A descriptor is able to issue a descriptor interrupt on completion of its processing. The setting of the descriptor interrupt enable bits (DESCR.DIE) in each descriptor selects disabling or generation of the descriptor interrupt.

EthernetAVB-IF provides two kinds of descriptor interrupts:

- Queue specific descriptor interrupt (1 per receive/transmit queue)
- Universal descriptor interrupt (15 shared between all receive/transmit queues)

The descriptor interrupt is a common resource that is shared between reception and transmission queues. Software control of the descriptor interrupt provides a flexible method of application-specific flag processing.

Figure 46.13 illustrates the way in which the AVB-DMAC generates descriptor interrupts (or sets bits in the descriptor interrupt status register (DIS.DPFi)). Processing of a descriptor with the value i in the descriptor interrupt enable bits (DESCR.DIE) leads to the corresponding bit in the descriptor interrupt status register (DIS.DPFi) being set.

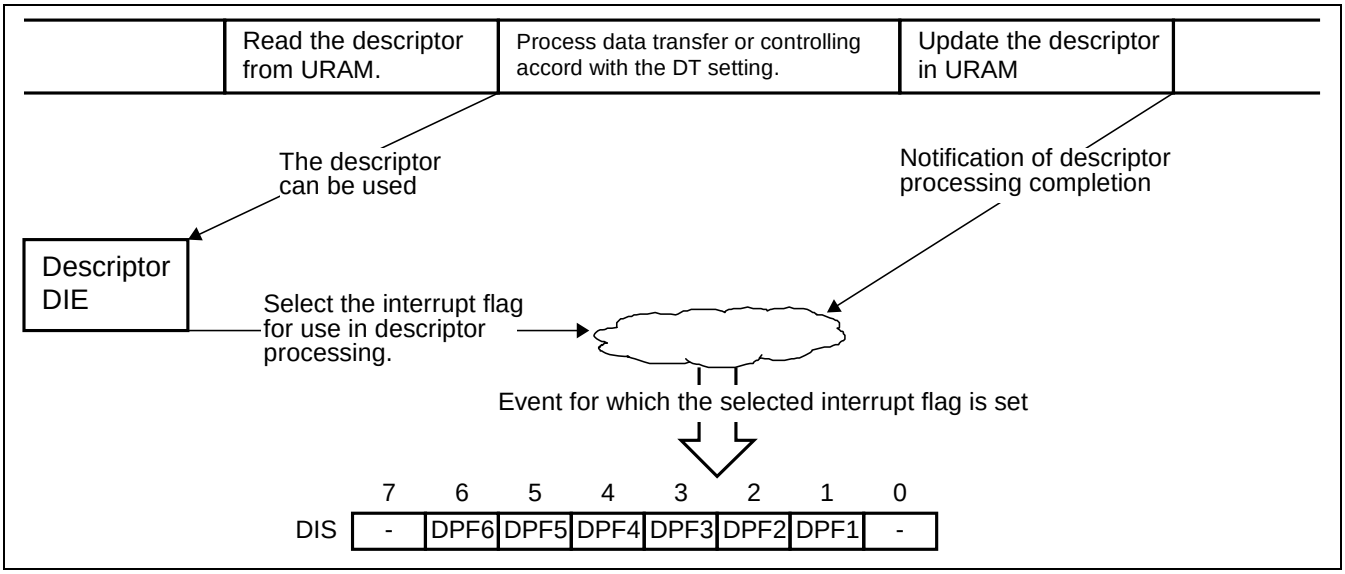

Figure 46.13 Method of Descriptor Interrupt Generation

(6) Descriptor Type

The descriptor types (indicated by the DESCR.DT bits) supported by the AVB-DMAC fall into the following three categories.

- Definitions of frame data
- Control of descriptor chains
- Hardware and software arbitration

Table 46.7 is a summary of the descriptor types available for the AVB-DMAC. Entries under “Name” are the names of the descriptor types and the values under “DT” are the corresponding values to be set in the descriptor type field (DESCR.DT). A given descriptor may be handled differently according to whether it is in a transmission or reception queue, so the transmission and reception columns list the scopes of control and processing of the descriptor types.

The abbreviations defined below are used in the transmission and reception columns.

Definition of SW:

— The descriptor is processed by software.
— Software has access to and may modify the descriptor and descriptor data area.
— This descriptor cannot be changed by hardware (AVB-DMAC).

Definition of HW:

— The descriptor is processed by hardware (AVB-DMAC).
— Software must modify neither the descriptor nor the descriptor data area.
— Hardware (AVB-DMAC) processes this descriptor and subsequently changes the descriptor type.

Invalid:

This descriptor type is not used in transfer in the given direction (transmission or reception).

Do not write this value to the descriptor type (DESCR.DT) field for transfer in the given direction.

Hardware does not process these descriptor types in the cases listed as invalid. The current descriptor address (CDARq.CDA) will not be changed when processing of a queue for the given direction arrives at a descriptor with this type setting.

Table 46.7 Summary of Descriptor Types

Name	DT	Description	Reception	Transmission
Frame data				
FSTART	5	Frame Start The descriptor points to valid data for a frame. The frame starts with the given data and continues with that indicated by the next descriptor.	SW	HW
FMID	4	Frame Middle The descriptor points to valid data for a frame. The frame started with a previous descriptor and continues to the data indicated by the next descriptor.	SW	HW
FEND	6	Frame End The descriptor points to valid data for a frame. The frame continues from the previous descriptor and ends with the data indicated by in this descriptor.	SW	HW
FSINGLE	7	Frame Single The descriptor points to valid data for a complete frame.	SW	HW
Chain control				
LINK	8	Link Defines the next descriptor in the chain.	HW	HW
LINKFIX	9	Fixed Link Same as LINK, but not changed by AVB-DMAC after processing.	SW	SW
EOS	10	End Of Set Control element to split a descriptor chain. The chain stops and waits for user interaction.	HW	HW
HW/SW arbitration				
FEMPTY	12	Frame Empty A descriptor related to frame data but not containing valid data for a frame	HW	SW
FEMPTY_IS	13	Frame Empty Incremental Start A descriptor related to frame data but not containing valid data for a frame. DESCR.DPTR sets the base address of an “incremental data area” in the URAM.	HW	Invalid
FEMPTY_IC	14	Frame Empty Incremental Continue A descriptor related to frame data but not containing valid data for a frame. Data is stored to the incremental data area in the URAM.	HW	Invalid
FEMPTY_ND	15	Frame Empty No Data storage A descriptor related to frame data but not containing valid data for a frame. The descriptor is processed in the same way as FEMPTY but data are not stored in the URAM.	HW	Invalid
LEMPTY	2	Link Empty A link descriptor for processing by the AVB-DMAC	SW	SW
EEMPTY	3	EOS Empty An EOS descriptor for processing by the AVB-DMAC	SW	SW
DT0	0	Reserved	Invalid	Invalid
DT1	1	Reserved	Invalid	Invalid
DT11	11	Reserved	Invalid	Invalid

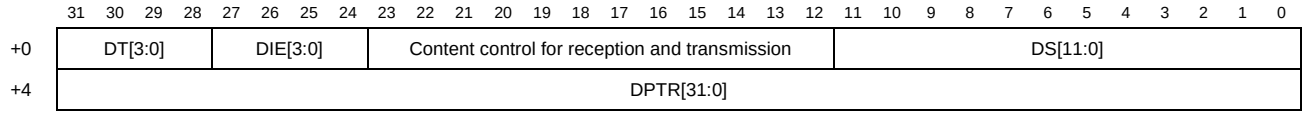
(7) Layout of General Descriptors in the URAM

The AVB-DMAC updates processed descriptors in the URAM. The field to be changed in the descriptor being updated depends upon whether the direction is transmission or reception and the queue mode. Other fields will not be changed. There are no restrictions on the values set in unused descriptor fields (indicated by "—" in the figure).

(a) Frame Data Descriptors

The allocation of bits in the frame data descriptors (FSTART, FMID, FEND, and FSINGLE) is shown below.

- Normal descriptor (usable in both reception and transmission)



- Extended descriptor (usable only in reception)

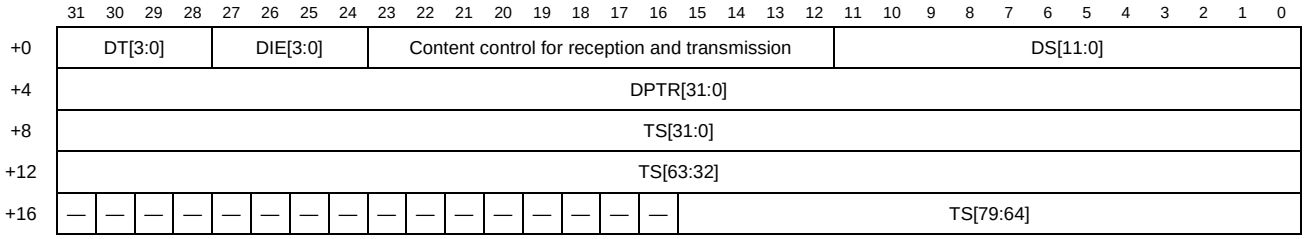


Table 46.8 Contents of Frame Data Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 5: FSTART 4: FMID 6: FEND 7: FSINGLE For details, see section 46.3.4 (2), Setting Up Reception Descriptors, and section 46.3.5 (2), Setting Up Transmission Descriptors.
DIE[3:0]	Descriptor Interrupt Enable B'0000: Descriptor interrupt is disabled. B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi).
—	Content Control For details, see section 46.3.4 (2), Setting Up Reception Descriptors, and section 46.3.5 (2), Setting Up Transmission Descriptors.
DS[11:0]	Data Size Size of the data area/frame data for the descriptor (in bytes)
DPTR[31:0]	Descriptor Pointer Pointer to the data area for the descriptor
TS[79:0]	Time Stamp Time stamp of the received frame (only available in extended descriptors)

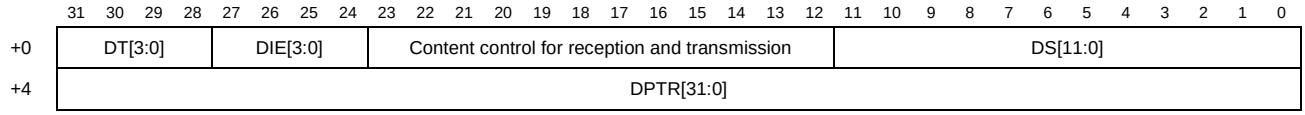
Note: Some bits in extended descriptors are reserved (The reserved bits (above DESCR.TS[79:64]) in an extended descriptor are set to H'0000 after the time stamp is stored).

(b) Hardware/Software Arbitration Descriptors (Only for Reception)

The allocation of bits in the descriptors for hardware/software arbitration (FEMPTY, FEMPTY_IS, FEMPTY_IC, and FEMPTY_ND) is shown below.

The allocation of bits in the arbitration descriptors for use in reception is the same as in frame data descriptors.

- Normal descriptor



- Extended descriptor (usable only in reception)

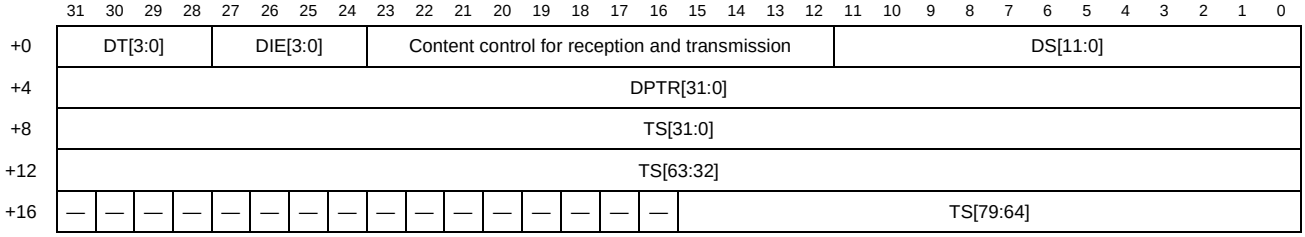


Table 46.9 Contents of Hardware/Software Arbitration Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 12: FEMPTY 13: FEMPTY_IS 14: FEMPTY_IC 15: FEMPTY_ND For details, see Table 46.7, Summary of Descriptor Types.
DIE[3:0]	Descriptor Interrupt Enable B'0000: Descriptor interrupt is disabled. B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi).
—	Content Control For details, see section 46.3.4 (2), Setting Up Reception Descriptors, and section 46.3.5 (2), Setting Up Transmission Descriptors.
DS[11:0]	Data Size Size of the data area/frame data for the descriptor (in bytes)
DPTR[31:0]	Descriptor Pointer Pointer to the data area for the descriptor
TS[79:0]	Time Stamp Time stamp of the received frame (only available in extended descriptors)

Note: When the descriptor is an extended descriptor, it has a 12-byte unused area.

In an FEMPTY descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), data size (DS), and descriptor pointer (DPTR) fields are used.

In an FEMPTY_IS descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), and descriptor pointer (DPTR) fields are used.

In an FEMPTY_IC descriptor, the descriptor type (DT) and descriptor interrupt enable (DIE) are used.

In an FEMPTY_ND descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), and data size (DS) are used.

(c) Link Descriptors

The allocation of bits in the link descriptors (LINK and LINKFIX) is shown below.

- Normal descriptor

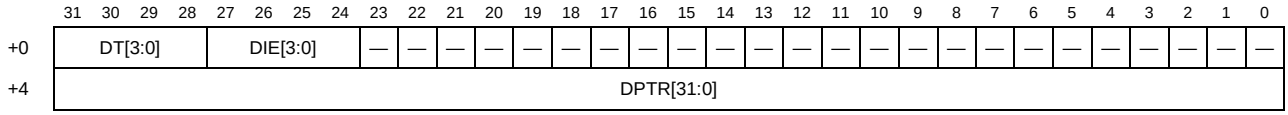

Table 46.10 Contents of Link Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 8: LINK 9: LINKFIX For details, see Table 46.7, Summary of Descriptor Types.
DIE[3:0]	Descriptor Interrupt Enable B'0000: Descriptor interrupt is disabled. B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi).
DPTR[31:0]	Descriptor Pointer Pointer to the data area for the descriptor Register an address on a 32-bit boundary.

Note: Register an address aligned with a 32-bit boundary as the descriptor pointer (DESCR.DPTR).

(d) Other Descriptors

The allocation of bits in the other descriptors (EOS, FEMPTY (only for transmission), LEMPTY, and EEMPTY) is shown below.

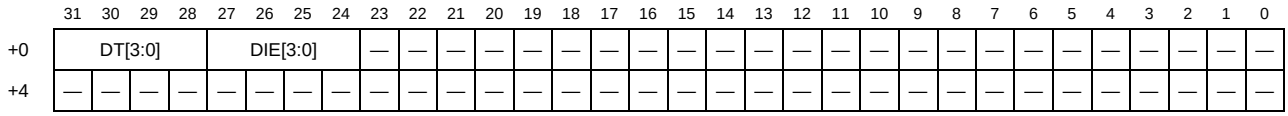

Table 46.11 Contents of Other Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 10: EOS 12: FEMPTY (only for transmission) 2: LEMPTY 3: EEMPTY For details, see Table 46.7, Summary of Descriptor Types.
DIE[3:0]	Descriptor Interrupt Enable B'0000: Descriptor interrupt is disabled. B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi).

(8) How to Use Frame Data Descriptors

The descriptor data area size field (DESCR.DS) can specify up to 2048 bytes of Ethernet frame data per data area. Settings higher than 2048 (bytes) cannot be made.

In general, Ethernet frames are not of uniform length. The AVB-DMAC is capable of dividing frame data into multiple descriptors in order to minimize the memory capacity for frame data. This function allows processing of frames that are longer than the limit for descriptor data areas. Division can also be applied to frames on the basis of their data structures.

To handle frames and descriptors, four descriptor types (DESCR.DT) as FSTART, FEND, FMID and FSINGLE are defined.

Figure 46.14 shows the mapping of frame data by frame data descriptors. The descriptor data areas are allocated to the URAM. For frames that require division into four or more data areas, additional FMID descriptors can be added as required.

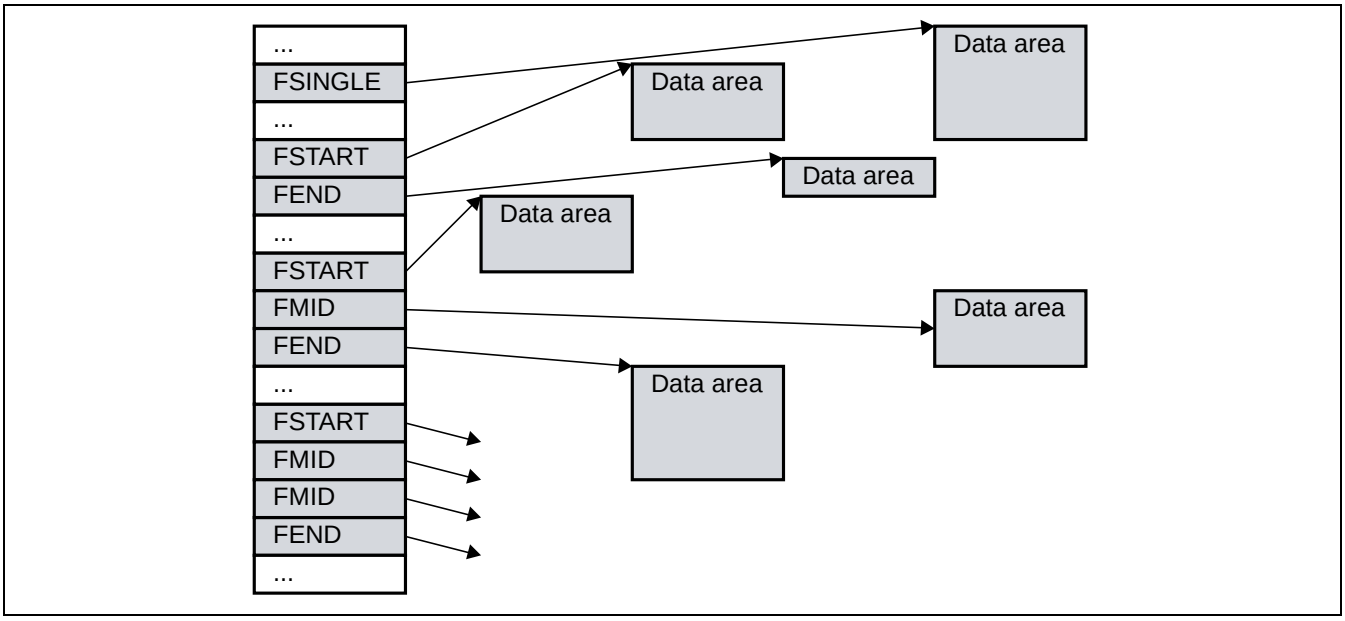

Figure 46.14 Mapping of Frame Data

For reception, set the descriptor data areas to the maximum size (i.e. give DESCR.DS its maximum value). The AVB-DMAC will store received frame data in the given area. If a received frame has more data than the maximum size, the AVB-DMAC will divide the data up.

For transmission, set the descriptor data area size field to the actual data size. The AVB-DMAC modifies the descriptor type (DESCR.DT) to FEMPTY after processing the relevant descriptor. The data size (DESCR.DS) and descriptor pointer (DESCR.PTR) fields retain their settings.

A descriptor data area including unused space produces an empty space between data areas. In reception, an “incremental data area” can be used to prevent empty spaces. For incremental data areas, see section 46.3.4(3)(b) Incremental Data Areas.

As well as reducing the memory capacity taken up by the descriptor area in the URAM, division into frames can be used to identify different sections of data (e.g. for separating a header and data).

(9) How to Use Chain Control Descriptors

Link Descriptors

The link descriptors can be used to set up cyclic descriptor chains (for details, see section 46.3.3(2) Using Descriptor Chains in Queues)

After a LINK descriptor is processed, its descriptor type (DESCR.DT) is changed to LEMPTY. The descriptor pointer (DESCR.PTR) retains its setting.

After processing of a LINKFIX descriptor, the descriptor type (DESCR.DT) is not updated. Software can change the descriptor type (DESCR.DT), descriptor interrupt enable (DESCR.DIE), and descriptor pointer (DESCR.DPTR). However, DESCR.DT should not be modified by software. Take care to check the current descriptor address register (CDARq.CDA) before changing the descriptor pointer (DESCR.DPTR).

EOS Descriptor

Use the EOS descriptor to divide a descriptor chain into various segments. The queue can continue even after an EOS descriptor.

In transmission, the response to an EOS descriptor is clearing of the transmit start request bit in the transmit configuration control register (TCCR.TSRQq) to 0.

In reception, the response is generation of a receive queue full interrupt (RIS2.QFFr), although if the frame currently being received is being divided for storage (received data such as those where some storage is in FMID- or FEND-type frames), the data are not completely stored.

(10) How to Use Hardware and Software Arbitration Descriptors

In hardware processing of descriptors, the empty descriptor types (FEMPTY, LEMPTY, and EEMPTY) are used to distinguish various descriptors. For software, they can be used to initiate checking for empty spaces, etc.

FEMPTY, FEMPTY_IS, FEMPTY_IC, and FEMPTY_ND

These descriptor types (DESCR.DT) are used for descriptors that do not contain effective data. Of these, only FEMPTY is used in transmission. The descriptor pointer of a FEMPTYxxx descriptor refers to a descriptor data area.

LEMPTY

This descriptor type (DESCR.DT) is assigned to LINK descriptors after they have been processed. The descriptor pointer (DESCR.DPTR) of an LEMPTY descriptor still points to the linked descriptor.

EEMPTY

This descriptor type (DESCR.DT) is assigned to EOS descriptors after they have been processed. The descriptor pointer (DESCR.DPTR) of an EEMPTY descriptor is not used.

(11) Synchronization between Descriptor Access by Hardware and Software

The allocation of descriptor types (DESCR.DT) to the URAM can be used to set up the primary synchronization between hardware and software. By this, the number of CPU accesses to registers of EthernetAVB-IF can be minimized and performance can be increased.

Basic concepts of synchronization:

- Each descriptor type in the set is exclusively for processing by hardware or software, depending on the direction of transfer (see Table 46.7 Summary of Descriptor Types).
- Software must not change a descriptor assigned to hardware processing (the hardware does not change descriptors assigned to software processing).

In the case of software processing, the software must process the information in the descriptor and the corresponding frame data before changing the descriptor type. If a descriptor type for hardware is set in DESCR.DT, the software should not change any part of the descriptor or of the corresponding frame data.

(12) Tips for Optimizing Performance in Handling Descriptors

The following items are recommended as ways to ensure the optimal use of data structures in the URAM.

They are not requirements, but using a different approach may increase the load on the system bus within the LSI chip.

- Register descriptors with 64-bit alignment (this does not apply to extended descriptors).
- While in operation mode, use LINKFIX instead of LINK whenever a descriptor need not be changed. Hardware modifies the descriptor type (DESCR.DT) fields of LINK descriptors.
- Frame data is accessed in blocks up to 128 bytes.
- The number of 128 byte borders (addresses H'x_xx00 and H'x_xx80) and frame data inside should be minimized.
- Design the descriptor chains in ways that minimize parallelism of processing. This helps in dividing the chains into segments allocated to different cache pages, and in arranging the different segments exclusively for access by software or hardware.
- Minimize the number of divided frames. This can reduce the overhead of descriptor handling.

46.3.4 Control in Reception

The point of the AVB-DMAC is to transfer data between the E-MAC and URAM without intervention by the CPU.

AVB-DMAC needs descriptors that define the amounts of frame data to be stored and the locations. After the E-MAC receives a frame, it stores the received frame data and the conditions of reception as the E-MAC state. If the descriptor is extended, the time stamp is also stored. For a description of how to set up descriptors for use in reception, see section 46.3.4(2) Setting Up Reception Descriptors.

The AVB-DMAC filters received frames to separate them into various classifications (separation filtering). More specifically, this is done to separate received frames into the various reception queues and to set the priorities of different classes of received frames. For more on separation filtering, see section 46.3.4(1)(a) Separation Filtering.

Figure 46.15 shows the reception data bus and the selection of queues for use in reception.

Each frame received from the E-MAC is stored in the reception FIFO; in parallel with this, the frame is analyzed to identify its type and the target queue number. After the E-MAC completes reception, the target queue number is generated and stored in the reception FIFO. Appending of a reception flag depends on the storage of one frame among the reception queues in the URAM, and the unread frame counter (UFC) is also associated with frame storage.

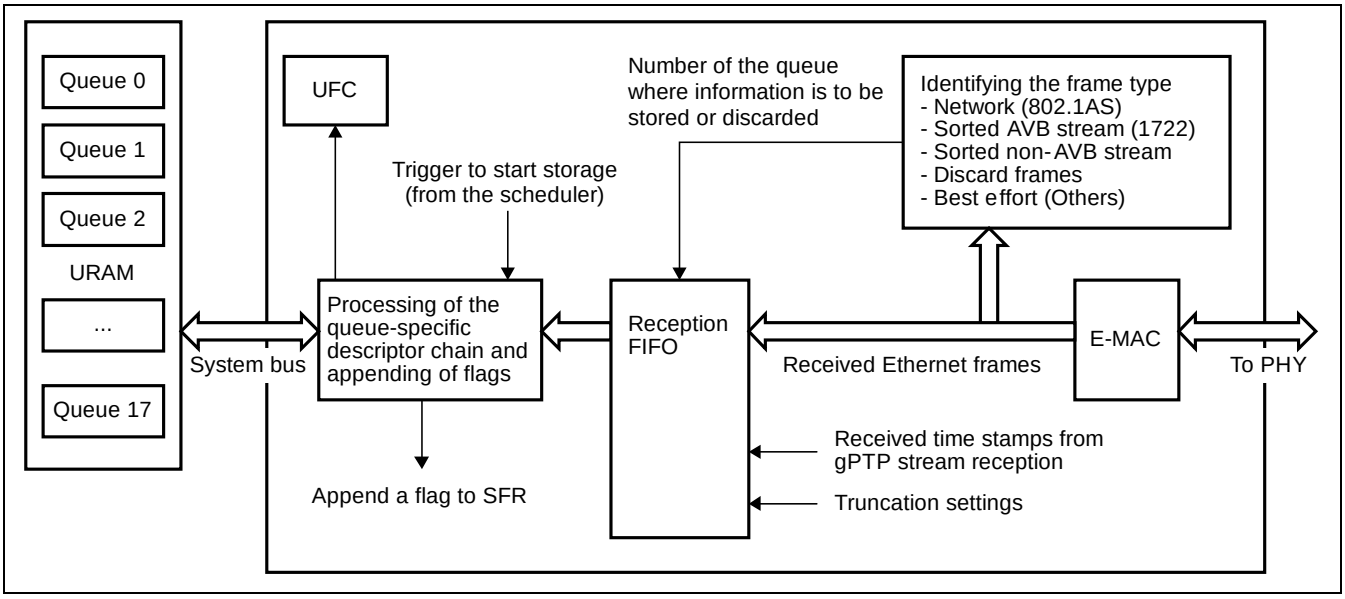

Figure 46.15 Mechanism of General Reception Queue Selection

(1) Reception Queues

The AVB-DMAC applies its separation filtering mechanism to select the reception queue for storing a received frame. The AVB-DMAC stores all received frames in the URAM.

There are two conditions for the AVB-DMAC to discard a received frame.

- Detection of an error during reception by the E-MAC
  - Whether error frames are discarded or stored in reception queue 0 (best effort) depends on the setting of the error frame enable bit in the receive configuration register (RCR.EFFS). If error frames are to be stored (RCR.EFFS = 1), they are always stored in queue 0 (best effort). In this case, characteristics specific to the queue (e.g. truncation) will vary. If the storage of time stamps for reception queue 0 (best effort) is enabled (the time stamp enable bit in the receive configuration register RCR.ETS0 = 1), time stamps are stored even for error frames.
- Frame fails the separation filter
  - It depends on RCR.ESF if such frame is discarded or stored in receive queue 0 (best effort).

The flowchart in Figure 46.16 shows how the AVB-DMAC selects the reception queue in accord with the frame type, including judgment by the separation filter. Selection of the queue starts when the E-MAC completes frame reception. The result is storage of the frame in the proper queue or the frame being discarded.

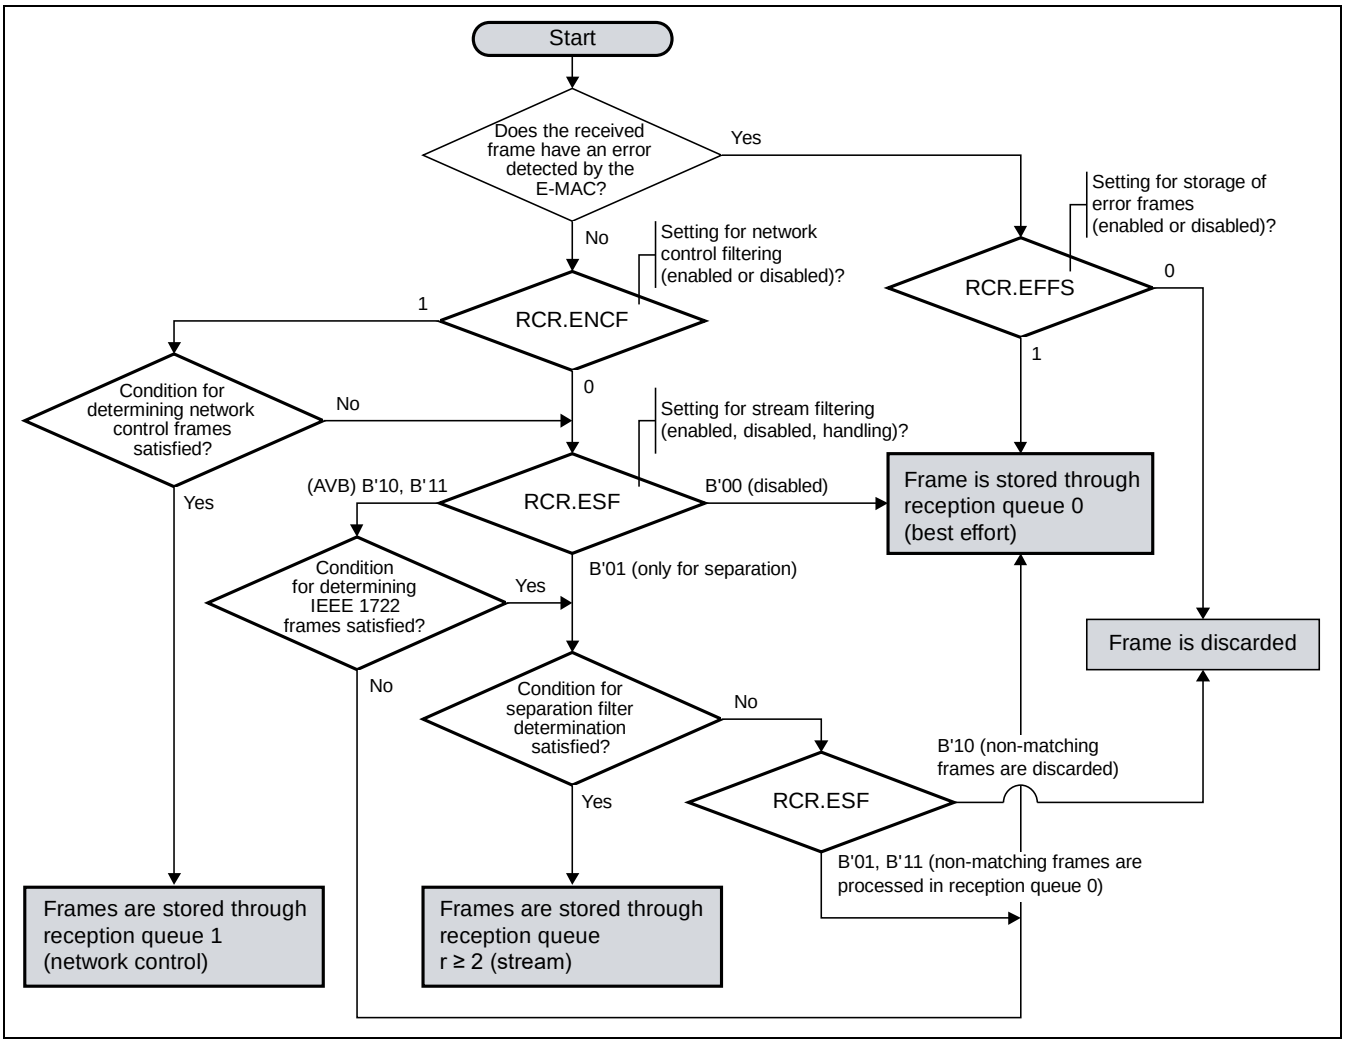

Figure 46.16 Mechanism of Reception Queue Selection

Notes on the meanings of entries in the flowchart

- “Condition for determining network control frames”
  The Ethernet destination address (DA) is 01:80:C2:00:00:0E.
  The Ethernet type (ET) is 88:F7.
- “Condition for determining IEEE 1722 frames”
  The Ethernet destination address (DA) is within the range from 91:E0:F0:00:00:00 to 91:E0:F0:00:FE:FF.
  The VLAN tagged TPID (tag protocol identifier) field (VL) is 81:00.
  The Ethernet type (ET) is 22:F0.
- “Condition for separation filter determination”
  See section 46.3.4(1)(a) Separation Filtering.

Figure 46.17 shows the allocation of bits related to the network and stream types in Ethernet frames. The preambles of Ethernet frames are not taken into account.

Data bytes	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19
Network type	DA1	DA2	DA3	DA4	DA5	DA6	SA1	SA2	SA3	SA4	SA5	SA6	ET1	ET2	...	...	...	...	...	...
Stream type	DA1	DA2	DA3	DA4	DA5	DA6	SA1	SA2	SA3	SA4	SA5	SA6	VL1	VL2	-	-	ET1	ET2	...	...

Figure 46.17 Data Bytes of Ethernet Frames Used in Classification

(a) Separation Filtering

Separation filtering involves the checking of up to 64 bits (eight successive bytes) in received Ethernet frames. The setting for the first byte (i.e. the setting of the separation filter offset configuration register (SFO.FBP)), selects the part of frames to be used in separation filtering. There is also a common filter mask (set in the separation filter mask configuration register (SFMi.CFM)) that can be freely set to reduce the number of bytes used in separation filtering or to mask particular bits.

Examples

To use one byte in separation, set separation filter mask configuration register 0 (SFM0.CFM) to H'0000_00FF and separation filter mask configuration register 1 (SFM1.CFM) to H'0000_0000.

To use seven bytes in separation, set separation filter mask configuration register 0 (SFM0.CFM) to H'FFFF_FFFF and separation filter mask configuration register 1 (SFM1.CFM) to H'00FF_FFFF.

Note: If bits at some positions are set to 0 in the separation mask, in order to match with the pattern, the bits at the corresponding positions of the pattern must also be set to 0. Only those bits in which the separation filter pattern configuration register (SFPi.FPs) setting is equal to the separation filter mask configuration register (SFMi.CFM) are sorted by matching with received data.

Figure 46.18 shows separation filtering. The selected data from a received frame (Rx_Frame[63:0]) are masked by the common filter mask. As a result, the selected frame data can be obtained. This value is compared with all filter patterns. The separation filter circuit in the AVB-DMAC selects the filter pattern that matches the queue having the lowest index s or selects a flag to indicate that there is no matching separation pattern.

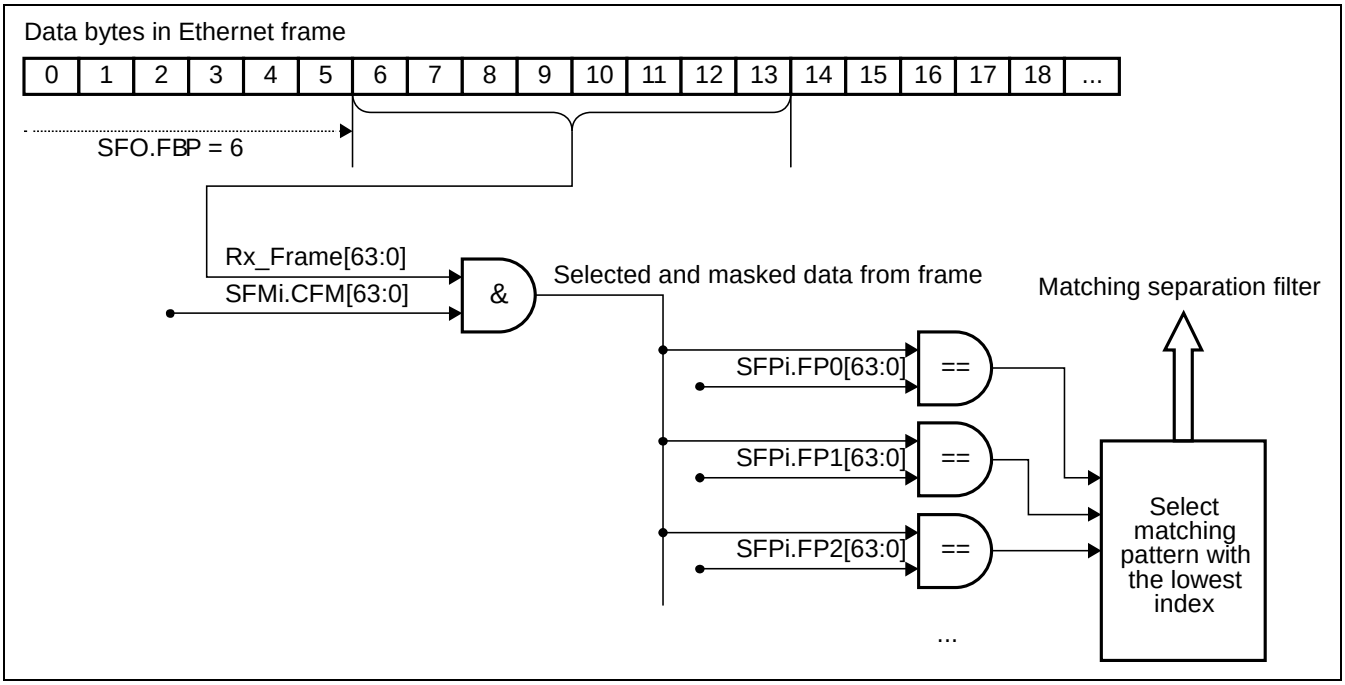

Figure 46.18 Separation Filtering

(b) Separating Streams

The AVB-DMAC applies separation filtering to sort frames received in streams. An AVB network has a concept of “Talker” and “Listener”. A Talker is an end station that generates one or more streams. A Listener is an end station that has the role of being a sink for at least one stream. The various A/V streams are identified by 8-byte stream IDs.

The number of end stations within an AVB network and their roles differ with the application.

The stream ID is a general pattern of the AVB network for identifying one stream. Figure 46.19 shows the bit allocation of bits in IEEE1722 Ethernet frames and stream ID fields.

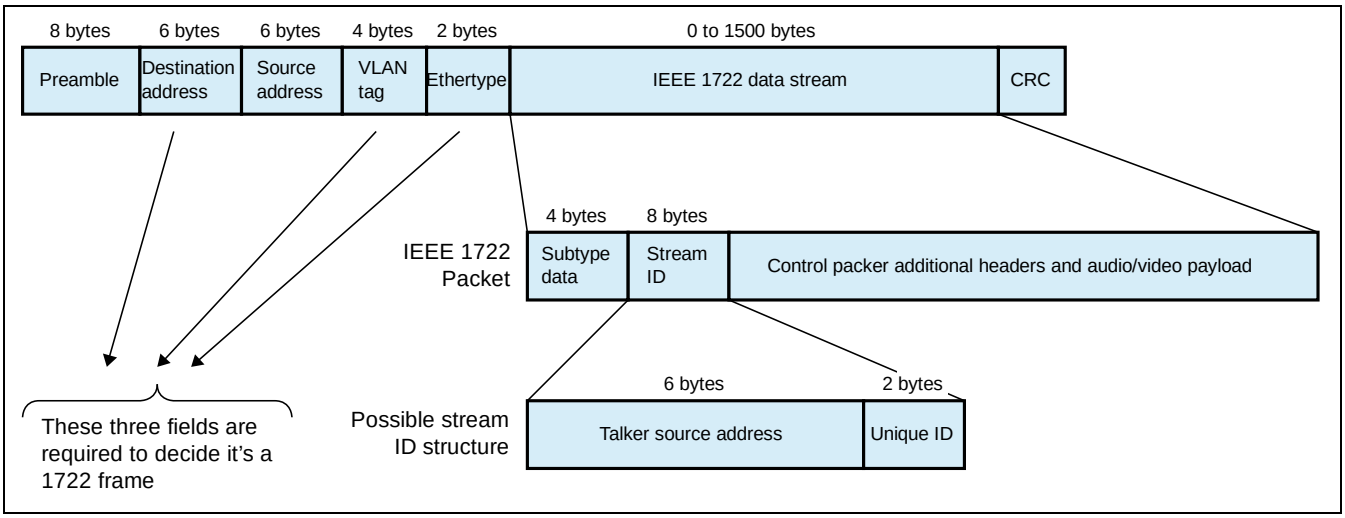

Figure 46.19 IEEE 1722 Frame Layout and Stream ID

The IEEE 1722 standard stipulates that the stream ID field starts from the 23rd byte (not counting the preamble). Accordingly, set the separation filter offset (SFO.FBP) to 22 in operations on IEEE 1722 streams. Set the separation filter mask (SFMi) and separation filter pattern (SFPi) in accord with the specification of the product in which the chip is being used.

Example: In the example of a stream ID shown in Figure 46.19, the current application divides the field into the talker source address and the unique stream ID. The unique ID is used to differentiate between multiple streams from the same talker. Based on this, there are two settings for separation filter masking:

- To divide various streams into individual queues, set SFM0.CFM to H'FFFF_FFFF and SFM1.CFM to H'FFFF_FFFF.
- To divide streams from various talkers into individual queues, set SFM0.CFM to H'FFFF_FFFF and SFM1.CFM to H'0000_FFFF. This excludes the unique ID from the filter condition.

