D conversion of the signals in scan group 2 by software trigger.
4. Write 01_H to the hold start bit (HLDST) of the hold start control register (ADCGnTHAHLSTCR) to cause the T&H circuits of group A to hold the input voltages.*1
5. Write 1 to the scan group start bit (SGST) of the scan group 1 start control register (ADCGnSGSTCR1) to start conversion of the signals in scan group 1.
6. Wait for the first A/D conversion completed interrupt from ADCGnVCR0 for scan group 2 and write 1_H to the pin-level self-diagnosis level specification bit (TDLV) of the pin-level self-diagnosis control register (ADCGnTDCR) while A/D conversion is in progress to change the self-diagnosis level.
7. After the A/D conversion completed interrupt from ADCGnVCR5 for scan group 1, check the results of conversion by scan group 1.

If the results in the respective data registers (ADCGnDRj) of the even- and odd-numbered physical channel groups all match the diagnostic voltage when tested with the pin-level self-diagnosis level specification bits (TDLV) set to all values from 0_H to 3_H , the results of the pin-level self-diagnosis when the T&H circuits are used are considered normal. Also, the results of conversion by scan group 2 are not used but discarded.

- Note 1. Wait for at least 32 cycles of CLK_ADC after the start of sampling by T&H circuits in step (1) before setting the hold start control register in step (3) in Figure 30.16, Example of Timing Chart for Self-Diagnosis of T&H Paths (the voltage held by the T&H circuits used) (TDLV = $0_H \rightarrow 1_H$)

NOTE

The results of conversion of diagnosis voltage at self-diagnosis include the total errors at selfdiagnosis (TESH0SN). For the values of TESH0SN, see **Section 37.14, A/D Converter Characteristics**.

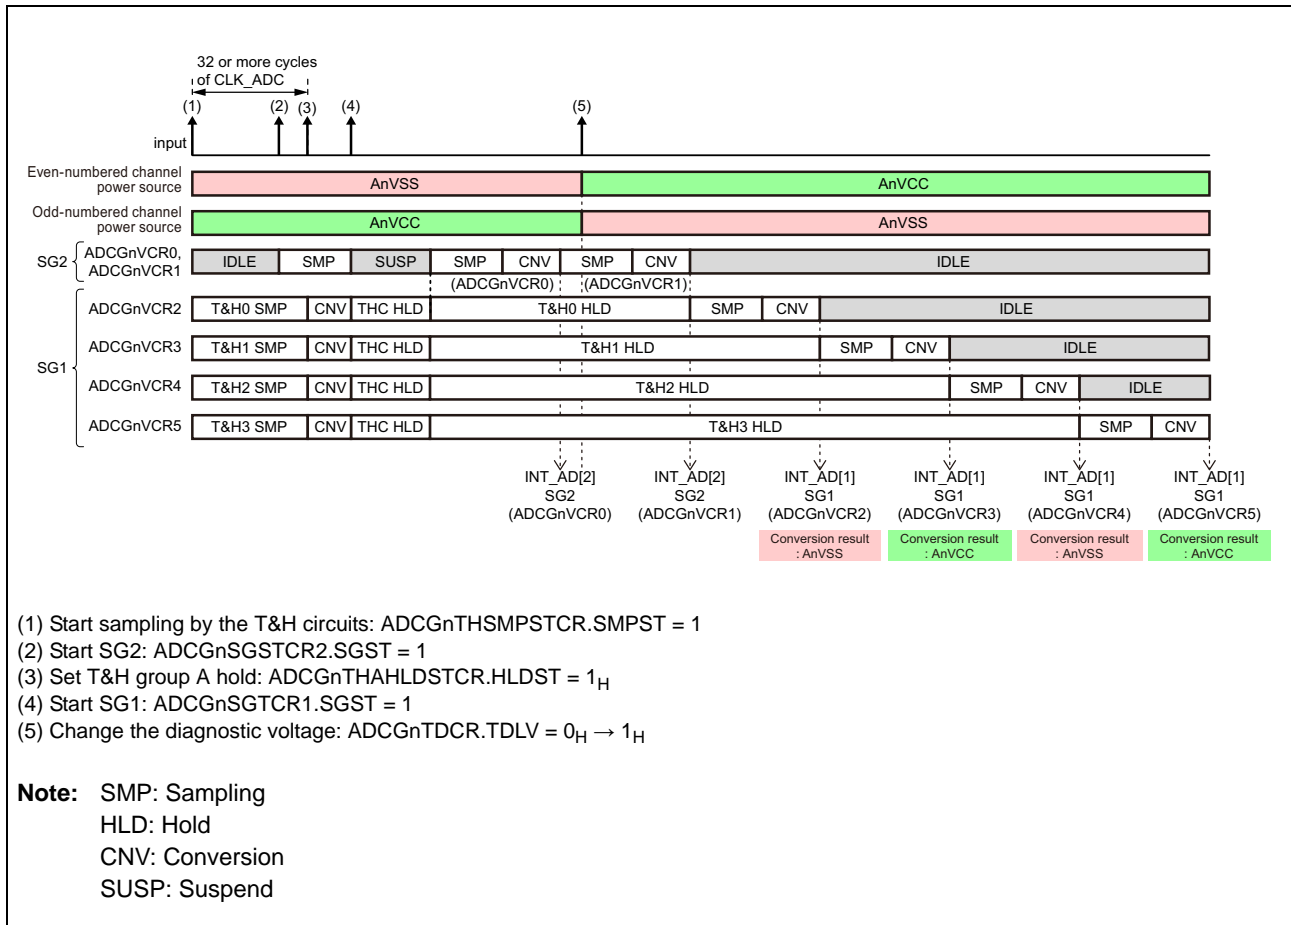

Figure 30.17 Example of Timing Chart for Self-Diagnosis of T&H Paths (the voltage held by the T&H circuits used) (TDLV = 0_H → 1_H)

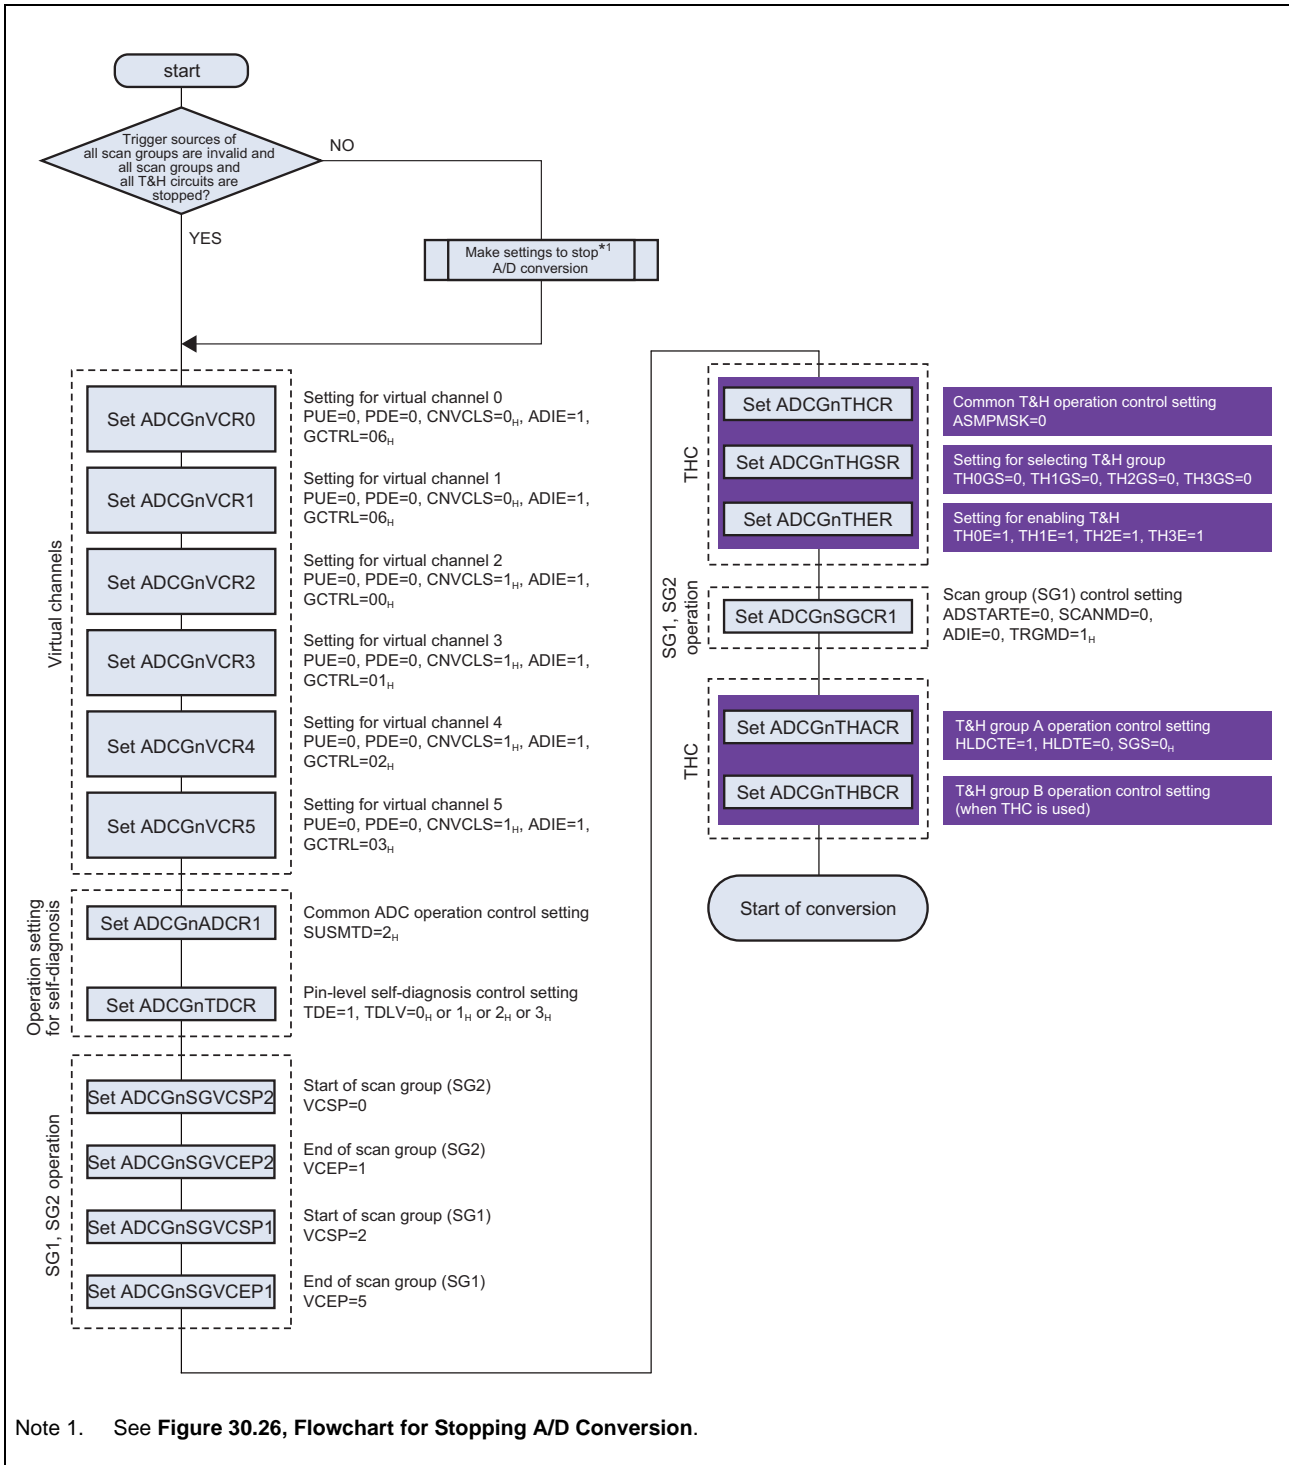

Figure 30.18 Initial Settings for Self-Diagnosis of T&H Paths (the voltage held by the T&H circuits used)

(2) Pin-level self-diagnosis of T&H paths (the voltage held by the T&H circuits not used)**[Settings]**

1. Make initial settings as shown in **Figure 30.20**.
2. Write 1 to the sampling start bit (SMPST) of the T&H sampling start control register (ADCGnTHSMPSTCR) to start sampling by the T&H circuits.
3. Write 1 to the scan group start bit (SGST) of the scan group 2 start control register (ADCGnSGSTCR2) as the software trigger for A/D conversion of the signals in scan group 2.
4. Write 01_H to the hold start bit (HLDST) of the hold start control register (ADCGnTHAHLSTCR) to cause the T&H circuits of group A to hold the input voltages.*¹
5. Write 1 to the scan group start bit (SGST) of the scan group 1 start control register (ADCGnSGSTCR1) to start conversion of the signals in scan group 1.
6. Wait for the first A/D conversion completed interrupt from ADCGnVCR0 for scan group 2 and write 1_H to the pin-level self-diagnosis level specification bit (TDLV) of the pin-level self-diagnosis control register (ADCGnTDCR) while A/D conversion is in progress to change the self-diagnosis level.
7. After the A/D conversion completed interrupt from ADCGnVCR5 for scan group 1, check the results of conversion by scan group 1.
If the respective data registers (ADCGnDRj) hold the results of A/D conversion of the self-diagnosis level voltages by the even- and odd-numbered physical channel groups when tested with the pin-level self-diagnosis level specification bits (TDLV) set to all values from 0_H to 3_H, the results of the pin-level self-diagnosis when the T&H circuits are not used are considered normal. Also, the results of conversion by scan group 2 are not used but discarded.

Note 1. Wait for at least 32 cycles of CLK_ADC after the start of sampling by T&H circuits in step (1) before setting the hold start control register in step (3) in **Figure 30.17, Example of Timing Chart for Self-Diagnosis of T&H Paths (the voltage held by the T&H circuits used) (TDLV = 0_H → 1_H)**.

NOTE

The results of conversion of diagnosis voltage at self-diagnosis include the total errors at selfdiagnosis (TESH0SN). For the values of TESH0SN, see **Section 37.14, A/D Converter Characteristics**.