(c) Reconfiguration of separation filter during OPERATION

In CONFIG mode the initial separation filter configuration is defined. To prevent inconsistent filter results during OPERATION direct parameter change is not possible; instead update mechanism by SFVi.LV and SFL.LC should be used.

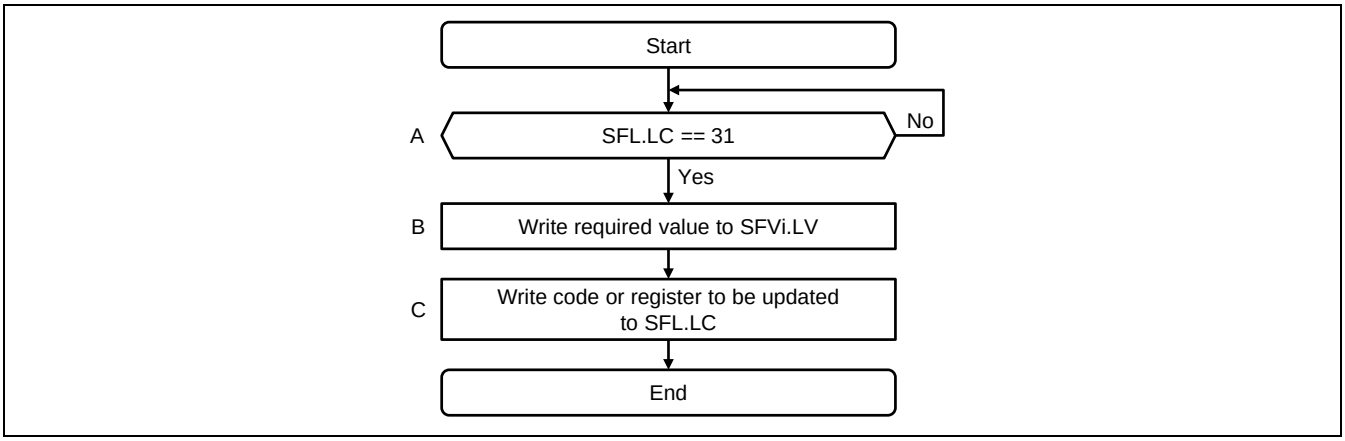

Figure 46.20 SW flow to update separation filter during OPERATION

When reconfigure separation filter, EthernetAVB-IF guarantees consistent classification for one received frame. If reconfiguration requires a sequence of parameter changes, CPU has to order reconfiguration based on application demand.

EthernetAVB-IF updates filter configurations when no frame reception is handled. In worse case the update is delayed by one frame reception. Exact duration depends on PHY speed and frame size. By reading SFL.LC CPU can observe when a previous update has been processed.

Note: Frame classification happens during frame reception and storage into internal Rx-FIFO. There may be frames with old classification pending in Rx-FIFO or under storage to URAM when filter reconfiguration is accepted.

(2) Setting Up Reception Descriptors

For reception, the descriptor mechanism is essentially as described in section 46.3.3 Descriptors.

This section describes memory operations that are especially required in handling reception queues.

(a) Reception Descriptor Type

The type of a descriptor is defined by the descriptor type (DESCR.DT) field.

Table 46.12 shows the descriptor types used in reception.

Table 46.12 Descriptor Types in Reception

Descriptor Type (DESCR.DT)	Operation	Write-back
Frame Start (FSTART)	Condition for data not being stored in a reception queue: The RIS2.QFFr bit indicates that queue r is full and the received frame is not stored. Descriptor processing proceeds again in response to further reception.	Not changed
Frame Middle (FMID)	Same as FSTART	Not changed
Frame End (FEND)	Same as FSTART	Not changed
Frame Single (FSINGLE)	Same as FSTART	Not changed
Link (LINK)	Processing proceeds to the descriptor specified by DESCR.DPTR.	LEMPTY
Fixed Link (LINKFIX)	Same as LINK	Not changed
End Of Set (EOS)	A stop point defined by software has been reached. A descriptor of this type within a divided frame (writing of FMID or FEND) stops the frame being stored and the frame is lost. RIS2.QFFr indicates that the frame has been lost. If this happens at the start of a frame (writing of FSTART or FSINGLE), storing of frames starts from the next descriptor. In either case, processing shifts to the next descriptor in the chain.	EEMPTY
Frame Empty (FEMPTY)	The descriptor can be used to store received data. Up to DESCR.DS bytes are stored in the descriptor data area. For details, see section 46.3.4(3)(a) Storing Frame Data in the Descriptor Data Area.	FSTART, FMID, FEND, or FSINGLE
Frame Empty Incremental Start (FEMPTY_IS)	The descriptor can be used to store received data. All data for the frame are stored in the descriptor data area. DESCR.DPTR indicates the base address of the incremental data area. For details, see section 46.3.4(3)(b) Incremental Data Areas.	FEND or FSINGLE
Frame Empty Incremental Continue (FEMPTY_IC)	The descriptor can be used to store received data. The remaining bytes of frame data are stored in the descriptor data area. DESCR.DPTR is undefined, but is written back at the start position within the incremental data area after processing. For details, see section 46.3.4(3)(b) Incremental Data Areas.	FEND or FSINGLE
Frame Empty No Data storage (FEMPTY_ND)	The descriptor can be used to store received data. Up to DESCR.DS bytes are captured from the reception FIFO but not stored. After processing, DESCR.DS is written back as 0. For details, see section 46.3.4(3)(b) Incremental Data Areas.	FSTART, FMID, FEND or FSINGLE
Link Empty (LEMPTY)	Same as FSTART	Not changed
EOS Empty (EEMPTY)	Same as FSTART	Not changed

(b) Configuration of Reception Frame Data Descriptors

Figure 46.21 shows the configuration of descriptors for use with reception queues. The reception-specific fields are the same whether the descriptor is normal or extended. The reception-specific fields (DESCR.MSC, DESCR.PS, DESCR.EI, and DESCR.TI) are described in Table 46.13.

For the other fields and the descriptor types, see section 46.3.3(6) Descriptor Type.

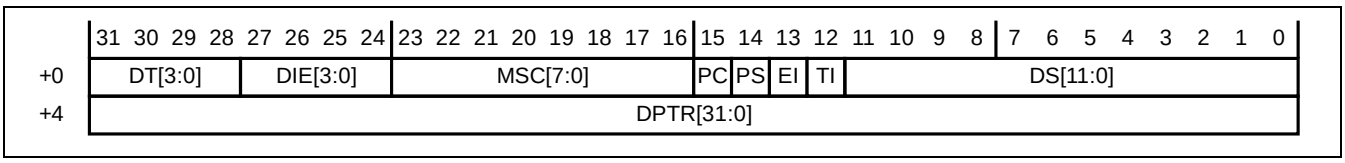

Figure 46.21 Configuration of Descriptor for a Received Frame

Table 46.13 Configuration of a Received Descriptor

Bit Name	Function
MSC	E-MAC Status Code These bits indicate errors in reception detected by the E-MAC. In the case of a divided frame, these bits are set to the same value within all descriptors for the frame data. Details of the bits are as follows. MSC[7]: Received frame has a multicast address. MSC[6]: Carrier extend error MSC[5]: Carrier sense error MSC[4]: Received frame has alignment error. MSC[3]: Received frame is too long. MSC[2]: Received frame is too short MSC[1]: Error in frame reception (PHY detects an error) MSC[0]: Received frame has a CRC error.
PS	Padding Selection These bits specify whether frame data are to be padded when stored in the incremental data area. Insertion of padding data is in accord with the settings in the RPC register. 0: Padding is not to be inserted. 1: Padding data may be inserted. This depends on the RPC settings.
EI	Error Indication This bit indicates the detection of an error in frame data while a frame was being stored. The bit is set to 1 for a descriptor in which an error has been detected. If the descriptor is for a divided frame, storage of the frame is aborted. 0: No error 1: Error is detected
TI	Truncation Indication This bit indicates whether frame data received from the E-MAC have been truncated before being stored. These bits are set to the same value within all frame data descriptors for a divided frame. 0: Data have not been truncated. 1: Data have been truncated.

Note: The RCR.EFFS bit specifies whether or not frames with errors detected by the E-MAC are to be stored in the URAM. When the storing of error frames is disabled, error codes are not written to DESCR.MSC.

(3) Reception Processing

After initialization, the AVB-DMAC is able to select the proper reception queue and store received frames in the data area in the URAM as indicated by the descriptor. The AVB-DMAC continues to store received data in the URAM as long as space is available for descriptors and data areas.

Received frames are classified and stored in the reception FIFO in accord with the algorithm described in section 46.3.4(1)(a) Separation Filtering.

If the reception FIFO contains even one frame, storing is executed to the reception queue.

If there is even one empty data descriptor in a queue for which reception has started, the storage of frame data starts. Received frames for a queue that is already full (there is no empty frame descriptor or the UFC stop level has been reached) are discarded from the reception FIFO. This ensures that one queue being full does not prevent the storage of data in the other queues.

(a) Storing Frame Data in the Descriptor Data Area

Frame data for storage are assumed to be in either of the two patterns described below.

- The data for an entire frame will fit in the descriptor data area.
  - In this case, the descriptor type (DESCR.DT) is FSINGLE.
- Frame data to be stored in the descriptor data area arrive in divided form.
  - In this case, FSTART is written to the descriptor type (DESCR.DT) bits of the first descriptor of the frame data to arrive and FMID and FEND are written to the type bits of descriptors for subsequent data.

The descriptor type is updated by the AVB-DMAC in the last step of descriptor processing, so software can always access the descriptor assigned to DESCR.DT.

When normal synchronization mode is used, the CPU can write FEMPTYxxx directly to the descriptor type field after processing the stored element. Do not change the descriptor or any part of the descriptor data area after FEMPTYxxx is written to DESCR.DT.

Storing Frame Data for a Whole Single Frame

For a frame with an FSINGLE descriptor, all data for the frame are held at the position defined by DESCR.DPTR. DESCR.DS indicates the length of the received frame.

If DESCR.DS is bigger than the actual size of a received frame, the FSINGLE descriptor is stored in place of the FEMPTY or FEMPTY_ND descriptor after processing.

Also, the FSINGLE descriptor is stored in place of the FEMPTY_IS or FEMPTY_IC descriptor, which always hold the descriptor data area greater than all frame data in Rx-FIFO after processing.

Storing Frame Data as Divided Frames

Divided frames are handled in the same way as a single frame. A frame stored with divided descriptors must be recombined before use. DESCR.EI and DESCR.TS are only valid in the last descriptor of the sequence for a divided frame.

Note: If the data area size setting in DESCR.DS is not a multiple of four, the number of bytes set in DESCR.DS is fetched from the reception FIFO and the remaining bytes are used as the next storage area.

After a received frame is divided into different descriptors, each storage element is handled separately, and the descriptor type is assigned by software after processing. Accordingly, an error frame (FEMPTYxxx instead of FMID or FEND) may exist while a descriptor chain is being processed. In such a case, the CPU must postpone processing of the error frame to the next trigger point.

No Data are Stored

The application specification may lead to some types of received frames being unimportant (for example, when the application only requires stream data from the Ethernet frames). Storing frames in divided form makes separating out the unnecessary parts of Ethernet frames possible.

If part of a divided frame is not required, use the FEMPTY_ND descriptor for that part so that it is not stored in the URAM. Not storing the data negates the need for bandwidth on the data bus, improving the overall performance.

When an FEMPTY_ND descriptor is processed, DESCR.DS is set to 0. This brings the frame data section of the descriptor into agreement with the FEMPTY type. DESCR.DS = 0 is for the unique identification of the descriptor after writing.

(b) Incremental Data Areas

Secure space in the URAM for storing received data. Even when data are placed in the URAM area such that all descriptor data areas of a chain are contiguous, a received frame being shorter than the descriptor data area will lead to an empty space. Figure 46.22 shows an example of settings and the memory map.

Certain applications require that data areas be contiguous (e.g. when received data are to be processed other than by hardware as the A/V codec module). When the length of received frames differs (e.g. when payloads vary between having one or two A/V packages), the use of a static pointer in the descriptor produces empty spaces in the data area. This may necessitate direct additional processing to remove the empty spaces.

Accordingly, and to reduce the CPU load imposed by copying data, the AVB-DMAC supports an “incremental data area” function.

When incremental data areas are in use, all descriptors use a common data area for storage. One descriptor (FEMPTY_IS) defines the base address of the incremental data area and the next descriptor (FEMPTY_IC) within the descriptor chain holds received data. Figure 46.23 shows an example of settings and the memory map.

Use of an incremental data area does not reduce the memory space in the individual descriptor data areas.

The hardware and software synchronization strategy and performance are also not changed.

It is also possible to divide a frame up among various descriptors in a way that reflects its structure (e.g. one descriptor for the Ethernet header and one for the data payload).

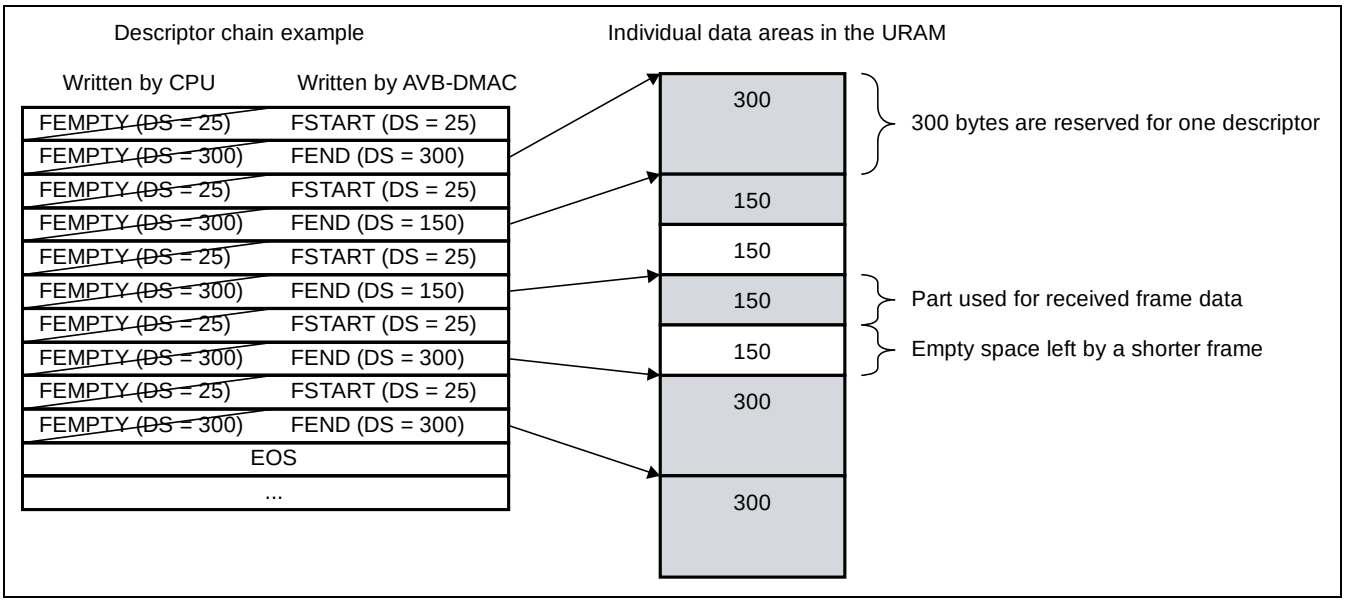

Figure 46.22 A Reception Queue Using Individual Descriptor Data Areas

Figure 46.22 and Figure 46.23 show how control of the data storage areas by a descriptor chain varies according to whether individual or incremental data areas are in use. The chains are configured for storing received frames consisting of a 25-byte header (which is treated as one descriptor; and is outside the scope) and a 150- or 300-byte payload (whether one or two 150-byte payload packages are transmitted with one Ethernet frame depends on the data source).

In Figure 46.22, the EOS descriptor is added as an example of a re-synchronization point. If the frame source transmits a frame containing more than 325 bytes, the frame will be divided among three descriptors, meaning that synchronization of the header and data sequences is lost. Despite this, however, the frame is not divided across the EOS descriptor, so recovery is automatic without software interaction. The EOS is not required with the incremental descriptors because all data being processed are always stored while an incremental data area is in use.

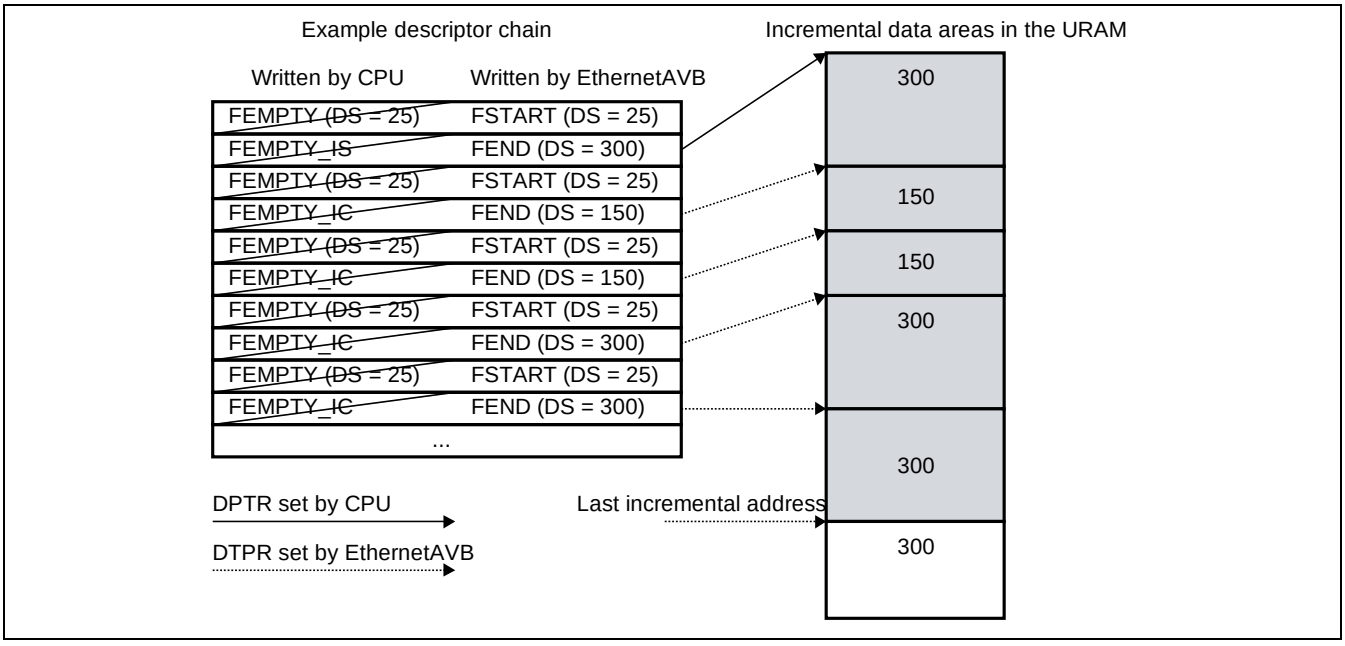

Figure 46.23 Reception Queue Using a Common Incremental Data Area

As Figure 46.23 shows, when data are stored in an incremental data area, the descriptor pointers in the FEMPTY_IC descriptors (DESCR.DPTR) are updated. Accordingly, the resulting FEND or FSINGLE descriptor is in the same format as after writing to an FEMPTY descriptor.

Software captures received data from an incremental data area, which has no empty storage areas between frame data. The only empty space is that at the end of the incremental data area. The sizes of incremental data areas and of blocks of data for storage in incremental data areas must be multiples of four bytes. When the amount of data for storage in an incremental data area is not a multiple of four bytes, from one to three bytes of empty space will be produced. DESCR.DS can be read to check for such empty spaces.

CPU cannot restrict directly the amount of received data stored by an incremental descriptor (FEMPTY_IS, FEMPTY_IC) as this is possible for other descriptors (FEMPTY, FEMPTY_ND) by DESCR.DS. Incremental descriptors store always all received data.

Setting Up an Incremental Data Area

A descriptor chain in the incremental data area having N descriptors (one FEMPTY_IS and N-1 FEMPTY_IC) means that the incremental storage area of N times of maximum frame size is needed.

As Figure 46.23 shows, DESCR.DPTR of an FEMPTY_IS descriptor indicates the base address of the incremental data area. The next FEMPTY_IS descriptor in the chain indicates the processing step where data must be stored in the incremental data area.

Processing an Incremental Data Area Based on Descriptors

Since data processing by the CPU is the same regardless of how the AVB-DMAC stores the data, data stored in an incremental data area do not require any special handling.

Padding

Use padding for received frame data that are not aligned correctly in the specified memory structure. Padding can be set individually for each descriptor. Accordingly, in the reception of divided frames, padding can be restricted to only those frames that require it (e.g. A/V payload data.)

Padding can also be used to optimize system performance in an incremental data area (e.g. to prevent inefficient access by aligning received data with 32-byte boundaries in the incremental data area), as well as to fulfill application-specific requirements for specified memory structures (e.g. formats required by other modules that will be processing the received data).

Padding can only be used in an incremental data area.

The value H'0000_0000 is always used in padding.

Padding is the addition of the number of words (from one to seven 32-bit words) set in the stored padding counter in the receive padding configuration register (RPC.PCNT). This padding is repeatedly inserted in accord with the value in the stored data counter (RPC.DCNT) (from one to 255 32-bit words). When the stored data counter (RPC.DCNT) reaches 0, however, padding is not repeated.

The first word of padding is always inserted at the position specified by DESCR.DPTR. When divided frames are in use, a padding word can be inserted at any byte position, and padding is handled on a 32-bit basis (e.g. an incremental data area where the first descriptor is for a 42-byte header data and the second descriptor holds padded payload data).

The next figure shows a general example of how padding is inserted and an example of setting up padding. A indicates frame data A received by the E-MAC, and B indicates the frame data stored in the descriptor data area (32-bit word units).

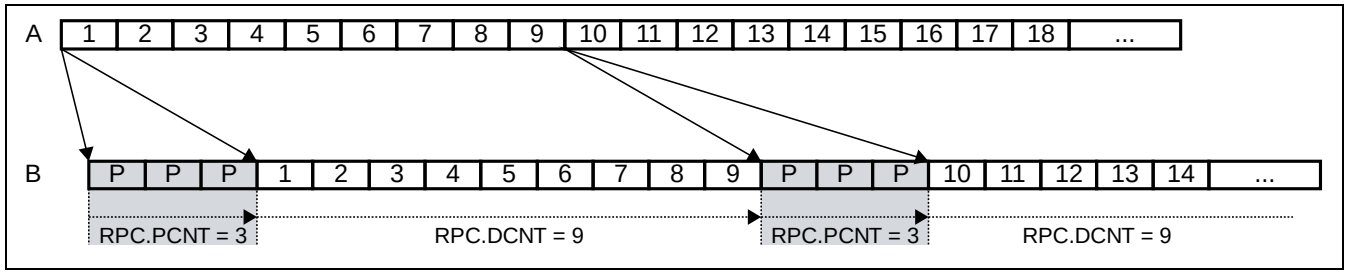

Figure 46.24 Example of a Padding Setting

Both padding and received frame data are counted in the descriptor size (DESCR.DS).

(c) Mode with Write-Back

Constructing a descriptor chain requires software (see Figure 46.25).

In the example in the figure, the variable SWdescr (software descriptor pointer) is a structure to identify a descriptor being processed. SWdescr must be initialized after operation mode is entered and a descriptor base address load request (DLR.LBAq) is executed (condition for starting the flow of software operations).

The frame_processing() function processes the stored data. The function can use SWdescr.DT to check whether processing of a frame is completed. How frame data are processed differs with the application, so create functions that handle processing in accord with the specification.

The processing section is common to all modes of reception. The number of frames processed in response to each trigger can be restricted. When multiple frames have to be processed in a batch, waiting for individual trigger boxes must be skipped for these frames.

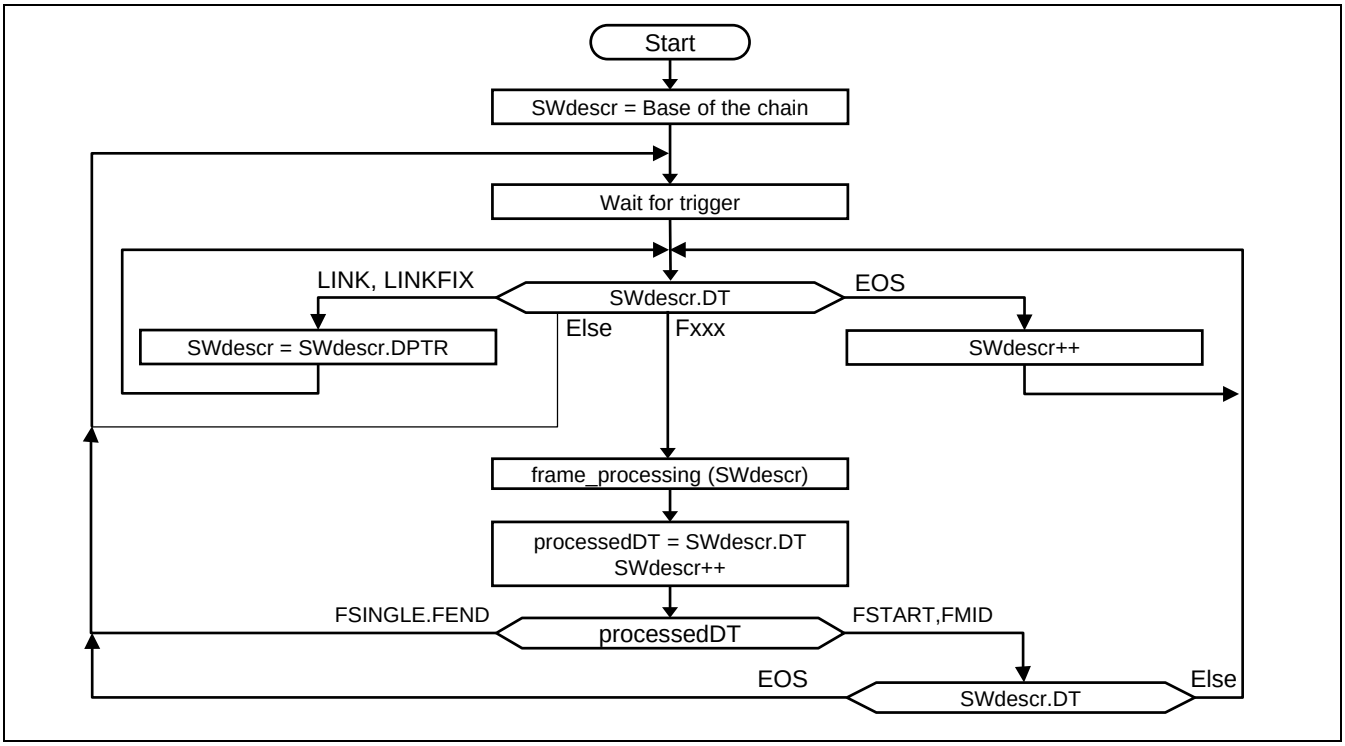

Figure 46.25 Flow of Reception Descriptor Processing (with Write-Back)

(d) Support for Reception Time Stamps

Capturing reception time stamps is essential for IEEE 802.1AS time synchronization. Other types of received frames may also require that a reception time stamp be appended; this depends on the application. The AVB-DMAC supports reception time stamps based on the gPTP timer by storing time stamps, which have been captured when Start Frame Delimiter (SFD) of a received frame is arrived, in the last frame data descriptor (FEND or FSINGLE). For the gPTP timer, see section 46.3.7(1) gPTP Timer.

When time stamps are to be stored, use extended descriptors for the entire reception queue. Furthermore, time stamps are always stored for reception queue 1 (network control). Time stamps for reception queue 0 (best effort) and reception queue r ($r \geq 2$; for stream data) can be selected by the time stamp enable bits in the receive configuration register (RCR.ETS0 or RCR.ETS2).

(4) Unread Frame Counters

Each reception queue has an unread frame counter (UFCVi). Use the unread frame counter configuration bits in the receive queue configuration register (RQCi.UFCCr) to select from among the four warning and stop levels for each unread frame counter. The 0 setting disables the stop and warning functions. For how to set this up, see Figure 46.26.

Operations of the AVB-DMAC (hardware) and CPU (software) drive an unread frame counter (UFC) in the following ways.

- The hardware indicates that it has added a new frame to the descriptor chain for the queue (this increments the counter).
- Software indicates how many frames from the descriptor chain it has processed by writing to the corresponding bits of the unread frame counter decrement register for the queue (this decrements the register by the number written).

The unread frame counter is based on the number of frames stored in the URAM and is only incremented by one even when a received frame is divided into different descriptors. Failure in storing a descriptor chain requires care because this may unread frame counter may fail in synchronization as described in section 46.3.4(4)(a) Unread Frame (UFC) Synchronization Failure.

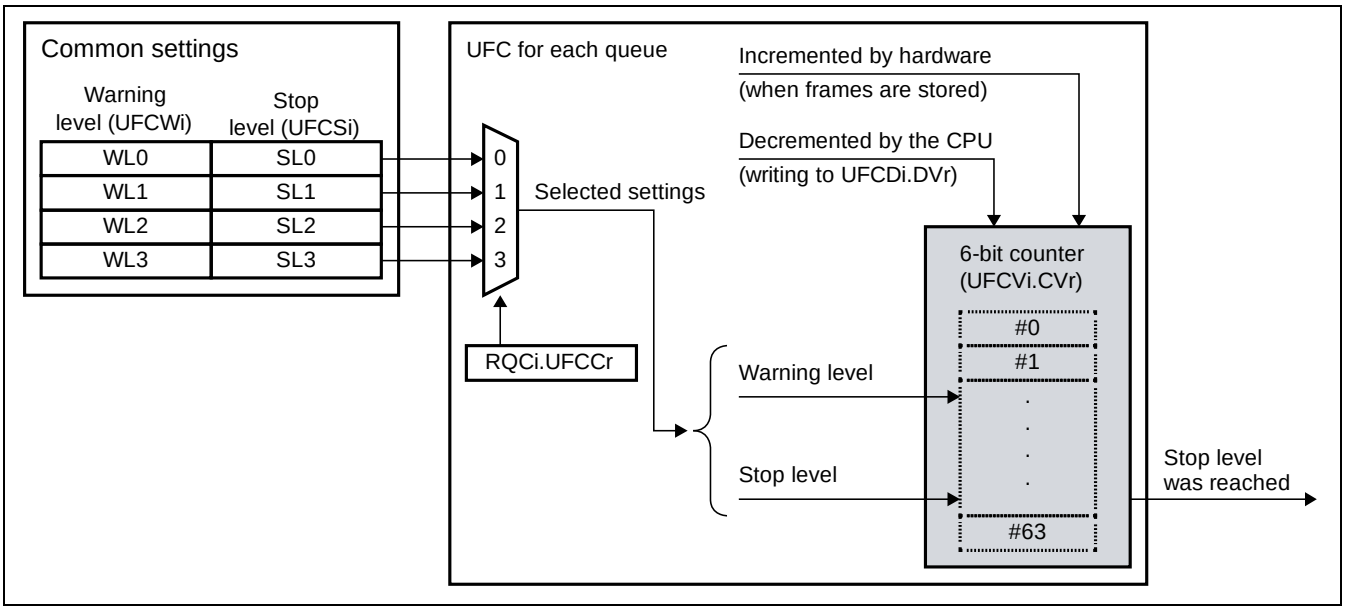

Figure 46.26 Overview of an Unread Frame Counter

Unless synchronization of hardware and software is lost, the current unread frame counter value (UFCVi.CVr) indicates the number of unread frames in the queue.

The indicator that the stop level has been reached prevents the storage of further received frames in the descriptor chain. Selecting 0 as the stop level disables this function. Otherwise, further received frames for the queue are discarded once its unread frame counter reaches the stop level. Activation of the unread frame counter stop function is indicating by setting of the receive queue full interrupt flag in the receive interrupt status register 2 (RIS2.QFFr).

Set the unread frame counter warning level configuration register (UFCW) and the unread frame counter stop level configuration register (UFCS) for each reception queue that will use the unread frame counter function while the current operating mode is configuration mode.

(a) Unread Frame (UFC) Synchronization Failure

The unread frame counters do not recognize failure to store a frame in the URAM. In other words, the AVB-DMAC increments the counter for a queue each time it captures a frame for that queue from the reception FIFO whether or not it succeeds in storing the frame normally in the descriptor chain.

In general, synchronization of hardware and software fails under the following conditions.

- An unread frame counter reaching its maximum value
  When the value of a counter in an unread frame counter register i (UFCVi) (i = 0 to 4) reaches 63, synchronization for the corresponding queue can fail.
  The CPU can only judge that a failure in synchronization has not occurred when the stop level is set to 63.
- A queue not having enough space for a descriptor
  In this case, the corresponding receive queue full interrupt flag (RIS2.QFFr) in receive interrupt status register 2 (RIS2) is set.
  If an unread frame counter reaches its stop level while synchronization remains normal, the receive queue full interrupt flag (RIS2.QFFr) in the receive interrupt status register 2 (RIS2) is set. Software must respond to this.
- A problem occurring during access to memory

The result of a failure in synchronization is the unread frame counter indicating that the corresponding descriptor chain may contain more available frames than it actually can. To retrieve the correct starting point for operations, use the descriptor base address load request (DLR.LBAq) for the given queue.

46.3.5 Transmission Control

Areas in the URAM for storing transmission descriptors must also be secured (for descriptors, see section 46.3.3 Descriptors).

The AVB-DMAC fetches data from the URAM in accord with the procedure the descriptor describes. The descriptor also retains tag information once the frame has been fetched for transmission. The tag information is used to maintain the relationships between status and time stamps for the software and the AVB-DMAC. The status and time stamp information for transmitted frames remains accessible after their transmission is completed.

(1) Transmission Modes

The AVB-DMAC has two modes of transmission.

- AVB transmission mode
  This mode is selected by the priority level setting for the transmission queue in the transmit configuration register (setting of the TGC.TQP[1:0] bits) being B'01 or B'11.
- Non-AVB transmission mode
  This mode is selected by the priority level setting for the transmission queue in the transmit configuration register (setting of the TGC.TQP[1:0] bits) being B'00.

(a) AVB Transmission Mode

AVB transmission supports the control of traffic through the output port to implement various traffic classes.

Support for Traffic Classes and Associated Priority

When transmission is in AVB transmission mode, streams of traffic are transmitted in accord with the part of the AVB specification called Forwarding and Queuing for Time Sensitive Streams (FQTSS; for details on this, see the IEEE 802.1Q standard).

In the AVB specification, at least one queue for a reserving stream under the Stream Reservation Protocol (SR stream) and at least one queue for a non-SR stream are present, and the queues for SR traffic is Highest priority queue.

The AVB-DMAC supports four traffic classes: SR class A, SR class B, network control (NC) traffic (gPTP frames), and best effort (BE) traffic. Allocating a specific queue to network control (NC) frames ensures the control of synchronization.

The AVB-DMAC realizes compliance with the AVB standards by handling queues with the following architecture (in terms of traffic classes).

- Four transmission queues (Q3, Q2, Q1, and Q0) are available.
- Q3 and Q2 are for SR streams (one each for class A and class B).
- Q1 is for low-bandwidth network control (NC) traffic (gPTP frames)
- Q0 is for other types of traffic (MSRPDU*1, MVRPDU*2, best effort (BE), etc.)

Notes: 1. MSRPDU: Multiple Stream Registration Protocol Data Unit
2. MVRPDU: Multiple VLAN Registration Protocol Data Unit

Fetching from queues proceeds in order of priority of the above traffic types. Three systems of priority are available through the setting of the transmit queue priority bits in the transmit configuration register (TGC.TQP[1:0]). In the default priority scheme, which is called AVB mode 1 (selected by TGC.TQP[1:0] = B'01), operation of the AVB-DMAC is fully in accord with the AVB specification. AVB mode 2 (transmit queue priority bits (TGC.TQP[1:0] = B'11) is an alternative priority scheme and varies from the AVB specification. Using this scheme thus requires more care. The other setting is for non-AVB-mode transmission.

Table 46.14 Default and Alternative Priority Orders in AVB Transmission Mode

Priority Schemes (AVB Mode)	Priority Order of Queues
Default	Q3 (SR class A) > Q2 (SR class B) > Q1 (NC) > Q0 (BE)
Alternative	Q1 (NC) > Q3 (SR class A) > Q2 (SR class B) > Q0 (BE)

Transmission Selecting Algorithm and CBS

The algorithm the AVB-DMAC applies to select frames for transmission is in accord with the specifications under section 11.6.8, Transmission selection, of the IEEE 802.1Q standard. For AVB mode, the CBS (credit-based shaping) algorithm is applied to the class A and class B SR queues (Q3 and Q2). Use of the CBS enables correct handling of the priorities of transmission from the SR queues. For the CBS algorithm, see section 46.3.6 CBS (Credit-Based Shaping).

When the following conditions both hold, transmission from an SR queue (Q3 or Q2) proceeds at the specified time.

- The queue contains at least one frame ready for transmission.
- The queue has available credit.
- Unless an SR queue satisfies the above conditions, a higher priority queue is not present (not ready for transmission).

A non-SR queue (Q1 or Q0) is selected if the conditions below both hold.

- The queue contains at least one frame ready for transmission.
- As well as the above condition, a higher priority queue is not present (not ready for transmission).

Figure 46.27 and Figure 46.28 are flowcharts of selection for transmission in AVB mode 1 (default) and AVB mode 2 (alternative).

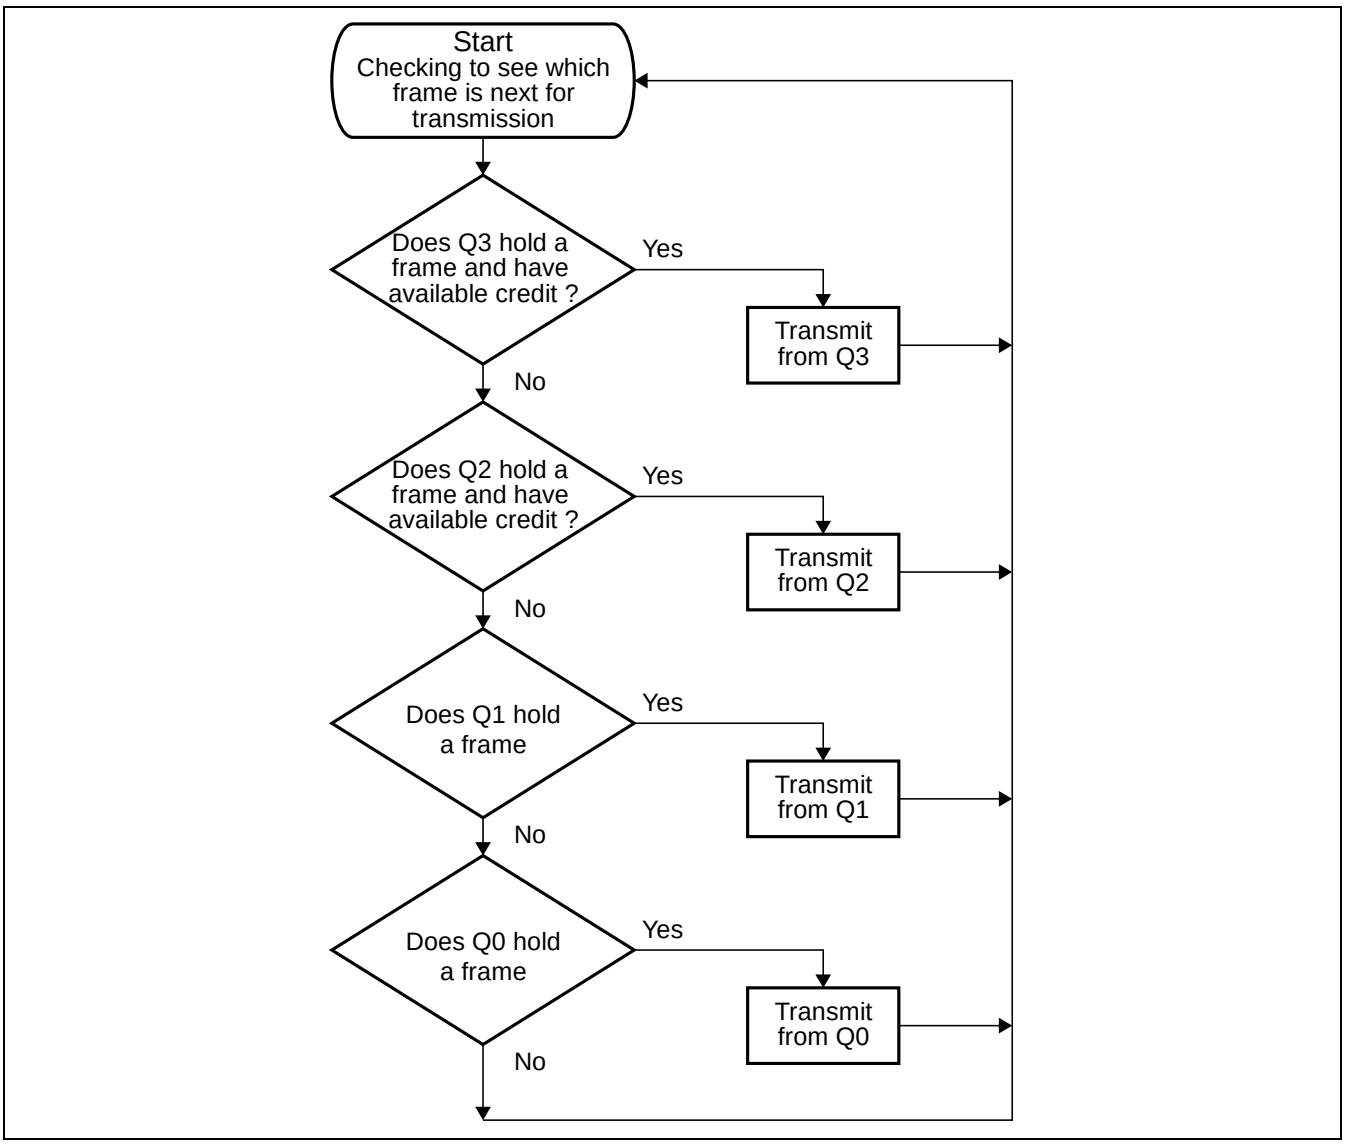

Figure 46.27 Flow of Selection for Transmission in AVB Mode 1 (Default)

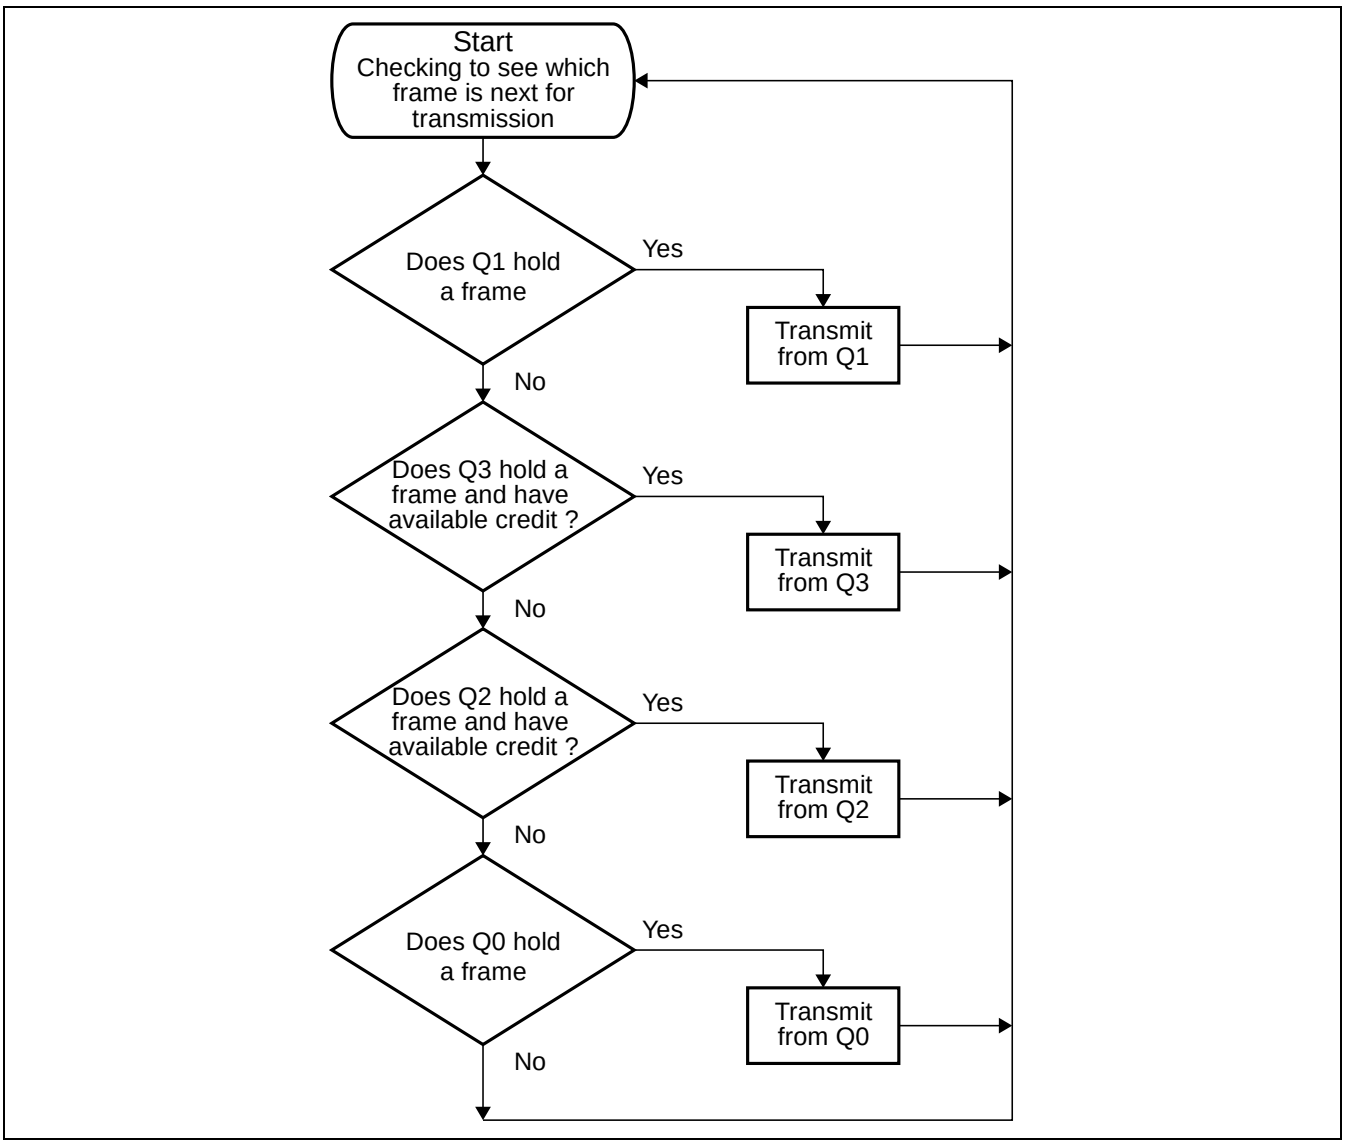

Figure 46.28 Flow of Selection for Transmission in AVB Mode 2 (Alternative)

(b) Non-AVB Transmission Mode

In non-AVB transmission mode, an absolute priority scheme is used. The SR class is not supported and the CBS algorithm is not used.

In non-AVB transmission mode (when the transmit queue priority bits in the transmit configuration register (TGC.TQP[1:0]) are B'00), data is fetched for transmission in a strict order of priority (Q3 > Q2 > Q1 > Q0).

Figure 46.29 shows the flow of selection in non-AVB transmission mode.

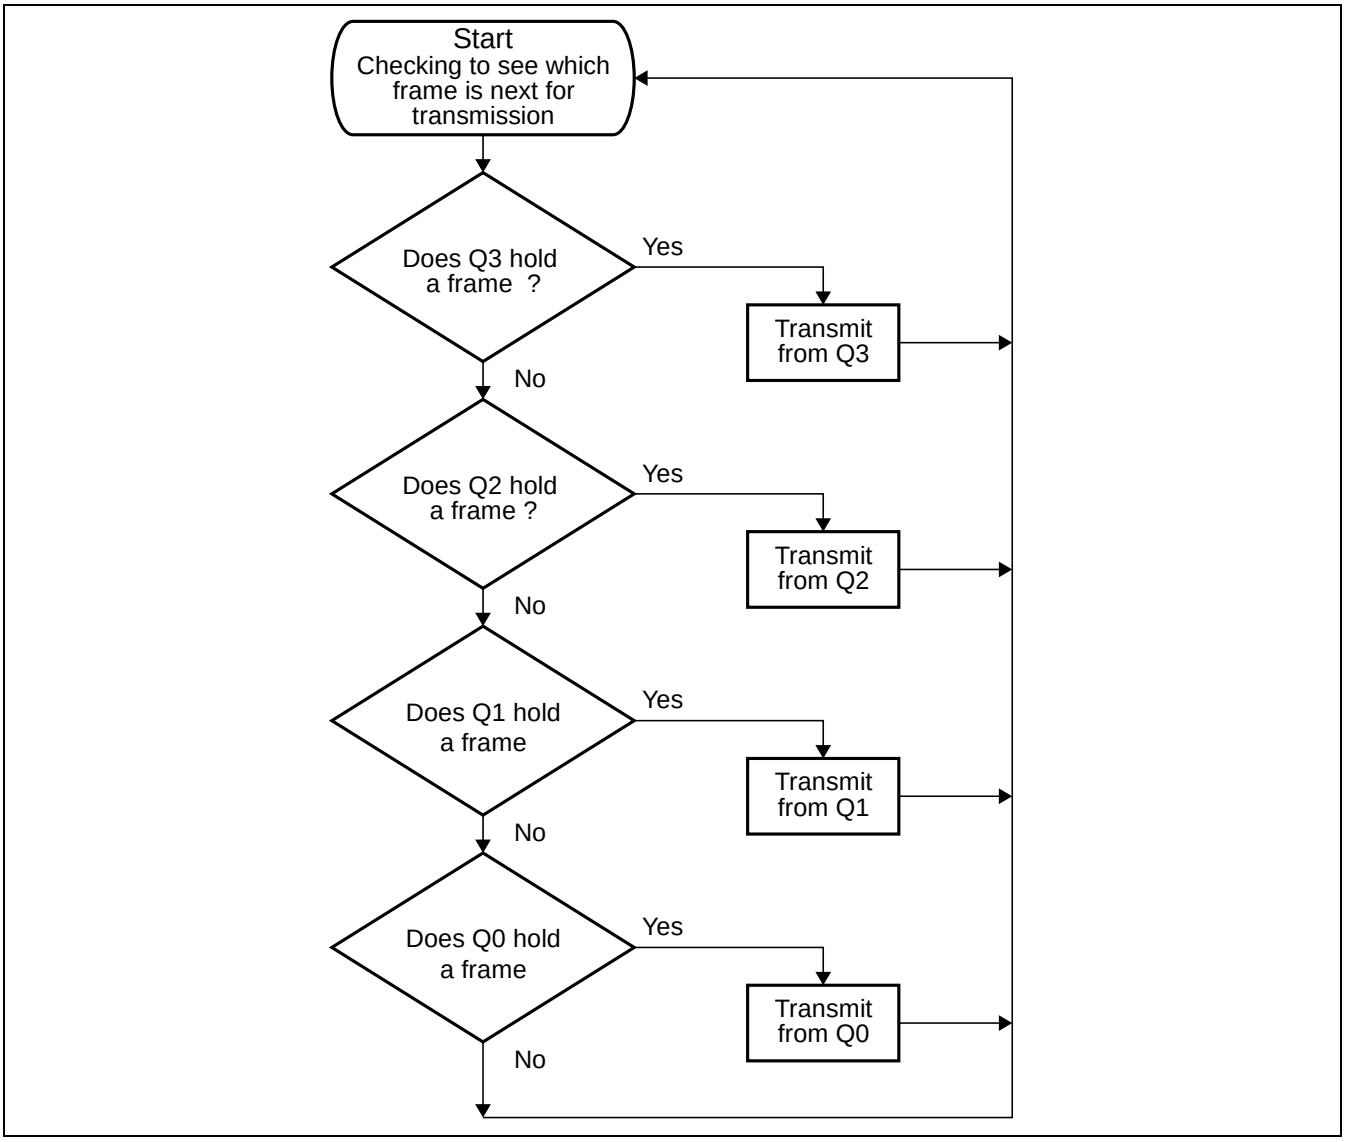

Figure 46.29 Flow of Selection for Transmission in Non-AVB Mode

(c) Setting the Size of the Transmission FIFO

The transmission FIFO is made up of 122 clusters. Each cluster can hold up to 128 bytes.

The size of the part of the transmission FIFO for use by each of the four transmission queues can be set by the corresponding transmit queue configuration q bits in the transmit control register (TGC.TBDq).

General Usage Examples:

Q0: Frames containing up to 1500 bytes → 1500/128 = 11.7 → 12 clusters
Q1: Frames containing up to 1024 bytes → 1024/128 = 8.0 → 8 clusters
Q3: Frames containing up to 1996 bytes → 1996/128 = 15.6 → 16 clusters
Q4: Frames containing up to 1996 bytes → 1996/128 = 15.6 → 16 clusters
When the depth of all transmission queues is 2, only the following number of clusters is required.
$2 \times (12 + 8 + 16 + 16) + 16 = 2 \times 52 + 16 = 120$

In the worst case (each of the transmission queues holds 1996 bytes), $2 \times 64 + 16 = 144$ clusters are required, so the maximum length of transmission frames must be less than 1996 bytes for some queues.

(2) Setting Up Transmission Descriptors

(a) Transmission Descriptor Type

The type of a descriptor is defined by the descriptor type (DESCR.DT) field.

Table 46.15 shows the descriptor types used in transmission.

Table 46.15 Descriptor Types in Transmission

Descriptor Type (DESCR.DT)	Operation	Write-back
Frame Start (FSTART)	The AVB-DMAC fetches the first of the data for the divided frame and proceeds to processing of the next descriptor.	FEMPTY
Frame Middle (FMID)	The AVB-DMAC fetches the second or subsequent data for the divided frame and proceeds to processing of the next descriptor.	FEMPTY
Frame End (FEND)	The AVB-DMAC fetches the last of the data for the divided frame. The frame of data that has been fetched to the transmission FIFO is ready for transmission by the E-MAC, and then the AVB-DMAC proceeds to processing of the next descriptor.	FEMPTY
Frame Single (FSINGLE)	The AVB-DMAC fetches the frame of data. The frame of data that has been fetched to the transmission FIFO is ready for transmission by the E-MAC, and then the AVB-DMAC proceeds to processing of the next descriptor.	FEMPTY
Link (LINK)	Processing proceeds to the descriptor specified by DESCR.DPTR.	LEMPTY
Fixed Link (LINKFIX)	Same as LINK	Not changed
End Of Set (EOS)	This is a transmission stop point defined by software This leads to clearing of the transmit start request bit (TCCR.TSRQt), which stops transmission. When the TCCR.TSRQt is again set to 1 (a new transmission start request is issued), processing proceeds to the next descriptor.	EEMPTY
Frame Empty (FEMPTY)	No frame data are ready for transmission This leads to clearing of the transmit start request bit (TCCR.TSRQt), which stops transmission. When the TCCR.TSRQt is again set to 1 (a new transmission start request is issued), processing starts at this descriptor.	Not changed
Link Empty (LEMPTY)	Same as FEMPTY	Not changed
EOS Empty (EEMPTY)	Same as FEMPTY	Not changed

(b) Configuration of Transmission Frame Data Descriptors

Figure 46.30 shows the configuration of descriptors for use with transmission queues. The transmission-specific fields (DESCR.MSR, DESCR.TSR, and DESCR.TAG) are described in Table 46.16.

For the other fields and the descriptor types, see section 46.3.3(6) Descriptor Type.

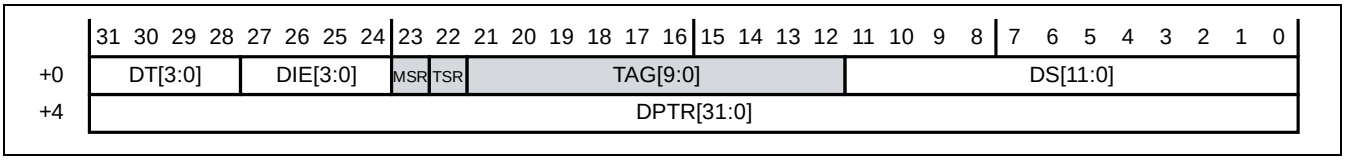

Figure 46.30 Configuration of Descriptor for a Transmitted Frame

Table 46.16 Configuration of a Transmission Descriptor

Bit Name	Function
MSR	MAC Status storage Request This bit configures if E-MAC transmission status of the frame is stored in E-MAC status FIFO. 0: No status information is stored 1: Status information is to be kept for this frame in MAC status FIFO This bit is considered only if DESCR.DT = FEND or FSINGLE. Note: If there is error during transmission of frame by E-MAC then status is always stored.
TSR	Time Stamp Store Request This bit specifies whether the transmission time stamp is to be stored within the EthernetAVB-IF module. 0: The time stamp status FIFO within the EthernetAVB-IF module does not retain a transmission time stamp. 1: The time stamp status FIFO within the EthernetAVB-IF module retains a transmission time stamp. This bit is available while the current DESCR.DT is FEND or FSINGLE.
TAG	Frame Tag This TAG field is used to associate each frame data with a time stamp. Frame TAG is not required but is recommended. This bit is available while the current DESCR.DT is FEND or FSINGLE.

For the time stamp FIFO function, see section 46.3.5(4) Time Stamping in Transmission.

(3) Transmission

(a) Transmitting Frames

Setting the transmit start request bit in the transmit configuration control register (TCCR.TSRQt) starts the transfer of frames from the corresponding transmission queue.

The descriptor in the current descriptor address (CDARq.CDA) for the queue t (with q = t) is read first.

If this descriptor is a descriptor for frame transmission (FSINGLE, etc.), the AVB-DMAC fetches the frame data from the data area indicated by the descriptor, writes FEMPTY back to the descriptor type (DESCR.DT) bits to indicate completion of this processing, then proceeds to processing of the next descriptor.

If the descriptor is not for transmission, processing is as dictated by the given descriptor (for these descriptors, see the descriptions in section 46.3.3 Descriptors).

If a base address load request is issued for a descriptor chain while it is being processed (by setting 1 in the LBAq bit for transmission queue q that is currently being processed in the descriptor base address load request register, DLR), processing proceeds to the new descriptor chain. Changing the chain does not interrupt frame fetching, but note that frames that have not been fetched from the old chain remain where they are.

Figure 46.31 shows descriptor processing during transmission.

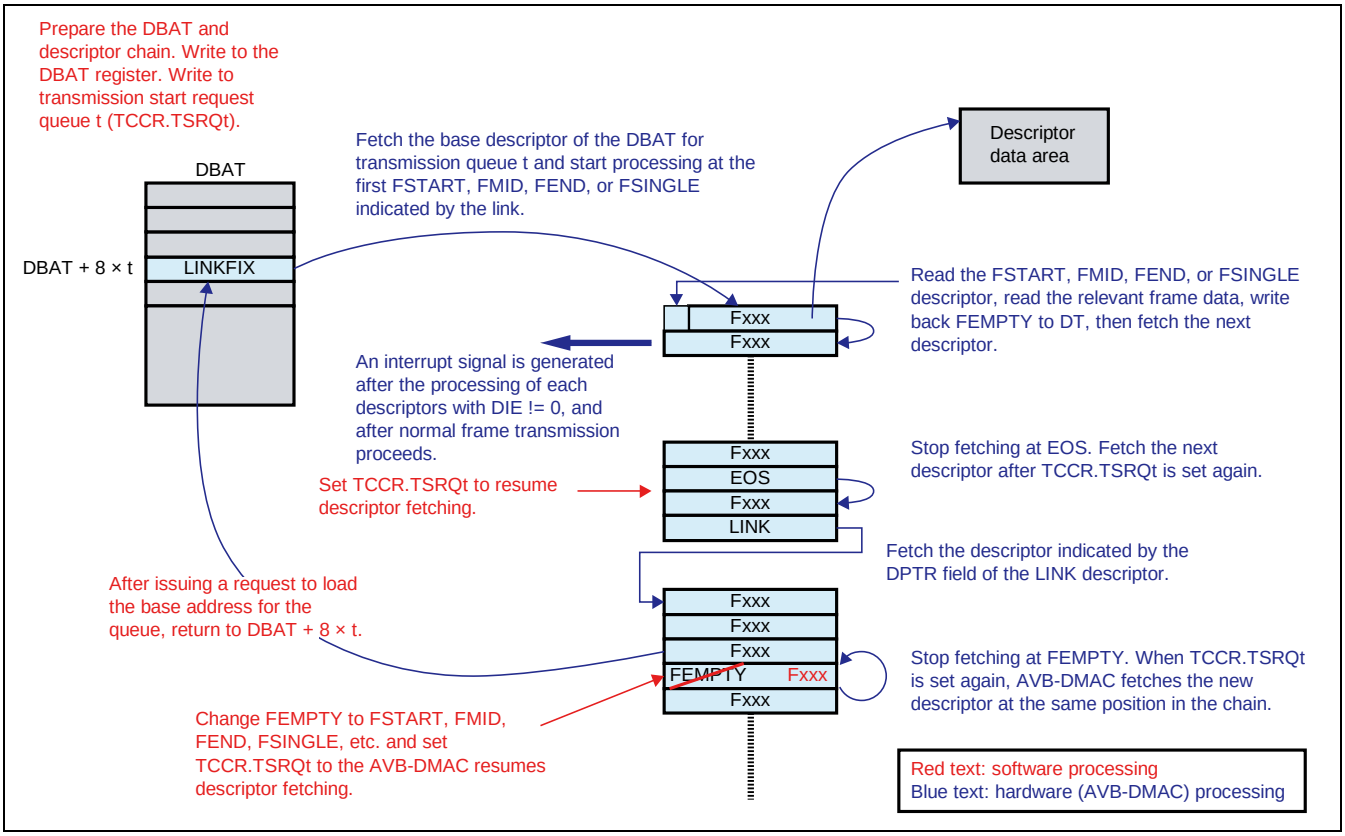

Figure 46.31 Descriptor Processing During Transmission

(b) Examples of Descriptor Usage

Immediate Frame Transmission

Immediate frame transmission is a pattern in which fetching by the AVB-DMAC starts whenever software adds data to a queue. FEMPTY descriptors are used as stop points to keep the hardware and software in synchronization.

Create descriptor chains that have FEMTPY descriptors at the stop points.

Figure 46.32 shows the flow for software implementing this pattern. SW should read back written descriptor between changing FEMPTY descriptor before writing to TCCR.TSRQt.

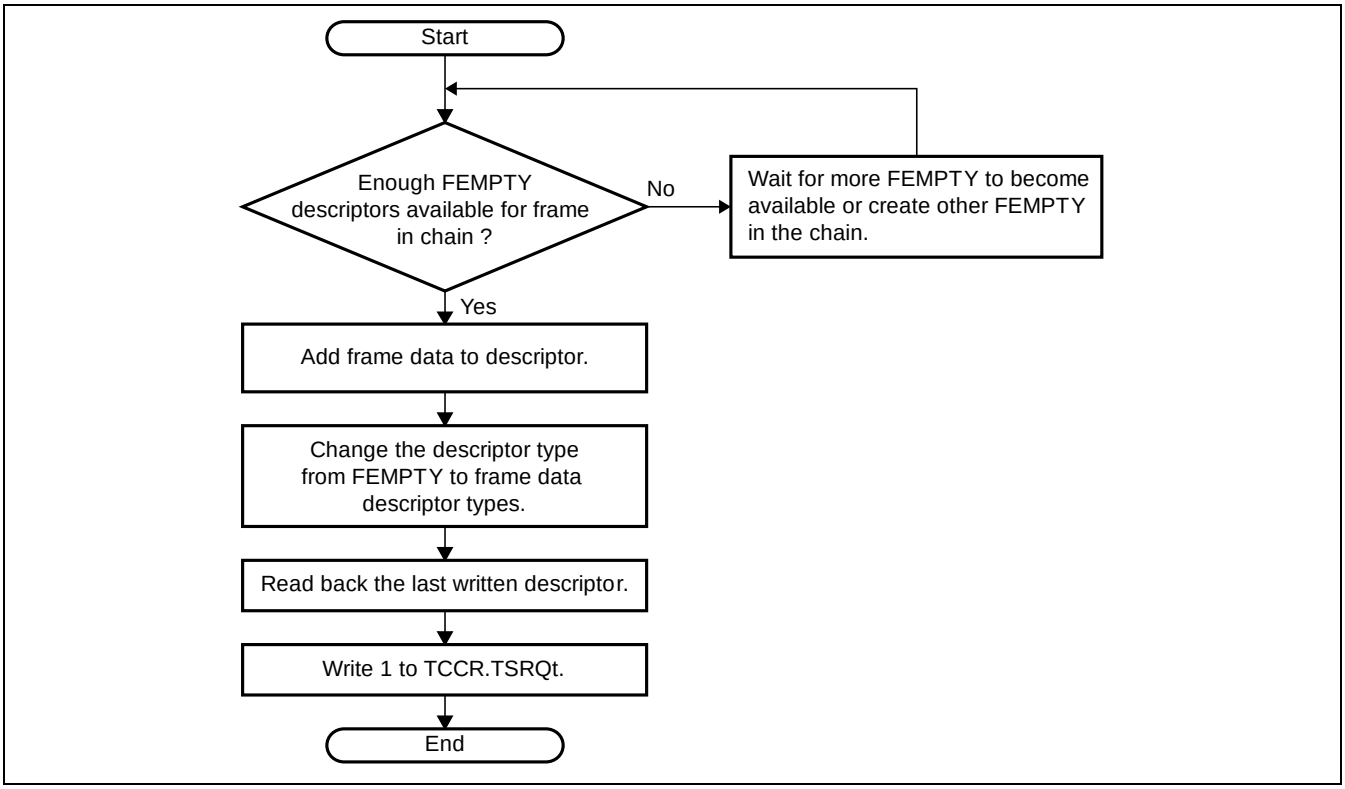

Figure 46.32 Software Flow for Immediate Frame Transmission

Figure 46.33 shows software and AVB-DMAC operations for immediate frame transmission.

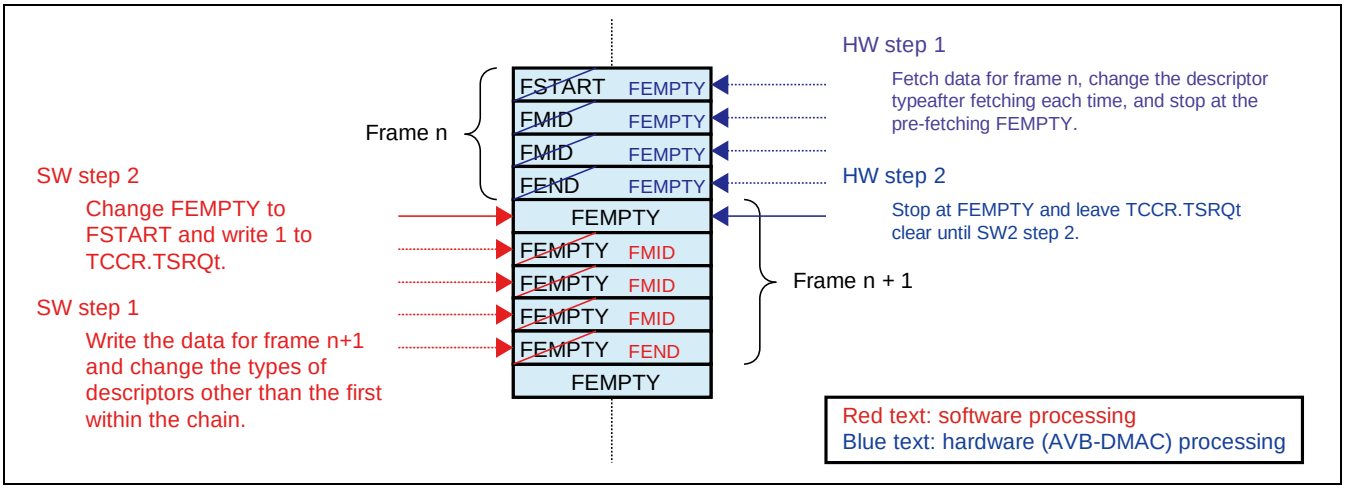

Figure 46.33 Software and AVB-DMAC Operations for Immediate Frame Transmission

Frame Set Transmission with Changing of the Active Descriptor Chain

This pattern is used when data are transmitted with a delay for software control to secure bandwidth or for other reasons, rather than immediately transmitted. EOS descriptors are used for the stop points. Start by creating a descriptor chain that has a FEMPTY descriptor as its stop point.

Figure 46.34 shows the software flow in this pattern.

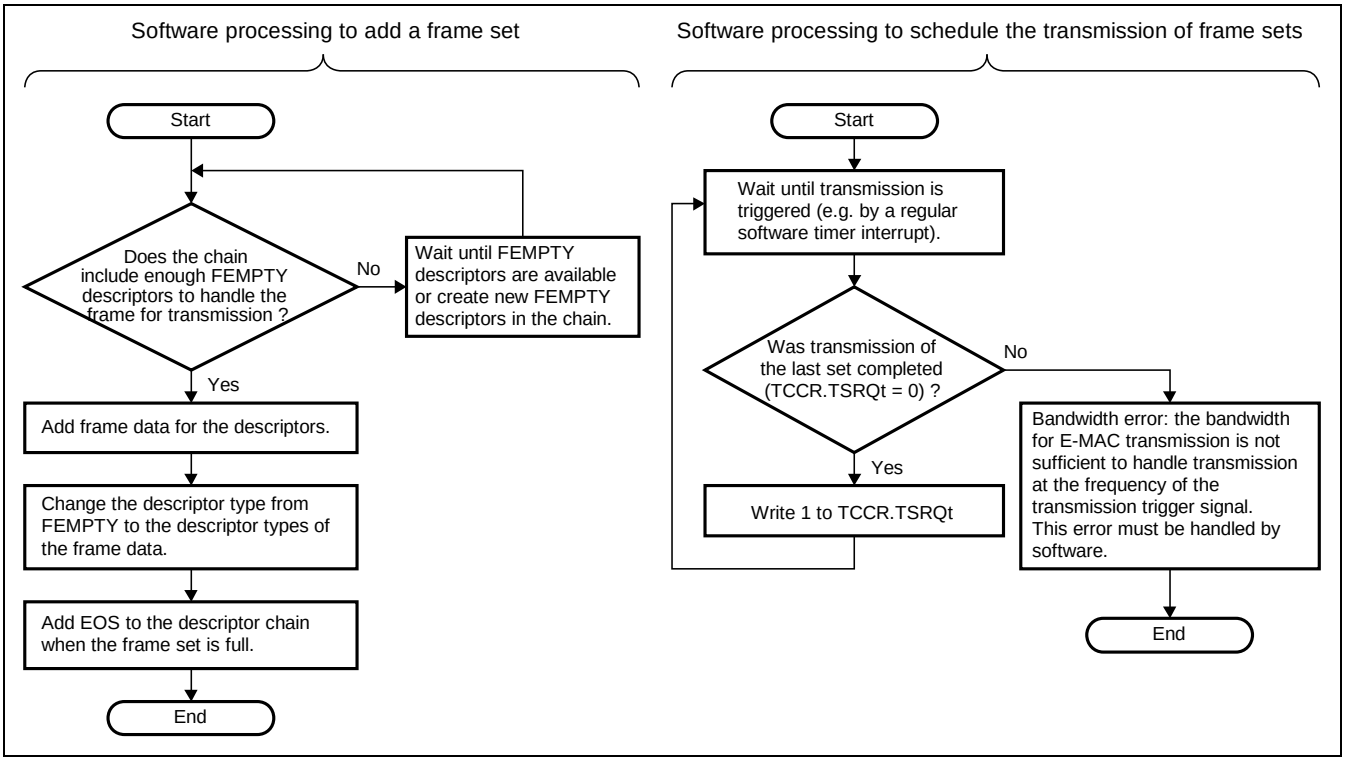

Figure 46.34 Software Flow for Frame Set Transmission with Changing of the Active Descriptor Chain

Figure 46.35 shows software and AVB-DMAC operations for frame set transmission.

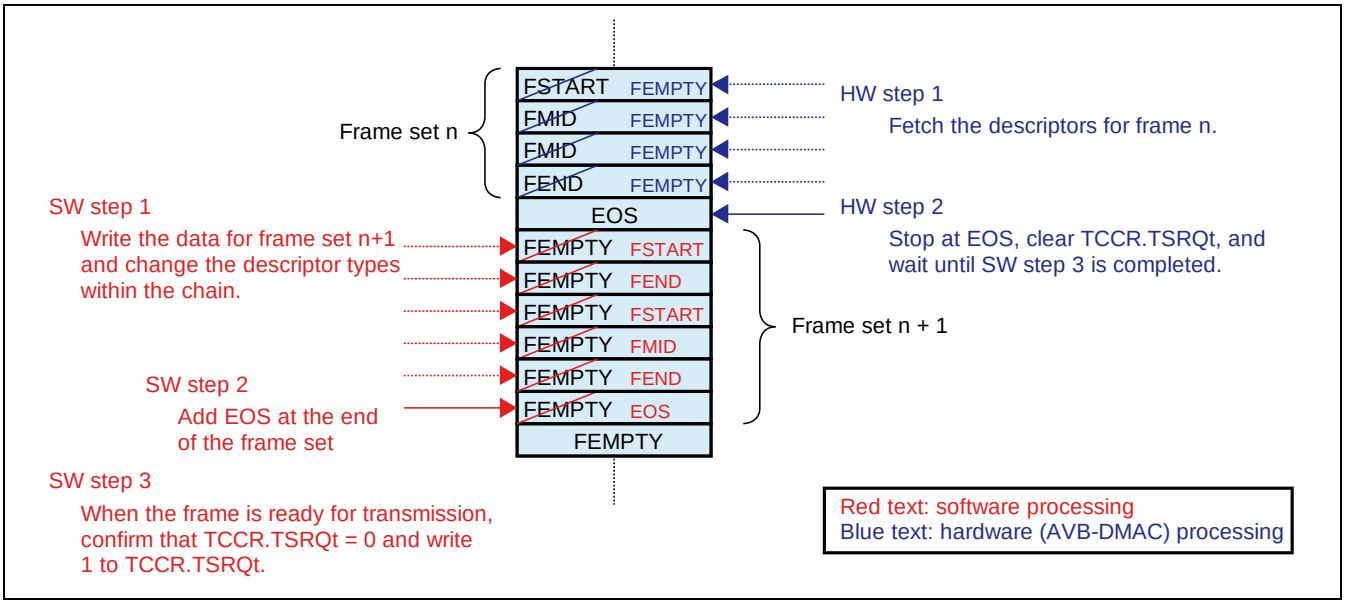

Figure 46.35 SW and AVB-DMAC Operations for Frame Set Transmission with Changing of the Active Descriptor Chain

Frame Set Transmission Using a Shadow Descriptor Chain

This pattern is used when data are transmitted with a delay for software control to secure bandwidth or for other reasons, rather than immediately transmitted. Two or more descriptor chains are used. The chains are classified as active or shadow chains. EOS descriptors are used for the stop points.

Create descriptor chains that have FEMPTY descriptors at the stop points.

Figure 46.36 shows the flow for software implementing this pattern.

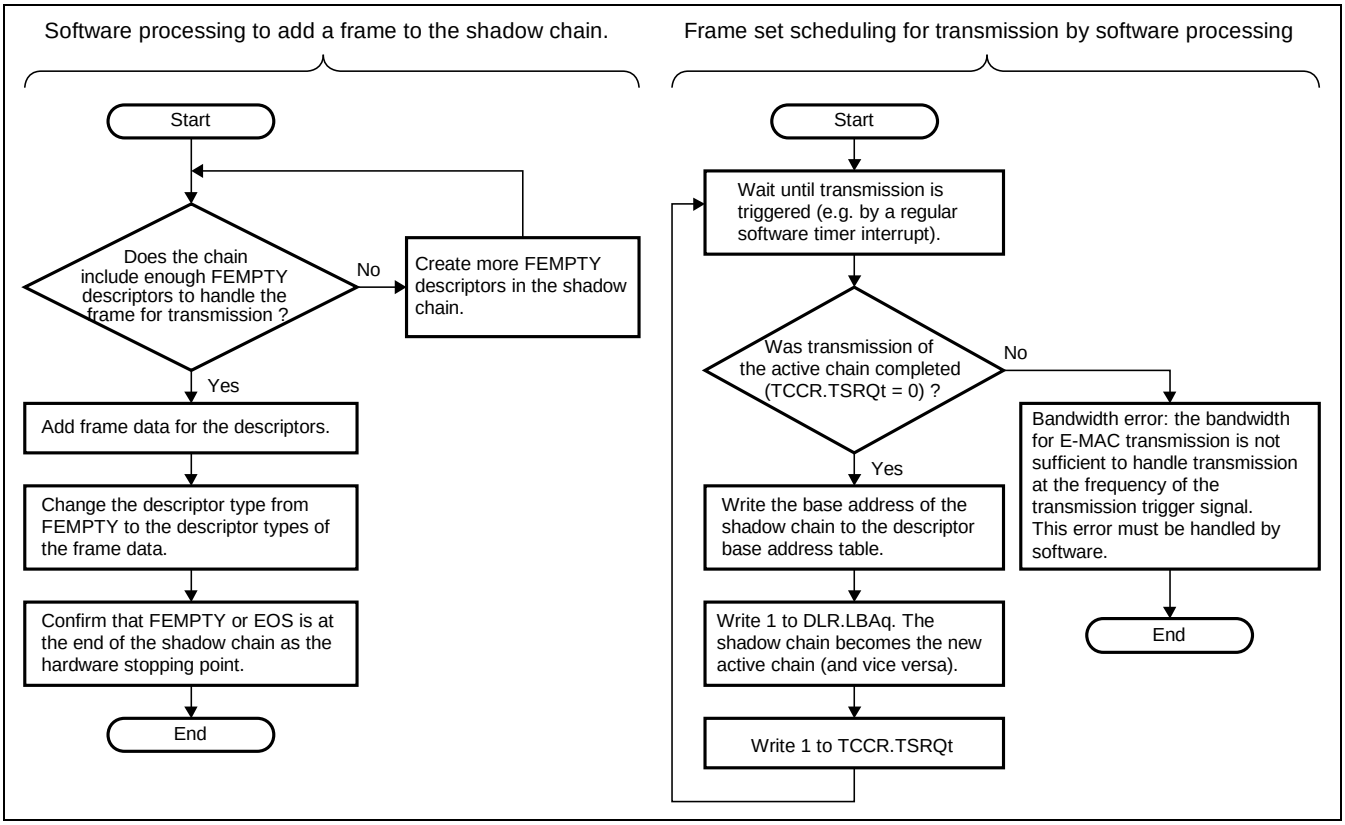

Figure 46.36 Software Flow for Frame Set Transmission Using the Shadow Descriptor Chain

Figure 46.37 shows software and AVB-DMAC operations for frame set transmission.

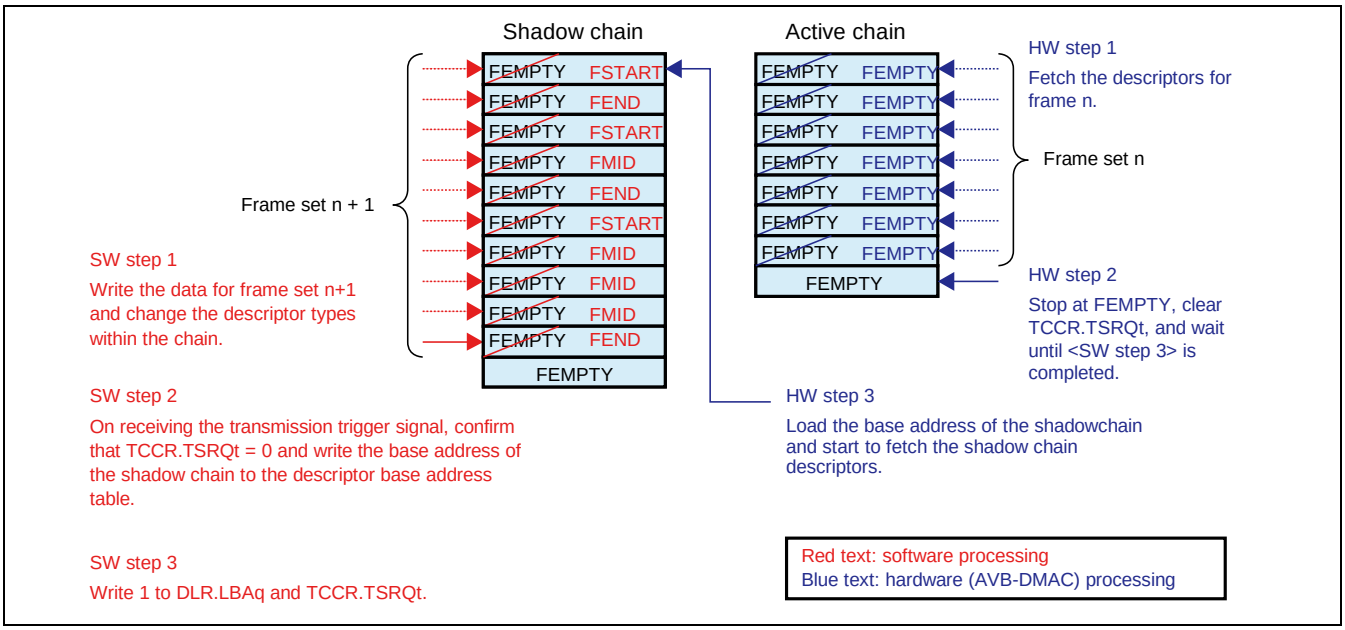

Figure 46.37 SW and AVB-DMAC Operations for Frame Set Transmission Using the Shadow Descriptor Chain

(4) Time Stamping in Transmission

Transmission time stamps are important in satisfying the requirements for timing and synchronization of the IEEE 802.1AS standard. Reference to this information can also be useful to other applications and in testing. The AVB-DMAC supports the storage of time stamps for transmitted frames. The time-stamp values are based on the gPTP timer and are captured at the same time as sending of the Start of Frame Delimiter (SFD) for transmitted frames.

When the time stamp storage request field (DESCR.TSR) is set to 1, selecting storage of a time stamp, the tag number defined in the tag field (DESCR.TAG) of the last descriptor (FEND or FSINGLE) for the frame being transmitted is stored with the time stamp. This eases identification and association. The time-stamp FIFO is accessible at any time.

Figure 46.38 shows the mechanism supporting transmission time stamping.