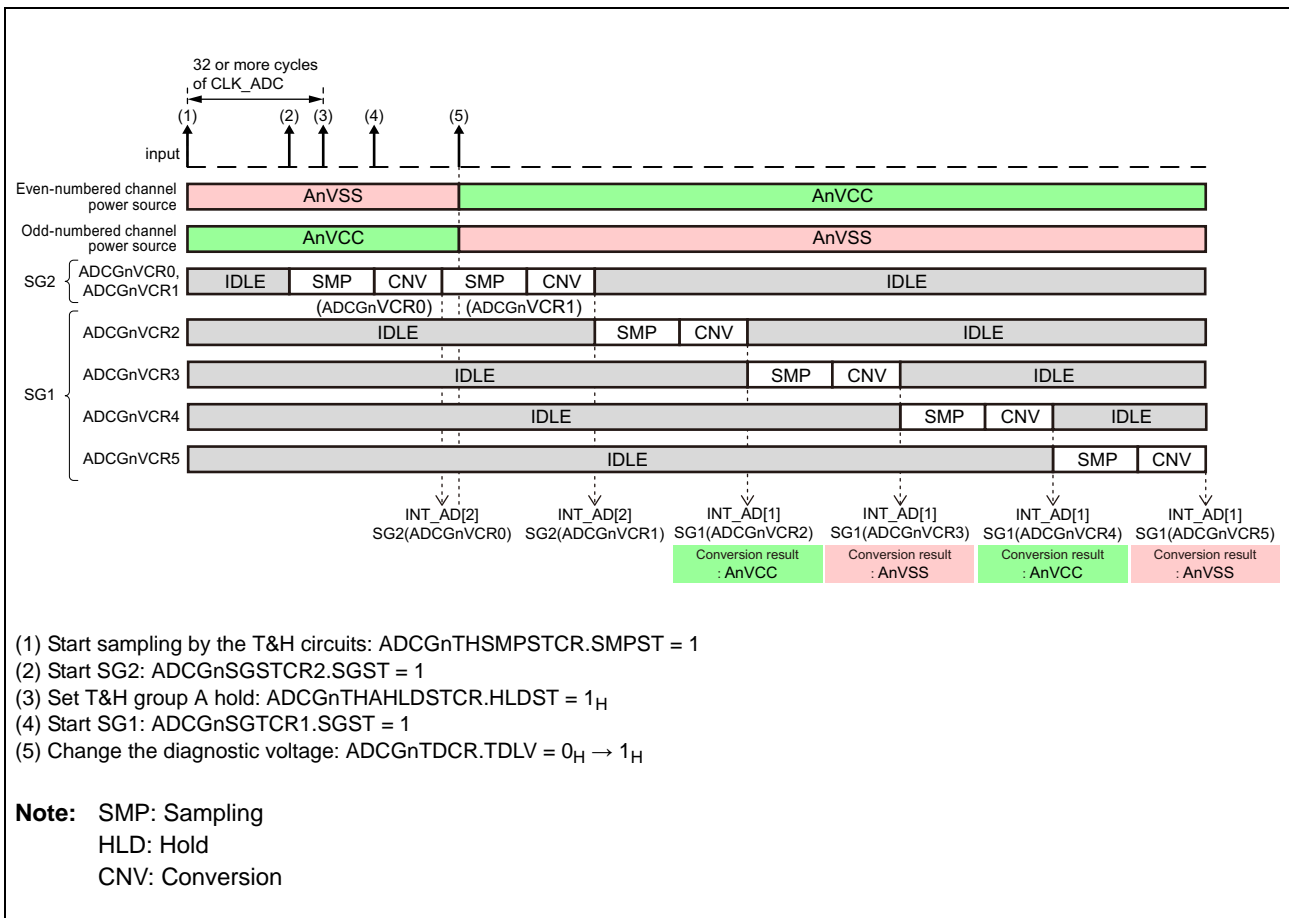

Figure 30.19 Example of Timing Chart for Self-Diagnosis of T&H Paths (the voltage held by the T&H circuits not used) (TDLV = 0_H → 1_H)

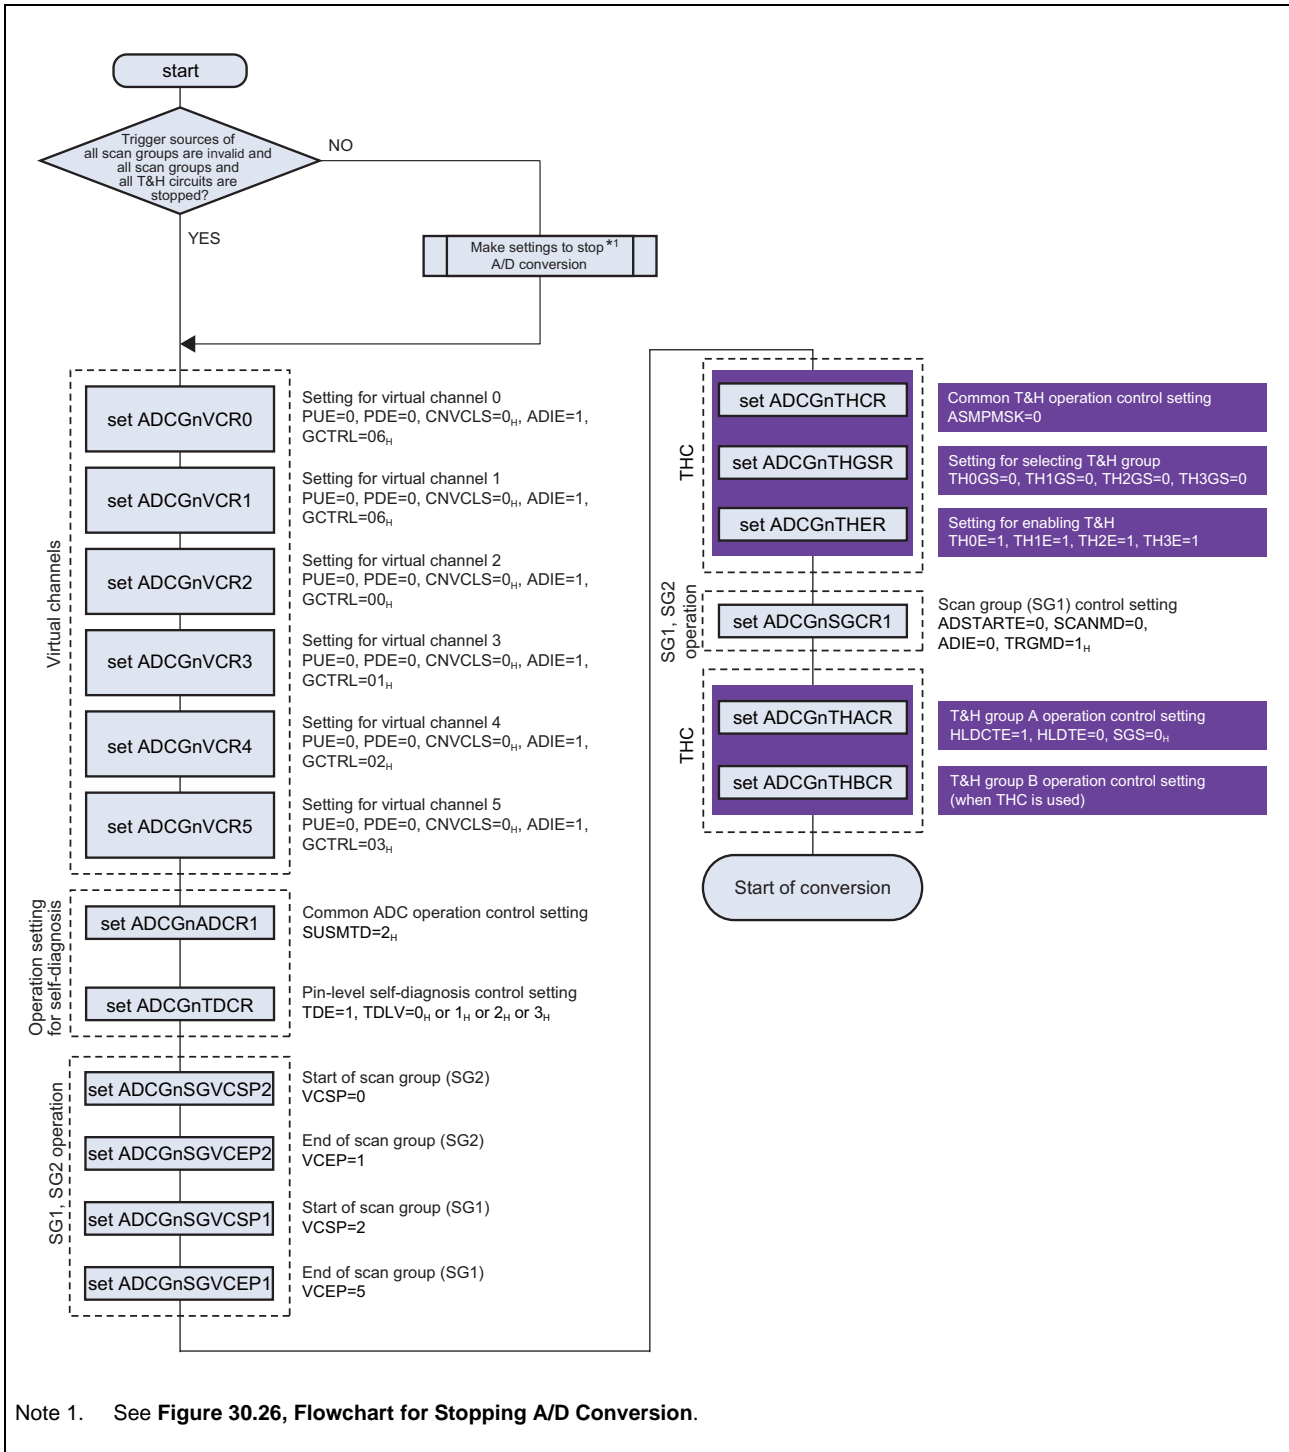

Figure 30.20 Initial Settings for Self-Diagnosis of T&H Paths (the voltage held by the T&H circuits not used)

30.4.5 Interrupt Request Function

There are two interrupt requests: scan group x end and A/D error. An interrupt request signal is a pulse. The scan group x end interrupt can activate the DMA and DTS.

30.4.5.1 Scan End Interrupt Request

Scan group x can issue a scan end interrupt request (INTADCGnIx) to the INTC. When ADIE in ADCGnSGCRx is set to 1, INTADCGnIx is output after the SGx scan ends. When ADIE in ADCGnSGCRx is set to 0, the INTADCGnIx output at the end of the SGx scan is disabled. When ADIE in ADCGnVCRj is set to 1, INTADCGnIx is output when A/D conversion for virtual channel n in SGx ends. When ADIE in ADCGnVCRj is set to 0, the INTADCGnIx output at the end of the A/D conversion for virtual channel n in SGx is disabled. The setting of ADIE in ADCGnSGCRx is independent of the setting of ADIE in ADCGnVCRj.

Example 1) Scans are executed for virtual channel 0 and 1 in SG0 when ADIE in ADCGnSGCR0 is 0, ADIE in ADCGnVCR0 is 1, and ADIE in ADCGnVCR1 is 0. INTADCGnIx is output when A/D conversion ends for virtual channel 0.

Example 2) Scans are executed for virtual channel 0 and 1 in SG0 when ADIE in ADCGnSGCR0 is 0, ADIE in ADCGnVCR0 is 1, and ADIE in ADCGnVCR1 is 1. INTADCGnIx is output when A/D conversion ends for virtual channel 0 and virtual channel 1.

Example 3) Scans are executed for virtual channel 0 and 1 in SG0 when ADIE in ADCGnSGCR0 is 1, ADIE in ADCGnVCR0 is 0, and ADIE in ADCGnVCR1 is 0. INTADCGnIx is output when a scan ends (at the end of A/D conversion for virtual channel 1). INTADCGnIx is output after every two (or more) cycles in multicycle scan mode, or each time a scan ends (at the end of A/D conversion for virtual channel 1) in continuous scan mode.

Furthermore, the DMAC can be activated when INTADCGnIx occurs.

For the DMAC setting, see **Section 7, DMA**.

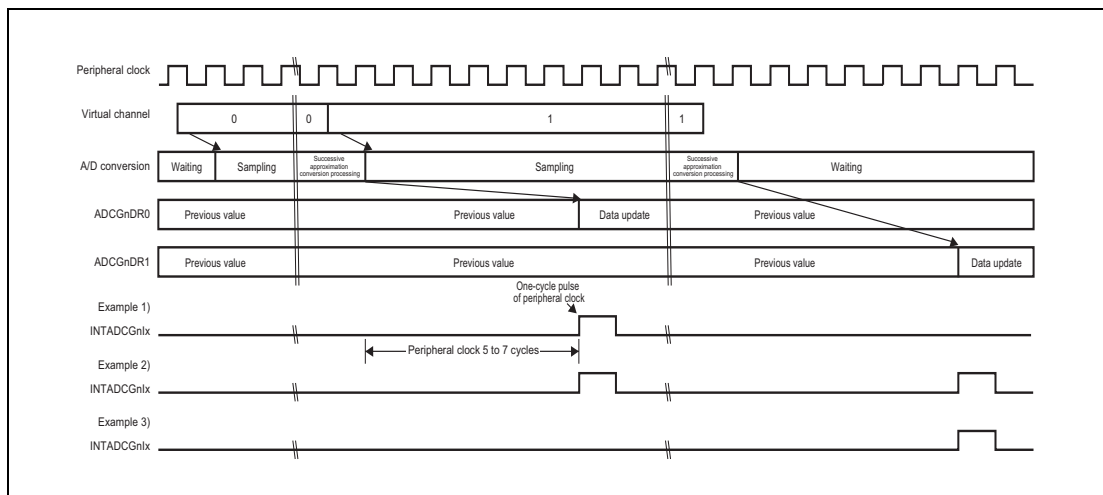

Figure 30.21 Scan Conversion End Interrupt Occurrence Timing

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.4.5.2 A/D Error Interrupt Request and A/D Parity Error Interrupt Request

The ADCG can generate the following error interrupts:

- Upper Limit/Lower Limit Error
- Overwrite Error
- ID Error
- Parity Error

The related registers and the unit to which the interrupts are output differ depending on the source of the error, as shown in **Table 30.53**.

Table 30.53 A/D Error Source

Error Source	Occurrence condition	Control Register.Bit	Status Register	Clear Register.Bit	Unit Where Error Signal Is Output
Upper Limit/Lower Limit Error	The A/D converted value exceeds the range of the specified upper limit/lower limit table	ADCGnSFTCR. ULEIE	ADCGnULER	ADCGnECCR. ULEC	The OR signal of three error interrupts (AD_ERR) is output to the INTC as the interrupt request INTADCGNERR.
Overwrite Error	The A/D converted value is written to ADCGnDRj when ADCGnDIRj.WFLG = 1	ADCGnSFTCR. OWEIE	ADCGnOWER	ADCGnECCR. OWEC	
ID Error	The physical channel specified in ADCGnVCRj does not match the physical channel actually converted.	ADCGnSFTCR. IDEIE	ADCGnIDER	ADCGnECCR. IDEC	
Parity Error	A parity error is detected	ADCGnSFTCR. PEIE	ADCGnPER	ADCGnECCR. PEC	A/D parity errors (ACPEn) are output to the ECM.