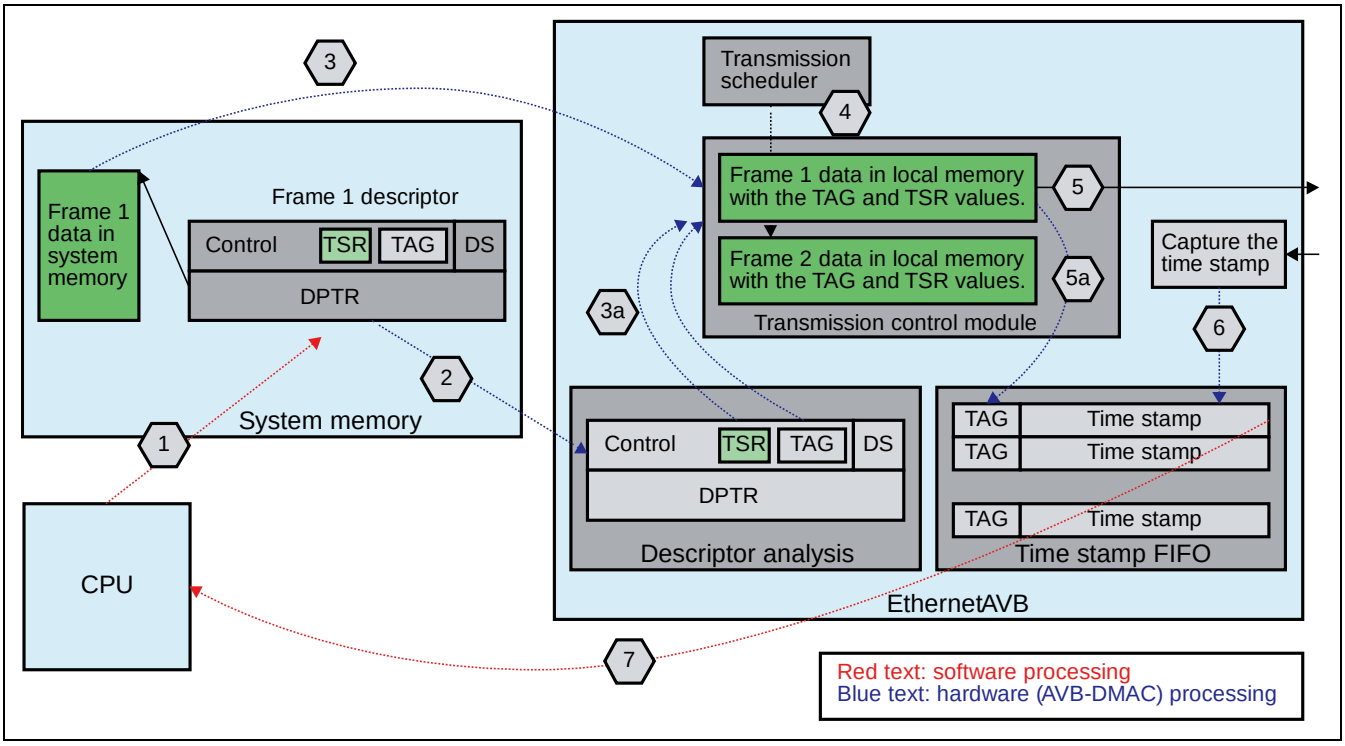

Figure 46.38 Mechanism to Support Transmission Time Stamps

The method of using this function is described below:

1. Secure space in the URAM for the frame requiring time stamping.
   Write the tag number of the frame to the frame tag field (DESCR.TAG) and set the time stamp storage request field (DESCR.TSR) to 1.
2. The AVB-DMAC fetches and analyzes the descriptor. The time stamp storage request field (DESCR.TSR) is 1, so it recognizes that transmitting this frame also requires storage of the time stamp.
3. The AVB-DMAC fetches the data for frame 1 and temporarily stores the frame in internal memory for scheduling.
   3a: The frame tag field (DESCR.TAG) and time stamp storage request field (DESCR.TSR) are stored with the fetched data.)
4. Under the control of priority settings according to credit-based shaping (CBS) or another scheme, the transmission scheduler decides it is time to transmit frame 1.
5. Transmission of frame 1 starts.
   5a: Frame 1's tag is stored in the time-stamp FIFO.
6. The gPTP time stamp is captured at the start of frame delimiter (SFD) for transmission and stored with the tag in the time-stamp FIFO when the frame is completely transmitted. An interrupt is generated to indicate existence of new timestamp information. For this to happen, the descriptor interrupt control register (DIC) must be set beforehand.
7. The entry can now be read from the time-stamp FIFO.

Use the time-stamp FIFO for the timing and synchronization of frames with IEEE 802.1AS compliance.

Time stamping can also be used with other frames, but take care not to allow the time-stamp FIFO to overflow. When the FIFO is full, further time stamps supplied to it are lost.

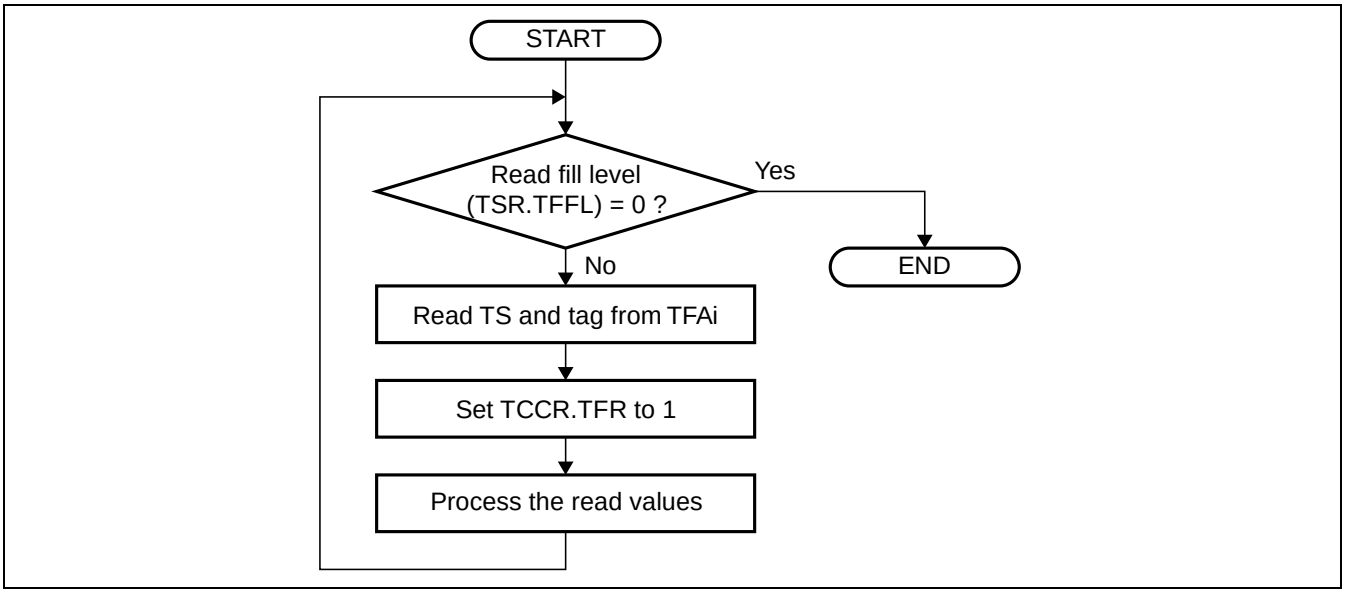

Figure 46.39 Flow of Transmission Time Stamping

(5) Ending Transmission

Figure 46.40 shows the procedure for ending transmission.

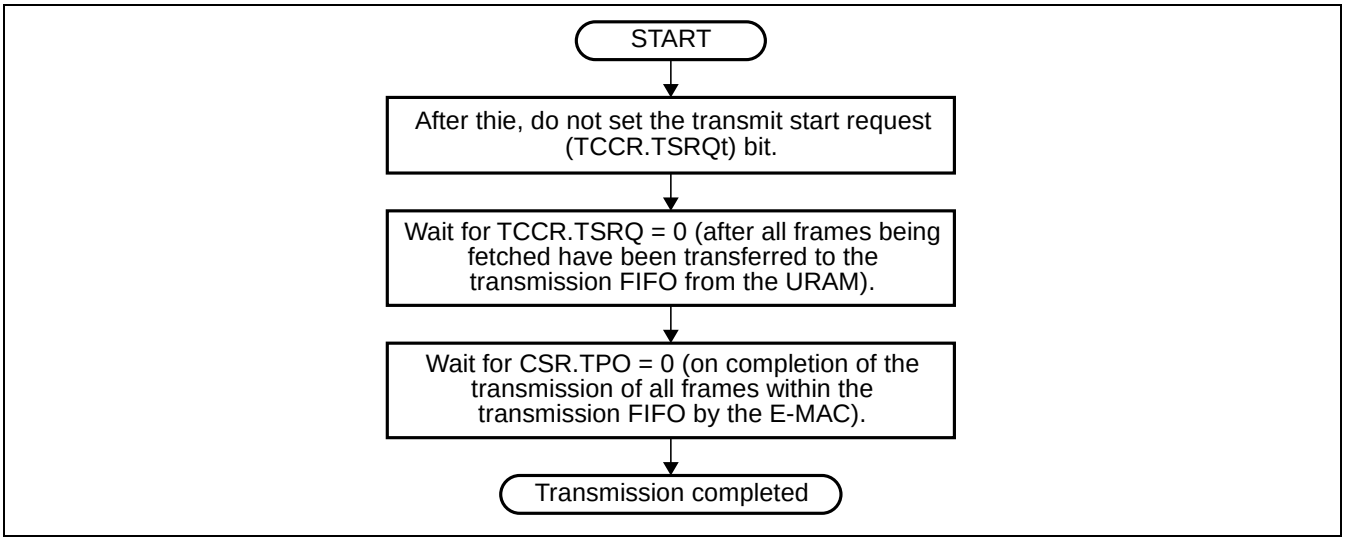

Figure 46.40 Procedures for Ending Transmission

46.3.6 CBS (Credit-Based Shaping)

In AVB transmission mode (i.e. when the transmit queue priority field in the transmit configuration register (TGC.TQP) is B'01 or B'11), transmission queues Q3 and Q2 are respectively assigned to class A and class B stream traffic and the CBS (Credit Based Shaping) algorithm is used to select the transmission queues in order to satisfy the Forwarding and Queuing for Time Sensitive Streams (FQTSS) specification (see section 11.6.8 or section 35 in IEEE 802.1Q).

The CBS algorithm is based on the concept of transmission credit for each queue. Credit can be thought of as the degree to which a queue has the “right” to transmit at a given time. Actually, in AVB transmission mode as specified in IEEE 802.1Q, queues that are subject to the CBS algorithm are able to transmit when the following conditions are met.

At least one frame is stored in the queue.

The credit for the queue is 0 or a positive value.

The credit for a transmission queue is incremented while one or more frames from the queue are present in the transmission FIFO but transmission of these frames is not proceeding. This state is indicated by the transmission process status bit for queue t in the AVB-DMAC status register (CSR.TPOt). The credit is decremented while transmission of a frame from the queue is in progress. This mechanism is used to control transmission so that the transmission of frames from the queues for each of the traffic classes does not exceed the specified maximum bandwidths.

IEEE 802.1Q defines the following parameters for queues under the control of the CBS algorithm.

portTransmitRate: Maximum transmission data rate of an external port. The E-MAC determines this parameter.

bandwidthFraction: Maximum fraction of portTransmitRate that can be used for a queue.

idleSlope: Rate of change of credit for a queue when transmission of frames from the queue is not proceeding so the credit value (in bits per second) is increasing. idleSlope is also equal to the maximum fraction of the total bandwidth (portTransmitRate) that is available to the given queue under a specified condition (frames from the queue can be placed in a continuous stream. See Annex L of IEEE 802.Q.
idleSlope = bandwidthFraction × portTransmitRate

sendSlope: Rate of change of credit for a queue while transmission of a frame from the queue is in progress so the credit value is decreasing.
The value of sendSlope is defined as follows:
sendSlope = idleSlope – portTransmitRate

Furthermore, the values below are used to define individual traffic classes (or queues for the classes) under control of the algorithm. See Annex L of IEEE 802.Q.

maxFrameSize: Maximum size of frames (in bits) of the corresponding traffic class that can be transmitted from a port

maxInterferenceSize: Maximum burst size (in bits) by which delays for the corresponding traffic class can be allowed

hiCredit: Maximum credit value (positive number). Can be calculated by using the following equation: hiCredit = maxInterferenceSize × (idleSlope / portTransmitRate)

loCredit: Minimum credit value (negative number). Can be calculated by using the following equation:
loCredit = maxFrameSize × (sendSlope / portTransmitRate)

Figure 46.41 shows how the CBS algorithm works and the meaning of the above parameters.

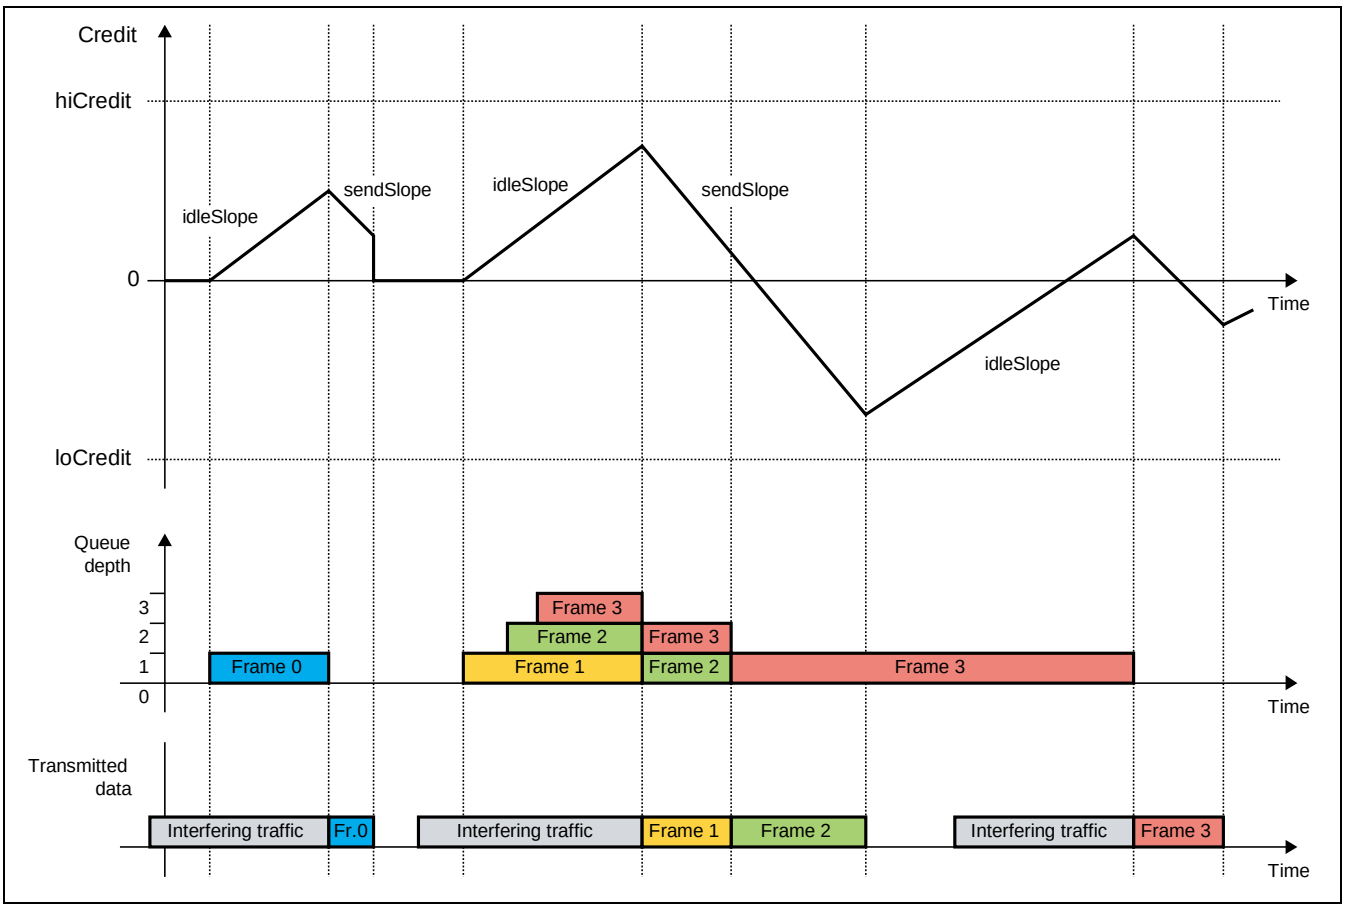

Figure 46.41 CBS (Credit-Based Shaping) Operation

Figure 46.42 shows the implementation of CBS in the AVB-DMAC.

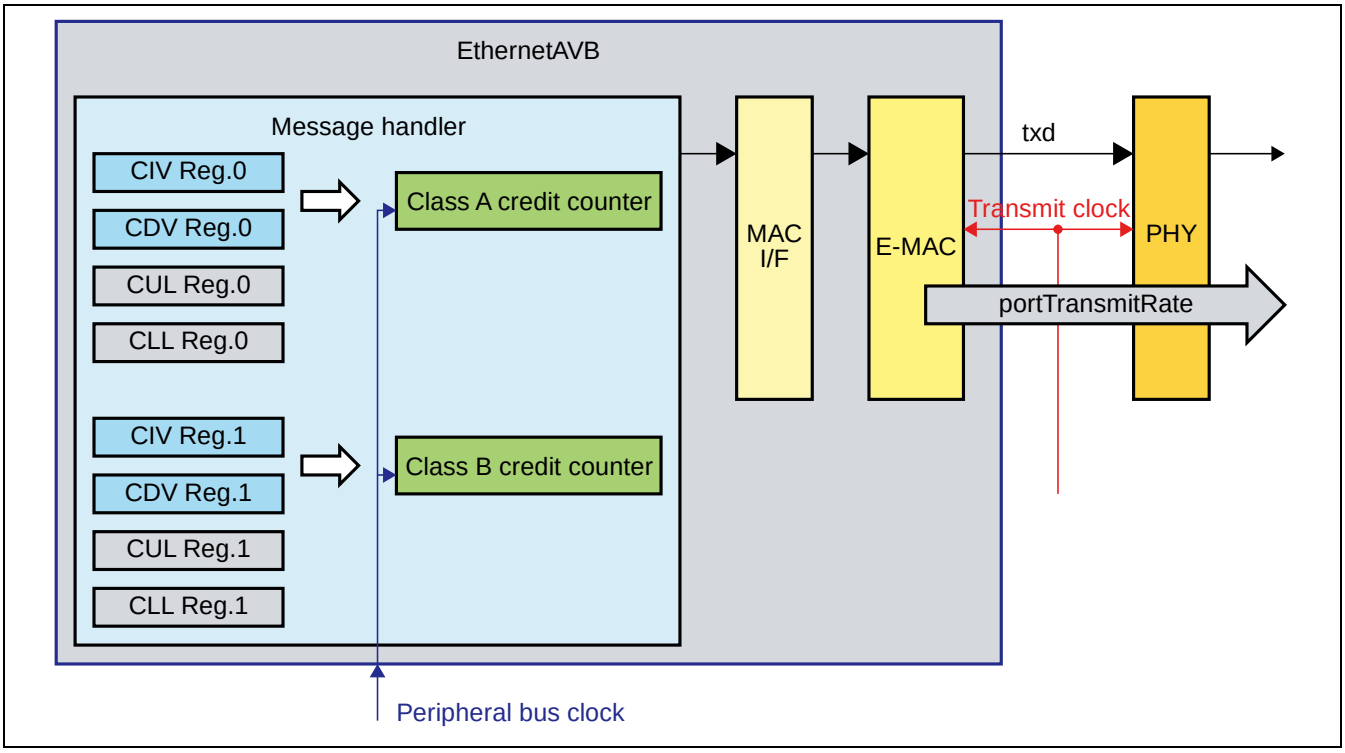

Figure 46.42 CBS (Credit-Based Shaping) Operation in the AVB-DMAC

The above implementation is based on “credit counters” for the respective traffic classes (SR class A and class B). The following parameters apply for these classes.

CBS increment value (CIV): Signed positive number
The credit is incremented by this amount every high-speed peripheral bus clock cycle while a frame from the queue is pending but transmission has not started (idleSlope).

CBS decrement value (CDV): Signed negative number
The credit is decremented by this amount every high-speed peripheral bus clock cycle while transmission of a frame from the queue is proceeding (sendSlope).

The CBS increment value (CIV) and CBS decrement value (CDV) are defined as follows.

CIV = idleSlope × Mfactor
CDV = sendSlope × Mfactor

Mfactor is a multiplier factor to ensure accuracy for CIV and CDV. CIV and CDV are calculated by using the following equations.

CIV = (portTransmitRate/HPϕ) × bwFraction × Mfactor
CDV = (portTransmitRate/HPϕ) × (bwFraction – 1) × Mfactor

HPϕ is the frequency of the high-speed peripheral bus clock. The credit counters are driven by the high-speed peripheral bus clock, so calculating the slope parameters for CBS requires (1/HPϕ).

Use software to prepare Mfactor for the CBS parameters. All queues for the same class must have the same Mfactor for all CBS parameters. Mfactor for a specified class c can be changed during operation, unless transmission is pending for that class (i.e. the transmit process status bit in the AVB-DMAC status register (CSR.TPOt) = 0). At that time, the credit counter values for class A and class B are 0. Note that the credit value will not match a new incrementation or decrementation parameter if Mfactor is changed while the credit counter value is non-zero. Mfactor is not present in the AVB-DMAC registers.

Set the CIV and CDV parameters in the CBS increment value registers (CIVRc) and the CBS decrement value registers (CDVRc). These are treated as dynamic settings since they should be updated when streams are registered and erased in accord with IEEE 802.1Qat.

The AVB-DMAC also has CBS upper limit registers (CULc) (the upper limit registers for classes A and B) and CBS lower limit registers (CLLc) (the lower limit registers for classes A and B). Set Mfactor to match the credit value and set the upper limit (hiCredit) and the lower limit (loCredit) for each class as defined above.

CUL = hiCredit × Mfactor = maxInterferenceSize × bwFraction × Mfactor
CLL = loCredit × Mfactor = maxFrameSize × (bwFraction – 1) × Mfactor

Example:

Assume that portTransmitRate = 100 Mbps, HPϕ = 133.33 MHz and bwFraction = 3%. Then idleSlope and sendSlope represented as one bit vs. cycles of the high-speed peripheral bus clock are as follows.

idleSlope = (portTransmitRate/HPϕ) × bwFraction = 100/133.33 (Mbps/MHz) × 3% = 0.023 bit per high-speed peripheral bus clock cycle
sendSlope = idleSlope – (portTransmitRate / HPϕ) = –0.727 bits per high-speed peripheral bus clock cycle
Let Mfactor be 100, then CIV and CDV parameters are determined as follows.

CIV = idleSlope × Mfactor = 2.3
CDV = sendSlope × Mfactor = –72.7

(1) Restrictions on CIV, CDV and Mfactor

The maximum value (the minimum value for negative numbers) up to which the credit counter will not overflow determines the maximum values of CIV and CDV that can be set in the CBS registers. This maximum credit value is equivalent to the worst case of the hiCredit value, and the maximum values for class A and class B are calculated as follows.

<Conditions>

- Class A maximum value (hiCredit_max_classA)
  classA bwFraction ≅ 100%
  Maintaining the proper relations in the transmission priority order requires waiting for a period equivalent to the maximum frame size.
  hiCredit_max_classA ≅ maxInterferenceSize for class A = Interference due to one max. sized frame = header + max. size payload + CRC (2000 bytes) + preamble (8 bytes) + IFG (12 bytes) + processing_delay (≅80 bytes) ≅ 2100 bytes
- Class B maximum value (hiCredit_max_classB)
  classB bwFraction ≅ 100%
  Maintaining the proper relations in the transmission priority order requires waiting for a period equivalent to the maximum size of frames in the class A transmission queue and other transmission queues.
  hiCredit_max_classB ≅ maxInterferenceSize for class B = Interference due to two max-size frames = 2 × hiCredit_max_classA ≅ 4200 bytes

hiCredit_max_classA = 16800

hiCredit_max_classB = 33600

The maximum values that can be selected with Mfactor for the 32-bit signed counter without overflow are:

Mfactor_max_classA = 2^{31}–1 / hiCredit_max_classA ≅ 127826 and
Mfactor_max_classB = 2^{31}–1 / hiCredit_max_classB ≅ 63913.

A high degree of accuracy can be achieved even with a low bandwidth. In class B, bandwidthFraction = 0.05% and the bandwidth error < 0.1%.

The maximum value of CIV is calculated from the following equation.

CIV = idleSlope x Mfactor = (portTransmitRate / HPϕ) × bandwidthFraction × Mfactor

When Mfactor is the maximum value and bandwidthFraction is the maximum value (up to 100%):

CIV_max_classA = (portTransmitRate / HPϕ) × Mfactor_max_classA and
CIV_max_classB = (portTransmitRate / HPϕ) × Mfactor_max_classB.

The maximum values when portTransmitRate = 1000 Mbps and HPϕ = 133.33 MHz are as follows:

CIV_max_classA ≅ 958719

CIV_max_classB ≅ 479359

These values in the table are the limits of CIV up to which the 32-bit credit counter will not overflow. The CIV parameters are implemented as 16 bits + a sign bit, so a further limit of CIV ≤ 65535 applies to both class A and class B.

(2) Credit Incrementation during Inter-Frame Gaps (IFGs)

The inter-frame gap (IFG) after a frame is transmitted is not treated as part of frame transmission by the CBS credit counter. During an IFG, the credit is incremented for all SR queues that have pending frames or negative credit. Figure 46.43 illustrates credit operations during IFGs.

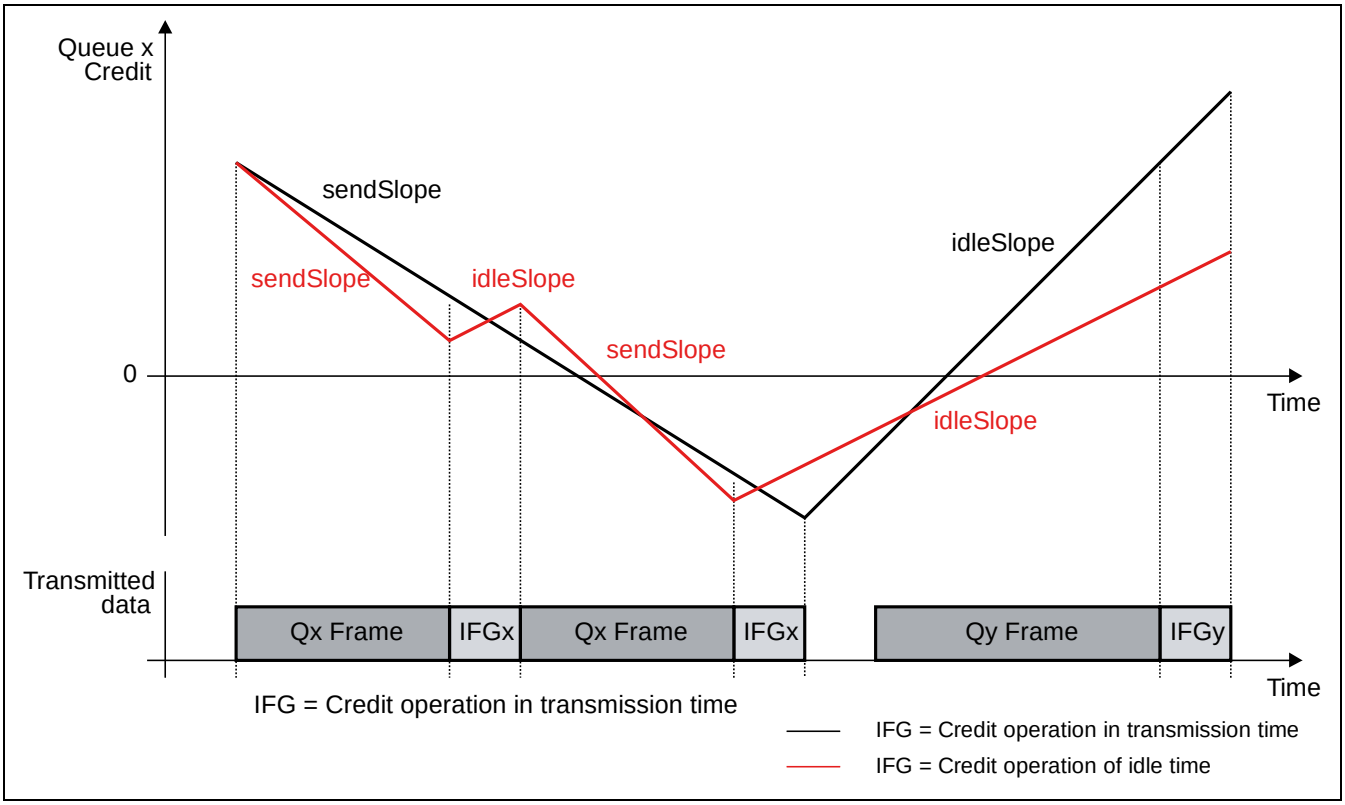

Figure 46.43 Credit Operations during IFGs

Accordingly, the IFG need not be included in calculation of the bandwidth requirements for the specified SR class when deciding the idleSlope, sendSlope, and CIV and CDV parameters. However, IFG must also be included in the calculation in order to confirm that the total bandwidth allocated to all SR classes does not exceed 100% of portTransmitRate. This is described in *Section 36.2.2.8.4* of *IEEE 802.1Q*.

(3) Example

The case of a class A 48-kHz stereo audio stream among Ethernet frames is described as an example.

After every class A measurement interval (125 µs), 80 octets consisting of two sets of six 32-bit samples plus a 32-octet header are stored as audio data within a frame. The IEEE 802.3 also imposes a 42-octet media-specific framing overhead (an 8-octet preamble, 14-octet IEEE 802.3 header, 4-octet IEEE 802.1Q priority/VID Tag, 4-octet CRC, and 12-octet IFG) are also added. Accordingly, the total frame size is 80 + 42 = 122, and one such frame is transmitted after every class measurement interval.

This represents a total bandwidth of about 7.8 Mbits per second (122 octets × 8 bits per octet × 8000 frames per second) for this class. If the E-MAC is assumed to run at 1 Gbps (portTransmitRate), this is equivalent to the allocation of about 0.78% of the total bandwidth to each class A queue. If other traffic classes are to share the total transmission bandwidth, checking that this 0.78% allocation does not lead to the total allocation of bandwidth being greater than 100% of portTransmitRate is required.

To obtain the CIV and CDV parameters for a given class, the IFG must not be taken into account in calculation of the frame size must not include the IFG. For this case, therefore, we obtain an 80-bit payload + 30-bit overhead = 110-octet measurement interval for the class → the total bandwidth for the class = 7.04 Mbps = 0.704% of portTransmitRate.

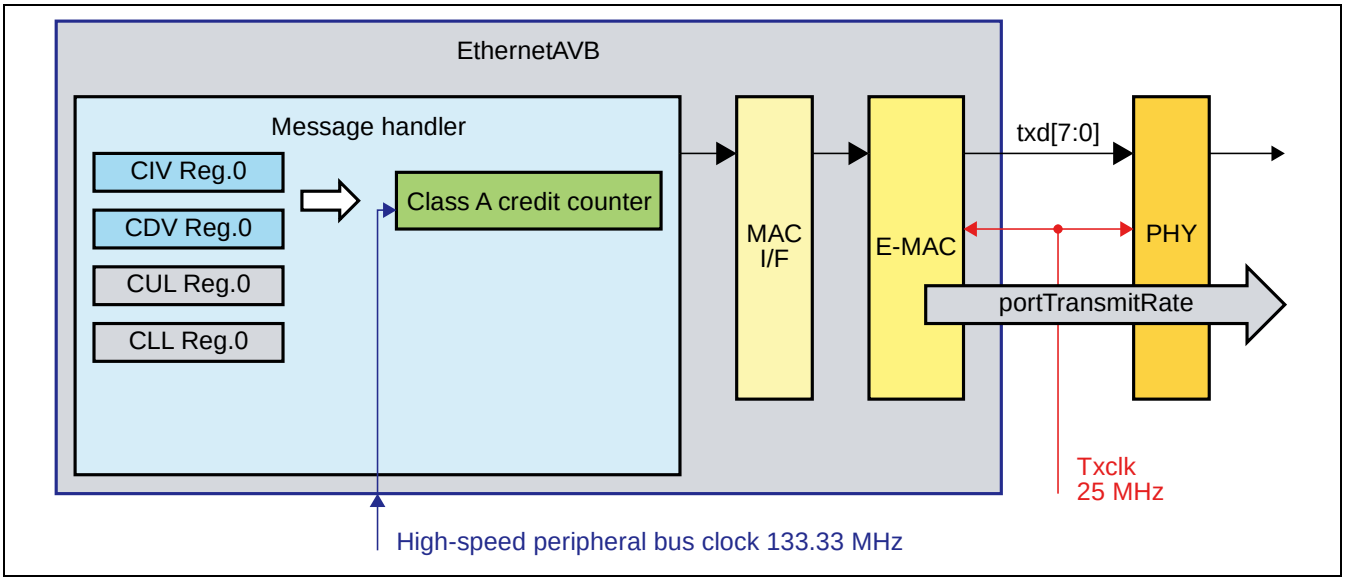

Figure 46.44 Example of CBS Settings

Given that:

- the E-MAC runs at 1000 Mbps, so portTransmitRate = 1000 Mbps and
- high-speed peripheral bus clock (operating clock for the credit counter) frequency = 133.33 MHz, securing a bandwidth of 7.04 Mbits/sec for class A requires configuring the CBS parameters as follows.
  bandwidthFraction = 0.704%
  idleSlope = (portTransmitRate / HPϕ) × bandwidthFraction ≅ 0.0528 bits per high-speed peripheral bus clock cycle
  sendSlope = idleSlope – (portTransmitRate / HPϕ) ≅ –7.44739 bits per high-speed peripheral bus clock cycle

When Mfactor = 100000, the parameters are as follows.

- CIV = idleSlope × Mfactor = 5280 bits per high-speed peripheral bus clock cycle
- CDV = sendSlope × Mfactor = 744739bits per high-speed peripheral bus clock cycle

These are the final values for setting in the CIVR1 and CDVR1 registers.

46.3.7 Time Synchronization

(1) gPTP Timer

An 84-bit timer is provided to support the gPTP function. Figure 46.45 shows the definitions of bits for the timer and in related registers.

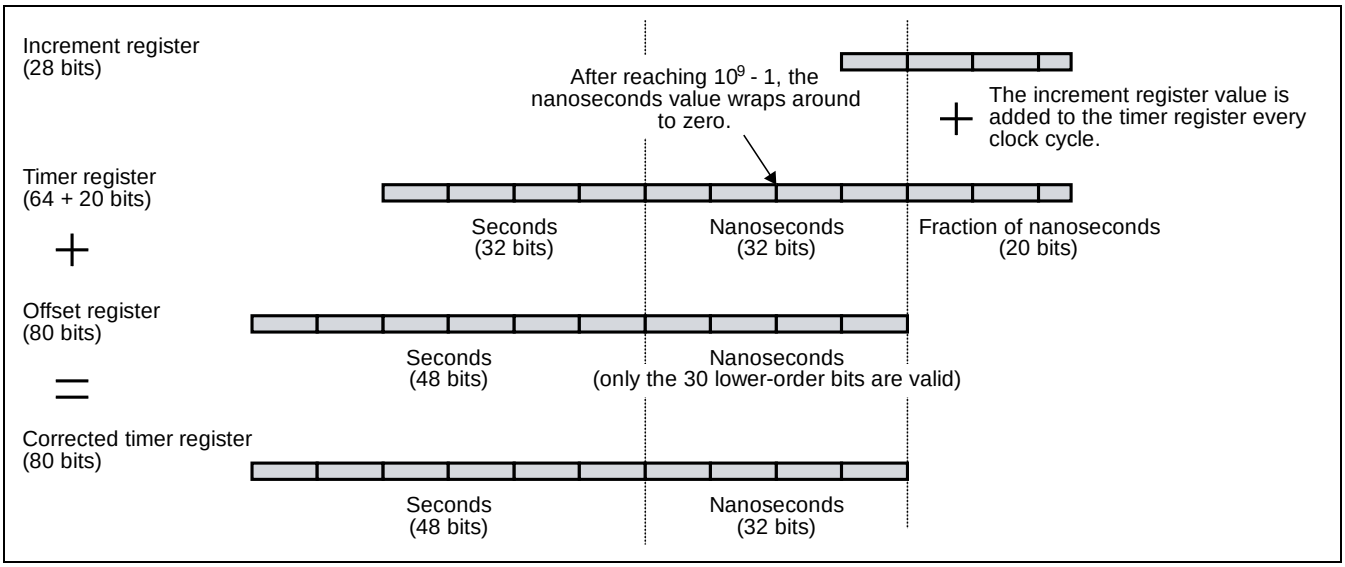

Figure 46.45 Definitions of gPTP Timer Bits and Related Bits

The higher-order 32 bits indicate seconds. For the next 32 bits, counting by one corresponds to the passage of 1 ns. The lower-order 20 bits are a fractional value (less than 1 ns). Software can only read the 32 higher-order bits, indicating seconds, and the subsequent 32-bits, indicating nanoseconds. The 20 lower-order 20 bits, representing less than 1 ns, are not readable. They are only used within the AVB-DMAC to maintain accuracy in time measurement.

The timer can be reset by setting the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) to B'01. These bits are set to B'00 on completion of normal resetting of the timer.

After the timer starts, the value in the gPTP timer increment register (GTI.TIV) is added to the value of the gPTP timer every clock cycle.

Before setting a value in the gPTP timer increment register (GTI.TIV), set the timer increment value setting request bit in the gPTP configuration control register (GCCR.LTI). If this bit is not set to 1, new values that are written will not be reflected in the register. This bit returns to 0 after the setting is completed.

An offset to the gPTP timer is also available. If this is required, set the value in the gPTP timer offset register (GTO.TOV). After setting a value in this register, set the timer offset value setting request bit in the gPTP configuration control register (GCCR.LTO). If this bit is not set to 1, new values that are written will not be reflected in the register. This bit returns to 0 after the setting is completed. When adding an offset, take care that it does not exceed 80 bits.

The value of the gPTP timer can be read from the gPTP timer capture register (GCTi.CTV). Set the timer capture source select bits in the gPTP configuration control register (TCCR.TCSS) to select the timer value for capture as the value of the gPTP timer, the corrected value of the gPTP timer (value with the offset added), or the AVTP presentation time. Setting the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) to B'11 initiates the capture. Once normal capture of the timer is complete, the value of the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) returns to B'00.

The timer for gPTP operates as a free-running timer but can be synchronized with the Grandmaster clock.

(2) Free-Running Operation

The IEEE 802.1 AS standard for timing and synchronization does not prescribe the physical adjustment of local clocks to the Grandmaster clock. To avoid negative effects from the correction procedure, we recommend the use of a free-running timer.

As a free-running timer, the timer counts the local time in seconds or nanoseconds. The gPTP timer increment register (GTI.TIV) is set to 1 ns (the setting value = H'0010_0000) and the gPTP timer offset register (GTOi.TOV) is set to 0. The ratio information captured at the time of the gPTP delay measurement and synchronization procedures is used to correct the frequency ratio to that of the Grandmaster clock. The Grandmaster clock can be calculated from the local clock by using the information collected during the gPTP measurement and synchronization procedures.

(3) Synchronization with the Grandmaster Clock

In situations requiring physical synchronization of the local clock with the Grandmaster clock, the fractional nanoseconds value (the 20 lower-order bits of the gPTP timer) is used to make the adjustment. Specifically, the increment value is finely adjusted to correct for deviations of the clock frequency from that of the Grandmaster clock.

Use the timer offset value (in the gPTP timer offset registers, GTOi.TOV) to correct for offsets from the theoretical value (at start-up, etc.). The sum of the timer value and the offset register is the “corrected timer” value.

Note that for the nanoseconds part of the Offset register GTOi.TOV[31:0] should be below 10^9.

The following equation gives a method of calculating the increment (GTI.TIV) from the frequency of the gPTP clock and its deviation from that of the Grandmaster clock. Variable d is the deviation (d = 10^{-6} for 1 ppm).

$$GTI.TIV = round\left(\frac{2^{20}\,GHz}{f_{GPTP}} \times (1 + d)\right)$$

After adjusting for the current deviation of clock frequency, reset the gPTP timer increment register (GTI.TIV).

After calculating the new offset value, reset the gPTP timer offset register (GTOi.TOV).

(4) Continuous AVTP capture

CPU can request a selected timer value by setting bit GCCR.TCR to B'11. GCCR.TCSS determines which of the three values:

- gPTP Timer value,
- Corrected Timer value or
- AVTP Timer value

is captured in GCTi.CTV. GCCR.TCR is set to B'00 after capturing the related timer value.
Successful capturing operation can be confirmed by checking GCCR.TCR is B'00.

By setting GCCR.TCR to B'10 continuous AVTP timer value capture is activated. In this mode CPU has always access to current AVTP value by reading GCTi.CTV[31:0].