The ADCG can issue an A/D error interrupt request (INTADCGnERR) to the INTC and an A/D parity error notification (ADPEn) to the error control module (ECM). For an error source for which ULEIE, OWEIE, and IDEIE in ADCGnSFTCR is set to 1, the OR condition of the error source is issued as INTADCGnERR. For an error source for which ULEIE, OWEIE, and IDEIE in ADCGnSFTCR is set to 0, INTADCGnERR can be disabled. ADPEn is enabled when PEIE in ADCGnSFTCR is set to 1. ADPEn is disabled when PEIE in ADCGnSFTCR is set to 0.

Figure 30.22 Example of an Occurrence of A/D Error Interrupt and A/D Parity Error Notification

NOTE

For the number of units and indices, see **Section 30.1.1, Number of Units**.

30.4.6 Combination of Wiring Break Detection and A/D Conversion for Same Physical Channel

Detection of wiring breaks*1 and A/D conversion with T&H on the same physical channel is supported.

Note 1. In case of using the Wiring-break detection mode 2.

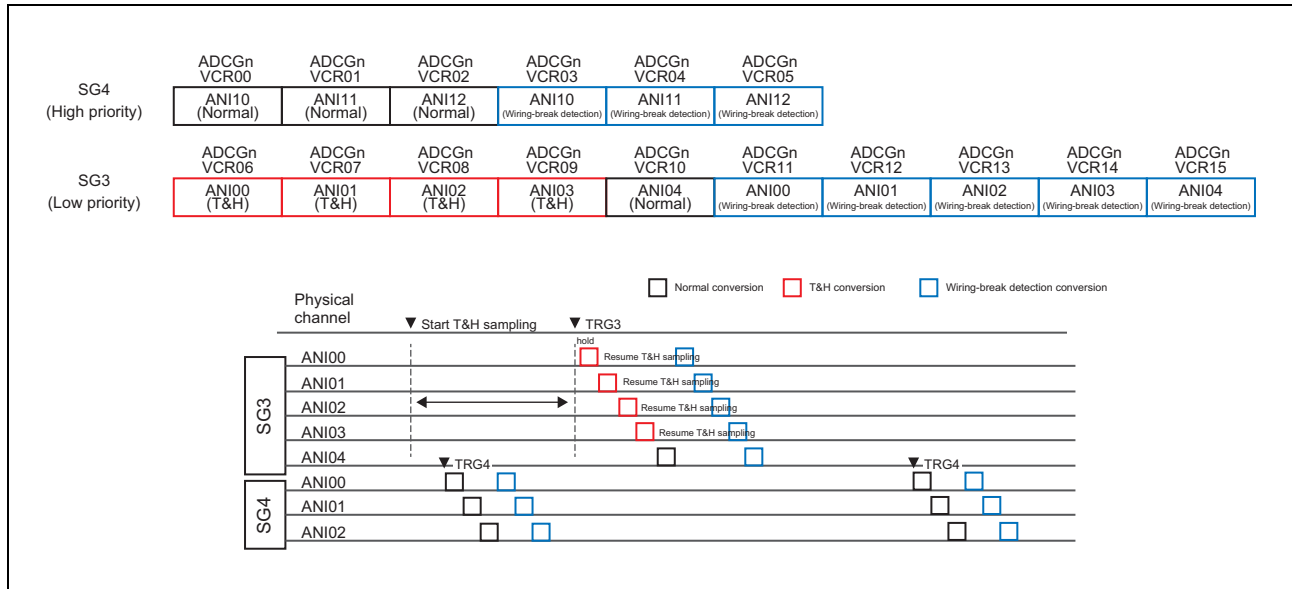

Figure 30.23 Combination of Wiring-Break Detection and A/D Conversion for Same Physical Channel

30.5 Operation

30.5.1 Initial Settings

Figure 30.24 is a flowchart for initial settings. Make initial settings while trigger sources of all scan groups are invalid and all scan groups and all T&H circuits are stopped. If they are in operation, make settings to stop A/D conversion. See **Section 30.5.3, Procedure for Stopping A/D Conversion**.
Set the value after a reset for the functions not to be used.

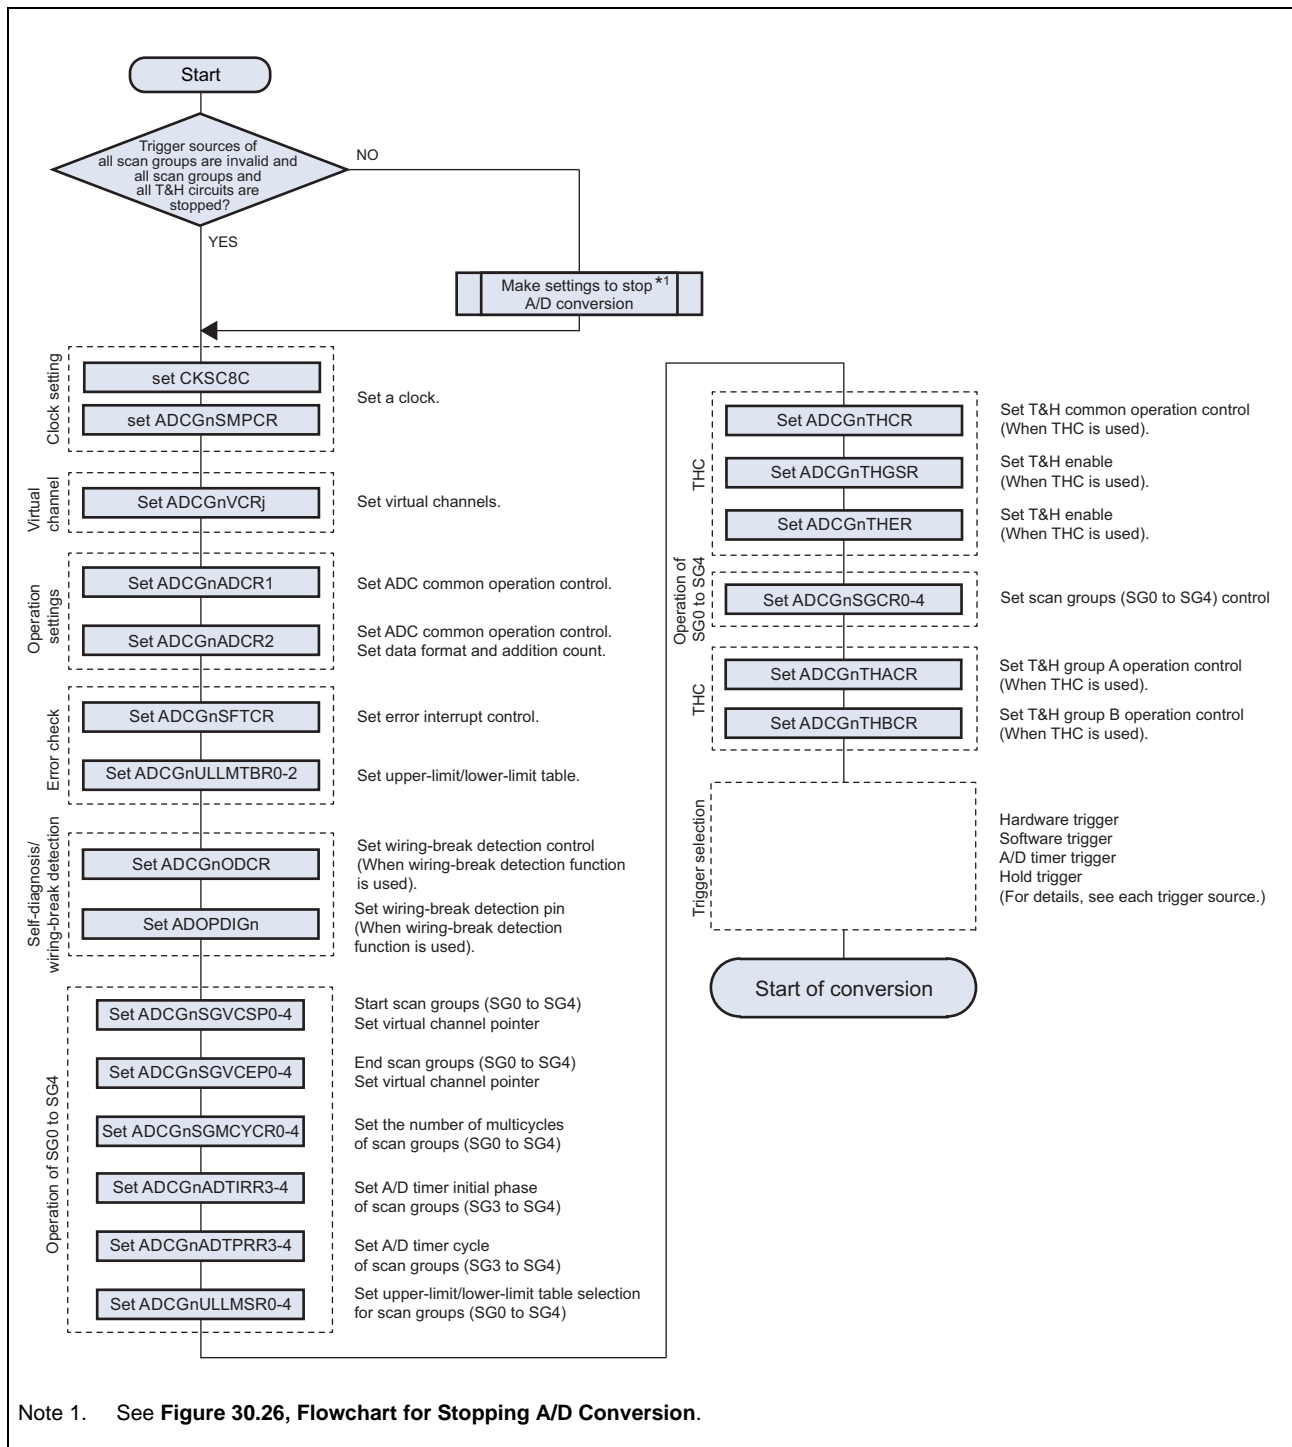

Figure 30.24 Initial Settings

30.5.2 Procedure for Starting A/D Conversion

Figure 30.25 is a flowchart for starting A/D conversion.

The flowchart below is for starting A/D conversion using a hardware trigger when the T&H function is in use. If simultaneous tracking and holding on multiple channels is in use, be sure to only hold the voltage after 32 cycles of CLK_ADC have elapsed after T&H sampling start for tracking and holding.

The flowchart in **Figure 30.25** shows the case where A/D conversion starts under the following conditions.

- Select hardware trigger input to scan group x:
ADCGnSGCRx.TRGMD[1:0] = 1_H
- Automatic sampling of T&H circuits:
ADCGnTHCR.ASMPMSK = 0_H
- Automatic control of T&H hold trigger:
ADCGnTHACR.HLDCTE = 1_H and ADCGnTHACR.HLDTE = 1_H
(or ADCGnTHBCR.HLDCTE=1_H and ADCGnTHBCR.HLDTE=1_H)

Figure 30.25 Flowchart for Starting A/D Conversion

30.5.3 Procedure for Stopping A/D Conversion

Figure 30.26 is a flowchart for stopping A/D conversion.

The flowchart below is for stopping A/D conversion by disabling the trigger signal for all scan groups and stopping all scan groups and all T&H circuits.

Figure 30.26 Flowchart for Stopping A/D Conversion

30.6 Definition of A/D Conversion Accuracy

A/D conversion accuracy is defined below.

- Resolution
Number of digital output codes of the A/D converter
- Quantization error
An error essentially contained in A/D converters, which is given as 1/2 LSB (**Figure 30.27**).
- Offset error
Deviation of the analog input voltage value from the ideal A/D conversion characteristics when the digital output changes from the minimum voltage value 000_H to 001_H. The quantization error is not included (**Figure 30.27**).
- Full-scale error
Deviation of the analog input voltage value from the ideal A/D conversion characteristics when the digital output changes from FFE_H to FFF_H. The quantization error is not included (**Figure 30.27**).
- DNL (Differential nonlinear error)
Deviation between the ideal digital output code width (V_q) and the actual digital output code width (V_a), which is given as $(V_a - V_q)/V_q$. The offset error, the full-scale error, and the quantization error are not included (**Figure 30.27**).
- INL (Integral nonlinear error)
Deviation of the actual value from the ideal A/D conversion characteristics, from the zero voltage to the full-scale voltage, which is given as an integral of DNL from 000_H to a digital output code. The offset error, the full-scale error, and the quantization error are not included (**Figure 30.27**).
- Total errors
Maximum difference between the observed value and logical value. The offset error, the full-scale error, the quantization error, DNL, and INL are included (**Figure 30.27**).

Figure 30.27 Definition of A/D Conversion Accuracy

Section 31 Functional Safety

31.1 Overview

This section describes the failure detection functions provided to detect the LSI failures in the early stage.

31.2 ECC and EDC

31.2.1 Overview

31.2.1.1 ECC

This product incorporates ECC for the following memories. The ECC enables detection and correction of errors of the data retained in the memories. The ECC also enables detection and correction of errors generated between the ECC encoder and memories and between memories and ECC decoder.

Table 31.1 ECC Overview

Applicable Memory	Applicable Data Width [bits]	Operation upon Error Detection				Failure Insertion
		Detection/Correction	Notify ECM	Error Status	Address Capture	
Code flash	128	SEC-DED	Possible	Possible	Possible	Possible
Data flash Local RAM (CPU1) Global RAM	32	SEC-DED	Possible	Possible	Possible	Possible
Instruction cache (data)	64	SED-DED	Possible	Possible	Possible	Possible
Instruction cache (tag)	32	SED-DED	Possible	Possible	Possible	Possible
RAM for DTS	32	SEC-DED	Possible	Possible	Possible	Possible
Peripheral RAM (32 bits)	32	SEC-DED	Possible	Possible	Possible	Possible
Data transfer path	32	SEC-DED	Possible	Possible	Possible	Possible

ECC code

ECC code with a Hamming distance of minimum 4 is used. Combination of data and ECC code space excludes all 0s or all 1s for RAM and code flash.

Detection/Correction

SEC-DED: 1-bit errors can be detected and corrected, and 2-bit errors can only be detected.

SED-DED: 1-bit errors and 2-bit errors can only be detected.

Notify ECM

The detected error can be notified to the ECM (Error Control Module).

Error status

The status of the detected error is retained.

Address capture

The address of the detected error is retained.

Failure insertion

An ECC error can be intentionally caused to enable self-diagnosis of the ECC decoder operation.

31.2.1.2 Address Parity

This product incorporates address EDC (parity) for the following memories. The address EDC allows detection of errors during address decoding. The EDC also allows detection of errors generated at addresses between the parity encoder and memories.

Table 31.2 Address Parity Overview

Applicable Memory	Parity Bit	Notify ECM	Error Status	Address Capture	Failure Insertion
Code flash	1 bit	Possible	Possible	Possible	Possible

31.2.2 Code Flash ECC and Address Parity

31.2.2.1 Overview

The code flash ECC is summarized in the table below.

Table 31.3 Code Flash ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled.</p> <p>When enabled, either of the following settings can be selected.</p> <ul style="list-style-type: none"> ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out.</p> <p>In the initial state, this function is enabled, and 1-bit error detection, correction and notification and 2-bit error detection and notification are carried out.</p>
Address parity	<p>Address parity check can be either enabled or disabled.</p> <p>Address parity is checked during address decoding.</p> <p>In the initial state, this function is enabled.</p>
Error notification	<p>Upon occurrence of an ECC error or parity error, it is notified to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is enabled upon detection of an ECC 1-bit error.</p> <p>Parity Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled upon detection of an address parity error. <p>In the initial state, error notification is enabled upon detection of an address parity error.</p> <p>Overflow Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled of an address buffer overflow error for ECC 1-bit error. In the initial state, error notification is enabled upon detection of an address buffer overflow error. <p>The error notification signal is issued to the ECM, in which an ECC 2-bit error and an address parity error are handled as one source, and an ECC 1-bit error is handled as one source, and an ECC 1-bit overflow error is handled as one source. An ECC 1-bit error signal is only issued to the ECM when the detected ECC 1-bit error address is different from the address stored in the error address buffer.</p>
Error status	<p>A status register is provided, which indicates the statuses of ECC 2-bit error detection, ECC 1-bit error detection, and address parity error detection. A four-stage buffer is provided for 1-bit errors. A one-stage buffer is provided for 2-bit errors and it is shared with parity errors. The status register indicates the state of each stage. The error status can be cleared using the clear register.</p>
Address capture	<p>The address is captured when an ECC 2-bit error, an ECC 1-bit error, or an address parity error is detected.</p> <p>The error status also serves as the enable bit of the captured address.</p>

31.2.2.2 List of Registers

Table 31.4 List of Registers

Address	Symbol	Register Name	R/W	Value after reset	Access Size
FFC6 2000 _H	UCFERRINT	Code Flash Error Information Control Register	R/W	0000 0047 _H	32/16/8
FFC6 2004 _H	UCFSERSTCLR	Code Flash ECC SED Status Clear Register	W	0000 0000 _H	32/16/8
FFC6 2008 _H	UCFDERSTCLR	Code Flash ECC DED/ Address Parity Error Status Clear Register	W	0000 0000 _H	32/16/8
FFC6 200C _H	UCFOVFSTR	Code Flash Error Count Overflow Status Register	R	0000 0000 _H	32/16/8
FFC6 2020 _H	UCFSERSTR	Code Flash ECC SED Status Register	R	0000 0000 _H	32/16/8
FFC6 2030 _H	UCFDERSTR	Code Flash ECC DED/ Address Parity Error Status Register	R	0000 0000 _H	32/16/8
FFC6 2040 _H	UCF1SEADR	Code Flash 1 ECC SED Address Register	R	0000 0000 _H	32

FFC6 2048 _H	UCF3SEADR	Code Flash 3 ECC SED Address Register	R	0000 0000 _H	32
FFC6 204C _H	UCF4SEADR	Code Flash 4 ECC SED Address Register	R	0000 0000 _H	32
FFC6 20C0 _H	UCFDEADR	Code Flash ECC DED/ Address Parity Error Address Register	R	0000 0000 _H	32
FFC6 2100 _H	CFAPCTL	Code Flash Address Parity Control Register	R/W	0000 0000 _H	32/16
FFC6 2200 _H	CFECCCTL_VCI2CFBA	Code Flash ECC Control Register	R/W	0000 0000 _H	32/16
FFC6 22F0 _H	CFSTSTCTL_VCI2CFBA	Code Flash Sub-Test Control Register	R/W	0000 0000 _H	32/16
FFC6 2400 _H	CFECCCTL_PE1	Code Flash ECC Control Register	R/W	0000 0000 _H	32/16
FFC6 24F0 _H	CFSTSTCTL_PE1	Code Flash Sub-Test Control Register	R/W	0000 0000 _H	32/16

Note 1. The registers with symbols “_VCI2CFBA” and “_PE1” as suffixes are provided to the particular ECC controllers.

The registers with “_VCI2CFBA” are provided to the ECC controller for access from the system interconnect to the code flash, the registers with “_PE1” are provided to the ECC controller for access from the CPU1.

31.2.2.3 Details of Registers

(1) UCFERRINT — Code Flash Error Information Control Register

UCFERRINT register controls whether error information is reported to ECM, when data ECC 2-bit error, data ECC 1-bit error, and ECC 1-bit error overflow are detected.

Access: UCFERRINT can be read/written in 32/16/8-bit units.

Address: FFC6 2000_H

Value after reset: 0000 0047_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	SEOVFI E	—	—	—	APEIE	DEDIE	SEDIE
Value after reset	0	0	0	0	0	0	0	0	0	1	0	0	0	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W

Table 31.5 UCFERRINT Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	SEOVFIE	ECC 1bit error overflow report enable bit Controls overflow report when 1bit error overflow flag (SERROVF) in CFOVFSTR register is set. 0: ECC 1-bit error overflow report disabled 1: ECC 1-bit error overflow report enabled
5 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	APEIE	Address parity error report enable bit Controls error report of address parity error detection when address parity check is enabled. 0: Address parity error report disabled 1: Address parity error report enabled
1	DEDIE	ECC 2-bit error report enable bit Controls error report of 2-bit error detection when ECC error detection/correction is enabled 0:ECC 2-bit error report disabled 1:ECC 2-bit error report enabled
0	SEDIE	ECC 1-bit error report enable bit Controls error report of 1-bit error detection when ECC error detection/correction is enabled 0:ECC 1-bit error report disabled 1:ECC 1-bit error report enabled

(2) UCFSERSTCLR — Code Flash ECC SED Status Clear Register

UCFSERSTCLR register is used to clear SEDF[3:0] in UCFSERSTR, SERROVF in UCFOVFSTR, and error address in UCFnSEDADR (n = 1 to 4). This is write only register and read value is always “0”. UCFSERSTCLR register has a lower priority than a set factor. Priority is given to a set factor when UCFSERSTCLR and a set factor compete. A set factor is a trigger for setting SEDF[3:0] in UCFSERSTR, setting SERROVF in UCFOVFSTR, or capturing an error address in UCFnSEDADR (n = 1 to 4).

Access: UCFSERSTCLR can be written only in 32/16/8-bit units.

Address: FFC6 2004_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	SSTCLR3	SSTCLR2	SSTCLR1	SSTCLR0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	W	W	W	W

Table 31.6 UCFSERSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When writing, write the value after reset.
3 to 0	SSTCLR[3:0]	1-bit error flag clear (n-th) 0: Nothing operates 1: All 1-bit error flags clear UCFSERSTR.SEDF(n-1), UCFOVFSTR.SERROVF, UCFnSEDADR.SEADR

(3) UCFDERSTCLR — Code Flash ECC DED/Address Parity Error Status Clear Register

UCFDERSTCLR register is used to clear DEDF and APEF in UCFDERSTR and error address in UCFDEDADR. This is write only register and read value is always “0”. UCFDERSTCLR register has a lower priority than a set factor. Priority is given to a set factor when UCFDERSTCLR and a set factor compete. A set factor is a trigger for setting APEF/DEDF in UCFDERSTR.

Access: UCFSERSTCLR can be written only in 32/16/8-bit units.

Address: FFC6 2008_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DSTCLR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 31.7 UCFDERSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When writing, write the value after reset.
0	DSTCLR	0: Nothing operates 1: All 2-bit error flags clear UCFDERSTR.APEF, UCFDERSTR.DEDF, UCFDEDADR.DEADR

(4) UCFOVFSTR — Code Flash Error Count Overflow Status Register

UCFOVFSTR register monitors occurrence of error overflow. Overflow occurs when an SED for which the error address has not been captured is detected while ECC 1-bit error status register is full. If the ECC 1-bit error status register is full and the error address is the same as the one of the error addresses already captured, this flag is not set. SERROVF flag is cleared when at least one bit of SSTCLR[3:0] in UCFSERSTCLR register is asserted.

Access: UCFOVFSTR can be read in 32/16/8-bit units.

Address: FFC6 200C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.8 UCFOVFSTR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read.
0	SERROVF	1-bit error overflow flag When all bits of the ECC 1-bit error status register (UCFSERSTR.SEDF[3:0]) are "1", an ECC 1 bit error occurs and the error address does not match any of the captured error addresses, this flag is set.

(5) UCFSERSTR — Code Flash ECC SED Status Register

UCFSERSTR is the error monitor register for 1-bit ECC error. Each error flag is “0” and when a new error occurs, an error status flag is set. An error flag is set at the lowest number empty bit of UCFSERSTR (e.g. If SEDF[0][1][3] have been set to “1” and all other bits have been empty, the next flag is set at SEDF[2]). If multiple SED causes are simultaneously detected and there are sufficient empty bits, all detected SEDs are set (e.g. if a SED and another SED which occurs at a different address are detected simultaneously, both SEDFs are set.). However, if SEDs occur at a same address simultaneously, only one of errors is set according to the fixed priority. The priority order is the PE1, and VCI2CFB. (e.g. if a SED which is input from the PE1 path and an SED which is input from the VCI2CFB path are detected simultaneously and those occur at the same address, only SEDF from the PE1 path is set and SEDF from the VCI2CFB path is not set.) Furthermore, an error address which has already been captured in UCFnSEDADR (n = 1 to 4) must not be captured again. UCFSERSTR register is cleared by setting SSTCLR[3:0] in UCFSERSTCLR register to 1.

Access: UCFSERSTR can be read in 32/16/8-bit units.

Address: FFC6 2020_H

Value after reset: 0000 0000_H

Table 31.9 UCFSERSTR Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read.
3 to 0	SEDF[3:0]	ECC 1-bit error monitor flag (n-th) Condition for “0”: write “1” to SSTCLR(n-1) in UCFSERSTCLR Condition for “1”: ECC 1-bit error is detected.

(6) UCFDERSTR — Code Flash ECC DED/Address Parity Error Status Register

UCFDERSTR is the error monitor register for 2-bit ECC error and address parity error. All error flags are “0” and when a new error occurs, an error status flag is set. If multiple error causes which are input from different access ports are detected simultaneously, only one of detected errors is set according to the fixed priority. The reason is that there is only one 2-bit error Address Register. The priority order is the PE1, and VCI2CFB. (e.g. if a DED which is input from the PE1 path and an APE which is input from the VCI2CFB path are detected simultaneously and these occur at the same address, only DEDF from the PE1 path is set and APEF from the VCI2CFB path is not set.) If multiple error causes occur from same access port simultaneously, all detected errors are set. (e.g. if DED and APE are simultaneously input from the PE1 path, both DEDF and APEF are set.) UCFDERSTR register is cleared by setting DSTCLR in UCFDERSTR register to 1.

Access: UCFDERSTR can be read in 32/16/8-bit units.

Address: FFC6 2030_H

Value after reset: 0000 0000_H

Table 31.10 UCFDERSTR Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is read.
2	APEF	Address parity error monitor flag Condition to “0”: write “1” to DSTCLR in UCFDERSTR Condition to “1”: APEF/DEDF is all “0” and address parity error is detected.
1	Reserved	When read, the value after reset is read.
0	DEDF	ECC 2-bit error monitor flag Condition to “0”: write “1” to DSTCLR in UCFDERSTR Condition to “1”: DEDF is “0” and ECC 2-bit error is detected.

(7) UCFnSEDADR — Code Flash n ECC SED Address Register (n = 1 to 4)

UCFnSEDADR registers are used to hold the address when an error is detected. SEADR[24:4] in this register is corresponding to actual address [24:4]. Actual address can be calculated by adding high-order address which is mapped in Code Flash onto base address. Error address capture trigger is same as corresponding SEDFF (n – 1) set in UCFSERSTR. UCFnSEDADR is cleared by setting SSTCLRF (n – 1) in UCFSERSTCLR register to 1.

Access: UCFnSEDADR can be read in 32-bit units.

Address: UCF1SEDADR: FFC6 2040_H
 UCF2SEDADR: FFC6 2044_H
 UCF3SEDADR: FFC6 2048_H
 UCF4SEDADR: FFC6 204C_H

Value after reset: 0000 0000_H

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is read.
24 to 4	SEADR[24:4]	1-bit error address
3 to 0	Reserved	When read, the value after reset is read.

(8) UCFDEDADR — Code Flash ECC DED/Address Parity Error Address Register

UCFDEDADR register is used to hold the address when an error is detected. DEADR[24:4] in this register is corresponding to actual address [24:4]. Actual address can be calculated by adding high-order address which is mapped in Code Flash onto base address. Error address capture trigger is same as corresponding APEF/DEDF set in UCFDERSTR. If this register captures an error address, it does not capture any more addresses until it is cleared. UCFDEDADR is cleared by setting DSTCLR in UCFDERSTCLR register to 1.

Access: UCFDEDADR can be read in 32-bit units.

Address: FFC6 20C0_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.12 UCFDEDADR Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is read.
24 to 4	DEADR[24:4]	2-bit error or address parity error address
3 to 0	Reserved	When read, the value after reset is read.

(9) CFAPCTL — Code Flash Address Parity Control Register

CFAPCTL register enables or disables address parity check. Address parity control register must be written while $PROT[1:0] = 01_B$.

Access: CFAPCTL can be read/written in 32/16-bit units.

Address: FFC6 2100_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection bit 01: write is enabled. Other: write is disabled These bits are always read as 0.
13 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	APTESTA	Address Parity Check TEST bit (Bank-A) 0: Address Parity Not Inverted (Normal Mode) 1: Address Parity Inverted (Test Mode)
0	APARIDIS	Address Parity disable bit Enables or disables address parity check. 0: Address Parity Check is enabled 1: Address Parity Check is disabled

(10) CFECCTL_VCI2CFBA/PE1 — Code Flash ECC Control Register

CFECCTL_VCI2CFBA/PE1 registers enable or disable the ECC error detection/correction and 1-bit error correction. ECC control registers must be written while $PROT[1:0] = 01_B$.