Flow to enter continuous AVTP capture mode:

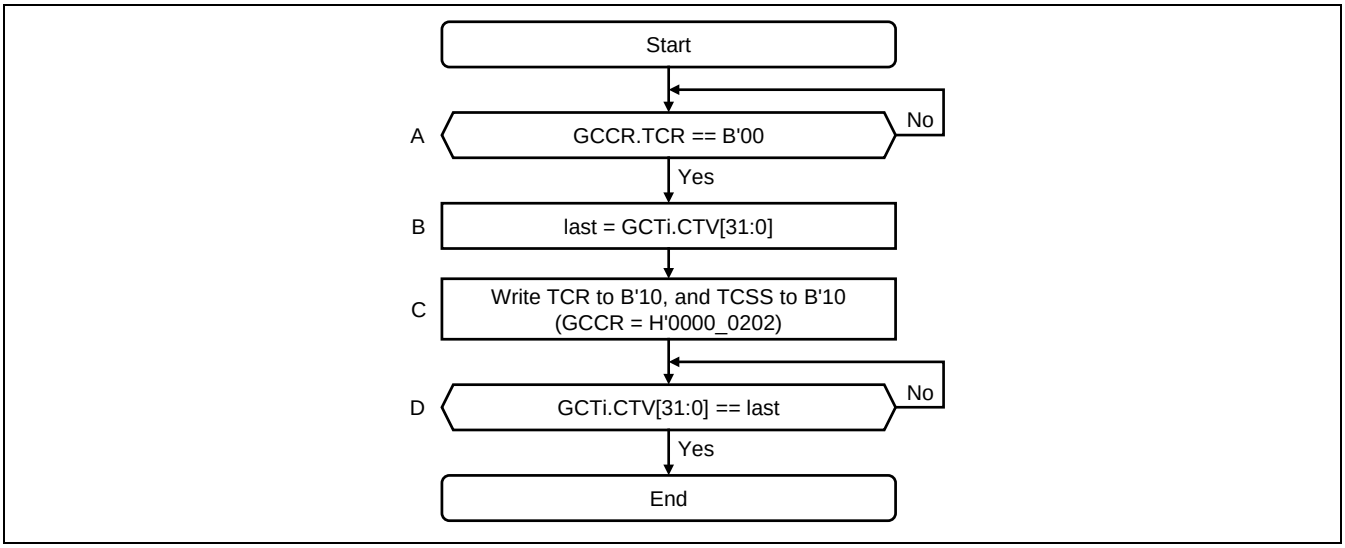

Figure 46.46 SW flow entering continuous AVTP capture mode

Flow to leave continuous AVTP capture mode:

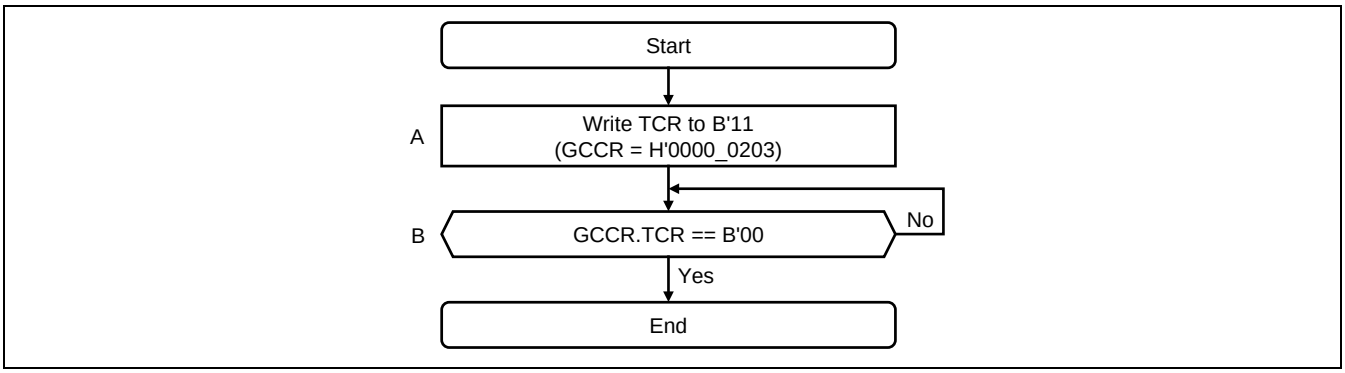

Figure 46.47 SW flow leaving continuous AVTP capture mode

(5) Support Provided by the gPTP Timer in Transmission and Reception

The timer value described above is used in the time-stamp values captured when start frame delimiters are detected in reception and generated in transmission at PHY interface.

Captured time stamp values for received frames are stored in the corresponding descriptors. Those for transmitted frames are stored with tag information in the time-stamp FIFO. The time stamp values are thus correlated with both transmitted and received frames.

Note that the use of corrected timer values can introduce an error due to the offset correction in the gPTP synchronization procedure.

Due to asynchronous interface between the SFD notification and the timer modules, errors must also be taken into account.

46.3.8 Support for IEEE 1722

For IEEE 1722, the following two functions are supported.

- Output and capture of values in the IEEE 1722 AVTP (Audio/Video Transport Protocol) presentation time format
- Comparison of IEEE 1722 AVTP presentation time stamps

The 32-bit AVTP time stamp field of IEEE 1722 frames holds the AVTP presentation time when the AVTP time-stamp enable bit in the frame is 1. The AVTP time stamp field is generated from the gPTP timer and is given as seconds (gPTP_seconds) and nanoseconds (gPTP_nanoseconds) according to the following equation.

AVTP time stamp = (gPTP_seconds $\times 10^9$ + gPTP_nanoseconds) modulo 2^{32}

The AVTP presentation time can be read from the gPTP timer capture register (GCTi.CTV). Set the timer capture source select bits in the gPTP configuration control register (GCCR.TCSS) to select the timer value for capture as the AVTP presentation time. Setting the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) to B'11 initiates the capture. The value is obtained by adding the maximum transit time defined in the gPTP maximum transit time register (GMTT.MTTV) to the corrected timer value. The AVTP presentation time wraps around approximately every four seconds.

Note: The AVTP presentation time captured in GCTi.CTV is only valid when the corrected timer value is in synchronization with the Grandmaster clock. That is, the timer increment and timer offset values for the corrected timer value must be adjusted during the synchronization procedure so that the corrected gPTP clock is physically adjusted to match the time kept by the Grandmaster clock.

(1) AVTP capture(HW)

EthernetAVB-IF provides 17 units to capture AVTP based on external events.

Table 46.17 to Table 46.20 lists the assignment of the EthernetAVB-IF capture unit.

Table 46.17 Capture unit assignment for RZ/G2H

avb_pt_capture[15]	VSYNC	DU1	Vsync signal from DU module
avb_pt_capture[16]	VSYNC	DU3	Vsync signal from DU module

To allow proper detection of the edges of avb_pt_capture[i] signal, a pulse equal to or longer than 3 peripheral bus clock cycles should be provided on this input to trigger AVTP capture. Also SW should limit frequency of external capturing signal; period should be at least (6 peripheral bus clock periods + 3 gPTP periods).

There are two variants of capture units in EthernetAVB-IF:

- First one captures AVTP presentation time (including max transit time) and have overflow flagging.
- Second one captures AVTP timer value (without max transit timing) and have prescaler.

The AVTP capture units provides always the first captured value until SW has acknowledged reading of this value.

(a) AVTP presentation time capture unit

EthernetAVB-IF provides one capture unit of this functionality.

When a rising edge is applied to avb_pt_capture[0], AVTP presentation time is captured to GCPT.CPTV and the interrupt flag GIS.PTCF is set to 1.

The captured value includes the configured max transit time value.

Capture of a new AVTP presentation time is suppressed until CPU acknowledges processing of the captured value by setting GIS.PTCF to 0. GIS.PTOF informs about one or more lost capture events.

(b) AVTP timer capture unit

EthernetAVB-IF provides sixteen capture unit (i = 0 to 15) of this functionality.

Each N-times when a rising edge is applied to avb_pt_capture[i+1], AVTP timer value is captured to GCATi.CATV and the interrupt flag GIS.ATCFi is set to 1. The prescaler factor N is configured by GACP register for each unit individually.

The captured value does not include the configured max transit time value.

Capture of a new AVTP timer value is suppressed until CPU acknowledges processing of the captured value by setting GIS.ATCFi to 0.

(c) Prescaler configuration

CPU should use this flow to configure prescaler value of capture unit i:

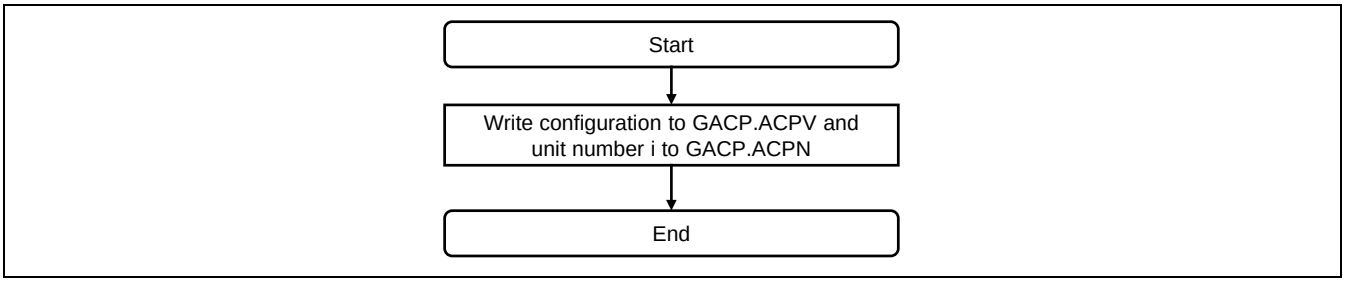

Figure 46.48 SW flow to program prescaler value of capture unit

This figure illustrates prescaler function of AVTP timer capture unit. The prescaler is free running, there is no visible relation which capture pulse triggers capturing of AVTP timer. When prescaler value is reconfigured, there may be one capturing based on old prescaler configuration.

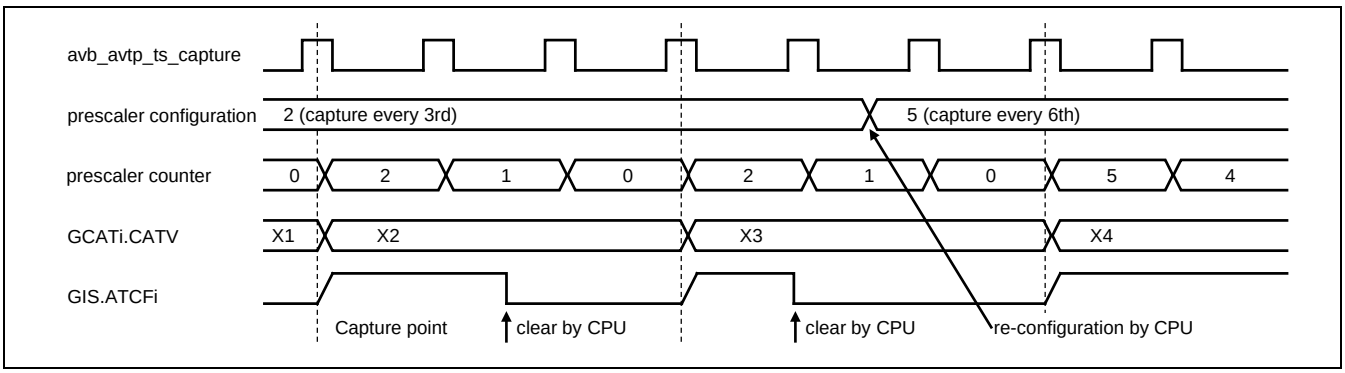

Figure 46.49 Example of capture timing when prescaler value is reconfigured

It is recommended not to change prescaler value again before there is at least one match related to previous prescaler value flagged by GIS.ATCFi.

(2) AVTP compare

EthernetAVB-IF provides 8 independent AVTP compare units. Each unit is able to handle single shot comparison as well as periodic comparison. GSR.PCMi informs about the current mode of unit i. To 4 units (0 to 3) the single shot compare value can provided via AVTP-FIFO to relax timing requirements to application SW.

When the AVTP Presentation Time value has reached or exceeded the configured comparison value the interrupt flag GIS.PTMFi is set to 1.
And Comparison unit 0, a pulse of one or four High speed Peripheral clock cycle is applied to AVB_AVTP_MATCH.

The configured max transit time value is not taken in count when comparing.

SW should ensure that configured comparison value is well in future to take into account SW inaccuracy.

SW should ensure that comparison value is not too far in future (more than 2 seconds) with respect to current AVTP timer value to guarantee comparison functionality.

When writing to GCCR, SW can use a 32 bit access if GCCR.TCSS is written to B'11 and all other bits not required for comparison value programming are written to 0.

(a) Single shot compare

An AVTP compare unit used in single shot mode generates exactly one match after CPU programs the comparison value.

CPU should use this flow to program absolute comparison values in single shot mode:

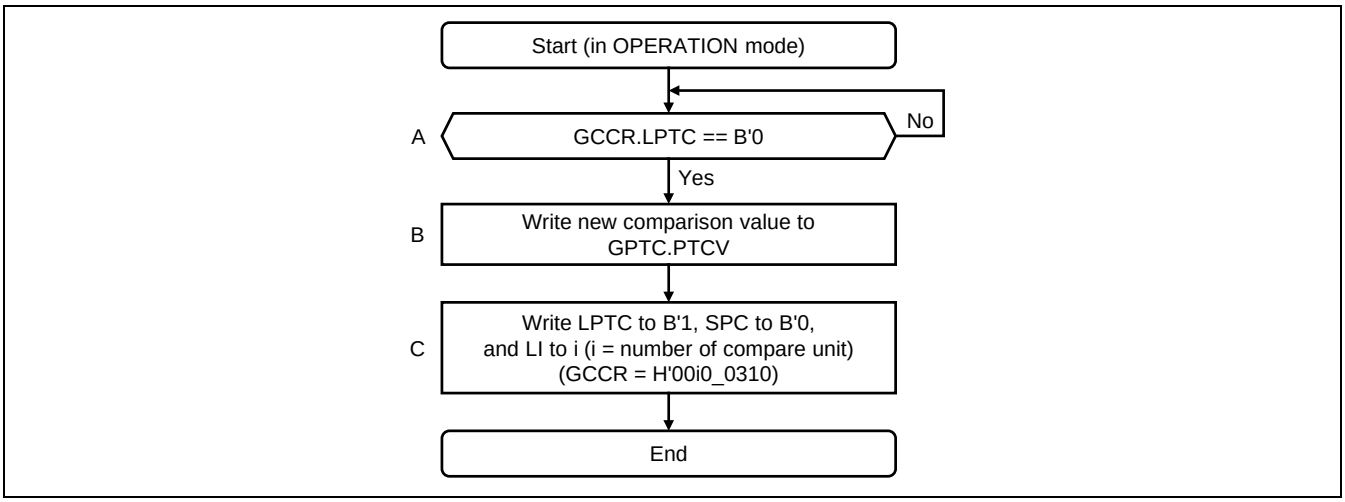

Figure 46.50 SW flow to program a single shot compare value

(b) Periodic compare

An AVTP compare unit used in periodic compare mode generates matches of configured period until CPU disables periodic mode. Optional it is possible to define the initial phase before repetition starts.

CPU should use this flow to start periodic compare mode or to change period value:

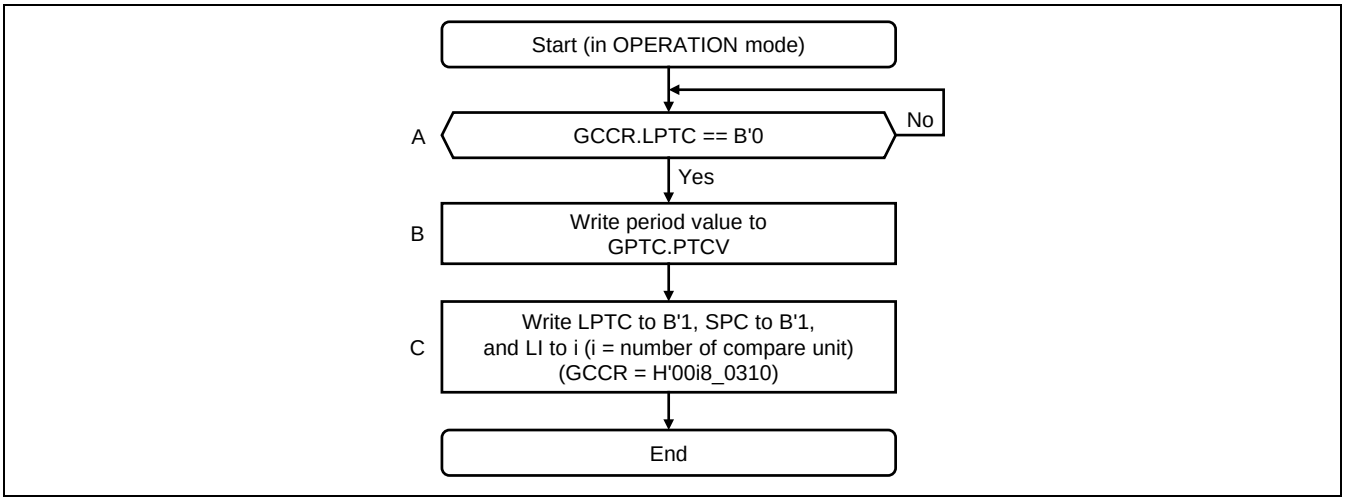

Figure 46.51 SW flow to program period value (without phase relation)

Some application may require phase relation between periodical match events generated by different units. In this case the next flow can be used to enter periodic compare mode with phase relation. A compare unit will only start a period when there is no pending comparison. If the absolute starting point of all units (box B in flow) is well in future the period of all units start at the same time (e.g. 48 kHz on unit 1 and 96 kHz on unit 2).

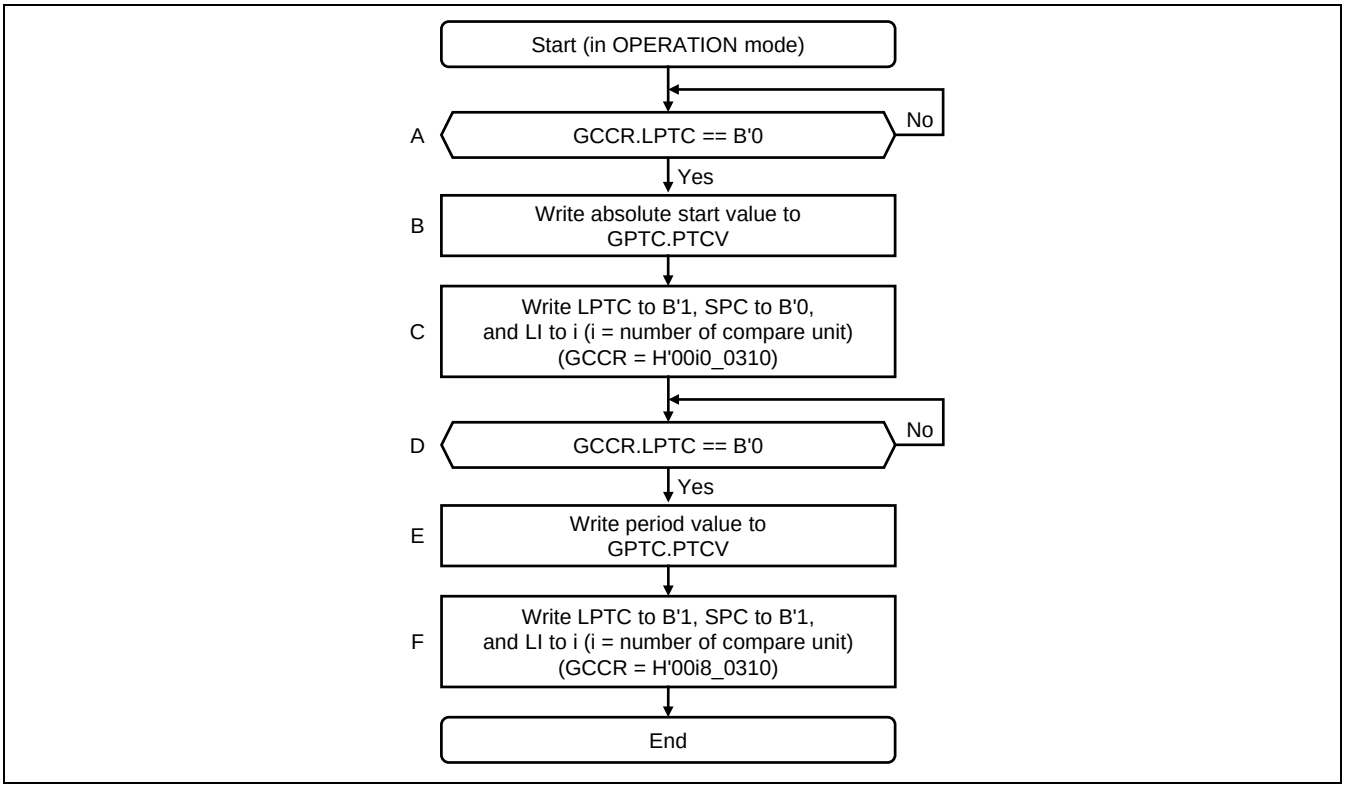

Figure 46.52 SW flow to program period value (with phase relation)

The periodic mode is left by entering single-shot mode. Do not write new comparison value in GPTC.PTCV for changing mode as shown in flow below, this value will not be used as new comparison value.

CPU should use this flow to leave periodic compare mode:

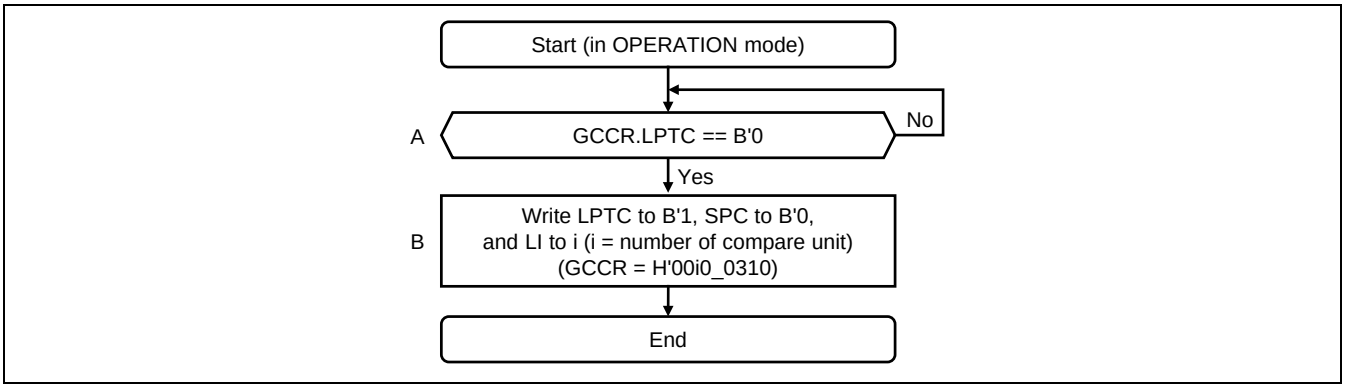

Figure 46.53 SW flow to end period mode

The last periodical comparison happens after Point B in SW flow. EthernetAVB-IF leaves periodic mode after last periodical comparison happens. This is flagged by GSR.PCMi. Comparison unit can only be reused after GCR.PCMi is 0.

(c) FIFO based single-shot comparison

Some comparison units provides the possibility to use timestamps from a FIFO. To use this possibility CPU writes AVTP timestamp to GPTFi instead of GPTC. By writing to GPTFi the value is added to FIFO, no load is required but CPU needs to check if AVTP-FIFO is able to accept new values.

FIFO usage may reduce CPU load because CPU can program a bunch of timestamps at same time.

When there is no comparison ongoing in AVTP compare unit, the next value from AVTP-FIFO is loaded and comparison starts. If the FIFO is empty no value is loaded and no further match event is generated.

When moving from single-shot comparison to FIFO based single-shot comparison, the 1st FIFO value is immediately loaded independent of an ongoing comparison.

By reading GSR.AFFLi CPU can observe number of pending timestamps.

CPU should use this flow to add timestamps to the AVTP-FIFO of compare unit. If FIFO depth is insufficient, FIFO size should be extended in SW (box E).

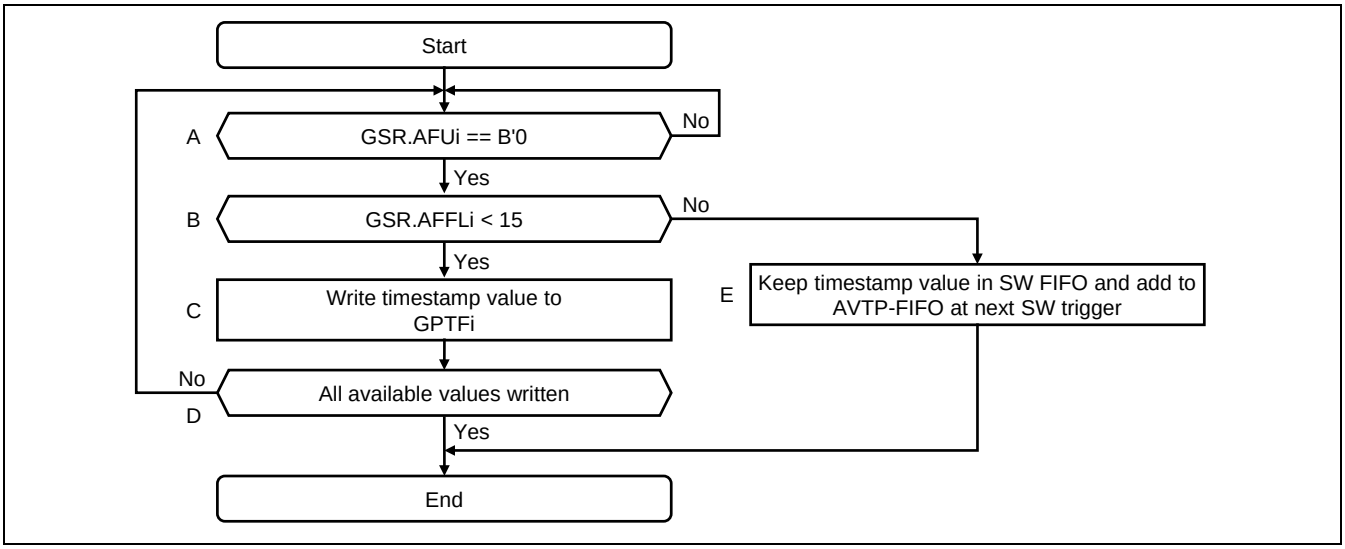

Figure 46.54 SW flow to add timestamp to AVTP-FIFO

It is recommended to combine box A and B into one access to limit accesses to GSR register.

(3) Pulse per second

EthernetAVB-IF provides by AVB_AVTP_PPS a pulse signal, which is generated at carryover of the nanosecond part of timer.

By GCCR.PGM it is selectable if the carryover of the gPTP timer (B'0) or the corrected gPTP timer (B'1) is used.

The pulse has a length of 32 gPTP clock cycles.

The CPU should not configure an offset correction value of 0 when using the corrected gPTP timer as source (GCCR.PGM is 1) for pulse per second function.

Note: A pulse may be lost or added when using the corrected gPTP timer as source and changing the offset value.

(a) Changing pulse per second source

When gPTP timer functionality is used in CONFIG mode (CCC.GAC is 1), following flow should be used to change pulse per second source by GCCR.PGM. When CCC.GAC is 0, CPU can change GCCR.PGM at any time.

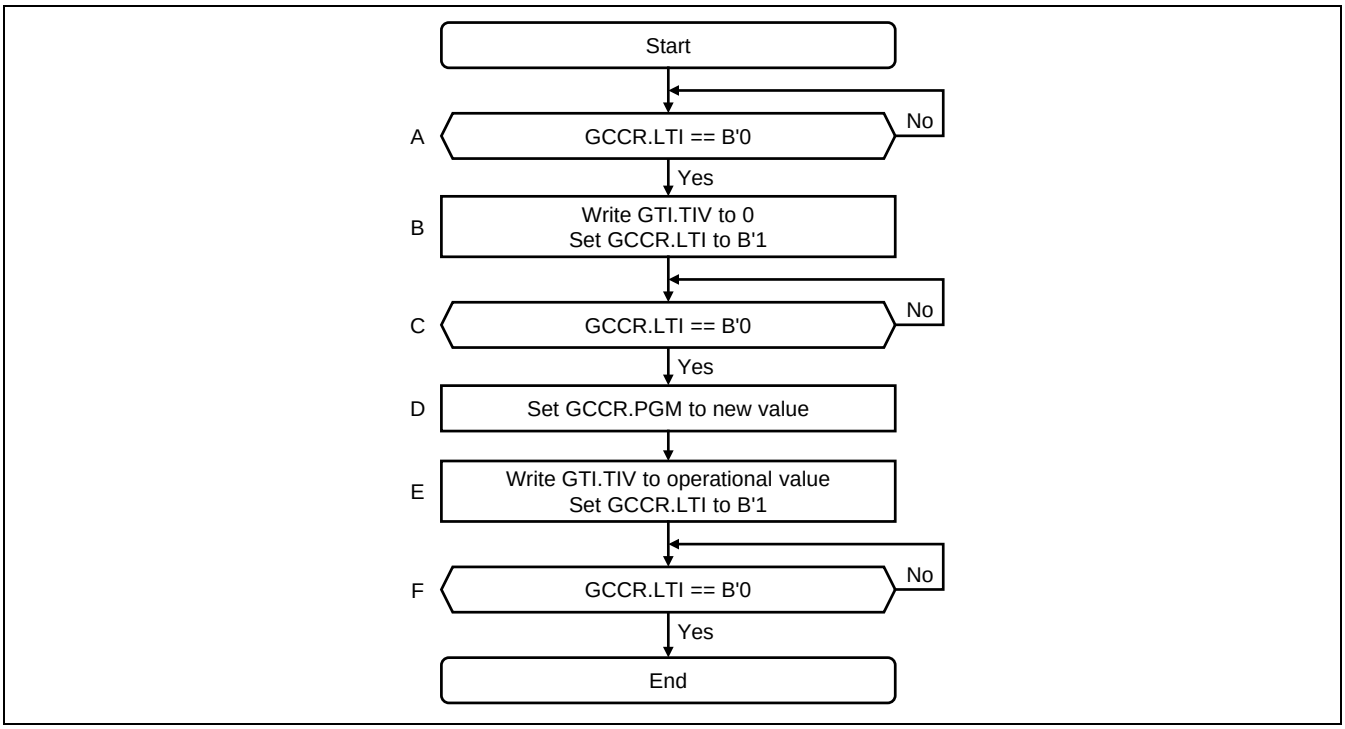

Figure 46.55 SW flow to change GCCR.PGM when CCC.GAC is 1

The increment value of 0 in box B intentionally violates SW restriction of GTI.TIV.

To limit side effects to other gPTP functions 8 bit access to GCCR should be used in box B and E.

EthernetAVB-IF does not guarantee that value read from GTI.TIV is same value as increment value used by timer. Due to this it is recommended, to use in box E. the increment value intended by SW.

(4) gPTP timer functionality in CONFIG mode

When CCC.GAC is 1, it is possible to use some gPTP functions in CONFIG mode. Because the frame handling mechanisms are not available in CONFIG mode, usage of gPTP support is restricted. Only basic timer functions of gPTP support can be used:

- gPTP timer is running based on selected clock source (CCC.CSEL),
- Offset and increment value can be configured and adjusted
- SW capture function (timer, corrected timer, AVTP)
- HW capture function (AVTP)
- SW compare function

Note: There is SW flow required to change pule per second source when gPTP timer is used in CONFIG mode. See section 46.3.8(3)(a) for details.

When AVTP FIFO functionality is used in CONFIG mode, there is no error flagging by ESR.ET = B'1011 available. CPU can use error flagging by external RAM protection directly, there are no other read accesses to RAM by EthernetAVB-IF.

46.3.9 Flow Control

The EthernetAVB-IF does not support flow control in the specification. Flow control is only effective when transmitting and receiving only normal (non-AVB) packets.

The E-MAC supports flow control for full-duplex operation in compliance with the IEEE 802.3 standards. This flow control is applicable to both reception and transmission. In regard to the transmission of PAUSE frames, flow control operates in the following ways.

(1) PAUSE Frame Transmission

PAUSE frames can also be transmitted in response to software operations. Writing a timer value to the manual PAUSE frame register (MPR) starts the transmission of a PAUSE frame. This only causes the transmission of one PAUSE frame.

(2) PAUSE Frame Reception

After reception of a PAUSE frame, transmission of the next frame does not proceed until the time indicated by the Timer value elapses. However, transmission of a frame currently being transmitted continues. PAUSE frames are only received while the RXF bit in the E-MAC mode register (ECMR) is set to 1. The number of received PAUSE frames is counted.

(3) PAUSE Frames with the Timer Value 0

The setting of the 0-time PAUSE frame enable bit (ECMR.ZPF) enables or disables the reception of PAUSE frames with the TIME parameter value 0.

- When control of PAUSE frames with the TIME parameter value 0 is disabled

  PAUSE frames with the TIME parameter value 0 are not transmitted. Received PAUSE frames with the TIME parameter value 0 are discarded.

46.3.10 Magic Packet Detection

The E-MAC has a Magic Packet detection function. This function provides a facility for host devices and other sources to start other peripheral devices connected to a LAN. A peripheral device that handles Magic Packets starts itself in response to receiving a Magic Packet.

When a Magic Packet is detected, data from broadcast packets that were previously being received are stored in the FIFO and the E-MAC is notified of the receiving status. To return to normal operation from the associated interrupt processing, the E-MAC and AVB-DMAC must be initialized by using the operating mode configuration bit in the AVB-DMAC mode register (CCC.OPC) to set the operating mode to reset mode.

Magic Packets are received regardless of the destination address. As a result, the AVB_MAGIC pin is only enabled in the case of a match with the destination address specified in the Magic Packet.

The procedure for using the Magic Packet detection function with this LSI chip is as follows.

1. Use the various interrupt enabling and masking registers to disable the output of interrupts from interrupt sources.
2. Set the Magic Packet detection enable bit in the E-MAC mode register (ECMR.MPDE).
3. Set the Magic Packet detection interrupt enable bit in the E-MAC interrupt enable register (ECSIPR.MPDIP) to enable the interrupt.
4. Place the CPU in sleep mode as required.
5. An interrupt is conveyed to the CPU on detection of a Magic Packet.
6. The AVB_MAGIC pin notifies connected devices of Magic Packet detection.

Note: The Magic Packet detection interrupt status can be read in the E-MAC status register (ECSR.MPD). The bit can be cleared by setting the E-MAC status register Magic Packet™ detection bit (ECSR.MPD) to 1.

But EthernetAVB-IF can’t detect 2nd or later Magic Packet™ and the AVB_MAGIC pin can be negated though the bit is cleared.

The AVB_MAGIC pin can be negated and EthernetAVB-IF can detect MAGIC Packet™ again according to below way.

1) Hardware reset — set reset pin in the RZ/G series to reset signal.
2) Software reset — set mstp/srst register for EthernetAVB-IF to software reset mode.
3) Software reset register in AVB — set AVB DMAC mode register Operating Mode Configuration bits (CCC.OPC) to reset mode.

46.3.11 Interrupts

The EthernetAVB-IF is capable of generating 25 interrupt (RZ/G2M V1.3, RZ/G2M V3.0).
The EthernetAVB-IF is capable of generating 27 interrupt (without RZ/G2M V1.3, RZ/G2M V3.0).

For details, refer to the “Interrupt Controller” section in the manual.

The interrupts of EthernetAVB-IF are indicated by individual flags DIS, EIS, RISi, TIS, and GIS. Each interrupt is controllable by the corresponding interrupt enable bit. The status flags are independent from this enable bits.

Additionally grouped interrupt status available in ISS and EIS.QFS. The summary status allows CPU to locate the interrupt source with a minimum number of read accesses to EthernetAVB-IF.

EthernetAVB-IF interrupts are combined to 4 groups of interrupt lines for request an interrupt service by CPU. Interrupt requests in group 0 and 1 are only generated in OPERATION mode. Interrupt requests in group 2 are only generated in OPERATION mode and in CONFIG mode if gPTP support is enabled (CCC.GAC). Interrupt request on line 3 depends on E-MAC configuration and can be generated in CONFIG, OPERATION and STANDBY mode.

Interrupt lines are level output and each line is asserted when at least one of the interrupt status registers bits belonging to the group associated with that line is set to 1, and the corresponding enable bit in the related interrupt control register is also set to 1.

For ISS bits the combined flag/enable is used. The green dots in detailed interrupt figures in detailed interrupt line description illustrates the point where status information for ISS is taken.

(1) Concurrent interrupt enable support

The interrupt enable bits can be directly modified by writing the interrupt control registers (**xxC.yyE**). If concurrent processes enable/disable interrupts located in same interrupt control register inter-process communication is required. To reduce SW overhead there are dedicated registers available controlling conflict free enable/disable of interrupts.

To enable an interrupt CPU should write 1 to the corresponding bit (xxE.yyS) in the enable register. Because written 0 have no effect, there is no side effect to concurrent processes.

To disable an interrupt CPU should write 1 to the corresponding bit (xxD.yyD) in the disable register. Because written 0 have no effect, there is no side effect to concurrent processes.

The current interrupt enable status is readable in xxC.yyE.

Grouping of interrupts for each interrupt line is as described in following sub-chapters.

(2) Group 0 (Data related interrupts)

This group consists on:

Frame received interrupts RIS0.FRFr (for each received frame stored in URAM)

Receive warning interrupts RIS1.RWFr (when Unread Frame Counter reaches warning level)

Descriptor processed interrupts RIS3.RDPFr (for reception) Frame transmitted interrupts TIS.FTFt (for completion of frame transmission by E-MAC)

Descriptor processed interrupts TIS.TDPFr (for transmission)

Descriptor processed interrupts DIS.DPFi (for reception and transmission)

By reading ISS, CPU get an overview of all data related interrupts (ISS.FRM, ISS.RWM, ISS.DPMi, ISS.FTM).

Interrupt group 0 consists on these 24 interrupt lines:

Line0_Rx[17:0]

Line0_Tx[3:0]

Line0_DiA (Share the interrupt line: Group0.Line0_DiA, Group1.Line1_A, Group2.Line2_A)

Line0_DiB (Share the interrupt line: Group0.Line0_DiB, Group1.Line1_B, Group2.Line2_B)

(a) Reception interrupts

There are 18 dedicated interrupt lines flagging frame reception. For the queue full flag it is configurable by CIE.RQFM if these notification are part of the queue specific reception interrupt lines or part of the error interrupt lines (group 1).

There is a common interrupt enable (CIE.CRIE) for all reception lines.

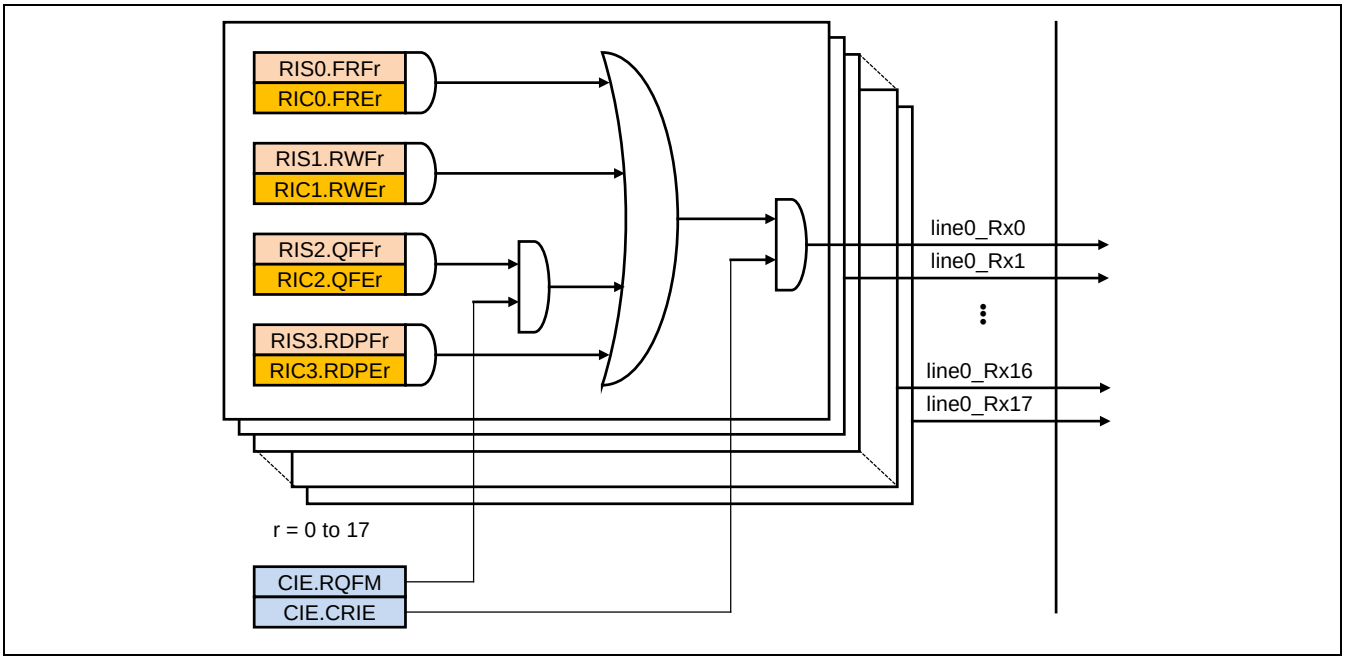

Figure 46.56 Interrupt group 0, reception interrupt lines

(b) Transmission interrupts

There are 4 dedicated interrupt lines flagging frame transmission.

There is a common interrupt enable (CIE.CTIE) for all reception lines.

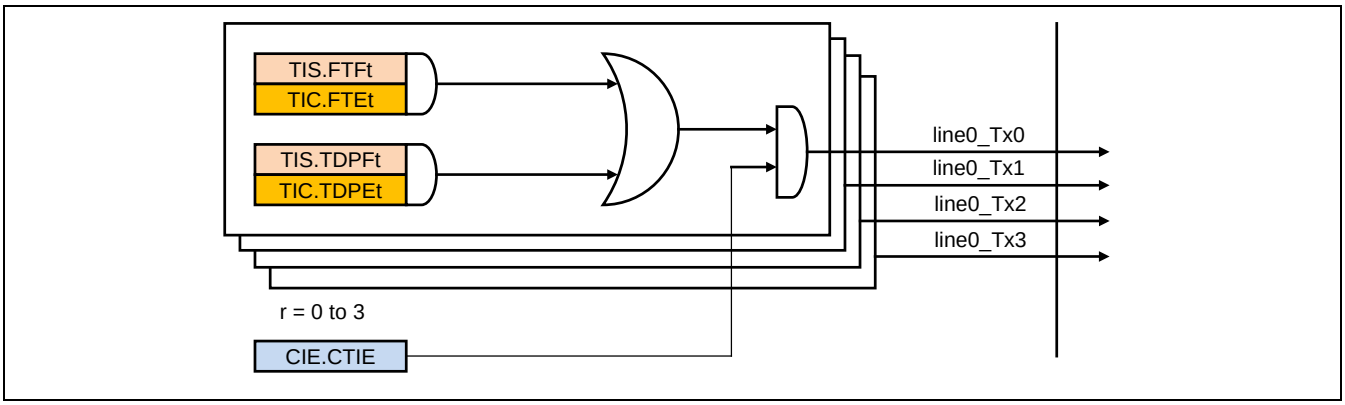

Figure 46.57 Interrupt group 0, transmission interrupt lines

(c) Descriptor and merged interrupts

There are 2 interrupt lines flagging descriptor interrupts. Line line0_DiA has also the capability to generate a merged data interrupt (controlled by CIE.CL0M).