Access: CFECCTL_VCI2CFBA/PE1 can be read/written in 32/16-bit units.

Address: CFECCTL_VCI2CFBA: FFC6 2200_H
CFECCTL_PE1: FFC6 2400_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.14 CFECCTL_VCI2CFBA/PE1 Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	SECDIS	ECC 1-bit error correction enable bit Enables or disables 1-bit error correction when using ECC error detection/correction (ECCDIS = 0). 0: Correction is done when 1-bit error is detected 1: No Correction is done when 1-bit error is detected
0	ECCDIS	ECC disable bit Enables or disables ECC error detection/correction. 0: ECC error detection/correction is enabled 1: ECC error detection/correction is disabled

(11) CFSTSTCTL_VCI2CFBA/PE1 — Code Flash Sub-Test Control Register

The CFSTSTCTL registers are used for the ECC test (self-diagnosis). These registers are dedicated for code flash. After ECC test mode is enabled by setting ECCTST = 1, the ECC bits and address parity bit can be read directly.

Access: CFSTSTCTL_VCI2CFBA/PE1 can be read/written in 32/16-bit units.

Address: CFSTSTCTL_VCI2CFBA: FFC6 22F0_H
CFSTSTCTL_PE1: FFC6 24F0_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	PROT[1:0]	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECCTST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 31.15 CFSTSTCTL_VCI2CFBA/PE1 Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ECCTST	ECC test bit for Code Flash By setting ECC test mode bit to "1" (ECCTST = 1), CPU can read ECC bits and address parity bit directly. In the read data, bit 9 is the parity bit and bits 0 to 8 are ECC bits.

Correctly reading instructions from the code flash access port is not possible while ECC test mode is selected (ECCTST = 1). While the access port for the CPU is set to test mode (including during changes to the value of the ECCTST bit), the CPU must run a program from the local RAM and must not fetch instructions from the code flash memory.

The CPU has a small data buffer. If an old value remains in this buffer, the correct value cannot be read even when the ECCTST bit is switched. When switching the ECCTST bit, be sure to clear the data buffer. For how to clear the data buffer, see **Section 3, CPU System**.

From the code flash access port with ECC test mode selected, access must be made by reading 4 bytes aligned to 16n (n: integer) address.

31.2.2.4 Test Function

Through appropriate register setting, the code flash data, ECC bits, and address parity bit can be read out.

(1) Reading code flash data

- (a) Set the ECCDIS bit in the code flash ECC control register to 1 to disable ECC error detection and correction.
- (b) When ECCDIS = 1, neither error detection nor correction is carried out when the code flash is read; the data output from the code flash is read unchanged.

How to exit this test mode:

- (a) Set the ECCDIS bit in the code flash ECC control register to 0 to enable ECC error detection and correction.

(2) Reading the ECC and address Parity bits

- (a) Set the ECCDIS bit in the code flash ECC control register to 1 to disable ECC error detection and correction.
- (b) Set the ECCTST bit in the code flash sub-test control register to 1 to enter test mode.
- (c) When the code flash is read, the ECC and address parity bits are read instead of the code flash data.

How to exit this test mode:

- (a) Set the ECCDIS bit in the code flash ECC control register to 0 to enable ECC error detection and correction.
- (b) Set the ECCTST bit in the code flash sub-test control register to 0 to return to normal mode.

(3) Self-diagnosis of ECC check function

Self-diagnosis of the ECC decoder for the access ports is possible by reading data from ECC test area.

For details on the ECC test area, refer to **Section 35, Flash Memory**.

(4) Self-diagnosis of address parity check function

- (a) Set the APTESTA bit in the code flash address parity control register to 1 to invert parity bit.
- (b) When code flash data on any address is read, a fault can be injected to the address parity checker to enable self-diagnosis of the address parity check function.

How to exit this test mode:

- (a) Set the APTESTA bit in the code flash address parity control register to 0 to return to normal mode.

31.2.3 Data Flash ECC

31.2.3.1 Overview

The data flash ECC is summarized in the table below.

Table 31.16 Data Flash ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled.</p> <p>When enabled, either of the following settings can be selected.</p> <ul style="list-style-type: none"> • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out. In the initial state, this function is enabled, and 1-bit error detection and correction and 2-bit error detection and notification are carried out.</p>
Error notification	<p>Upon occurrence of an ECC error, it is notified to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is disabled upon detection of an ECC 1-bit error.</p> <p>Overflow Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an address buffer overflow error. <p>In the initial state, error notification is enabled upon detection of an address buffer overflow error.</p> <p>The error notification signal is output, where an ECC 2-bit error is handled as one source, and an ECC 1-bit error and overflow error are handled as separate sources.</p>
Error status	<p>A status register is provided, which indicates the statuses of ECC 2-bit error detection and ECC 1-bit error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.</p>
Address capture	<p>If an ECC error occurs while no error status is set, the address at which the associated error has occurred is captured.</p> <p>The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected. The error status also serves as the enable bit of the captured address.</p>

31.2.3.2 List of Registers

Table 31.17 List of Registers

Address	Symbol	Register Name	R/W	Value after reset	Access Size
FFC5 B000 _H	DFECCCTL	Data Flash ECC control register	R/W	0000 0000 _H	32/16
FFC5 B004 _H	DFERSTR	Data Flash error status register	R	0000 0000 _H	32
FFC5 B008 _H	DFERSTC	Data Flash error status clear register	W	0000 0000 _H	32/16/8
FFC5 B00C _H	DFOVFSTR	Data Flash error overflow status register	R	0000 0000 _H	32
FFC5 B010 _H	DFOVFSTC	Data Flash error overflow status clear register	W	0000 0000 _H	32/16/8
FFC5 B014 _H	DFERRINT	Data Flash error notification control register	R/W	0000 0006 _H	32/16/8
FFC5 B018 _H	DFEADR	Data Flash 1st error address register	R	0000 0000 _H	32
FFC5 B01C _H	DFTSTCTL	Data flash test control register	R/W	0000 0000 _H	32/16

31.2.3.3 Details of Registers

(1) DFECCTL — Data Flash ECC Control Register

DFECCTL enables or disables ECC error detection and 1-bit error correction for read access to each data flash bank. Set the PROT1 and PROT0 bits to 01_B when writing to DFECCTL.

Access: DFECCTL can be read/written in 32/16-bit units.

Address: FFC5 B000_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT1	PROT0	—	—	—	—	—	—	—	—	—	—	—	—	SECDIS	ECCDIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 31.18 DFECCTL Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15	PROT1	Enables or disables modification of the ECCDIS and SECDIS bits. The value written is not retained. These bits are always read as 0. Set (PROT1, PROT0) = (0, 1) when writing to DFECCTL.
14	PROT0	
13 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	SECDIS	1-Bit Error Correction Disable Enables or disables 1-bit error correction when ECC error detection and correction are enabled. Set (PROT1, PROT0) = (0, 1) simultaneously when writing to this bit. 0: Enables correction of the 1-bit error detected. 1: Disables correction of the 1-bit error detected.
0	ECCDIS	ECC Disable Enables or disables ECC error detection and correction. Set (PROT1, PROT0) = (0, 1) simultaneously when writing to this bit. In the initial state, ECC error detection and correction are enabled. 0: Enables ECC error detection and correction. 1: Disables ECC error detection and correction.

(2) DFERSTR — Data Flash Error Status Register

DFERSTR monitors occurrence of errors.

The SEDF bit is set if an ECC 1-bit error is detected and the DEDF bit is set if an ECC 2-bit error is detected while ECC error detection and correction are enabled.

Access: DFERSTR can be read only in 32-bit units.

Address: FFC5 B004_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.19 DFERSTR Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is read.
1	DEDF	<p>ECC 2-bit Error Monitor Flag</p> <p>0: An ECC 2-bit error is not generated.</p> <p>1: An ECC 2-bit error is generated.</p> <p>Clearing condition: ERRCLR bit is set in Data Flash error status clear register.</p> <p>Setting condition: ECC 2-bit error is generated.</p>
0	SEDF	<p>ECC 1-bit Error Monitor Flag</p> <p>0: An ECC 1-bit error is not generated.</p> <p>1: An ECC 1-bit error is generated.</p> <p>Clearing condition: ERRCLR bit is set in Data Flash error status clear register.</p> <p>Setting condition: ECC 1-bit error is generated with both SEDF and DEDF being 0.</p>

(3) DFERSTC — Data Flash Error Status Clear Register

DFERSTC clears the error flags in the Data Flash error status register.

Access: DFERSTC can be written only in 32/16/8-bit units.

Address: FFC5 B008_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.20 DFERSTC Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When writing, write the value after reset.
0	ERRCLR	SEDF/DEDF Flag Clear 0: No effect (Setting the ERRCLR bit to 0 does not affect the DEDF and SEDF flags in DFERSTR.) 1: The SEDF/DEDF flags in DFERSTR are cleared.

(4) DFOVFSTR — Data Flash Error Overflow Status Register

DFOVFSTR monitors occurrence of Data Flash error overflow.

Access: DFOVFSTR can be read only in 32-bit units.

Address: FFC5 B00C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 31.21 DFOVFSTR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read.
0	ERROVF	Error Overflow Flag ERROVF is set as follows: <ul style="list-style-type: none"> • An ECC 1-bit error has occurred when DFERSTR.SEDF = 1 and access address is different from DFEADR. • An ECC 1-bit error has occurred when DFERSTR.DEDF = 1 • An ECC 2-bit error has occurred when DFERSTR.SEDF = 1 • An ECC 2-bit error has occurred when DFERSTR.DEDF = 1 and access address is different from DFEADR. 0: Not occurred 1: Occurred

Clearing condition: Set the ERROVFCLR bit in DFOVFSTC to 1.

(5) DFOVFSTC — Data Flash Error Overflow Status Clear Register

DFOVFSTC clears the data flash error overflow flag.

Access: DFOVFSTC can be written only in 32/16/8-bit units.

Address: FFC5 B010_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 31.22 DFOVFSTC Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When writing, write the value after reset.
0	ERROVFCLR	Error Overflow Flag Clear 0: No effect (Setting the ERROVFCLR bit to 0 does not affect the ERROVF flag in DFOVFSTR.) 1: The ERROVF flag in the DFOVFSTR register is cleared.

(6) DFERRINT — Data Flash Error Notification Control Register

DFERRINT enables or disables generation of the error notification signal to ECM upon detection of an ECC 2-bit error or an ECC 1-bit error.

Access: DFERRINT can be read/written in 32/16/8-bit units.

Address: FFC5 B014_H

Value after reset: 0000 0006_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.23 DFERRINT Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	EOVFIE	ECC Error Address Overflow Notification Control Enables or disables generation of the error notification signal upon detection of an address buffer overflow. 0: Disables notification of error address overflow 1: Enables notification of error address overflow
1	DEDIE	ECC 2-bit Error Notification Control Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 2-bit error. 1: Enables notification of the ECC 2-bit error.
0	SEDIE	ECC 1-bit Error Notification Control Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 1-bit error. 1: Enables notification of the ECC 1-bit error.

(7) DFEADR — Data Flash 1st Error Address Register

DFEADR holds the error address if the following occur.

- An ECC 1-bit or 2-bit error occurred when DFERSTR.SEDF = 0 and DFERSTR.DEDF = 0
- An ECC 2-bit error occurred when DFERSTR.SEDF = 1 and DFERSTR.DEDF = 0

Access: This register can be read only in 32-bit units.

Address: FFC5 B018_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	DFEADR[20:16]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DFEADR[15:2]														—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.24 DFEADR Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is read.
20 to 2	DFEADR[20:2]	ECC Error Address DFEADR is a read-only field to monitor the address at which an ECC error has occurred. This register holds an internal address. Convert it to the actual address by adding the data flash base address FF20 0000 _H .
1, 0	Reserved	When read, the value after reset is read.

(8) DFTSTCTL — Data Flash Test Control Register

DFTSTCTL is used for ECC testing.

The data of the ECC bit can be read after setting the ECC test mode (ECCTST = 1).

This register must be written while PROT[1:0] = 01_B.

Access: DFTSTCTL can be read/written in 32/16-bit units.

Address: FFC5 B01C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT1	PROT0	—	—	—	—	—	—	—	—	—	—	—	—	—	ECC TST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 31.25 DFTSTCTL Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15	PROT1	Enables or disables modification of the ECCTST bit.
14	PROT0	The value written is not retained. These bits are always read as 0. Set (PROT1, PROT0) = (0, 1) when writing to DFTSTCTL.
13 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ECCTST	ECC Test By setting ECC Test bit to "1" (ECCTST=1), CPU can read ECC bit. Set (PROT1, PROT0) = (0, 1) simultaneously when writing to this bit.

31.2.3.4 Test Function

Data in the ROM and the ECC bits can be read by setting the data flash test control register (DFTSTCTL).

(1) Reading the ROM Data

- (a) Set the ECCDIS bit in the data flash ECC control register to 1 to disable ECC error detection and correction.
- (b) When ECCDIS = 1, neither error detection nor correction is carried out when the data flash is read; the data output from the data flash is read unchanged.

How to exit this test mode:

- (a) Set the ECCDIS bit in the data flash ECC control register to 0 to enable ECC error detection and correction.

(2) Reading the ECC bits

- (a) Set the ECCDIS bit in the data flash ECC control register to 1 to disable ECC error detection and correction.
- (b) Set the ECCTST bit in the data flash test control register to 1 to enter test mode.
- (c) When the data flash is read, the 7 lower-order bits of read data are read as ECC data.

How to exit this test mode:

- (a) Set the ECCDIS bit in the data flash ECC control register to 0 to enable ECC error detection and correction.
- (b) Set the ECCTST bit in the data flash test control register to 0 to return to normal mode.

(3) Self-diagnosis of ECC check function

Self-diagnosis of the ECC decoder is possible by writing incorrect data to the data flash memory beforehand (fault injection) and then reading this data. A 1- or 2-bit ECC error fault can be injected by generating correct ECC bits once and inverting only the appropriate bits.

For details on programming of the data flash, refer to *RH850/P1M-E Flash Memory User's Manual: Hardware Interface*.

31.2.4 Local RAM (CPU1) ECC

31.2.4.1 Overview

Local RAM ECC of CPU1 is summarized in the table below.

Table 31.26 Local RAM ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected.</p> <ul style="list-style-type: none"> ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out. In the initial state, the ECC function is enabled; 1-bit error detection, correction, and notification, and 2-bit error detection and notification are carried out.</p>
Error notification	<p>Upon occurrence of an ECC error, it is notified to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, notification of the 2-bit error is enabled and notification of the 1-bit error is enabled.</p> <p>Overflow Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled upon detection of an address buffer overflow error for ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an address buffer overflow error.</p> <p>The error notification signal is output, where an ECC 2-bit error is handled as one source, an ECC 1-bit error is handled as one source, and an ECC 1-bit overflow error is handled as one source.</p> <p>An ECC1-bit error signal is only issued to the ECM when the detected ECC 1-bit error address is different from the address stored in the error address buffer.</p>
Error status	<p>A status register is provided, which indicates the statuses of ECC 2-bit error detection, ECC 1-bit error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.</p>
Address capture	<p>Multi-stage address buffers are provided for ECC 1bit errors as with code flash ECC.</p> <p>1-bit error: Eight stages (in 32-bit units) 2-bit error: One stage (in 32-bit units)</p> <p>The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected. The error status also serves as the enable bit of the captured address.</p>

CPU1 is capable of simultaneously writing or reading up to 128 bits of data at a time to or from the local RAM. Meanwhile, ECC bits are provided for each 32 bits of data and the locations for storage of each 32-bit data segment are referred to as banks 0 to 3. Addresses for the lowest-order bits (i.e., for the LSB side of the data) are for bank 0, while addresses for the highest-order bits (i.e., for the MSB side of the data) are for bank 3.

The relationship between addresses and banks is described below.

4 Lower-Order Bits of Address (Hexadecimal Notation)	F _H to C _H	B _H to 8 _H	7 _H to 4 _H	3 _H to 0 _H
Bank number	Bank 3	Bank 2	Bank 1	Bank 0

31.2.4.2 List of Registers

Table 31.27 List of Registers (1/2)

Address	Symbol	Register Name	R/W	Value after reset	Access Size
FFC65400 _H	LRECCCTL_PE1	Local-RAM ECC Control Register	R/W	0000 0000 _H	32/16

31.2.4.3 Details of Registers

(1) LRECCCTL_PE1 — Local-RAM ECC Control Register

LRECCCTL_PE1 register controls the ECC error detection/correction and 1-bit error correction.
Writing ECC control registers must be executed with PROT[1:0] = 01_B.

Access: LRECCCTL_PE1 can be read/written in 32/16-bit units.

Address: FFC6 5400_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 31.28 LRECCCTL_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	SECDIS	ECC 1-bit error correction enable bit Enables or disables 1-bit error correction when using ECC error detection/correction (ECCDIS = 0). 0: Correction is carried out when 1-bit error is detected 1: Correction is not carried out when 1-bit error is detected
0	ECCDIS	ECC disable bit Enables or disables ECC error detection/correction. 0: ECC error detection/correction is enable 1: ECC error detection/correction is disable

(2) LRERRINT_PE1 — Local-RAM Error Information Control Register

LRERRINT_PE1 register controls whether error information is reported to ECM, when data ECC 2-bit error, data ECC 1-bit error, and ECC 1-bit error overflow are detected.

Access: LRERRINT_PE1 can be read/written in 32/16/8-bit units.

Address: FFC6 5404_H

Value after reset: 0000 0043_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.29 LRERRINT_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	EOVFIE	ECC 1bit error overflow report enable bit Controls overflow report when 1bit error overflow flag (SERROVFn) in LROVFSTR register is set. 0: ECC 1bit error overflow report disabled 1: ECC 1bit error overflow report enabled
5 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	DEDIE	ECC 2-bit error report enable bit Controls error report of 2-bit error detection when ECC error detection/correction is enabled 0: ECC 2-bit error report disabled 1: ECC 2-bit error report enabled
0	SEDIE	ECC 1-bit error report enable bit Controls error report of 1-bit error detection when ECC error detection/correction is enabled 0: ECC 1-bit error report disabled 1: ECC 1-bit error report enabled

(3) LRSERSTCLR_PE1— Local-RAM ECC SED Status Clear Register

LRSERSTCLR_PE1 register is used to clear SEDF_{mn} (m = 1 to 8, n = 0 to 3) in LRSERSTR_PE1 and SERROVF_n (n = 0 to 3) in LROVFSTR_PE1, and error address in LR[m]SEDADR[n]_PE1. This is write only register and read value is always “0”.

Access: LRSERSTCLR_PE1 can be written in 32/16/8-bit units.

Address: FFC6 5408_H

Value after reset: 0000 0000_H

Table 31.30 LRSERSTCLR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 0	SSTCLR _{mn} (m = 1 to 8) (n = 0 to 3)	1-bit error flag clear (bank n) 0: Nothing operates 1: All 1-bit error flags clear LRSERSTR_PE1.SEDF _{mn} , LROVFSTR_PE1.SERROVF _n , LR[m]SEDADR[n]_PE1.SEADR

(4) LRDERSTCLR_PE1 — Local-RAM ECC DED Status Clear Register

LRDERSTCLR_PE1 register is used to clear DEDFn (n = 0 to 3) in LRDERSTR_PE1 and error address in LRDEDADRn_PE1 (n = 0 to 3). This is write only register and read value is always “0”.

Access: LRDERSTCLR_PE1 can be written in 32/16/8-bit units.

Address: FFC6 540C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.31 LRDERSTCLR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When writing, write the value after reset.
3 to 0	DSTCLR[3:0]	2-bit error flag clear (bank n) 1: All 2-bit error flags clear LRDERSTR_PE1.DEDFn, LRDEDADRn_PE1.DEADR

(5) LROVFSTR_PE1 — Local-RAM Error Count Overflow Status Register

LROVFSTR_PE1 register monitors occurrence of error overflow. ECC 1bit error occurs at same error address is detected while the error status is full. If the error status is full and the same error (same error address) has occurred, then this flag is not set. SERROVFn (n = 0 to 3) flag is cleared by setting SSTCLRmn (m = 1 to 8, n = 0 to 3) in LRSERSTCLR_PE1 register to 1.

Access: LROVFSTR_PE1 can be read in 32/16/8-bit units.

Address: FFC6 5410_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.32 LROVFSTR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read.
3 to 0	SERROVF[3:0]	1-bit error overflow flag (bank n) When all bits provided each bank of the ECC 1-bit error status register (LRSERSTR.SEDF[8:1]n) are "1", an ECC 1 bit error occurs and the error address does not match any of the captured error addresses, this flag is set.

(6) LRSERSTR_PE1 — Local-RAM ECC SED Status Register

LRSERSTR_PE1 is the error monitor register. If the error flag is “0” for each bank and a new error occurs, the error status flag is set. LRSERSTR_PE1 register is cleared by setting SSTCLRmn (m = 1 to 8, n = 0 to 3) in LRSERSTCLR_PE1 register to 1.

Access: LRSERSTR_PE1 can be read in 32/16/8-bit units.

Address: FFC6 5440_H

Value after reset: 0000 0000_H

Table 31.33 LRSERSTR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 0	SEDFmn (m = 1 to 8) (n = 0 to 3)	ECC 1-bit error monitor flag (bank n) Condition to “0”: write “1” to SSTCLRmn in LRSERSTCLR_PE1 Condition to “1”: SEDFmn is “0” and ECC 1-bit error is detected.

(7) LRDERSTR_PE1 — Local-RAM ECC DED Status Register

LRDERSTR_PE1 is the error monitor register. If the error flag is “0” for each bank and a new ECC 2-bit error occurs by reading from this bank, then error status flag is set. LRDERSTR_PE1 register is cleared by setting DSTCLRn (n = 0 to 3) in LRDERSTCLR_PE1 register to 1.

Access: LRDERSTR_PE1 can be read in 32/16/8-bit units.

Address: FFC6 5450_H

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is read.
25	DEDF3	ECC 2-bit error monitor flag (bank 3) Condition to “0”: write “1” to DSTCLR3 in LRDERSTCLR_PE1 Condition to “1”: DEDF3 is “0” and ECC 2-bit error is detected.
24 to 18	Reserved	When read, the value after reset is read.
17	DEDF2	ECC 2-bit error monitor flag (bank 2) Condition to “0”: write “1” to DSTCLR2 in LRDERSTCLR_PE1 Condition to “1”: DEDF2 is “0” and ECC 2-bit error is detected.
16 to 10	Reserved	When read, the value after reset is read.
9	DEDF1	ECC 2-bit error monitor flag (bank 1) Condition to “0”: write “1” to DSTCLR1 in LRDERSTCLR_PE1 Condition to “1”: DEDF1 is “0” and ECC 2-bit error is detected.
8 to 2	Reserved	When read, the value after reset is read.
1	DEDF0	ECC 2-bit error monitor flag (bank 0) Condition to “0”: write “1” to DSTCLR0 in LRDERSTCLR_PE1 Condition to “1”: DEDF0 is “0” and ECC 2-bit error is detected.
0	Reserved	These bits are always read as 0. The write value should also be 0.

(8) LRmSEDADRn_PE1 — Local-RAM 1st to 8th SED Address Register n (m = 1 to 8, n = 0 to 3)

LRmSEDADRn_PE1 (m = 1 to 8, n = 0 to 3) registers are used to hold the address when an error is detected. Error address capture trigger is same as corresponding SEDFmn (m = 1 to 8, n = 0 to 3) set in LRSERSTR_PE1. LRmSEDADRn_PE1 (m = 1 to 8, n = 0 to 3) are cleared by setting SSTCLRmn (m = 1 to 8, n = 0 to 3) in LRSERSTCLR_PE1 register to 1.

Access: LRmSEDADRn_PE1 can be read in 32-bit units.

Address:

Table 31.39 LRDATBF_j_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is read.
22 to 16	LRDATABF [22:16]	ECC Data at Bank (2j + 1) is stored in this register during the read operation from LRAM when ECCTST = 1.
15 to 7	Reserved	When read, the value after reset is read.
6 to 0	LRDATABF[6:0]	ECC Data at Bank (2j) is stored in this register during the read operation from LRAM when ECCTST = 1.

31.2.4.4 Test Function

Through appropriate register setting, desired values can be written to RAM data and the ECC bits. Also, data in the RAM and the ECC bits can all be read.

(1) Writing to RAM data

- (a) Set the ECCTST bit in the local RAM test control register to 1 to enter test mode.
- (b) Set the corresponding DATSEL bit in the local RAM test control register to 0 to select the RAM data to be written to.
- (c) When data is written to the local RAM, only the RAM data is modified without updating the ECC bits.

How to exit this test mode:

- (a) Set the ECCTST bit in the local RAM test control register to 0 to disable test mode (enable normal mode).

(2) Reading RAM data

- (a) Set the ECCDIS bit in the local RAM ECC control register to 1 to disable ECC error detection and correction.
- (b) Read the local RAM. Since neither error detection nor correction is carried out when the local RAM is read, the RAM data is read unchanged.

How to exit this test mode:

- (a) Set the ECCDIS bit in the local RAM ECC control register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC bits

- (a) Set the ECCTST bit in the local RAM test control register to 1 to enter test mode.
- (b) Set the corresponding DATSEL bit in the local RAM test control register to 1 to select the ECC bits to be written to.
- (c) When data is written to the local RAM, only the ECC bits are modified without updating the RAM data. At that time, bit[6:0] are respectively written to the ECC bits.

How to exit this test mode:

- (a) Set the ECCTST bit in the local RAM test control register to 0 to disable test mode (enable normal mode).

(4) Reading the ECC bits

- (a) Set the ECCTST bit in the local RAM test control register to 1 to enter test mode.
- (b) When the local RAM is read, the ECC bits are stored in the corresponding bank of local RAM test data read buffer 0 or local RAM test data read buffer 1.

How to exit this test mode:

- (a) Set the ECCTST bit in the local RAM test control register to 0 to disable test mode (enable normal mode).

(5) Self-diagnosis of the ECC check function

Desired values can be written to the RAM data and/or ECC bits by following the procedure described in (1) or (3) above. Therefore, a fault can be injected by, for example, inverting appropriate bits of the RAM data and/or ECC bits. After that, self-diagnosis of the ECC decoder is possible by reading the local RAM in normal mode and checking the result of error correction or detection.

31.2.5 Global RAM ECC

31.2.5.1 Overview

The global RAM ECC is summarized in the table below.

Table 31.40 Global RAM ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected.</p> <ul style="list-style-type: none"> ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out. In the initial state, the ECC function is enabled, and 1-bit error detection, correction and notification and 2-bit error detection and notification are carried out.</p>
Address ECC	<p>Address ECC check can be either enabled or disabled. Address ECC detects address error between Global RAM and master. In the initial state, 1-bit error detection, 2-bit error detection and notification are carried out.</p>
Error notification	<p>Upon occurrence of an ECC error or Address ECC error, it is notified to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is enabled upon detection of an ECC 1-bit error.</p> <p>Address ECC Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled upon detection of an address ECC error. <p>In the initial state, error notification is enabled upon detection of an address ECC error.</p> <p>Overflow Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled upon detection of an address buffer overflow error for Data ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an address buffer overflow error.</p> <p>ECC 2-bit error, address ECC 2-bit error, ECC 1-bit error, overflow error and address ECC 1-bit error are handled as separate sources. An ECC1-bit error signal is only issued to the ECM when the detected ECC 1-bit error address is different from the address stored in the error address buffer.</p>
Error status	<p>A status register is provided, which indicates the statuses of ECC 2-bit error detection, ECC 1-bit error detection, and Address ECC error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.</p>
Address capture	<p>Multi-stage address buffers are provided for a 1-bit data error, and check is performed in each stage. The address is latched when the state of each stage is cleared.</p> <ul style="list-style-type: none"> 1-bit data error: 32 stages 2-bit data and address ECC, shared: One stage <p>The address is captured when an ECC 2-bit error, an ECC 1-bit error, or an Address ECC error is detected. The error status also serves as the enable bit of the captured address.</p>

31.2.5.2 List of Registers

Table 31.41 List of Registers (1/2)

Address	Symbol	Register Name	R/W	Value after reset	Access Size
FFC64000 _H	UGRERRINT	Global RAM Error Information Control Register	R/W	0000 0073 _H	32/16/8

FFC64100 _H	GRECCCTL_GRAMC	Global RAM ECC Control Register	R/W	0000 0000 _H	32/16
FFC64104 _H	GRTSTCTL	Global RAM Test Control Register	R/W	0000 0000 _H	32/16
FFC64108 _H	GRTDATBF0L	Global RAM Test Data Read Buffer (Lower 32 bits of Bank A)	R	0000 0000 _H	32/16/8
FFC6410C _H	GRTDATBF0H	Global RAM Test Data Read Buffer (Upper 32 bits of Bank A)	R	0000 0000 _H	32/16/8
FFC64110 _H	GRTDATBF1L	Global RAM Test Data Read Buffer (Lower 32 bits of Bank B)	R	0000 0000 _H	32/16/8
FFC64114 _H	GRTDATBF1H	Global-RAM Test Data Read Buffer (Upper 32 bits of Bank B)	R	0000 0000 _H	32/16/8
FFC64118 _H	GRDECINBF0	GRAMC ECC Decoder Input Data Buffer 0	R/W	0000 0000 _H	32/16/8
FFC6411C _H	GRDECINBF1	GRAMC ECC Decoder Input Data Buffer 1	R/W	0000 0000 _H	32/16/8
FFC64200 _H	GRECCCTL_VCI2GRAM	Global RAM ECC Control Register	R/W	0000 0000 _H	32/16
FFC64E00 _H	GRECCCTL_AXI2GRAM	Global RAM ECC Control Register	R/W	0000 0000 _H	32/16

Note: The registers with symbols “_GRAMC”, “_VCI2GRAM” and “_AXI2GRAM” as suffixes are provided for particular ECC controllers corresponding to each access port; the registers with “_GRAMC” are provided for access from the CPU1 to Global RAM and for read-accesses for read-modify-write processing when 8-bit or 16-bit data is written to Global RAM, the registers with “_VCI2GRAM” are provided for access from the system interconnected with Global RAM, and the registers with “_AXI2GRAM” are provided for access from H-bus.