Descriptor interrupt 1 is not available as common descriptor interrupt; this descriptor interrupt is split into queue specific descriptor interrupts.

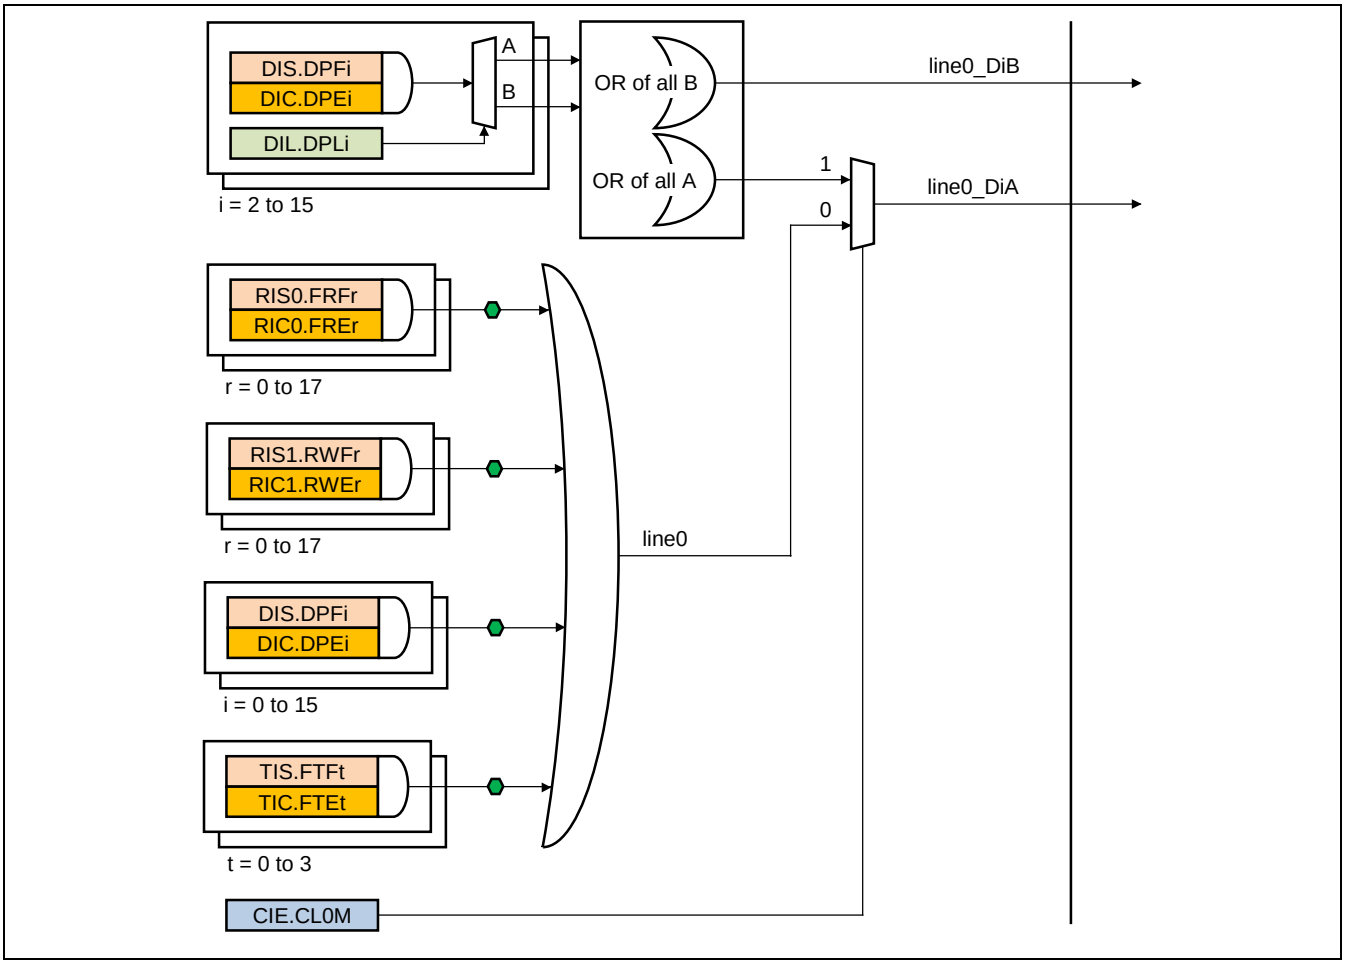

Figure 46.58 Interrupt group 0, common descriptor and merged interrupt lines

(3) Group 1 (Error related interrupts)

This group consists on:

Tx-Buffer full interrupt EIS.TBFF (when delaying fetching of transmit frame)
Interrupt for E-MAC Status FIFO overwrite (EIS.MFFF)
Interrupt for Timestamp FIFO overrun (EIS.TFFF)
Interrupts for CBS limits (EIS.CULF1, EIS.CULF0, EIS.CLLF1, EIS.CLLF0)
Interrupt for separation filtering error (EIS.SEF)
Interrupt for queue error (error while processing receive or transmit queue) (EIS.QEF)
Interrupt for transmission error detected by E-MAC (EIS.MTEF, EIS.MREF)
Rx-FIFO full interrupt RIS2.RFFF (when Rx-FIFO overflows)
Receive queue full interrupts RIS2.QFFr (when no sufficient space is in receive queue)

By reading EIS, CPU get an overview of all error interrupts. Additionally ISS.EM informs about pending error related interrupt.

Interrupt group 1 consists on these 2 interrupt lines:

Line1_A (Share the interrupt line: Group0.Line0_DiA, Group1.Line1_A, Group2.Line2_A)
Line1_B (Share the interrupt line: Group0.Line0_DiB, Group1.Line1_B, Group2.Line2_B)

For the queue full flag it is configurable by CIE.RQFM if these notification are part of the queue specific reception interrupt lines or part of the error interrupt line line1_A.

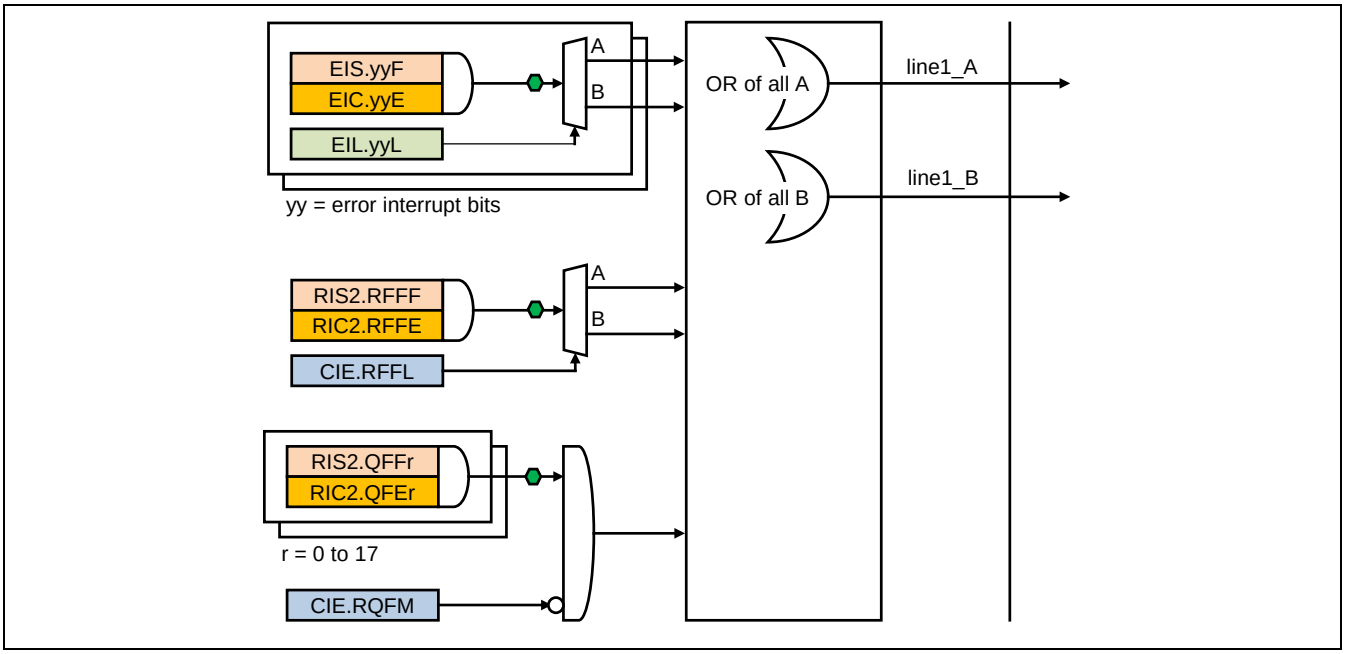

Figure 46.59 Interrupt group 1, error interrupt lines

The abbreviation yy in figure indicates error interrupts: TBF, MFF, TFF, CULFc, CLLFc, SE, QE, MTE, and MRE.

(4) Group 2 (Management related interrupts)

Reception

Rx-FIFO Warning interrupt RIS1.RFWF (Rx-FIFO has reached configured warning level)

Transmission

E-MAC status FIFO warning interrupt TIS.MFWF
E-MAC Status FIFO updated interrupt TIS.MFUF
Timestamp FIFO warning interrupt TIS.TFWF
Timestamp FIFO updated interrupt TIS.TFUF

gPTP

AVTP time captured interrupt GIS.ATCFi
AVTP presentation target matched interrupt GIS.PTMFi
AVTP presentation time overrun interrupt GIS.PTOF (when external trigger before old value is processed)
AVTP presentation time captured interrupt GIS.PTCF

By reading ISS, CPU get an overview of all management related interrupts (ISS.RFWM, ISS.MFWM, ISS.MFUM, ISS.TFWM, ISS.TFUM, ISS.CGIM).

Interrupt group 2 consists on these 2 interrupt lines:

Line2_A (Share the interrupt line: Group0.Line0_DiA, Group1.Line1_A, Group2.Line2_A)
Line2_B (Share the interrupt line: Group0.Line0_DiB, Group1.Line1_B, Group2.Line2_B)

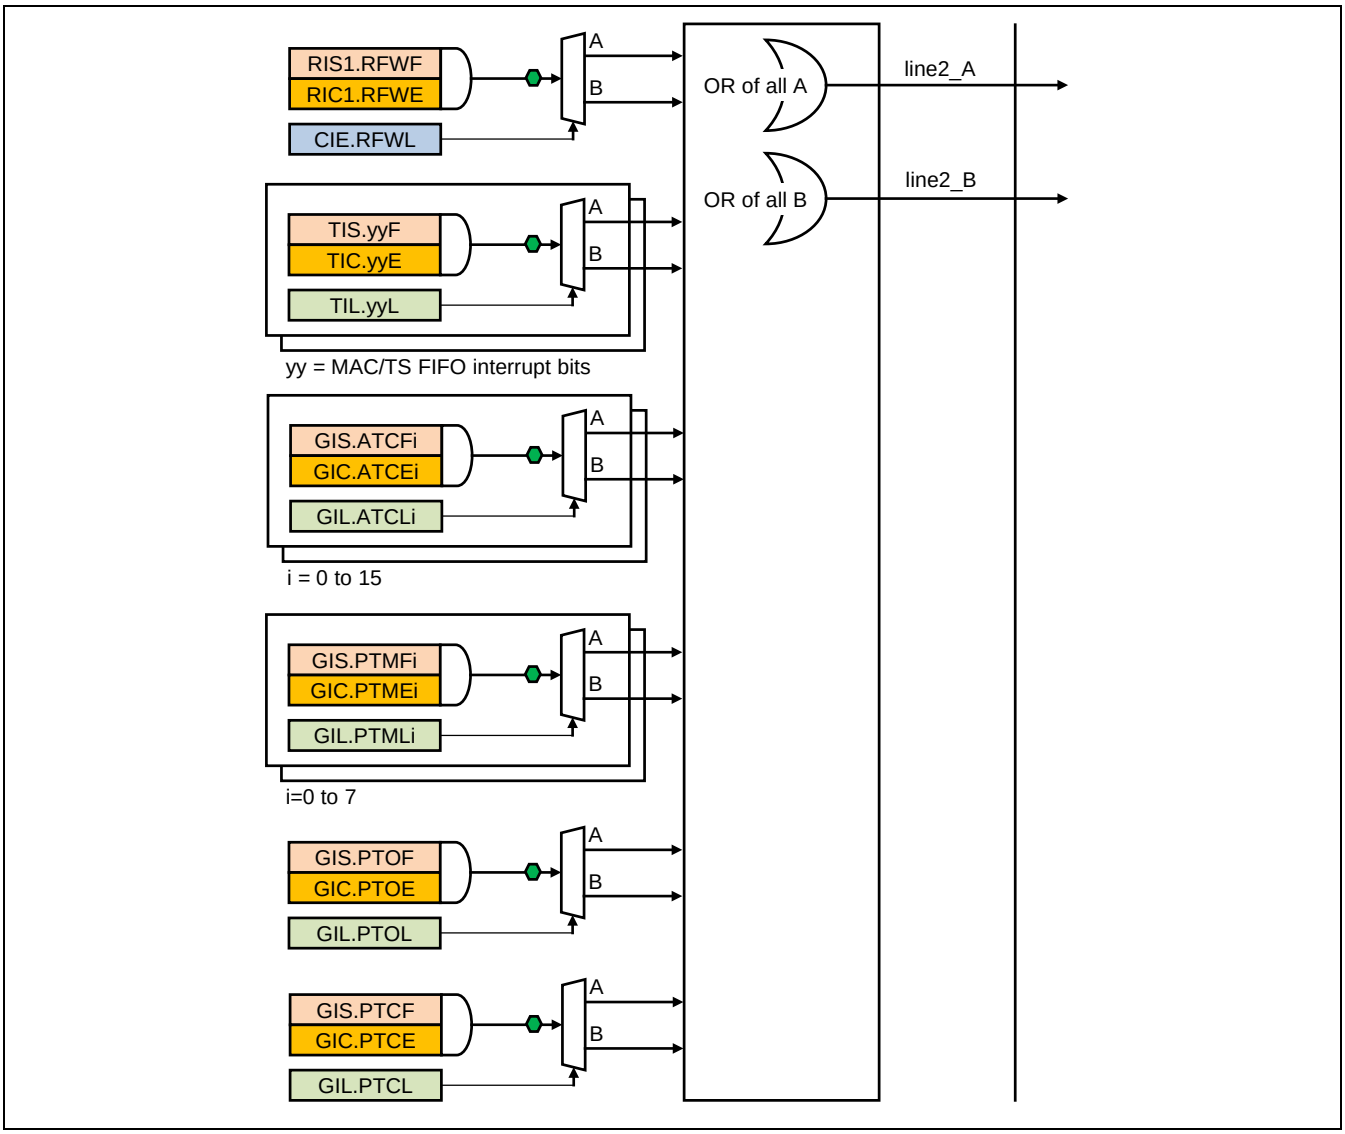

Figure 46.60 Interrupt group 2, management interrupt lines

The abbreviation yy in figure indicates error interrupts: MFW, MFU, TFW, and TFU.

(5) Line 3 (E-MAC interrupt)

The E-MAC interrupt is conveyed when the E-MAC interrupt source is generated.

The general error interrupt state can be checked by reading the E-MAC interrupt summary bit in the interrupt summary status register (ISS.MS).

46.3.12 Flows of Operations

(1) Flow of E-MAC Initialization

Figure 46.61 shows the flow of E-MAC initialization (for AVB mode and full-duplex operation).

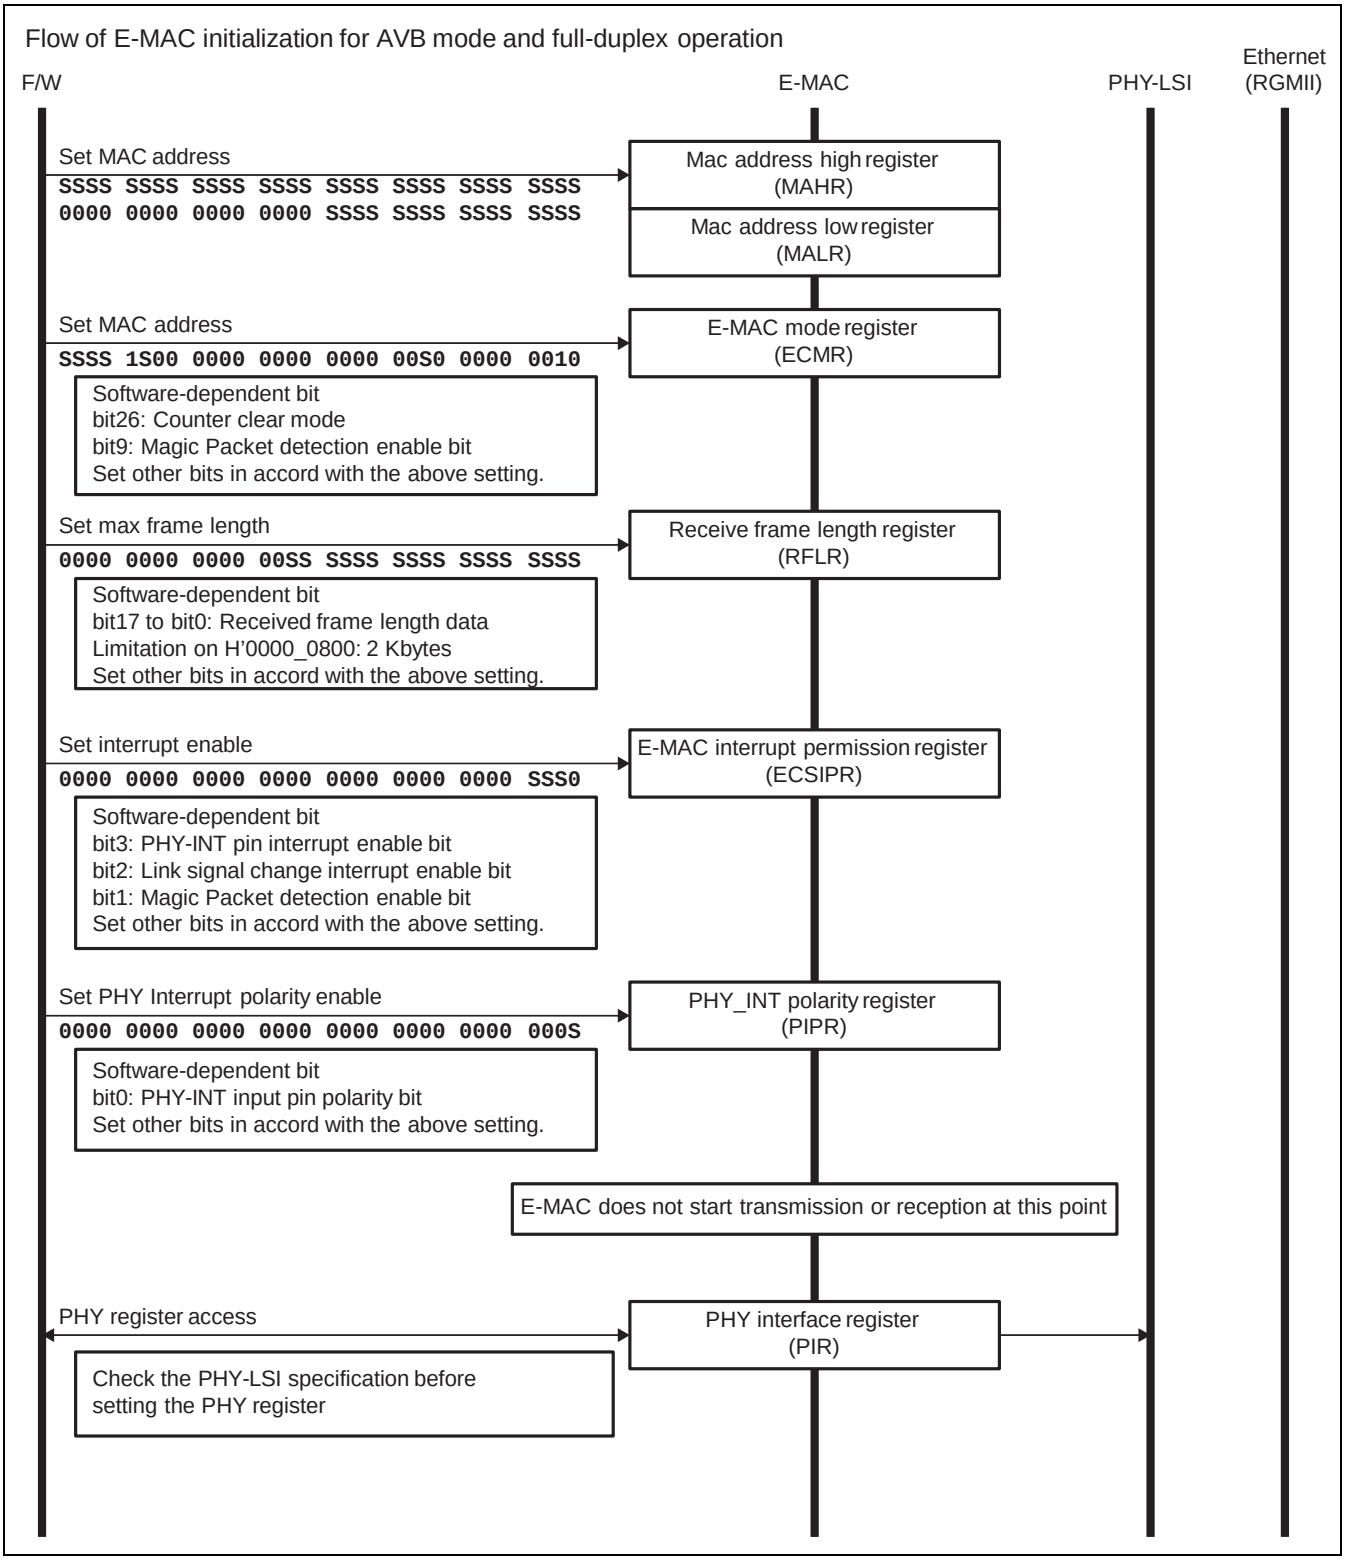

Figure 46.61 Flow of E-MAC Initialization (for AVB Mode and Full-Duplex Operation)

(2) Flow of AVB-DMAC Initialization

Figure 46.62 shows the flow of AVB-DMAC initialization (for AVB mode and full-duplex operation).

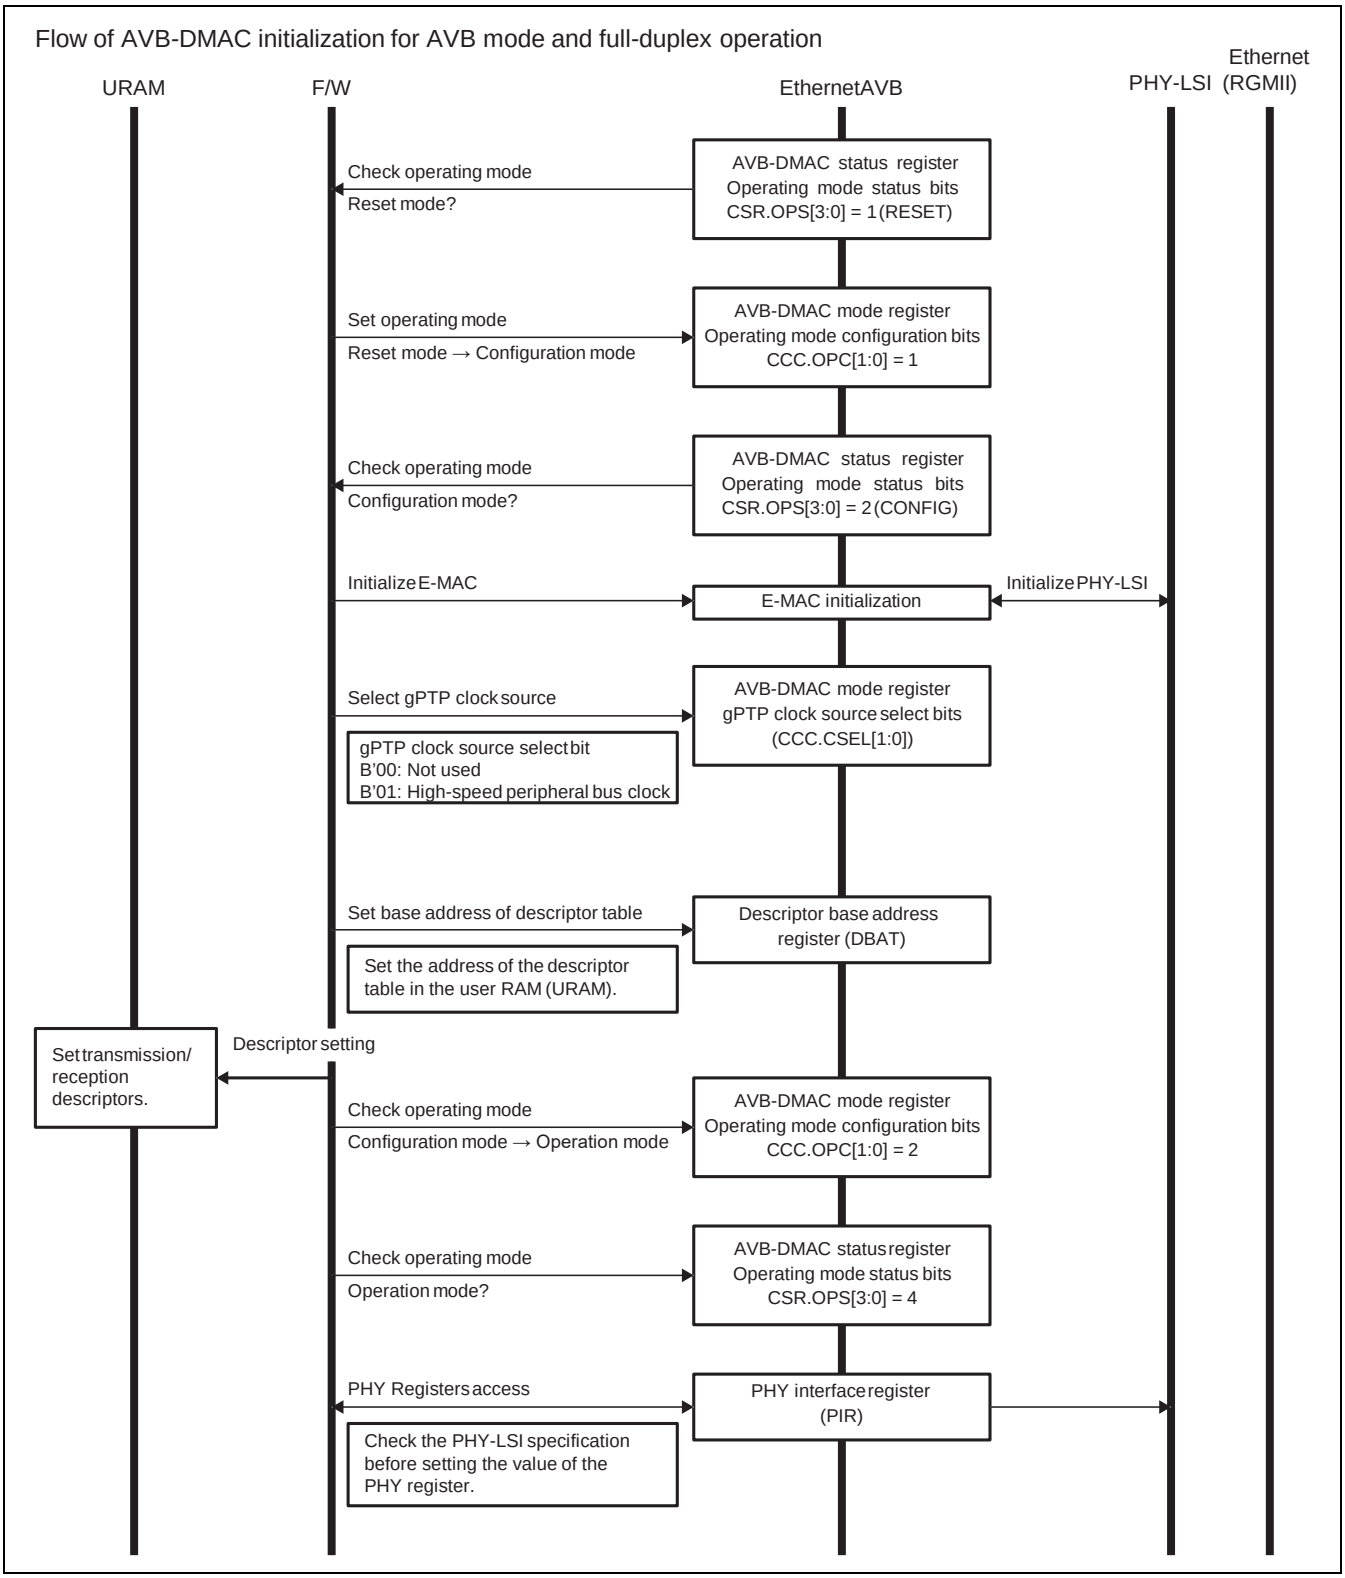

Figure 46.62 Flow of AVB-DMAC Initialization (for AVB Mode and Full-Duplex Operation)

(3) Flow for the AVB-DMAC in Reception

Figure 46.63 shows the flow for the AVB-DMAC in reception (in AVB mode and full-duplex operation).

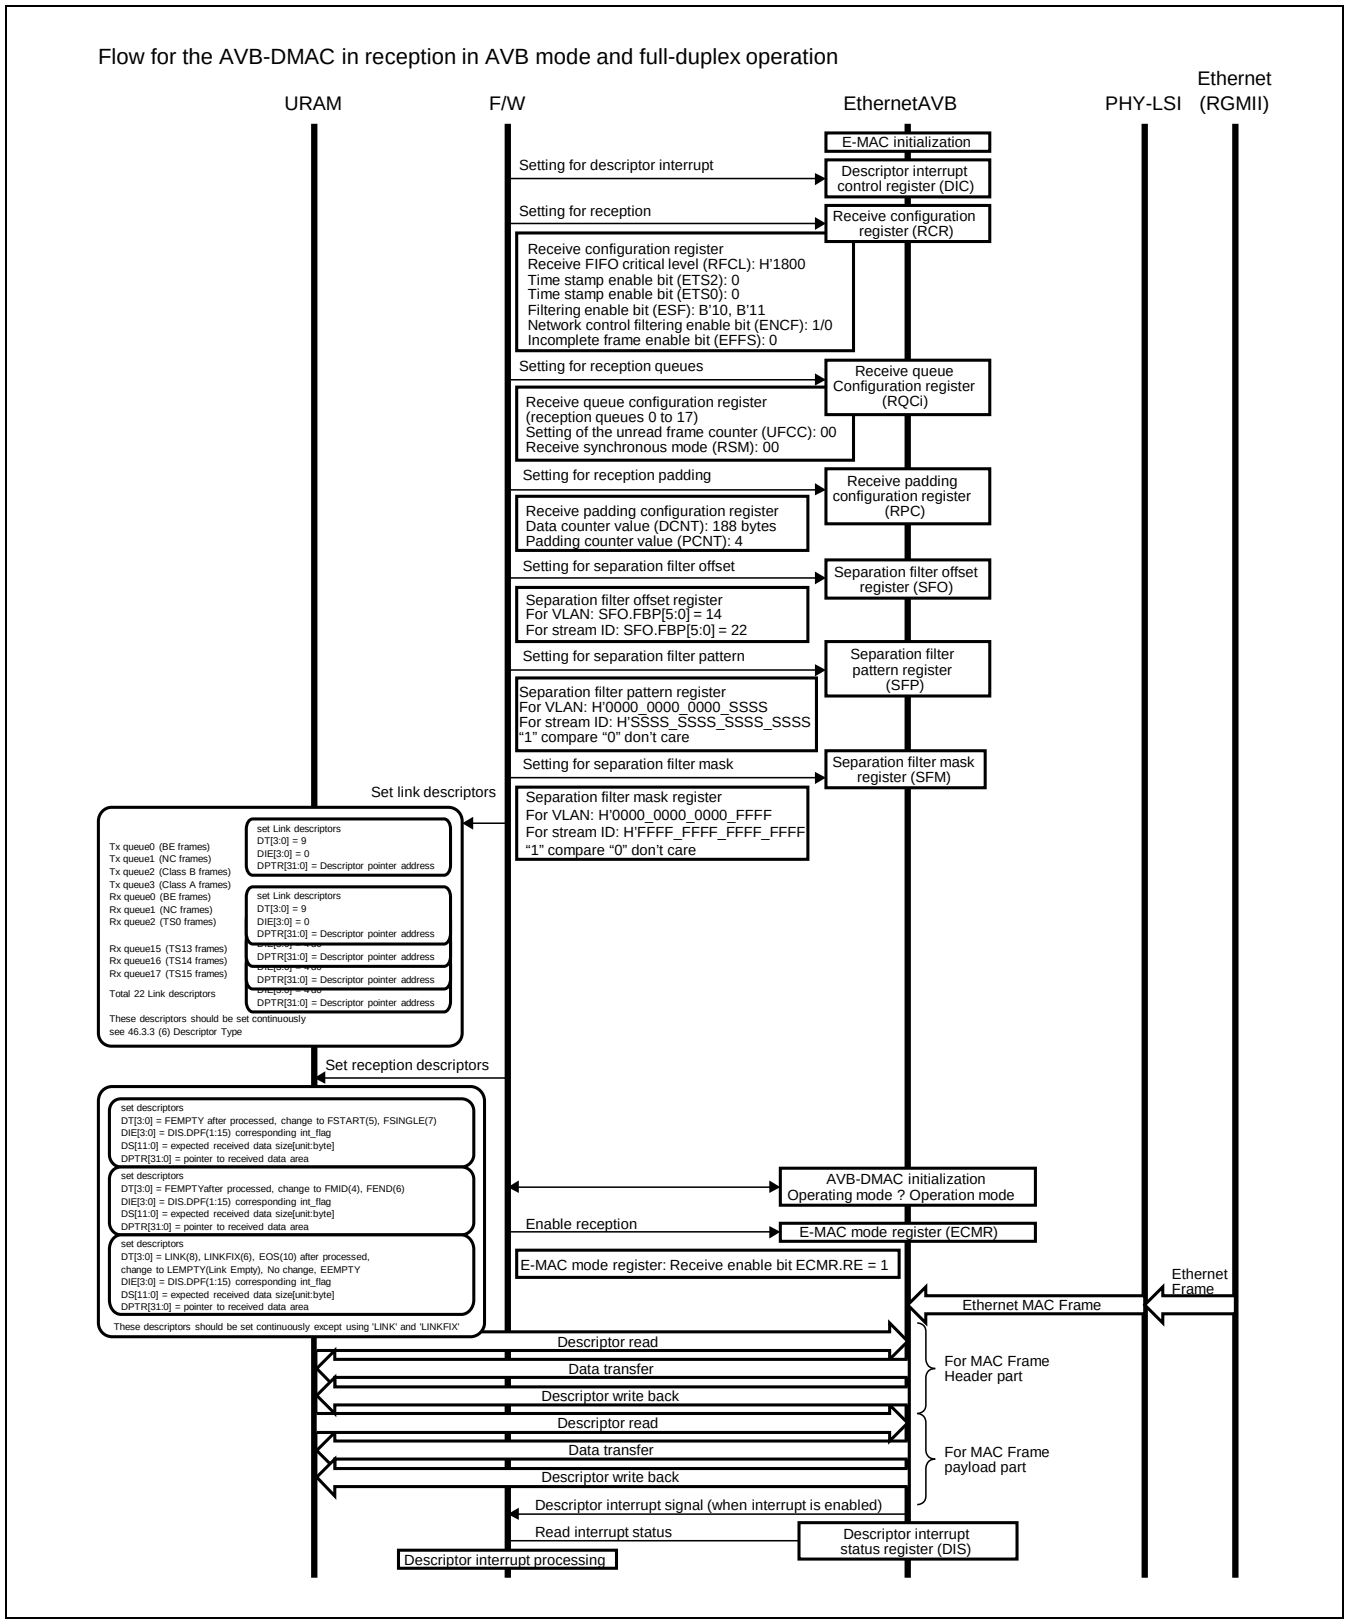

Figure 46.63 Flow for the AVB-DMAC in Reception (in AVB Mode and Full-Duplex Operation)

(4) Flow for the AVB-DMAC in Transmission

Figure 46.64 shows the flow for the AVB-DMAC in transmission (in AVB mode and full-duplex operation).

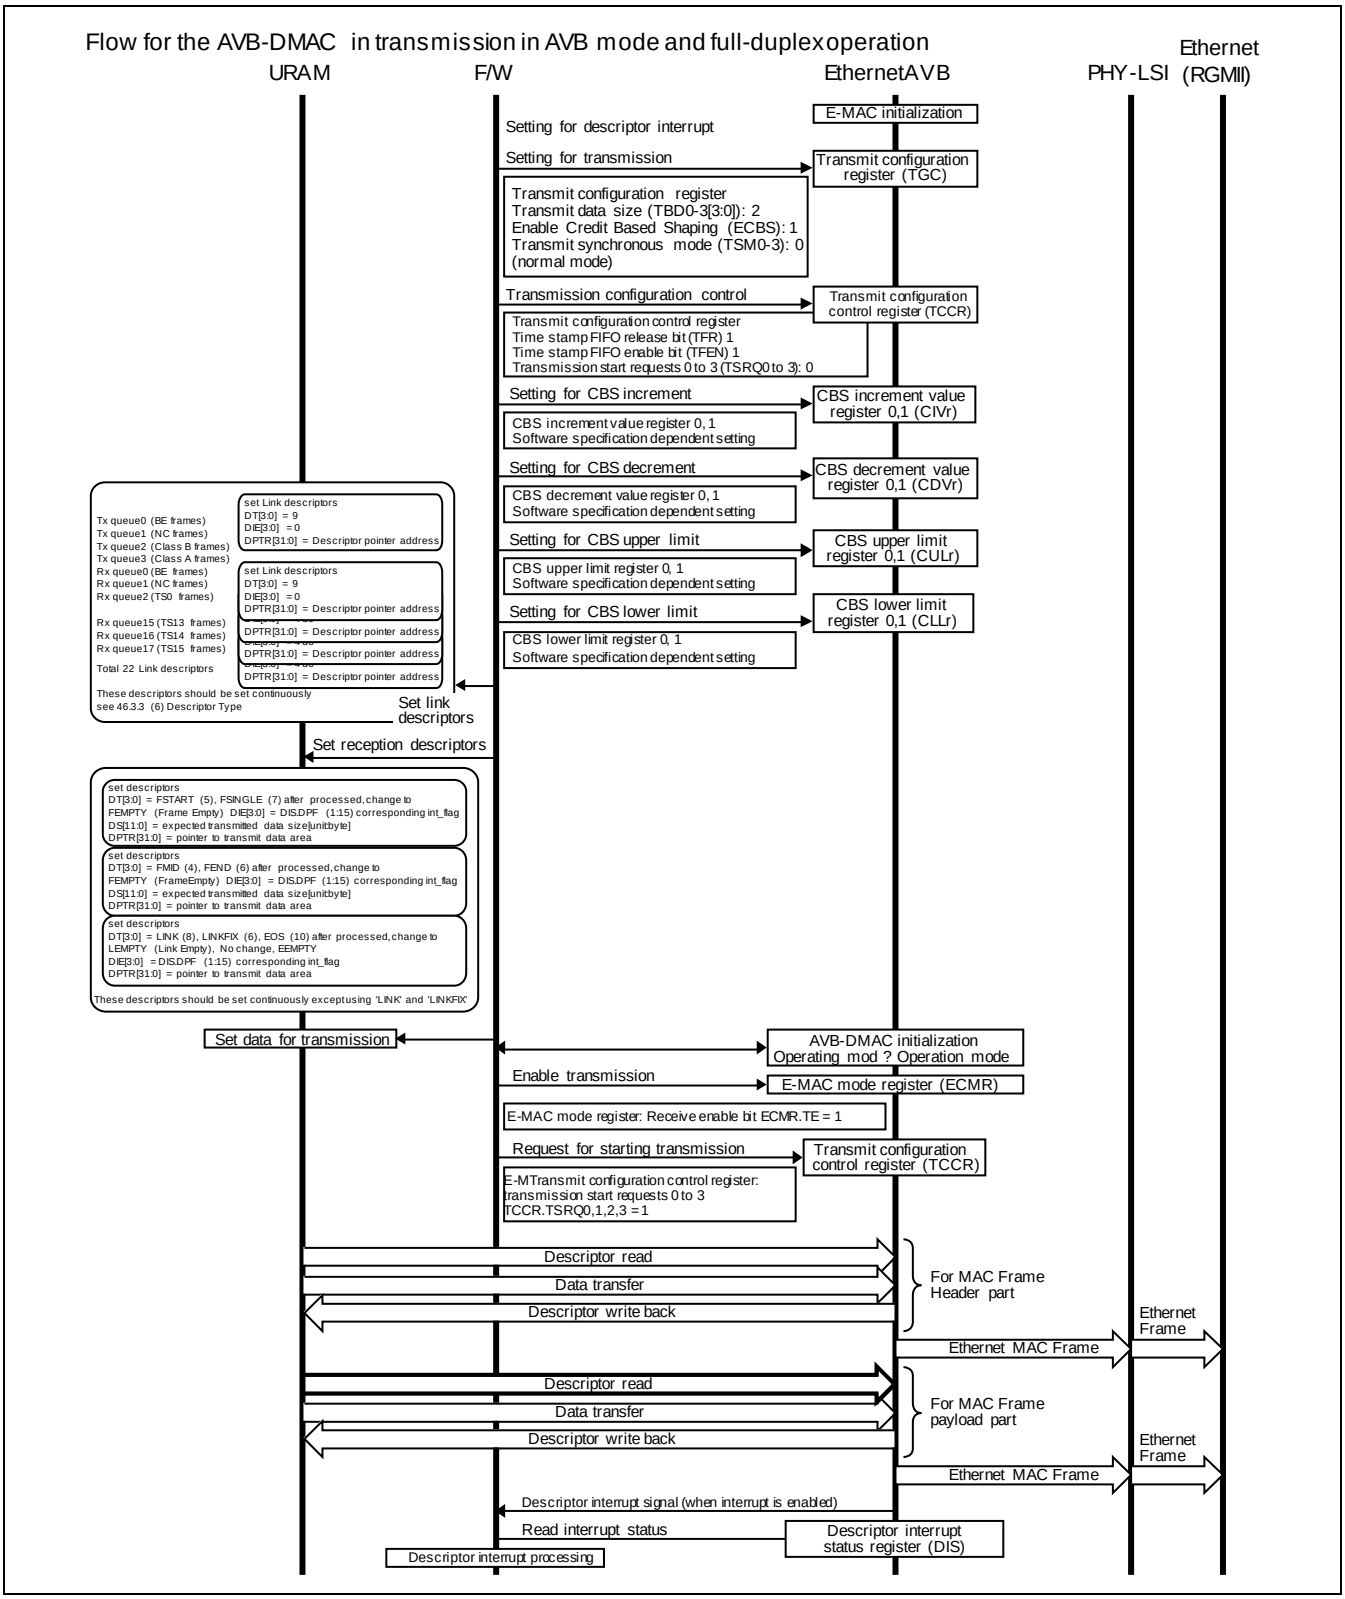

Figure 46.64 Flow for the AVB-DMAC in Transmission (in AVB Mode and Full-Duplex Operation)

(5) Flow for Stopping AVB-DMAC Operation in Reception

Figure 46.65 shows the flow for stopping AVB-DMAC operation in reception (normal, common to all modes).

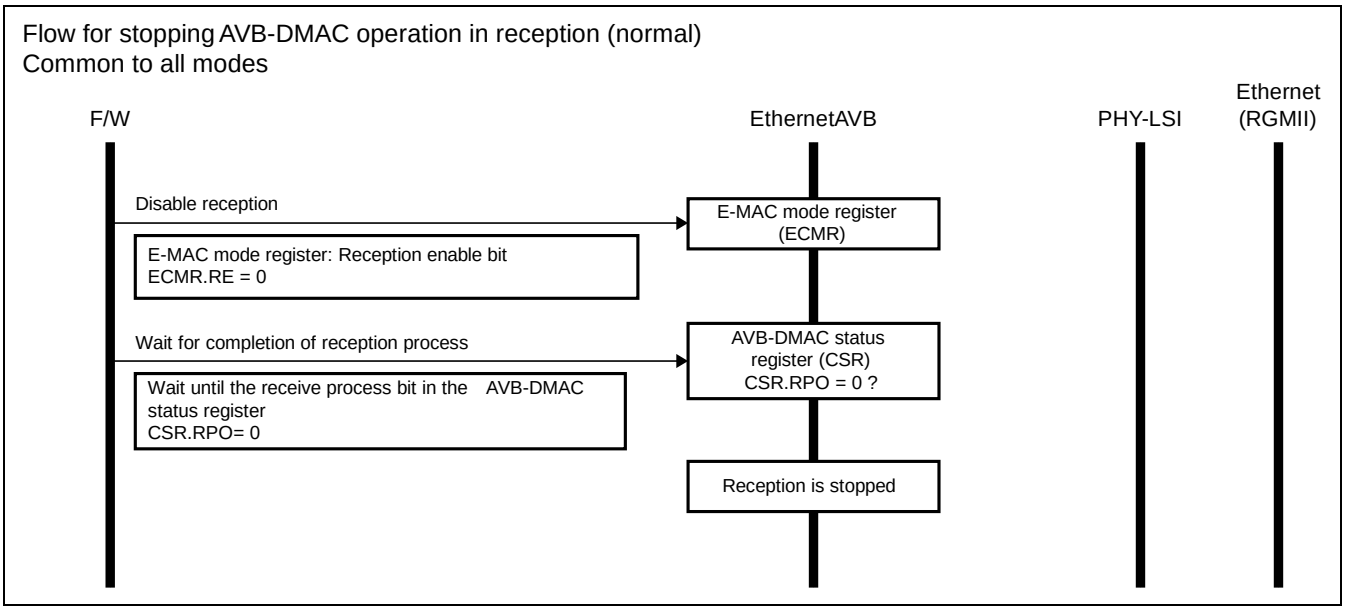

Figure 46.65 Flow for Stopping AVB-DMAC Operation in Reception (Normal, Common to All Modes)

(6) Flow for Stopping AVB-DMAC Operation in Transmission

Figure 46.66 shows the flow for stopping AVB-DMAC operation in transmission (normal, common to all modes).

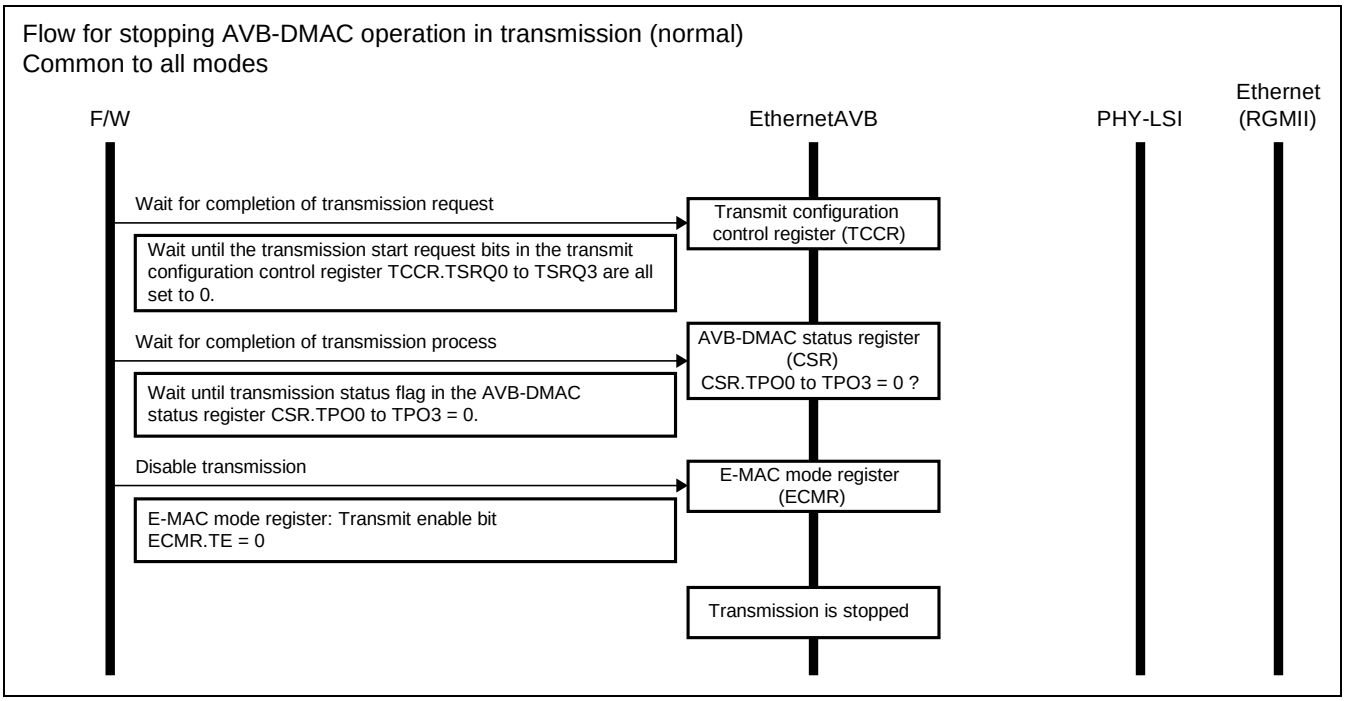

Figure 46.66 Flow for Stopping AVB-DMAC Operation in Transmission (Normal, Common to All Modes)

(7) Flow for Stopping and Resetting the AVB-DMAC

Figure 46.67 shows the flow for stopping and resetting the AVB-DMAC (normal, common to all modes).

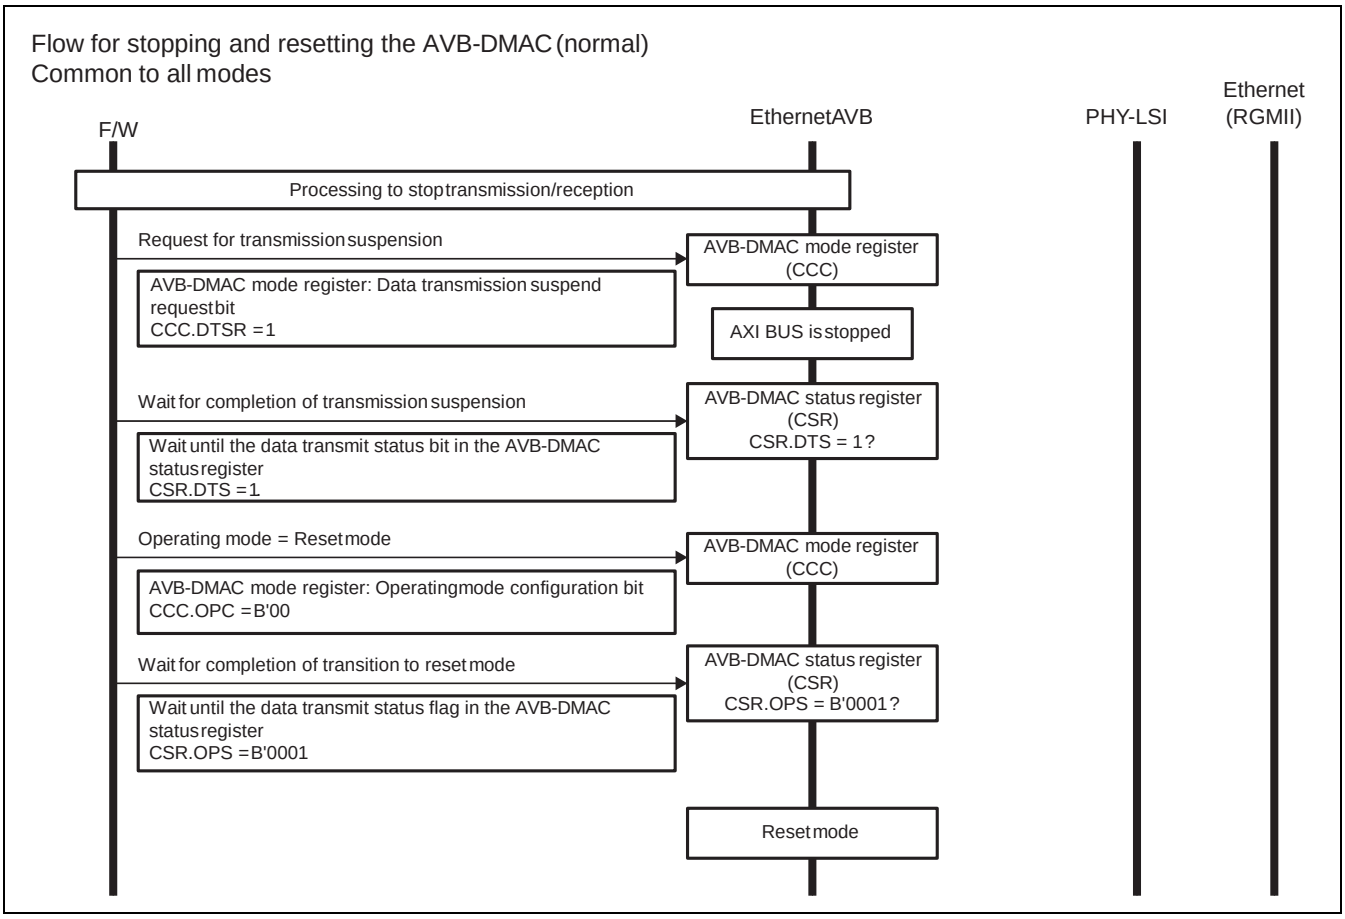

Figure 46.67 Flow for Stopping and Resetting the AVB-DMAC (Normal, Common to All Modes)

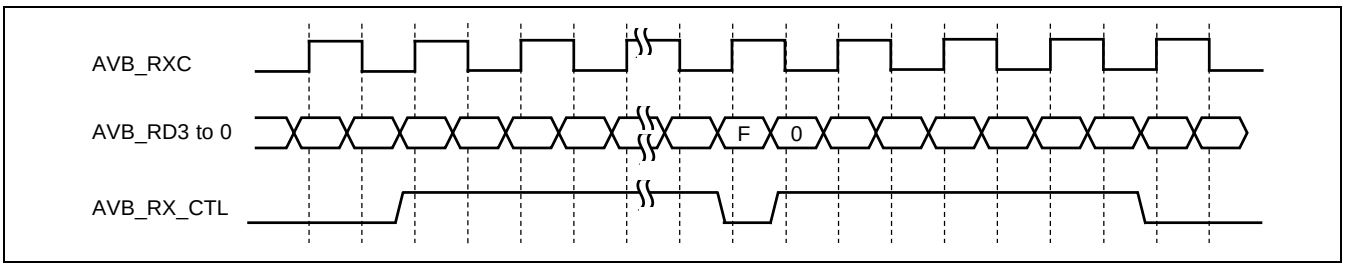

Figure 46.80 RGMII Fame Receive Timing (Carrier Extend)

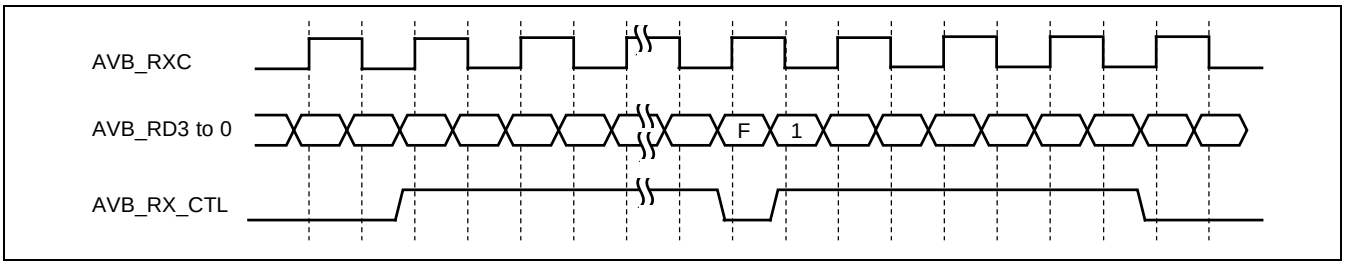

Figure 46.81 RGMII Frame Receive Timing (Carrier Extend Error)

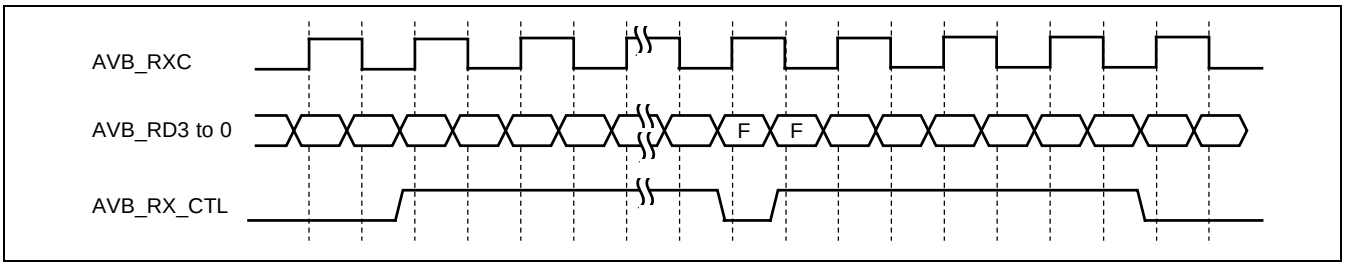

Figure 46.82 RGMII Fame Receive Timing (Carrier Sense)

(2) Accessing MII Management Registers

MII management registers in the PHY-LSI are accessed via PIR in this LSI. PIR is used as a serial interface conforming to the MII frame format specified in IEEE802.3u.

(a) MII Management Frame Format

Figure 46.83 shows the format of an MII management frame. To access an MII management register, a management frame is implemented by the program in accordance with the procedures shown in MII Management Register Access Procedure.

Access Type	MII Management Frame							
Item	PRE	ST	OP	PHYAD	REGAD	TA	DATA	IDLE
Number of bits	32	2	2	5	5	2	16	
Read	1..1	01	10	00001	RRRRR	Z0	D...D	
Write	1..1	01	01	00001	RRRRR	10	D...D	X

[Legend]
PRE: 32 consecutive 1 s
ST: Write of B'01 indicating start of frame
OP: Write of code indicating access type
PHYAD: Write of B'0_0001 if the PHY-LSI address is 1 (sequential write starting with the MSB).
This bit changes depending on the PHY-LSI address.
REGAD: Write of B'000q if the register address is 1 (sequential write starting with the MSB).
This bit changes depending on the PHY-LSI register address.
TA: Time for switching data transmission source on MII interface
(a) Write: 10 written
(b)Read: Bus release (notation: Z0) performed
DATA: 16-bit data. Sequential write or read from MSB
(c) Write: 16-bit data write
(d) Read: 16-bit data read
IDLE: Wait time until next MII management format input
(a) Write: Independent bus release (notation: X) performed
(b) Read: Bus already released in TA: control unnecessary

Figure 46.83 MII Management Frame Format

(b) MII Management Register Access Procedure

The program accesses MII management registers via PIR. Access is implemented by a combination of 1-bit-unit data write, 1-bit-unit data read, bus release, and independent bus release. Figure 46.84 to Figure 46.87 show the MII management register timing. The timing will differ depending on the PHY-LSI type.

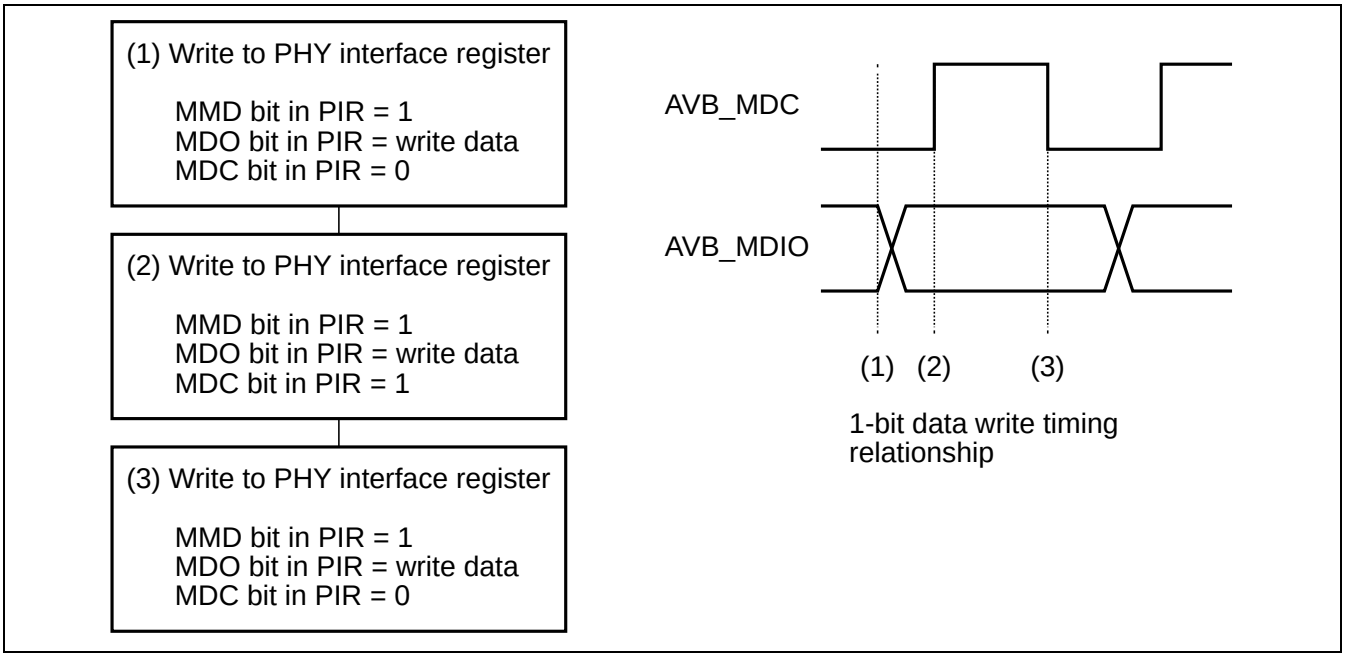

Figure 46.84 1-Bit Data Write Flowchart

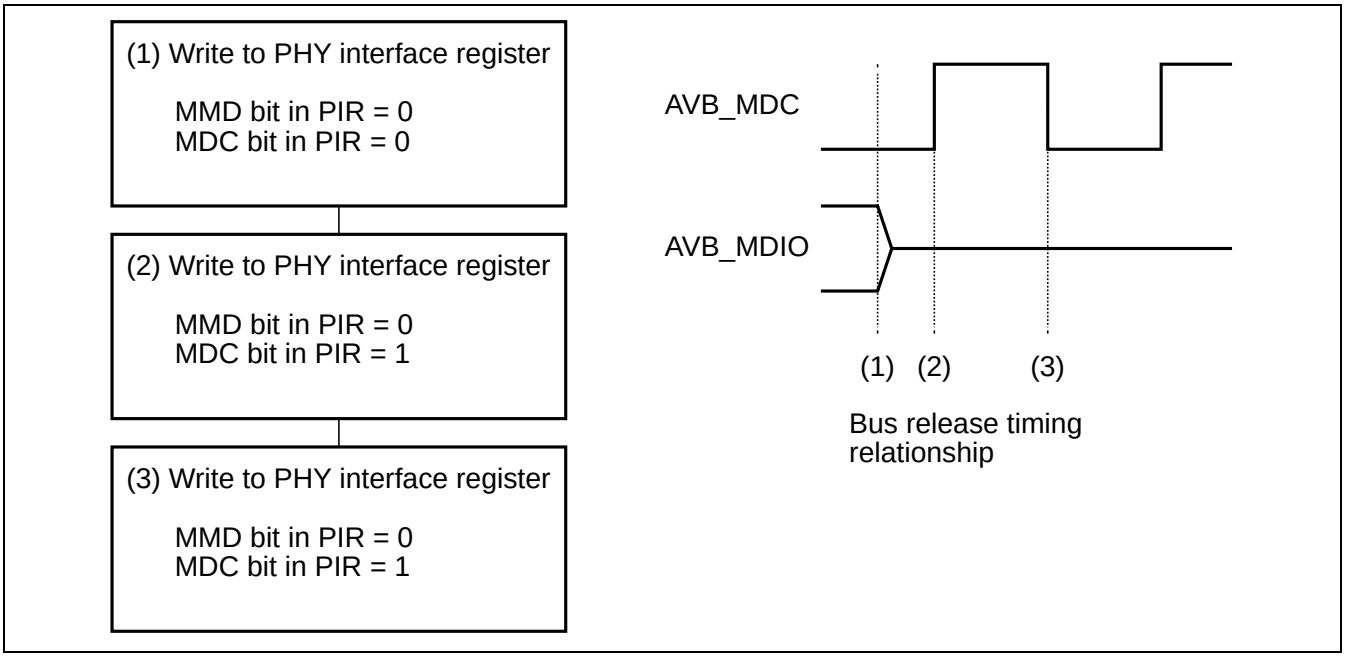

Figure 46.85 Bus Release Flowchart (TA in Read in Figure 46.83)

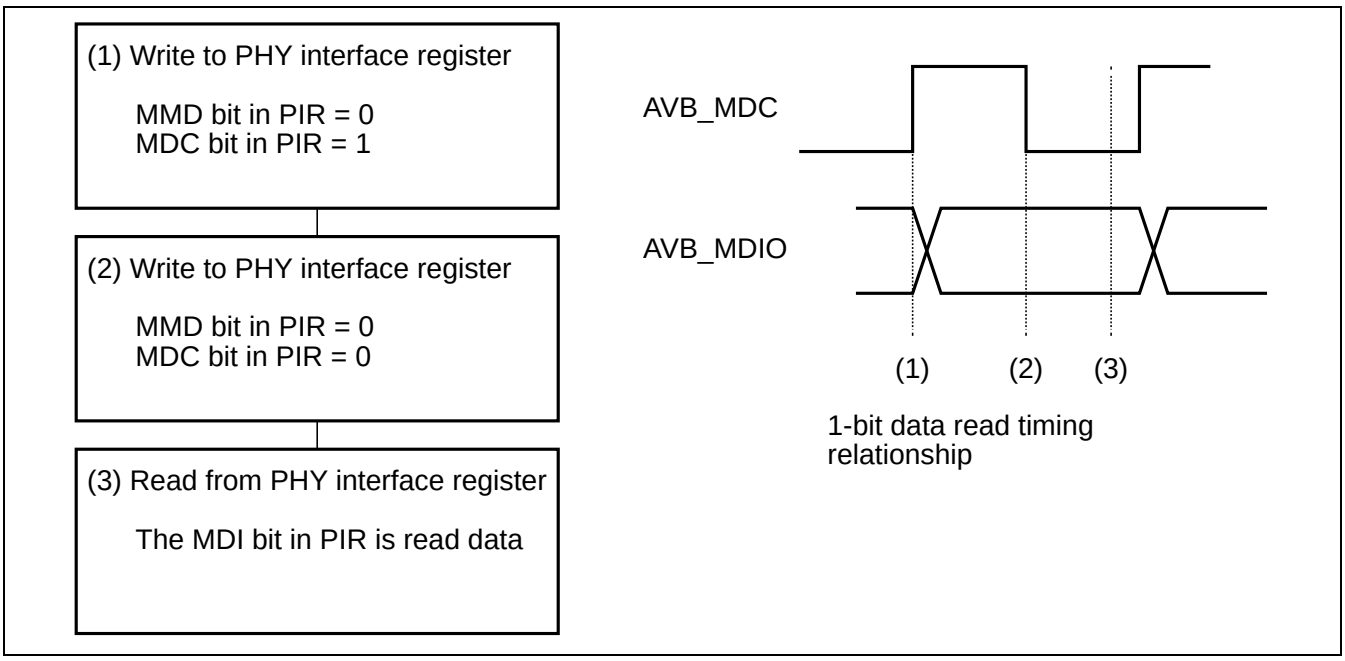

Figure 46.86 1-Bit Data Read Flowchart

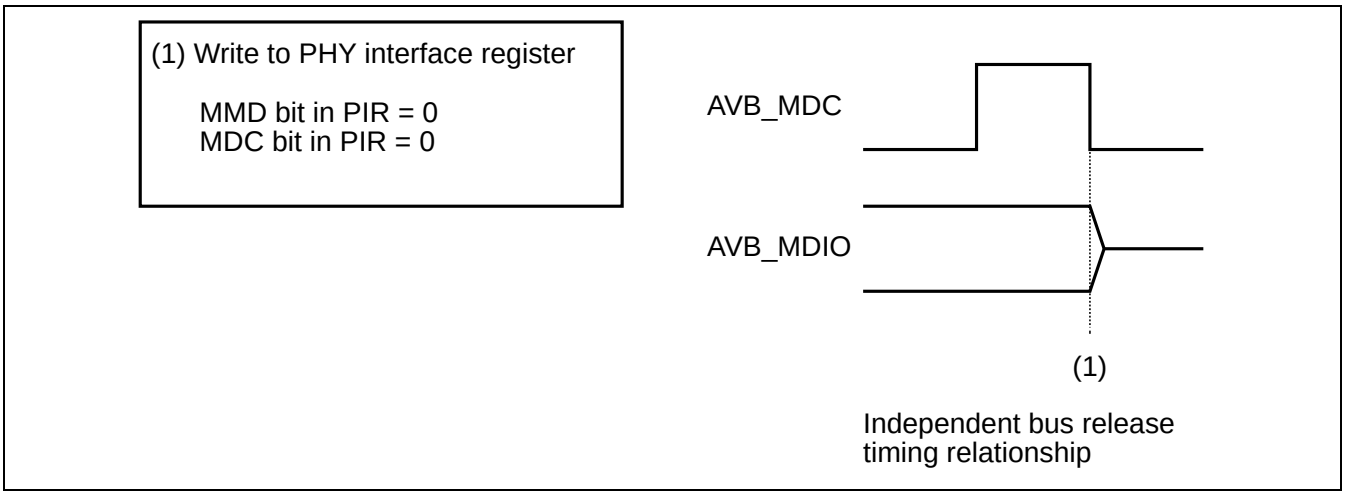

Figure 46.87 Independent Bus Release Flowchart (IDLE in Write in Figure 46.83)

46.3.14 Usage Notes

(a) Reception is Ignored when AVB_RX_CTL indicates an error from PHY is Flagged at 1st Data Byte

The issue is limited to reception of frames with physical faults. Flagging of occurrence in SFR is missing. When EthernetAVB-IF is configured to store faulty frames in reception queue 0 (BE) by RCR.EFFS there is no storage.

(b) Unexpected Data are Exported when AVB_RX_CTL indicates an error is Flagged at 8th Data Byte

The issue is limited to reception of frames with physical faults.

Flagging of occurrence in SFR is invalid. When EthernetAVB-IF is configured to store faulty frames in reception queue 0 (BE) by RCR.EFFS corrupted data is stored and MAC status code is wrong.

(c) Receive Frame Interrupt and Descriptor Interrupt may be Issued before Completion of Writing Data

When receive frame interrupt and descriptor interrupt are issued, whether writing data is completed by DESCR.DT in a descriptor can be confirmed.

And CDARq register has the descriptor address which EthernetAVB-IF is processing currently or is going to process at the next time.

The descriptors before one indicated by CDARq register are scope for receive frame interrupt and descriptor interrupt scope.

If there is a descriptor which wait for HW processing (ex. FEMPTY), it's delayed. Confirm the descriptor again after waiting for 1ms.

46.4 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

46.4.1 Checksum Calculation of Ethernet Frames

This LSI is capable of calculating the checksum data of the received frames. Only the data fields of the Ethernet frames are subject to checksum calculation. Specifically, a data field follows the length/type field and is followed by the CRC field. Figure 46.88 shows schematics indicating which parts of the Ethernet frames are calculated. Calculation involves 16-bit addition only; it does not involve bit inversion. Note that when the checksum data is valid, the CRC data (4 bytes) is not transferred as a receive frame, and the checksum data (sum data) is added automatically. Figure 46.89 shows schematics of Ethernet frames to which the checksum data has been added.

Note: Also for the frames with VLANtag inserted, the 15th byte from the top and the following bytes before the CRC field are subject to calculation.

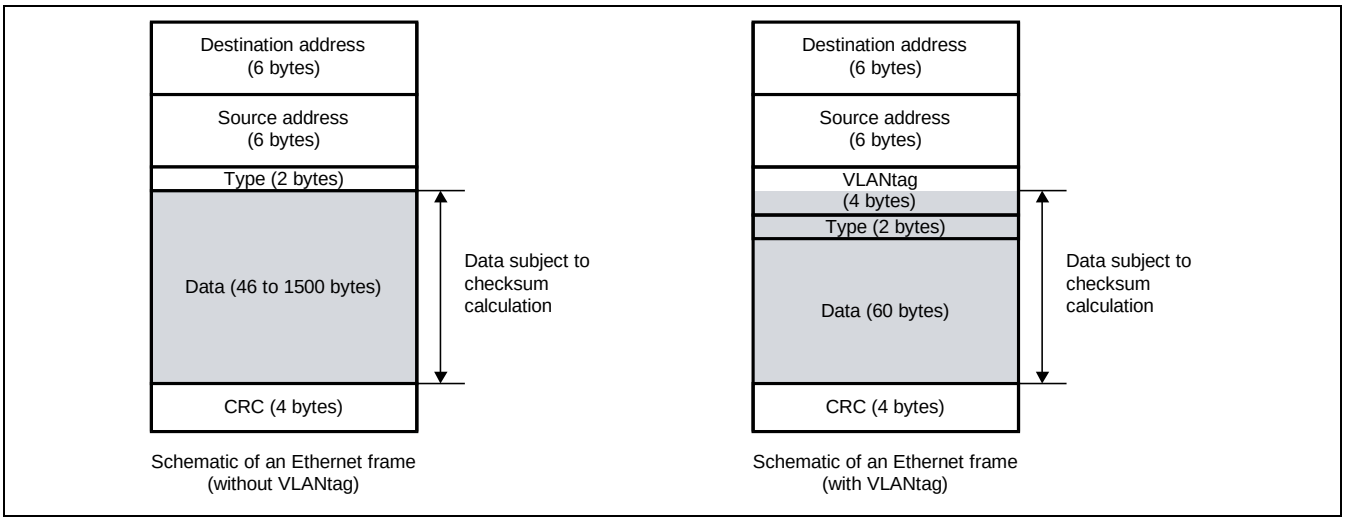

Figure 46.88 Data Subject to Checksum Calculation

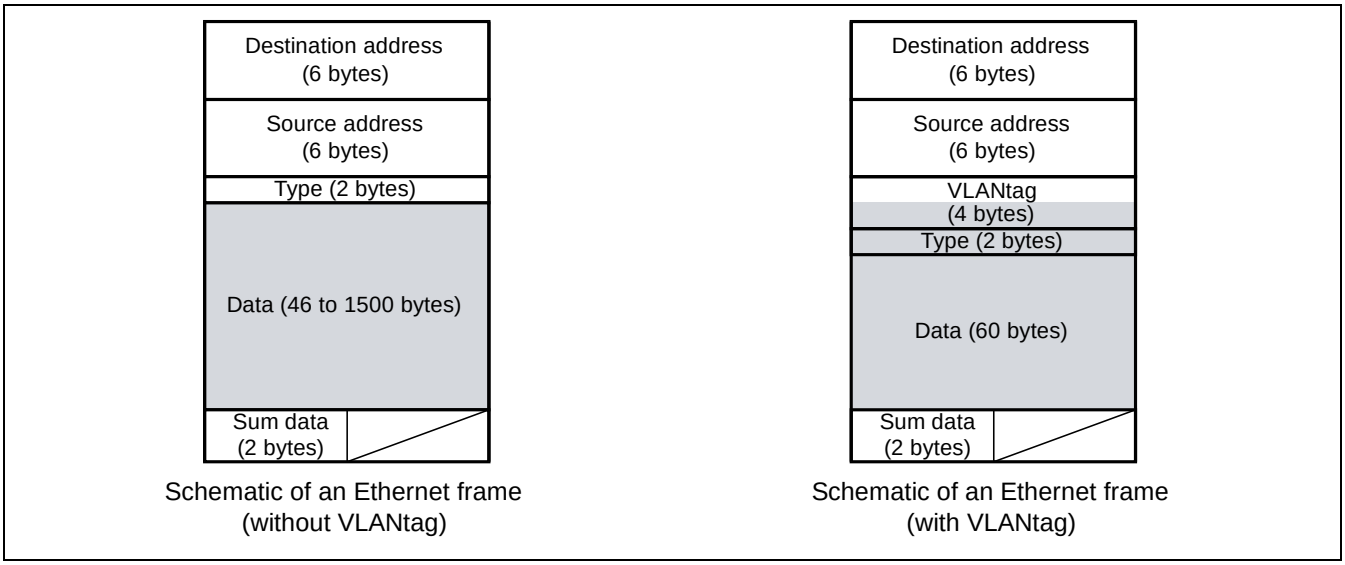

Figure 46.89 Data after Checksum Data Addition

46.4.2 Data Transfer Function Stops after Read Access Error

If EthernetAVB-IF gets an access error when reading from work RAM, it may happen that no further work RAM accesses are issued. So transfer of receive/transmit frames is halted. By using the data transfer suspend function SW can observe if data transfer function is available or not.

Perform one of given SW flows which are triggered by this start condition: when AXI read access error has been flagged by EIS.QEF is 1, and ESR.ET is B'0000 or B'0100; additionally when ESR.EIL is 1 (this is an indication that an work RAM read error may be lost).

There are two possible SW flows given. Figure 46.90 applies always the SW reset, independently if this is required or not. Figure 46.91 checks in addition if SW reset is required; checking CSR.DTS after wait gives an indication that issue has been occurred.

Note that the wait after write of CCC.DTSR is mandatory to prevent cases where issue has not been occurred.

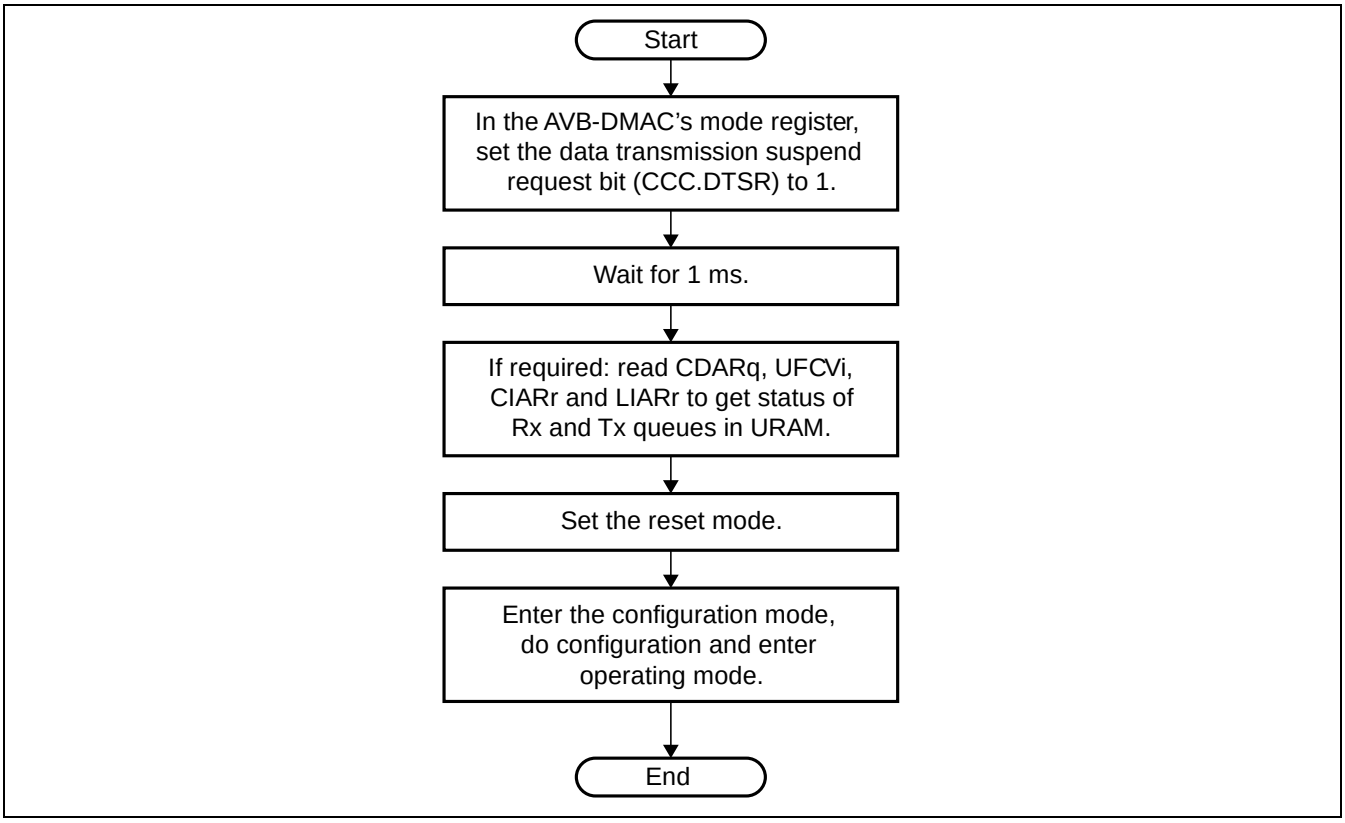

Figure 46.90 Data Transfer Function Stop Flow1 after Read Access Error

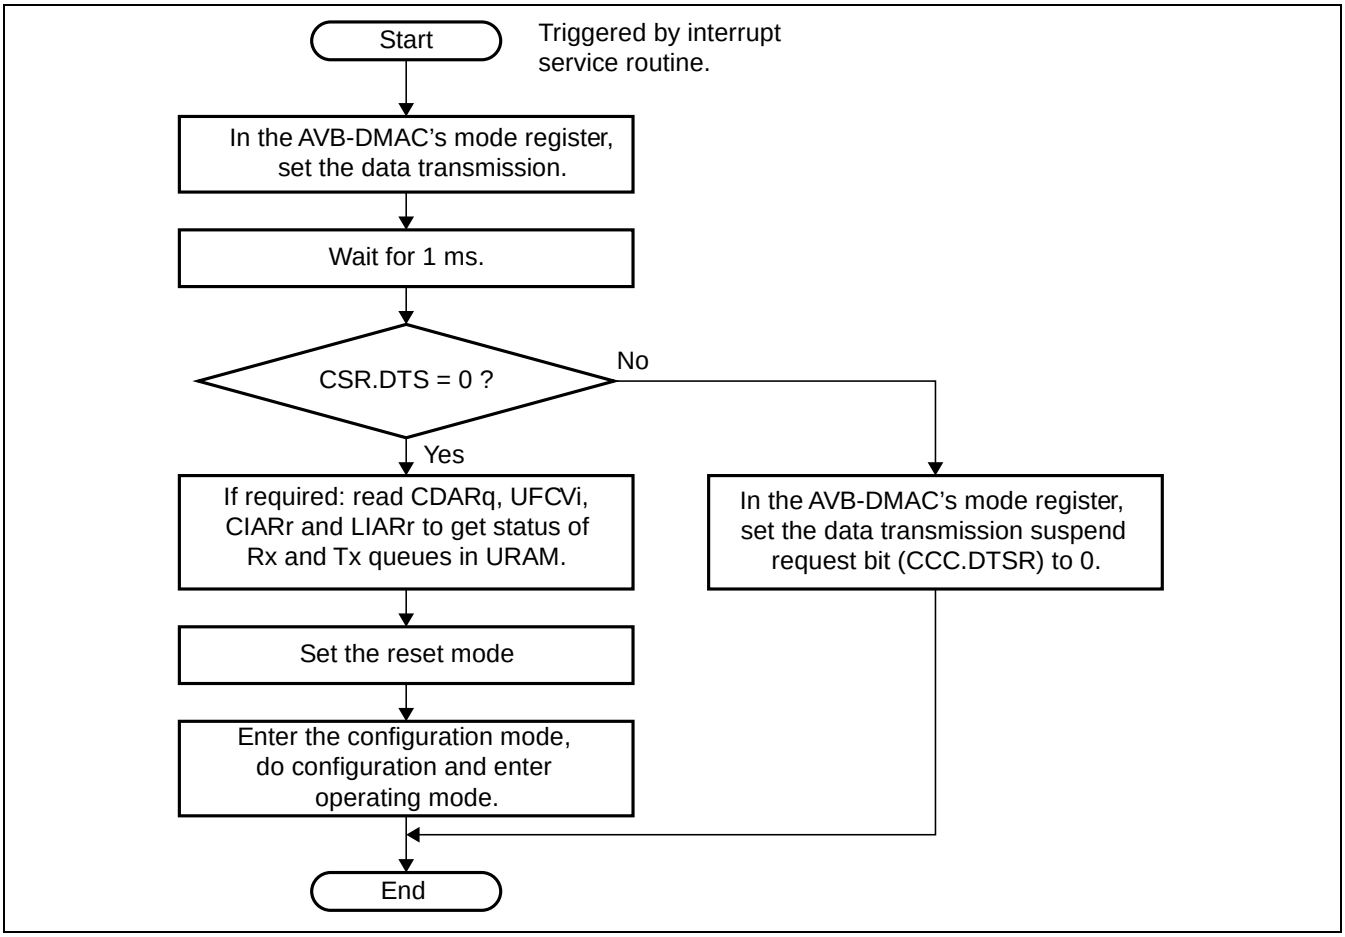

Figure 46.91 Data Transfer Function Stop Flow2 after Read Access Error

46.4.3 Power Down Request

If EthernetAVB-IF gets a power down request while writing to work RAM, it may happen that the request is not accepted even if the transfer is completed. Due to this the external power down module cannot complete the power down sequence.