31.2.5.3 Details of Registers

(1) UGRERRINT — Global RAM Error Information Control Register

UGRERRINT register controls whether error information is reported to ECM, when address/data ECC 2-bit error, address/data ECC 1-bit error, and ECC 1-bit error overflow are detected.

Access: UGRERRINT can be read/written in 32/16/8-bit units.

Address: FFC6 4000_H

Value after reset: 0000 0073_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	SEOVFI E	ADEDI E	ASEDIE	—	—	DEDIE	SEDIE
Value after reset	0	0	0	0	0	0	0	0	0	1	1	1	0	0	1	1
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R	R/W	R/W

Table 31.42 UGRERRINT Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	SEOVFIE	ECC 1-bit error overflow report enable bit Controls overflow report when 1-bit error overflow flag (SERROVF) in UGROVFSTR register is set. 0: ECC 1-bit error overflow report disabled 1: ECC 1-bit error overflow report enabled
5	ADEDIE	Address ECC 2-bit error on bus report enable bit Controls error report of 2-bit error detection when address ECC error detection/correction is enabled. 0: Address ECC 2-bit error report disabled 1: Address ECC 2-bit error report enabled
4	ASEDIE	Address ECC 1-bit error on bus report enable bit Controls error report of 1-bit error detection when address ECC error detection/correction is enabled. 0: Address ECC 1-bit error report disabled 1: Address ECC 1-bit error report enabled
3, 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	DEDIE	ECC 2-bit error report enable bit Controls error report of 2-bit error detection when ECC error detection/correction is enabled 0: ECC 2-bit error report disabled 1: ECC 2-bit error report enabled
0	SEDIE	ECC 1-bit error report enable bit Controls error report of 1-bit error detection when ECC error detection/correction is enabled 0: ECC 1-bit error report disabled 1: ECC 1-bit error report enabled

(2) UGRSERSTCLR — Global RAM ECC SED Status Clear Register

UGRSERSTCLR register is used to clear SEDF[31:0] in UGRSERSTR, SERROVF in UGROVFSTR, and error address in UGRnSEDADR (n = 1 to 32). This is write only register and read value is always “0”. UGRSERSTCLR register has a lower priority than a set factor. Priority is given to a set factor when UGRSERSTCLR and a set factor compete. A set factor is a trigger for setting SEDF[31:0] in UGRSERSTR, setting SERROVF in UGROVFSTR, or capturing an error address in UGRnSEDADR (n = 1 to 32).

Access: UGRSERSTCLR can be written in 32/16/8-bit units.

Address: FFC6 4004_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SSTCLR[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SSTCLR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 31.43 UGRSERSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 0	SSTCLR[31:0]	Data ECC 1-bit error flag clear n-th 1: Following flag and address clear UGRSERSTR.SEDF(n-1), UGROVFSTR.SERROVF, UGRnSEDADR.SEADR

(3) UGRDERSTCLR — Global RAM ECC DED Status Clear Register

UGRDERSTCLR register is used to clear ADEDF/ASEDF and DEDF in UGRDERSTR and error address in UGR00DEDADR. This is write only register and read value is always “0”.

UGRDERSTCLR register has a lower priority than a set factor. Priority is given to a set factor when UGRDERSTCLR and a set factor compete. A set factor is a trigger for setting ADEDF/ASEDF and DEDF in UGRDERSTR.

Access: UGRDERSTCLR can be written in 32/16/8-bit units.

Address: FFC6 4008_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 31.44 UGRDERSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When writing, write the value after reset.
0	DSTCLR	Data ECC 2-bit error flag and address ECC error flag clear 1: Following flags and addresses are cleared: UGRDERSTR.ADEDF, UGRDERSTR.ASEDF, UGRDERSTR.DEDF, UGR00DEDADR.DEADR

(4) UGROVFSTR — Global RAM Error Count Overflow Status Register

UGROVFSTR register monitors occurrence of error overflow. Overflow occurs when an SED for which the error address has not been captured is detected while ECC 1-bit error status register is full. If the ECC 1-bit error status register is full and the error address is the same as one of the error addresses already captured, this flag is not set. SERROVF flag is cleared when at least one bit of SSTCLR[31:0] in UGRSERSTCLR register is asserted.

Access: UGROVFSTR can be read in 32/16/8-bit units.

Address: FFC6 400C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.45 UGROVFSTR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read.
0	SERROVF	1-bit error overflow flag When all bits of the ECC 1-bit error status register (UGRSERSTR.SEDF[31:0]) are "1", an ECC 1 bit error occurs and the error address does not match any of the captured error addresses, this flag is set.

(5) UGRSERSTR — Global RAM ECC SED Status Register

UGRSERSTR is the error monitor register. Each error flag is “0” and when a new error occurs, an error status flag is set. An error flag is set at the lowest number empty bit of UGRSERSTR (e.g. If SEDF[0][1][3] have been set to “1” and all other bits have been empty, the next flag is set at SEDF[2]). If multiple SEDs causes are simultaneously detected and there are sufficient empty bits, all detected SEDs are set (e.g. if a SED and another SED which occurs at a different address are detected simultaneously, both SEDFs are set.). However, if SEDs occur at a same address simultaneously, only one of errors is set according to the fixed priority. The priority order is PE1, system interconnect and H-bus. (e.g. if a SED which is input from PE1 path and an SED which is input from another path are detected simultaneously and those occur at the same address, only SEDF from the PE1 path is set.) Furthermore, an error address which has already been captured in UGRnSEADR (n = 1 to 32) must not be captured again. UGRSERSTR register is cleared by setting SSTCLR[31:0] in UGRSERSTCLR register to 1.

Access: UGRSERSTR can be read in 32/16/8-bit units.

Address: FFC6 4020_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SEDF[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SEDF[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.46 UGRSERSTR Register Contents

Bit Position	Bit Name	Function
31 to 0	SEDF[31:0]	ECC 1-bit error monitor flag SEDF(n-1) in n-th buffer Condition to “0”: write “1” to SSTCLR(n-1) in UGRSERSTCLR Condition to “1”: ECC 1-bit error is detected.

(6) UGRDERSTR — Global RAM ECC DED Status Register

UGRDERSTR is the error monitor register. All error flags are “0” and when a new error occurs, an error status flag is set. If multiple error causes which are input from different access ports are detected simultaneously, only one of detected errors is set according to the fixed priority. The reason is that there is only one 2-bit error Address Register. The priority order is PE1, system interconnect and H-bus. (e.g. if a DED which is input from PE1 path and an ASED which is input from another path are detected simultaneously and those occur at the same address, only DEDF from the PE1 path is set.) If multiple error causes occur from same access port simultaneously, all detected errors are set. (e.g. if DED and ASED are simultaneously input from PE1 path, both DEDF and ASEDF are set.) UGRDERSTR register is cleared by setting DSTCLR in UGRDERSTR register to 1.

Access: UGRDERSTR can be read in 32/16/8-bit units.

Address: FFC6 4030_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	ADEDF	ASEDF	—	—	—	DEDF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.47 UGRDERSTR Register Contents

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is read.
5	ADEDF	Address ECC 2-bit error monitor flag Condition to “0”: write “1” to DSTCLR in UGRDERSTCLR Condition to “1”: ADEDF is “0” and address ECC 2-bit error is detected.
4	ASEDF	Address ECC 1-bit error monitor flag Condition to “0”: write “1” to DSTCLR in UGRDERSTCLR Condition to “1”: ASEDF is “0” and address ECC 1-bit error is detected.
3 to 1	Reserved	When read, the value after reset is read.
0	DEDF	ECC 2-bit error monitor flag Condition to “0”: write “1” to DSTCLR in UGRDERCTCLR Condition to “1”: DEDF is “0” and ECC 2-bit error is detected.

Note: This register has been named for capturing ECC 2-bit error (DED) error status, but the register captures Address ECC 1-bit error (ASED) too. Because ASED is also an emergency error and S/W should check the status immediately, ASED is treated like a DED error.

(7) UGRnSEDADR — Global RAM n ECC SED Address Register (n = 1 to 32)

UGRnSEDADR registers are used to hold the address when a 1-bit error is detected. Error address capture trigger is same as corresponding SEDF (n – 1) set in UGRSERSTR. UGRnSEDADR are cleared by setting SSTCLR (n – 1) in UGRSERSTCLR register to 1.

Access: UGRnSEDADR can be read in 32-bit units.

Address: UGR1SEDADR: FFC6 4040_H

(8) UGR00DEDADR — Global RAM ECC DED Address Register

UGR00DEDADR register is used to hold the address when an error is detected. Error address capture trigger is same as corresponding ADEDF/ASEDF/DEDF set in UGRDERSTR. If this register has captured an error address, it does not capture any more address. This register stores an address without correction even if the error is 1-bit error. UGR00DEDADR is cleared by setting DSTCLR in UGRDERSTCLR register to 1.

Access: UGR00DEDADR can be read in 32-bit units.

Address: FFC6 40C0_H

Value after reset: 0000 0000_H

(9) GRECCCTL_GRAMC — Global RAM ECC Control Register

GRECCCTL_GRAMC register controls the ECC error detection/correction and 1-bit error correction on address and data ECC. Writing ECC control registers must be executed with PROT[1:0] = 01_B.

Access: GRECCCTL_GRAMC can be read/written in 32/16-bit units.

Address: FFC6 4100_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15, 14	PROT[1:0]	Protection bit 01: write is enabled Other: write is disabled These bits are always read as 0.
13 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	ASECDIS	Address ECC 1-bit error correction enable bit Enables or disables 1-bit error correction when using Address ECC error detection/correction (AECDDIS = 0). 0: Correction is carried out when 1-bit error is detected 1: Correction is not carried out when 1-bit error is detected
3	AECDDIS	Address ECC disable bit Enables or disables ECC error detection/correction. 0: ECC error detection/correction is enable 1: ECC error detection/correction is disable
2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	SECDIS	Data ECC 1-bit error correction enable bit Enables or disables 1-bit error correction when using ECC error detection/correction (ECCDIS = 0). enable/disable. 0: Correction is carried out when 1-bit error is detected 1: Correction is not carried out when 1-bit error is detected
0	ECCDIS	Data ECC disable bit Enables or disables ECC error detection/correction. 0: ECC error detection/correction is enable 1: ECC error detection/correction is disable

(10) GRTSTCTL — Global RAM Test Control Register

GRTSTCTL register controls the ECC error injection. This register must be written while PROT[1:0] = 01_B.

Access: GRTSTCTL can be read/written in 32/16-bit units.

Address: FFC6 4104_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.54 GRDECINBF1 Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	GRDECINBF1 [6:0]	These bits are valid when ECCTST = 1 (selecting test mode) in the global RAM test control register. When DECINEN = 1, the value of this register is input to the ECC decoder as data for use in updating in response to the execution of an RmW instruction. The value is treated as if it were 7 bits of data from the ECC. This register is common to banks A and B and provides the values for both the 32 higher-order bits and the 32 lower-order bits.

(14) GRECCCTL_VCI2GRAM/AXI2GRAM — Global RAM ECC Control Register

GRECCCTL_VCI2GRAM/AXI2GRAM registers control the ECC error detection/correction and 1-bit error correction. Writing ECC control registers must be executed with $PROT[1:0] = 01_B$.

Access: GRECCCTL_VCI2GRAM/AXI2GRAM can be read/written in 32/16-bit units.

Address: GRECCCTL_VCI2GRAM: FFC6 4200_H
GRECCCTL_AXI2GRAM: FFC6 4E00_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.55 GRECCCTL_VCI2GRAM/AXI2GRAM Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	SECDIS	Data ECC 1-bit error correction enable bit Enables or disables 1-bit error correction when using ECC error detection/correction (ECCDIS = 0). 0: Correction is carried out when 1-bit is detected 1: Correction is not carried out when 1-bit is detected
0	ECCDIS	Data ECC disable bit Enables or disables ECC error detection/correction. 0: ECC error detection/correction is enable 1: ECC error detection/correction is disable

31.2.5.4 Test Function

Through appropriate register setting, desired values can be written to RAM data and the ECC bits. Also, data in the RAM and the ECC bits and the ECC decoder output data for RmW can all be read. It is possible to input the desired data in the ECC decoder for RmW. When using the test function, set the WTBufMode bit in the WTbuf configuration register to "0" to disable the write-through buffer.

(1) Writing to RAM data

- (a) Set the ECCTST bit in the global RAM test control register to 1 to enter test mode.
- (b) Set the corresponding DATSEL1 to 0 and DATSEL0 to 0 in the global RAM test control register to select the RAM data to be written to.
- (c) When data is written to the global RAM, only the RAM data is modified without updating the ECC bits.

How to exit test this mode:

- (a) Set the ECCTST bit in the global RAM test control register to 0 to disable test mode (enable normal mode).

(2) Reading RAM data

- (a) Set the ECCDIS bit in the global RAM ECC control register to 1 to disable ECC error detection and correction.
- (b) Read the global RAM. Since neither error detection nor correction is carried out when the global RAM is read, the RAM data is read unchanged.

How to exit this test mode:

- (a) Set the ECCDIS bit in the global RAM ECC control register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC bits

- (a) Set the ECCTST bit in the global RAM test control register to 1 to enter test mode.
- (b) Set the corresponding DATSEL1 bit to 0 and DATSEL0 bit to 1 in the global RAM test control register to select the ECC bits to be written to.
- (c) When data is written to the global RAM, only the ECC bits are modified without updating the RAM data. At that time, bit[6:0] are respectively written to the ECC bits.

How to exit this test mode:

- (a) Set the ECCTST bit in the global RAM test control register to 0 to disable test mode (enable normal mode).

(4) Reading the ECC bits

- (a) Set the ECCTST bit in the global RAM test control register to 1 to enter test mode.
- (b) Set the corresponding DATSEL1 bit to 0 and DATSEL0 bit to 1 in the global RAM test control register to select the ECC bits to be read.
- (c) When data in the global RAM is read, the ECC bits are stored in the corresponding Global RAM test data read buffer registers.

How to exit this test mode:

- (a) Set the ECCTST bit in the global RAM test control register to 0 to disable test mode (enable normal mode).

(5) Self-diagnosis of the ECC check function for the access ports

Desired values can be written to the RAM data and/or ECC bits by following the procedure described in (1) or (3) above. Therefore, a fault can be injected by, for example, inverting appropriate bits of the RAM data and/or ECC bits. After that, self-diagnosis of the ECC decoder is possible by reading the global RAM in normal mode and checking the result of error correction or detection.

(6) Self-diagnosis of the ECC decoder for the data read out in an RmW operation

- (a) Inject suitable erroneous values as RAM data or to the ECC bits by following procedure (1) or (3) above.
- (b) Set the DATSEL1 bit to 1 and the DATSEL0 bit to 0 in the global RAM test control register to make the output data from the ECC decoder for the data read out in an RmW operation the target for reading.
- (c) After RmW processing for the global RAM proceeds, the data read out in an RmW operation for global RAM are stored in the corresponding Global RAM test data read buffer registers. Checking the result allows self-diagnosis of the ECC decoder for the data read out in an RmW operation.

(7) Self-diagnosis of the ECC decoder for the data updated during RmW access

- (a) Set the DATSEL1 and DATSEL0 bits to 1 in the global RAM test control register to make the output data from the ECC decoder for the data updated during an RmW operation the target for reading.
- (b) Through the above setting, the data input from the ECC decoder for the data updated during RmW access is switched to data from the ECC decoder input buffer 0 or 1 (GRDECINBF0 or 1) instead of write data sent from the access ports. As a result, suitable erroneous values can be injected by setting an appropriate value in ECC decoder input buffer 0 or 1.

31.2.6 Instruction Cache ECC and EDC

31.2.6.1 Overview

The instruction cache ECC is summarized in the table below.

Table 31.56 Instruction Cache ECC

Item	Description
ECC error detection	<p>ECC error detection can be either enabled or disabled.</p> <p>When enabled, the following setting can be selected.</p> <ul style="list-style-type: none"> ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, error detection is not carried out.</p> <p>In the initial state, the ECC function is enabled, and 1-bit error detection, and notification, and 2-bit error detection and notification are carried out by the instruction cache.</p>
Error notification	<p>Upon occurrence of an ECC error, it is notified to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, notification of the ECC 2-bit error is enabled, and notification of the ECC 1-bit error is enabled.</p> <p>An ECC1-bit error signal is only issued to the ECM when the detected ECC 1-bit error address is different from the address stored in the error address buffer.</p>
Error status	<p>A status register is provided, which indicates the status of ECC 2-bit error detection and ECC 1-bit error detection. If an error occurs while no error status is set, the corresponding status is set.</p> <p>The error status can be cleared using the clear register.</p>
Address capture	<p>If an ECC error occurs while no error status is set, the address at which the associated error has occurred is captured.</p> <p>The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected.</p> <p>The error status also serves as the enable bit of the captured address.</p>

31.2.6.2 List of Registers

Table 31.57 List of Registers

Address	Symbol	Register Name	R/W	Value after reset	Access Size

31.2.6.3 Details of Registers

(1) IDECCCTL_PE1 — Instruction Cache Data RAM ECC Control Register

IDECCCTL_PE1 register controls the ECC error detection. Writing ECC control registers can only be executed with PROT[1:0] = 01_B. ECC error correction is controlled by D1EIV bit of ICCTRL register (refer to **Section 3, CPU System**).

Access: IDECCCTL_PE1 can be read/written in 32/16-bit units.

Address: FFC6 0400_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.58 IDECCCTL_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ECCDIS	ECC disable bit Enables or disables ECC error detection. 0: ECC error detection is enabled 1: ECC error detection is disabled

(2) IDERRINT_PE1 — Instruction Cache Data RAM Error Information Control Register

IDERRINT_PE1 register controls whether error information is reported to ECM, when data ECC 2-bit error and data ECC 1-bit error are detected.

Access: IDERRINT_PE1 can be read/written in 32/16/8-bit units.

Address: FFC6 0404_H

Value after reset: 0000 0003_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 31.59 IDERRINT_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	DEDIE	ECC 2-bit error notification enable bit Controls error notification of 2-bit error detection when ECC error detection is enabled 0: ECC 2-bit error notification disabled 1: ECC 2-bit error notification enabled
0	SEDIE	ECC 1-bit error notification enable bit Controls error notification of 1-bit error detection when ECC error detection is enabled 0: ECC 1-bit error notification disabled 1: ECC 1-bit error notification enabled

(3) IDSERSTCLR_PE1 — Instruction Cache Data RAM Data ECC SED Status Clear Register

IDSERSTCLR_PE1 register is used to clear SEDF0/1 in IDSERSTR_PE1 and SERROVF0/1 in IDOVFSTR_PE1, and error address in IDSEDADR0/1_PE1. This is write only register and read value is always “0”.

Access: IDSERSTCLR_PE1 can be written in 32/16/8-bit units.

Address: FFC6 0408_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.60 IDSERSTCLR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When writing, write the value after reset.
1	SSTCLR1	1-bit error flags clear (bank 1) 1: All of the following 1-bit error flags are cleared. IDSERSTR_PE1.SEDF1, IDOVFSTR_PE1.SERROVF1, IDSEDADR1_PE1.SEADR
0	SSTCLR0	1-bit error flags clear (bank 0) 1: All of the following 1-bit error flags are cleared. IDSERSTR_PE1.SEDF0, IDOVFSTR_PE1.SERROVF0, IDSEDADR0_PE1.SEADR

(4) IDDERSTCLR_PE1 — Instruction Cache Data RAM Data ECC DED Status Clear Register

IDDERSTCLR_PE1 register is used to clear DEDF0/1 in IDDERSTR_PE1 and error address in IDDEDADR0/1_PE1. This is write only register and read value is always “0”.

Access: IDDERSTCLR_PE1 can be written in 32/16/8-bit units.

Address: FFC6 040C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DSTCLR1	DSTCLR0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 31.61 IDDERSTCLR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When writing, write the value after reset.
1	DSTCLR1	2-bit error flags clear (bank 1) 1: All 2-bit error flags clear IDDERSTR_PE1.DEDF1, IDDEDADR1_PE1.DEADR
0	DSTCLR0	2-bit error flags clear (bank 0) 1: All 2-bit error flags clear IDDERSTR_PE1.DEDF0, IDDEDADR0_PE1.DEADR

(5) IDOVFSTR_PE1 — Instruction Cache Data RAM Error Count Overflow Status Register

IDOVFSTR_PE1 register monitors occurrence of error overflow. ECC 1bit error occurs at same error address is detected while the error status is full. If the error status is full and the same error (same error address) has occurred, then this flag is not set. SERROVF0/1 flag is cleared by setting SSTCLR0/1 in IDSERSTCLR_PE1 register to 1.

Access: IDOVFSTR_PE1 can be read in 32/16/8-bit units.

Address: FFC6 0410_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SERROVF1	SERROVF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.62 IDOVFSTR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is read.
1	SERROVF1	1-bit error overflow flag (bank1) When SEDF1 in IDSERSTR_PE1 is "1", an ECC 1bit error occurs and the error address does not match any of the captured error addresses, this flag is set.
0	SERROVF0	1-bit error overflow flag (bank0) When SEDF0 in IDSERSTR_PE1 is "1", an ECC 1bit error occurs and the error address does not match any of the captured error addresses, this flag is set.

(6) IDSERSTR_PE1 — Instruction Cache Data RAM Data ECC SED Status Register

IDSERSTR_PE1 is the error monitor register. IDSERSTR_PE1 monitors occurrence of the first error. Error detection and flag update condition are individually set in bank 0 and 1. IDSERSTR_PE1 register is cleared by setting SSTCLR1/0 in IDSERSTCLR_PE1 register to 1.

Access: IDSERSTR_PE1 can be read in 32/16/8-bit units.

Address: FFC6 0420_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SEDF1	—	—	—	—	—	—	—	SEDF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.63 IDSERSTR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is read.
8	SEDF1	ECC 1-bit error monitor flag (bank 1) Condition for "0": write "1" to SSTCLR1 in IDSERSTCLR_PE1 Condition for "1": SEDF1 is "0" and ECC 1-bit error is detected.
7 to 1	Reserved	When read, the value after reset is read.
0	SEDF0	ECC 1-bit error monitor flag (bank 0) Condition for "0": write "1" to SSTCLR0 in IDSERSTCLR_PE1 Condition for "1": SEDF0 is "0" and ECC 1-bit error is detected.

(7) IDDERSTR_PE1 — Instruction Cache Data RAM Data ECC DED Status Register

IDDERSTR_PE1 is the error monitor register. IDDERSTR_PE1 monitors occurrence of the first error. Error detection and flag update condition are individually set in bank 0 and 1. IDDERSTR_PE1 register is cleared by setting DSTCLR1/0 in IDDERSTCLR_PE1 register to 1.

Access: IDDERSTR_PE1 can be read in 32/16/8-bit units.

Address: FFC6 0450_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	DEDF1	—	—	—	—	—	—	—	DEDF0	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 31.64 IDDERSTR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is read.
9	DEDF1	ECC 2-bit error monitor flag (bank 1) Condition to "0": write "1" to DSTCLR1 in IDDERSTCLR_PE1 Condition to "1": DEDF1 is "0" and ECC 2-bit error is detected.
8 to 2	Reserved	When read, the value after reset is read.
1	DEDF0	ECC 2-bit error monitor flag (bank 0) Condition to "0": write "1" to DSTCLR0 in IDDERSTCLR_PE1 Condition to "1": DEDF0 is "0" and ECC 2-bit error is detected.
0	Reserved	When read, the value after reset is read.

(8) IDSEDADR0/1_PE1 — Instruction Cache Data RAM (Bank0/1) Data ECC SED Address Register

IDSEDADR0/1_PE1 registers are used to hold the address when an SED error is detected. Error address capture trigger is same as corresponding SEDF0/1 set in IDSERSTR_PE1. Since this register holds the internal address, add the base address of the associated memory to transform the internal address to the actual address. IDSEDADR0/1_PE1 are cleared by setting SSTCLR1/0 in IDSERSTCLR_PE1 register to 1.

Access: IDSEDADR0/1_PE1 can be read in 32-bit units.

Address: IDSEDADR0_PE1: FFC6 0460_H
IDSEDADR1_PE1: FFC6 0464_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 31.65 IDSEDADR0/1_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is read.
8 to 0	SEADR[8:0]	1-bit error detection address bank n (n = 0 or 1)

(9) IDDEDADR0/1_PE1 — Instruction Cache Data RAM (Bank0/1) Data ECC DED Address Register

IDDEDADR0/1_PE1 registers are used to hold the address when a DED error is detected. Error address capture trigger is same as corresponding DEDF0/1 set in IDDERSTR_PE1. Since this register holds the internal address, add the base address of the associated memory to transform the internal address to the actual address. IDDEDADR0/1_PE1 are cleared by setting DSTCLR0/1 in IDDERSTCLR_PE1 register to 1.

Access: IDDEDADR0/1_PE1 can be read in 32-bit units.

Address: IDDEDADR0_PE1: FFC6 04E0_H
IDDEDADR1_PE1: FFC6 04E4_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.66 IDDEDADR0/1_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is read.
8 to 0	DEADR[8:0]	2-bit error detection address bank n (n = 0 or 1)

(10) ITECCCTL_PE1 — Instruction Cache Tag RAM ECC Control Register

ITECCCTL_PE1 register controls the ECC error detection. Writing ECC control registers can only be executed with PROT[1:0] = 01_B.

Access: ITECCCTL_PE1 can be read/written in 32/16-bit units.

Address: FFC6 1400_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 31.67 ITECCCTL_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ECCDIS	ECC disable bit Enables or disables ECC error detection. 0: ECC error detection is enabled 1: ECC error detection is disabled

(11) ITERRINT_PE1 — Instruction Cache Tag RAM Error Information Control Register

ITERRINT_PE1 register controls whether error information is reported to ECM, when data ECC 2-bit error and data ECC 1-bit error are detected.

Access: ITERRINT_PE1 can be read/written in 32/16/8-bit units.

Address: FFC6 1404_H

Value after reset: 0000 0003_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 31.68 ITERRINT_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	DEDIE	ECC 2-bit error report enable bit Controls error report of 2-bit error detection when ECC error detection is enabled 0: ECC 2-bit error report disabled 1: ECC 2-bit error report enabled
0	SEDIE	ECC 1-bit error report enable bit Controls error report of 1-bit error detection when ECC error detection is enabled 0: ECC 1-bit error report disabled 1: ECC 1-bit error report enabled

(12) ITSERSTCLR_PE1 — Instruction Cache Tag RAM ECC SED Status Clear Register

ITSERSTCLR_PE1 register is used to clear SEDF in ITSERSTR_PE1 and SERROVF in ITOVFSTR_PE1, and error address in ITSEDADR_PE1. This is write only register and read value is always “0”.

Access: ITSERSTCLR_PE1 can be written in 32/16/8-bit units.

Address: FFC6 1408_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31.69 ITSERSTCLR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When writing, write the value after reset.
0	SSTCLR	1-bit error flag clear 0: Nothing operates 1: All 1-bit error flags clear ITSERSTR_PE1.SEDF, ITOVFSTR_PE1.SERROVF, ITSEDADR_PE1.SEADR

(13) ITDERSTCLR_PE1 — Instruction Cache Tag RAM ECC DED Status Clear Register

ITDERSTCLR_PE1 register is used to clear DEDF in ITDERSTR_PE1, and error address in ITDEDADR_PE1. This is write only register and read value is always “0”.

Access: ITDERSTCLR_PE1 can be written in 32/16/8-bit units.

Address: FFC6 140C_H

Value after reset: 0000 0000_H