A power down request is acceptable only when EthernetAVB-IF is in RESET state.

47. Controller Area Network Interface (CAN interface)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

47.1 Overview

47.1.1 Features

This MCU implements two channels (referred to as CAN0 and CAN1) of CAN (Controller Area Net-work) module that complies with the ISO11898-1 Specifications. The CAN module transmits and receives both formats of messages, namely the standard identifier (11 bits) (identifier hereafter referred to as ID) and extended ID (29 bits). Table 47.1 lists the CAN module overview and figure 47.1 shows the CAN module block diagram. Connect the CAN bus transceiver externally.

Table 47.1 CAN module overview

Item	Overview
Protocol	• ISO11898-1 compliant
Bit-rate	• Up to 1 Mbps
Message box	• 64 mailboxes: Two selectable mailbox mode Normal mailbox mode: Of the 64 mailboxes, 32 can be configured for either transmission or reception (and the other 32 are reception-only). FIFO mailbox mode: 24 mailboxes configurable as transmission or reception (and the other 32 are reception-only). 4 stages FIFO for transmission and 4 stages FIFO for reception
Reception	• Data frame and remote frame can be received. • Selectable receiving ID format (only standard ID, only extended ID or both ID) • Programmable one-shot reception function • Selectable overwrite mode (message overwritten) or overrun mode (message discarded) • The reception complete interrupt can be enabled or disabled for each mailbox.
Acceptance filter	• 8 acceptance masks (one mask every 4 mailboxes) • 2 acceptance masks (one mask every 16 mailboxes) • The mask can be enabled or disabled for each mailbox.
Transmission	• Data frame and remote frame can be transmitted. • Selectable transmitting ID format (only standard ID, only extended ID or both ID) • Programmable one-shot transmission function (enable or disable) • Selectable ID priority mode or mailbox number priority mode • Transmission request can be aborted (The completion of abort can be confirmed with a flag.) • The transmission complete interrupt can be enabled or disabled for each mailbox.
Mode transition for bus-off recovery	• Mode transition for the recovery from the bus-off state can be selected: Automatic entry to CAN halt mode at bus-off entry Automatic entry to CAN halt mode at bus-off end Entry to CAN halt mode by a program Transition into error-active state by a program

Item	Overview
Error status monitoring	• CAN bus errors (stuff error, form error, ACK error, CRC error, bit error, and ACK delimiter error) can be monitored. • Transition to error states can be detected (error-warning, error-passive, bus-off entry, and bus-off recovery). • The error counters can be read.
Time stamp function	• Time stamp function using a 16-bit counter • The reference clock can be selected from either 1-, 2-, 4- or 8-bit time periods.
Interrupt sources	• 5 types: Reception complete Transmission complete Receive FIFO Transmit FIFO Error
CAN sleep mode	• Current consumption can be reduced by stopping the CAN clock.
Software support unit	• 3 software support units: Acceptance filter support Mailbox search support (receive mailbox search, transmit mailbox search and message lost search) Channel search support
CAN clock source (fCAN)	• Peripheral clocks (clkp1 or clkp2) or externally input clock is selectable. clkp1 = S3D4ϕ, clkp2 = CANFDϕ
Test mode	• 3 test modes available for user evaluation: Listen-only mode Self-test mode 0 (external loop back) Self-test mode 1 (internal loop back)

47.1.2 Block Diagram

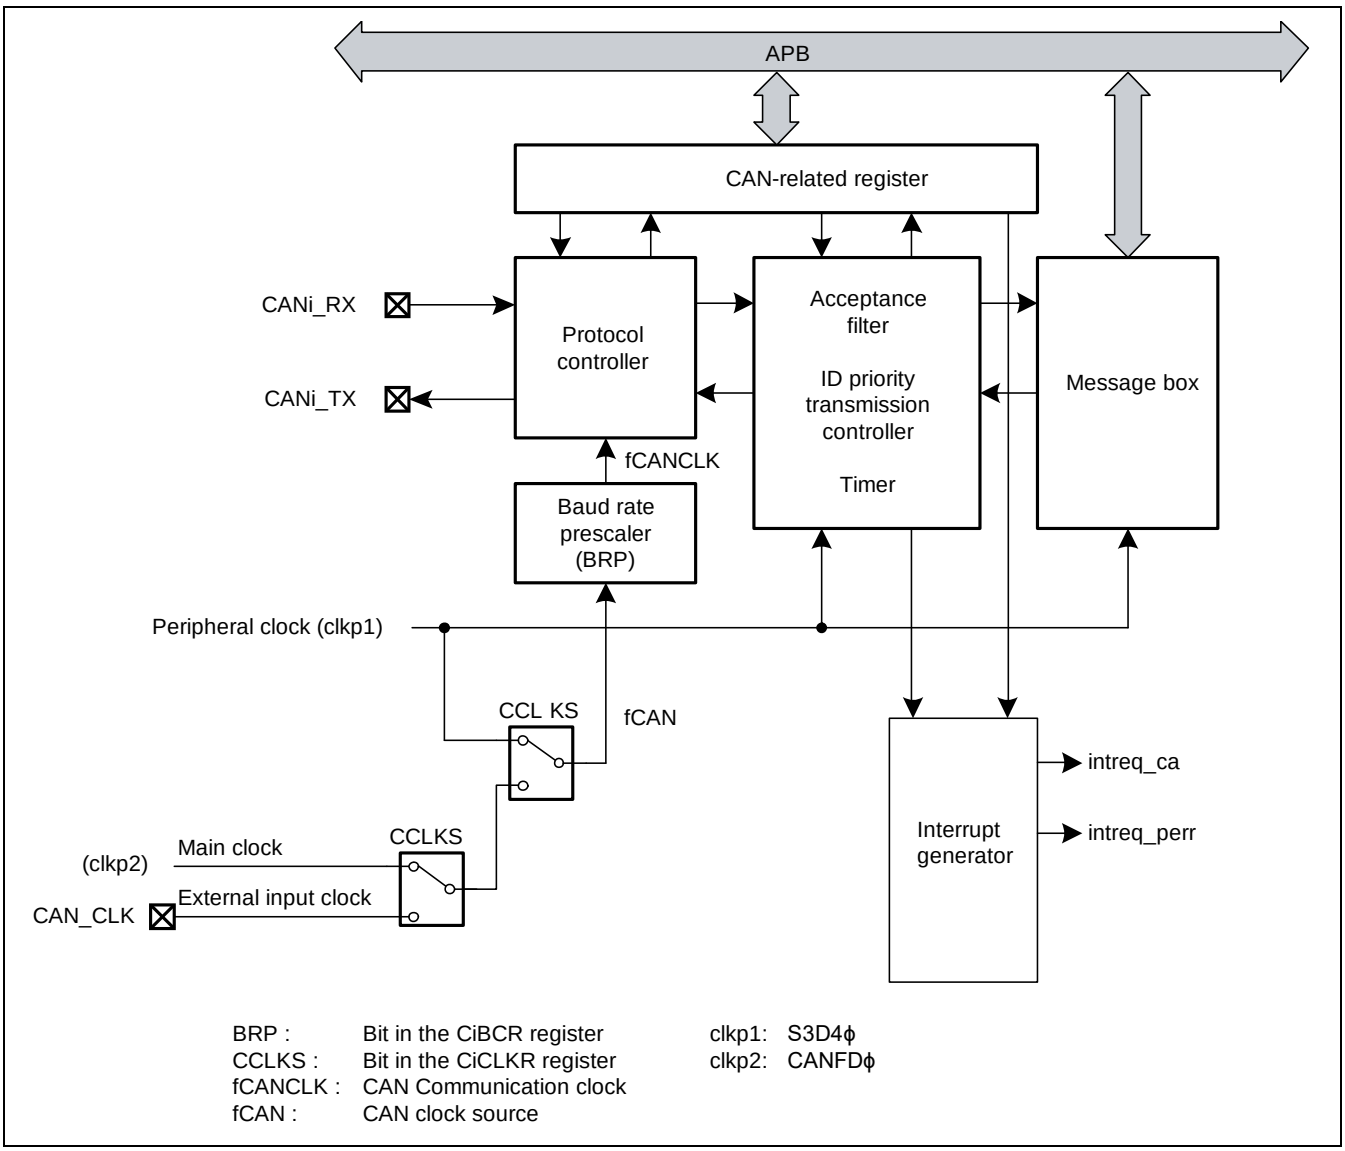

Figure 47.1 Block Diagram of CAN Module (i = 0, 1)

- CANi_RX/CANi_TX (i = 0 and 1):
  CAN input/output pins
- Protocol controller:
  Handles CAN protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, and error handling, etc.
- Message box:
  Consists of 64 mailboxes which can be configured as either transmit or receive mailboxes. Each mailbox has an individual ID, data length code, a data field (8 bytes), and a time stamp.
- Acceptance filter:
  Performs filtering of received messages. Registers CiMKR0 to CiMKR9 are used for the filtering process.
- Timer:
  Used for the time stamp function. The timer value when storing a message into the mailbox is written as the time stamp value.
- Interrupt generator:
  Generates the following five types of interrupts:
  CANi reception complete interrupt
  CANi transmission complete interrupt
  CANi receive FIFO interrupt
  CANi transmit FIFO interrupt
  CANi error interrupt
- Support parity error detection as safety mechanism function

47.1.3 External Pins

Table 47.2 shows the CAN module pin.

Pin switching is required for pins which are multiplexed with other functions. For details, see section 6, Pin Function Controller (PFC).

Table 47.2 Pin Configuration

47.2 Register Description

Legend:

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing1 is ignored.

R: Read-only. When writing to the register, read out the value of these bits and write it back without alteration.

W: Write-only. The read value is undefined.

47.2.1 CANi Control Register (CiCTLR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CAN0 Control Register (C0CTLR)

CAN1 Control Register (C1CTLR)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	RBOC	BOM		SLPM	CANM		TSPS		TSRC	TPM	MLM	IDFM		MBM
Initial value:	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

<After Reset: H'0500>

Bit	Symbol	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
13	RBOC	B'0	R/W	Forcible Return From Bus-OFF Bit*1 When the RBOC bit is set to "1" (forcible return from bus-off) in bus-off state, the CAN module forcibly returns from the bus-off state. This bit is automatically set to 0. The error state changes from bus-off to error-active. When the RBOC bit is set to "1", registers CiRECR and CiTECR are set to "H'00" and the BOST bit in the CiSTR register is set to "0" (the CAN module is not in bus-off state). The other registers remain unchanged. No bus-off recovery interrupt request is generated by this recovery from the bus-off state. Use the RBOC bit only when the BOM bit = "00" (normal mode). 0: Nothing occurred 1: Forcible return from bus-off*2

Bit	Symbol	Initial Value	R/W	Description
12, 11	BOM	All 0	R/W	Bus-Off Recovery Mode Bit*3 The BOM bit is used to select bus-off recovery mode. When the BOM bit is "B'00", the recovery from bus-off is compliant with ISO11898-1, i.e. the CAN module re-enters CAN communication (error-active state) after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off. When the BOM bit is "B'01", as soon as the CAN reaches the bus-off state, the CANM bit in the CiCTLR register is set to "B'10" (CAN halt mode) and the CAN enters CAN halt mode. No bus-off recovery interrupt request is generated when recovering from bus-off and registers CiTECR and CiRECR are set to "H'00". When the BOM bit is "B'10", the CANM bit is set to B'10 as soon as the CAN module reaches the bus-off state. The CAN module enters CAN halt mode after the recovery from the bus-off state, i.e. after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off and registers CiTECR and CiRECR are set to "H'00". When the BOM bit is "B'11", the CAN module enters CAN halt mode by setting the CANM bit to "B'10" while the CAN module is still in bus-off state. No bus-off recovery interrupt request is generated when recovering from bus-off and registers CiTECR and CiRECR are set to "H'00". However, if the CAN module recovers from bus-off after detecting 11 consecutive recessive bits 128 times before the CANM bit is set to "B'10", a bus-off recovery interrupt request is generated. If the CPU requests an entry to CAN reset mode at the same time as the CAN module attempts to enter CAN halt mode (at bus-off entry when the BOM bit is "B'01", or at bus-off end when the BOM bit is "B'10"), then the CPU request to enter CAN reset mode has higher priority. B'00: Normal mode (ISO11898-1 compliant) B'01: Entry to CAN halt mode automatically at bus-off entry B'10: Entry to CAN halt mode automatically at bus-off end B'11: Entry to CAN halt mode (during bus-off recovery period) by a program request
10	SLPM	B’1	R/W	CAN Sleep Mode Bit*4*5 When the SLPM bit is set to "1", the CAN module enters CAN sleep mode. When the SLPM bit is set to "0", the CAN module exits CAN sleep mode. Refer to section 47.3, Operating Mode for detail. 0: Other than CAN sleep mode 1: CAN sleep mode
9, 8	CANM	B’01	R/W	CAN Operating Mode Select Bit*4 The CANM bit selects one of the following modes for the CAN module: CAN operation mode, CAN reset mode or CAN halt mode. Refer to section 47.3, Operating Mode for detail. CAN sleep mode is set by the SLPM bit. When the CAN module enters CAN halt mode according to the setting of the BOM bit, the CANM bit is automatically set to "10". B’00: CAN operation mode B’01: CAN reset mode B’10: CAN halt mode B’11: CAN reset mode (forcible transition)

Bit	Symbol	Initial Value	R/W	Description
7, 6	TSPS	All 0	R/W	Time Stamp Prescaler Select Bit*3 The TSPS bit selects the prescaler for the time stamp. The reference clock for the time stamp can be selected to be either 1-, 2-, 4- or 8-bit time periods. B'00: Every bit time B'01: Every 2-bit time B'10: Every 4-bit time B'11: Every 8-bit time
5	TSRC	B'0	R/W	Time Stamp Counter Reset Command Bit*6 The TSRC bit is used to reset the time stamp counter. When the TSRC bit is set to "1", the CiTSR register is set to H'0000. It is automatically set to 0. 0: Nothing occurred 1: Reset*2
4	TPM	B'0	R/W	Transmission Priority Mode Select Bit*3 The TPM bit specifies the priority of modes when transmitting messages. ID priority transmit mode or mailbox number transmit mode can be selected. All mailboxes are set for either ID priority transmission or mailbox number priority transmission. When the TPM bit is 0, ID priority transmit mode is selected and transmission priority complies with the CAN bus arbitration rule, as defined in the ISO 11898-1 Specifications. In ID priority transmit mode, mailboxes [0] to [63] (in normal mailbox mode), and mailboxes [0] to [55] (in FIFO mailbox mode), and the transmit FIFO are compared for the IDs of mailboxes configured for transmission. If two or more mailbox IDs are the same, the mailbox with the smaller number has higher priority. Only the next message to be transmitted from the transmit FIFO is included in the transmission arbitration. If a transmit FIFO message is being transmitted, the next pending message within the transmit FIFO is included in the transmission arbitration. When the TPM bit is 1, mailbox number transmit mode is selected and the transmit mailbox with the smallest mailbox number has the highest priority. In FIFO mailbox mode, the transmit FIFO has lower priority than normal mailboxes (mailboxes [0] to [55]). 0: ID priority transmit mode 1: Mailbox number priority transmit mode
3	MLM	B'0	R/W	Message Lost Mode Select Bit*3 The MLM bit specifies the operation when a new message is captured in the unread mailbox. Overwrite mode or overrun mode can be selected. All mailboxes (including the receive FIFO) are set to either overwrite mode or overrun mode. When the MLM bit is "0", all mailboxes are set to overwrite mode and the new message is overwriting the old message. When this bit is "1", all mailboxes are set to overrun mode and the new message is discarded. 0: Overwrite mode 1: Overrun mode

Bit	Symbol	Initial Value	R/W	Description
2, 1	IDFM	All 0	R/W	ID Format Mode Select Bit*3 The IDFM bit specifies the ID format. B'00: Standard ID mode All mailboxes (including FIFO mailboxes) handle only standard IDs. B'01: Extended ID mode All mailboxes (including FIFO mailboxes) handle only extended IDs. B'10: Mixed ID mode All mailboxes (including FIFO mailboxes) handle both standard IDs and extended IDs. Standard IDs or extended IDs are specified by using the IDE bit in the corresponding mailbox in normal mail box mode. In FIFO mailbox mode, the IDE bit in the corresponding mailbox is used for mailboxes [0] to [55], the IDE bit in registers CiFIDCR0 and CiFIDCR1 is used for the receive FIFO, and the IDE bit in mailbox [56] is used for the transmit FIFO. B'11: Do not use this combination
0	MBM	B'0	R/W	CAN Mailbox Mode Select Bit*3 When the MBM bit is "0" (normal mailbox mode), mailboxes [0] to [63] are configured as transmit or receive mailboxes. When the MBM bit is "1" (FIFO mailbox mode), mailboxes [0] to [55] are configured as transmit or receive mailboxes. Mailboxes [56] to [59] are configured as a transmit FIFO and mailboxes [60] to [63] as a receive FIFO. Transmit data is written into mailbox [56] (mailbox [56] is a window mailbox for the transmit FIFO). Receive data is read from mailbox [60] (mailbox [60] is a window mailbox for the receive FIFO). Table 47.5 lists the Mailbox Configuration. 0: Normal mailbox mode 1: FIFO mailbox mode

Notes:
1. Set the RBOC bit to "1" in bus-off state.
2. Bits RBOC and TSRC are automatically set back to "0" after being set to "1". It should be read as "0".
3. Write to bits BOM, MBM, IDFM, MLM,, TPM, and TSPS in CAN reset mode.
4. When bits CANM and SLPM are changed, check the CiSTR register to ensure that the mode has been switched.
5. Write to the SLPM bit in CAN reset mode or CAN halt mode. When rewriting the SLPM bit, set only this bit to "0" or "1".
6. Set the TSRC bit to "1" in CAN operation mode.

Table 47.5 Mailbox Configuration

Mailbox	MBM Bit = "0" (Normal mailbox mode)	MBM Bit = "1" (FIFO mailbox mode)
Mailboxes [0] to [55]	Normal mailbox	Normal mailbox
Mailboxes [56] to [59]		Transmit FIFO
Mailboxes [60] to [63]		Receive FIFO

Notes: Points 1 to 5 below should be considered when the MBM bit is set to "1".

1. Transmit FIFO is controlled by the CiTFCR register.
   The CiMCTLj register of mailboxes [56] to [59] are disabled.
   Registers CiMCTL56 to CiMCTL59 cannot be used.
2. Receive FIFO is controlled by the CiRFCR register.
   The CiMCTLj register of mailboxes [60] to [63] are disabled.
   Registers CiMCTL60 to CiMCTL63 cannot be used.
3. Refer to the CiMIER1 register about the FIFO interrupts.
4. The corresponding bits in the CiMKIVLR register for mailboxes [56] to [63] are disabled. Set 0 to these bits.
5. Transmit/receive FIFOs can be used for both data frames and remote frames.

47.2.2 CANi Clock Select Register (CiCLKR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CAN0 Clock Select Register (C0CLKR)

CAN1 Clock Select Register (C1CLKR)

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CCLKS	
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 2	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
1, 0	CCLKS	B’00	R/W	CAN Clock Source Select Bits* The CCLKS bits select clock source from among the peripheral clock (clkp1 or clkp2) generated by the PLL frequency synthesizer, and an externally input clock. B’00: Peripheral clock (clkp1) B’01: Peripheral clock (clkp2) B’10: Illegal value B’11: Externally input clock

Note: * Write to the CCLKS bit in CAN reset mode.

47.2.3 CANi Bit Configuration Register (CiBCR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

For the bit timing configuration rule, refer to section 47.4, CAN Communication Speed Configuration.

Set the CiBCR register before entering CAN halt mode from CAN reset mode or CAN operation mode from CAN reset mode. After the setting is made once, this register can be written to in CAN reset mode or CAN halt mode.

The CiBCR register consists of 24 bits. A 32-bit read/write access should be performed carefully not to rewrite the CiCLKR register.

CAN0 Bit Configuration Register (C0BCR)

<After Reset: H'0000_0000>

Bit	Symbol	Initial Value	R/W	Description
31 to 28	TSEG1	All 0	R/W	Time Segment 1 Control Bits The TSEG1 bit is used to specify the total length of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1) with the value of Tq. A value from 4 to 16 time quanta can be set. B’0000: Do not use this combination B’0001: Do not use this combination B’0010: Do not use this combination B’0011: 4 Tq B’0100: 5 Tq B’0101: 6 Tq B’0110: 7 Tq B’0111: 8 Tq B’1000: 9 Tq B’1001: 10 Tq B’1010: 11 Tq B’1011: 12 Tq B’1100: 13 Tq B’1101: 14 Tq B’1110: 15 Tq B’1111: 16 Tq

Bit	Symbol	Initial Value	R/W	Description
27, 26	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
25 to 16	BRP	All 0	R/W	Prescaler Division Ratio Set Bits The BRP bit is used to set the peripheral bus clock periods contained in a Time Quantum. If the setting value is P (0 to 1023), the baud rate prescaler divides fCAN by P + 1.
15, 14	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
13, 12	SJW	All 0	R/W	Resynchronization Jump Width Control Bits The SJW bit is used to specify the resynchronization jump width with the value of Tq. A value from 1 to 4 time quanta can be set. Set the value smaller than or equal to that of the TSEG2 bit. B’00: 1 Tq B’01: 2 Tq B’10: 3 Tq B’11: 4 Tq
11	—	B’0	R	Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.
10 to 8	TSEG2	All 0	R/W	Time Segment 2 Control Bits The TSEG2 bit is used to specify the length of phase buffer segment 2 (PHASE_SEG2) with the value of Tq. A value from 2 to 8 time quanta can be set. Set the value smaller than that of the TSEG1 bit. B’000: Do not use this combination B’001: 2 Tq B’010: 3 Tq B’011: 4 Tq B’100: 5 Tq B’101: 6 Tq B’110: 7 Tq B’111: 8 Tq
7 to 0	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.

47.2.4 CANi Mask Register k (CiMKRk) (i = 0, 1; k = 0 to 9)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

For masking the function in FIFO mailbox mode, refer to section 47.6, Acceptance Filtering and Masking Function.

Write to registers CiMKR0 to CiMKR9 in CAN reset mode or CAN halt mode.

CAN0 Mask Register 0 (C0MKR0)

CAN0 Mask Register 1 (C0MKR1)

CAN0 Mask Register 2 (C0MKR2)

:

CAN0 Mask Register 9 (C0MKR9)

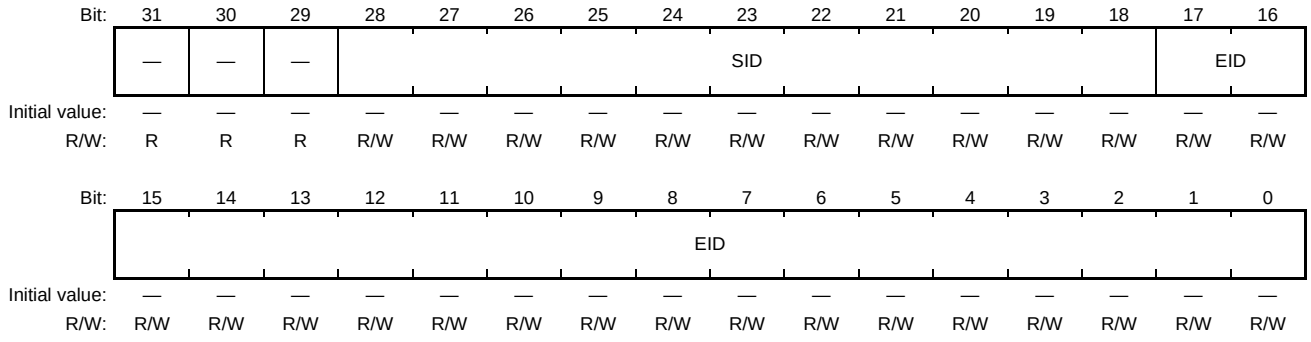
CAN1 Mask Register 0 (C1MKR0)

CAN1 Mask Register 1 (C1MKR1)

CAN1 Mask Register 2 (C1MKR2)

:

CAN1 Mask Register 9 (C1MKR9)



<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
31 to 29	—	Undefined	R	Reserved bits The reset value is undefined. The write value should be "0". These bits are read as "0" after "0" is written to.

Bit	Symbol	Initial Value	R/W	Description
28 to 18	SID	Undefined	R/W	Standard ID Bits The SID bit is the filter mask bit corresponding to the CAN standard ID bit. The SID bit is used to receive both standard ID and extended ID messages. When the SID bit is set to "0", the corresponding SID bit is not compared for the received ID and the mailbox ID. When the SID bit is set to "1", corresponding SID bit compares received ID with mailbox ID. 0: Corresponding SID bit is not compared 1: Corresponding SID bit is compared
17 to 0	EID	Undefined	R/W	Extended ID Bits The EID bit is the filter mask bit for CAN extended ID bit. This bit is used to receive extended ID messages. When the EID bit is set to "0", corresponding EID bit does not compare received ID with mailbox ID. When the EID bit is set to "1", corresponding EID bit compares received ID with mailbox ID. 0: Corresponding EID bit is not compared 1: Corresponding EID bit is compared

47.2.5 CANi FIFO Received ID Compare Registers (CiFIDCR0 and CiFIDCR1) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Registers CiFIDCR0 and CiFIDCR1 are enabled when the MBM bit in the CiCTLR register is set to "1" (FIFO mailbox mode). Bits EID, SID, RTR, and IDE in registers CiMB60 to CiMB63 are disabled.

For the usage of these registers, refer to section 47.6, Acceptance Filtering and Masking Function.

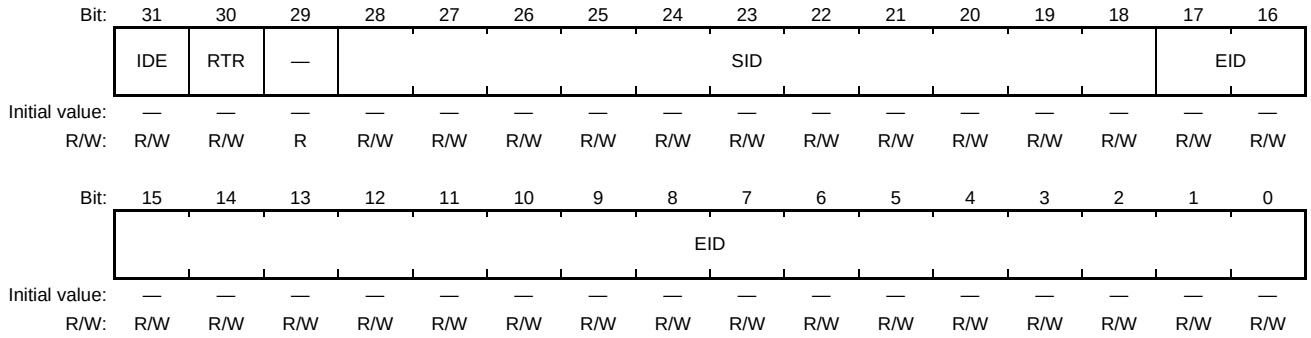
Write to registers CiFIDCR0 and CiFIDCR1 in CAN reset mode or CAN halt mode.

CAN0 FIFO Received ID Compare Register 0 (C0FIDCR0)

CAN0 FIFO Received ID Compare Register 1 (C0FIDCR1)

CAN1 FIFO Received ID Compare Register 0 (C1FIDCR0)

CAN1 FIFO Received ID Compare Register 1 (C1FIDCR1)



<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
31	IDE	Undefined	R/W	ID Extension Bit* The IDE bit sets the ID format to standard ID or extended ID. The IDE bit is enabled when the IDFM bit in the CiCTLR register is "10" (mixed ID mode). When the IDFM bit is "10", the IDE bit specifies the following operation. When both IDE bits in registers CiFIDCR0 and CiFIDCR1 are set to "0", only standard ID frames can be received. When both IDE bits in registers CiFIDCR0 and CiFIDCR1 are set to "1", only extended ID frames can be received. When the IDE bits in registers CiFIDCR0 and CiFIDCR1 are set to "0" or "1" individually, both standard ID and extended ID frames can be received. 0: Standard ID 1: Extended ID

Bit	Symbol	Initial Value	R/W	Description
30	RTR	Undefined	R/W	Remote Transmission Request Bit The RTR bit sets the specified frames format of data frame or remote frames. The RTR bit specifies the following operation. When both RTR bits in registers CiFIDCR0 and CiFIDCR1 are set to "0", only data frames can be received. When both RTR bits in registers CiFIDCR0 and CiFIDCR1 are set to "1", only remote frames can be received. When the RTR bits in registers CiFIDCR0 and CiFIDCR1 are set to "0" or "1" individually, both data frames and remote frames can be received. 0: Data frame 1: Remote frame
29	—	Undefined	R	Reserved bit The reset value is undefined. The write value should be "0". This bit is read as "0" after "0" is written to.
28 to 18	SID	Undefined	R/W	Standard ID Bits The SID bit sets the standard ID of data frames and remote frames. The SID bit is used to receive both standard ID and extended ID messages. 0: Corresponding SID bit is "0" 1: Corresponding SID bit is "1"
17 to 0	EID	Undefined	R/W	Extended ID Bits The EID bit sets the extended ID of data frames and remote frames. The EID bit is used to receive extended ID messages. 0: Corresponding EID bit is "0" 1: Corresponding EID bit is "1"

Note: * When the IDFM bit is not "10", the IDE bit should be written with "0".

47.2.6 CANi Mask Invalid Registers (CiMKIVLR0 and CiMKIVLR1) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Each bit in registers CiMKIVLR0 and CiMKIVLR1 corresponds to a mailbox. The correspondence between the bits and mailboxes is as follows:

- Bit 0 in the CiMKIVLR0 register corresponds to mailbox 0 (MB0).
- Bit 31 in the CiMKIVLR0 register corresponds to mailbox 31 (MB31).
- Bit 0 in the CiMKIVLR1 register corresponds to mailbox 32 (MB32).
- Bit 31 in the CiMKIVLR1 register corresponds to mailbox 63 (MB63).

When each bit is "1", the acceptance mask for the mailbox corresponding to the bit number is disabled. In this case, a receiving message is stored into mailbox only its ID matches bits SID and EID in the CiMBj register.

Write to registers CiMKIVLR0 and CiMKIVLR1 either in CAN reset mode or CAN halt mode.

CAN0 Mask Invalid Register 0 (C0MKIVLR0)

CAN1 Mask Invalid Register 0 (C1MKIVLR0)

H'E6C3_0000 + 16 × j + 15	H'E6C3_8000 + 16 × j + 15	Time stamp lower byte

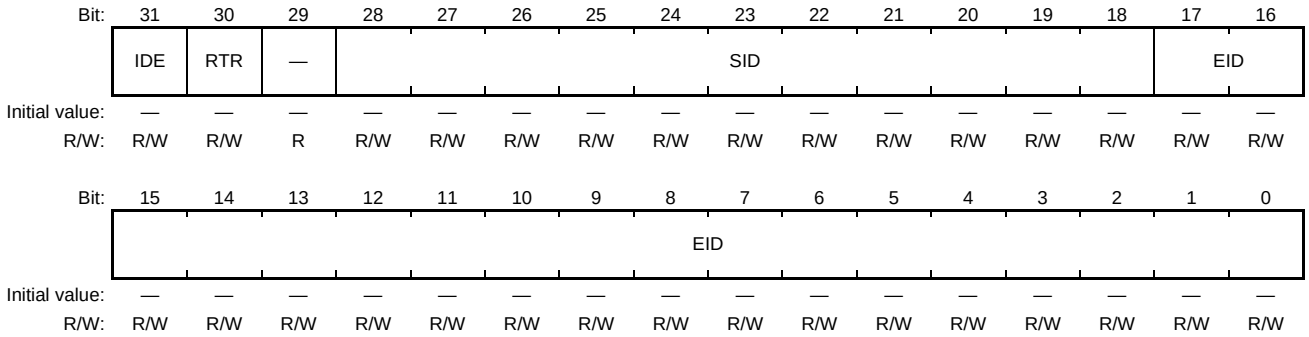
Table 47.7 CAN Data Frame Construction

SID10 to SID6	SID5 to SID0	EID17 to EID16	EID15 to EID8	EID7 to EID0	DLC3 to DLC0	DATA0	DATA1	…	DATA7

The previous value of each mailbox is retained unless a new message is received.

CAN0 Mailbox Register 0 to 63 (C0MB0 to 63)

CAN1 Mailbox Register 0 to 63 (C1MB0 to 63)



<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
31	IDE	Undefined	R/W	ID Extension Bit*1 The IDE bit sets the ID format of standard IDs or extended IDs. The IDE bit is enabled when the IDFM bit in the CiCTLR register is "10" (mixed ID mode). When the IDFM bit is "10", the IDE bit specifies the following operation. Receive mailbox receives only ID format specified by the IDE bit. Transmit mailbox transmits with ID format specified by the IDE bit. Receive FIFO mailbox receives messages with the standard ID, extended ID, or both IDs specified by the IDE bit in registers CiFIDCR0 and CiFIDCR1. Transmit FIFO mailbox transmits messages with the standard ID or extended ID specified by the IDE bit in the relevant transmitting message. 0: Standard ID 1: Extended ID
30	RTR	Undefined	R/W	Remote Frame Request Bit The RTR bit sets the frame format of data frames or remote frames. This bit specifies the following operation: Receive mailbox receives only frames with the format specified by the RTR bit. Transmit mailbox transmits according to the frame format specified by the RTR bit. Receive FIFO mailbox receives the data frame, remote frame, or both frames specified by the RTR bit in registers CiFIDCR0 and CiFIDCR1. Transmit FIFO mailbox transmits the data frame or remote frame specified by the RTR bit in the relevant transmitting message. 0: Data frame 1: Remote frame
29	—	Undefined	R	Reserved bit The reset value is undefined. The write value should be "0". This bit is read as "0" after "0" is written to.

Bit	Symbol	Initial Value	R/W	Description
28 to 18	SID	Undefined	R/W	Standard ID Bits The SID bit sets the standard ID of data frames and remote frames. The SID bit is used to transmit or receive both standard ID and extended ID messages. 0: Corresponding SID bit is "0" 1: Corresponding SID bit is "1"
17 to 0	EID	Undefined	R/W	Extended ID Bits*2 The EID bit sets the extended ID of data frames and remote frames. The EID bit is used to transmit or receive extended ID messages. 0: Corresponding EID bit is "0" 1: Corresponding EID bit is "1"

Notes: 1. When the IDFM bit is not "10", it should be written with "0".
2. If the mailbox has received a standard ID message, the EID bit in the mailbox is undefined.

CAN0 Mailbox Register 0 to 63 (C0MB0 to 63)

CAN1 Mailbox Register 0 to 63 (C1MB0 to 63)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	DLC			
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

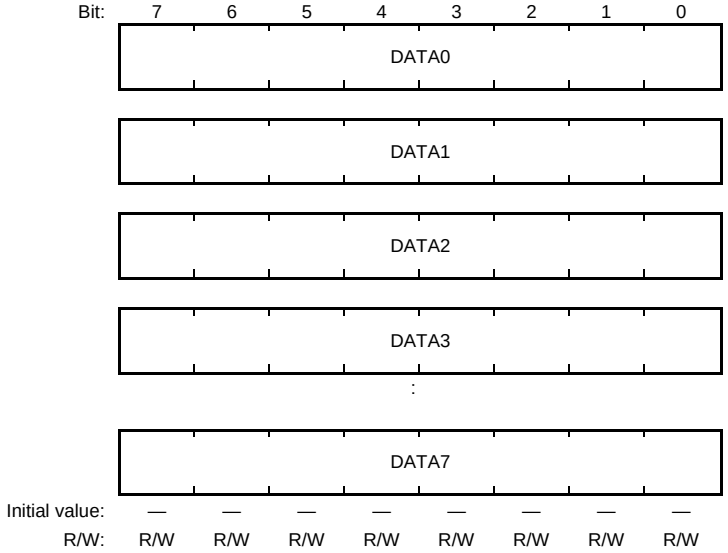
<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
15 to 4	—	Undefined	R	Reserved bits The reset value is undefined. The write value should be "0". These bits are read as "0" after "0" is written to.
3 to 0	DLC	Undefined	R/W	Data Length Code Bits* The DLC is used to set the number of data bytes to be transmitted in a data frame. When data is requested using a remote frame, the number of data bytes to be requested is set. When a data frame is received, the number of received data bytes is stored. When a remote frame is received, the number of requested data bytes is stored. B'0000: Data length = 0 byte B'0001: Data length = 1 byte B'0010: Data length = 2 bytes B'0011: Data length = 3 bytes B'0100: Data length = 4 bytes B'0101: Data length = 5 bytes B'0110: Data length = 6 bytes B'0111: Data length = 7 bytes B'1xxx: Data length = 8 bytes Legend: x represents any value.

Note: * If the mailbox has received a message with n bytes less than 8 bytes, the values of DATAn to DATA7 in the mailbox are undefined.

CAN0 Mailbox Register 0 to 63 (C0MB0 to 63)

CAN1 Mailbox Register 0 to 63 (C1MB0 to 63)



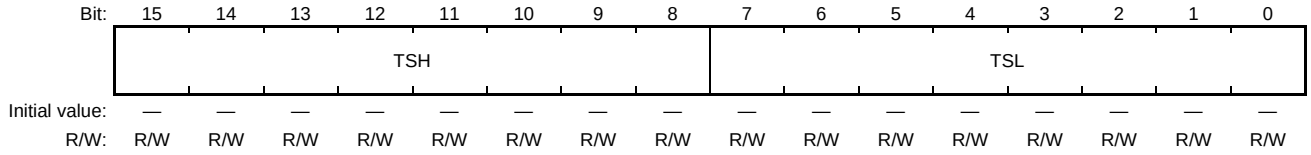
<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
7 to 0	DATA0 to 7	Undefined	R/W	Data Bytes 0 to 7*1*2 DATA0 to DATA7 store the transmitted or received CAN message data. Transmission or reception starts from DATA0. The bit order on the CAN bus is MSB first, and transmission or reception starts from bit 7.

Notes: 1. If the mailbox has received a message with n bytes less than 8 bytes, the values of DATAn to DATA7 in the mailbox are undefined.
2. If the mailbox has received a remote frame, the previous values of DATA0 to DATA7 in the mailbox are retained.

CAN0 Mailbox Register 0 to 63 (C0MB0 to 63)

CAN1 Mailbox Register 0 to 63 (C1MB0 to 63)



<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
15 to 8	TSH	Undefined	R/W	Time Stamp Higher Byte TSL and TSH store the counter value of the time stamp when received messages are stored in the mailbox.
7 to 0	TSL	Undefined	R/W	Time Stamp Lower Byte TSL and TSH store the counter value of the time stamp when received messages are stored in the mailbox.

47.2.8 CANi Mailbox Interrupt Enable Registers (CiMIER0 and CiMIER1) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Interrupts can enable individually for each mailbox.

In normal mailbox mode (all bits) and in FIFO mailbox mode (bits 23 to 0 in the CiMIER1 register and all bits in the CiMIER0 register), each bit corresponds to the mailbox with the related number. These bits enable or disable transmission/reception complete interrupts for the corresponding mailboxes.

- Bit 0 in the CiMIER0 register corresponds to mailbox 0 (MB0).
- Bit 31 in the CiMIER0 register corresponds to mailbox 31 (MB31).
- Bit 0 in the CiMIER1 register corresponds to mailbox 32 (MB32).
- Bit 31 in the CiMIER1 register corresponds to mailbox 63 (MB63).

In FIFO mailbox mode, bits 29, 28, 25, and 24 of the CiMIER1 register specify whether transmit/receive FIFO interrupts are enabled/disabled and timing when interrupt requests are generated.

Write to registers CiMIER0 and CiMIER1 only when the associated CiMCTLj register (i = 0, 1) (j = 0 to 63) is "H'00" and the corresponding mailbox is not processing a transmission or reception abort request. In FIFO mailbox mode, change the bits in the CiMIER1 register for the associated FIFO only when:

— The TFE bit in the CiTFCR register is 0 and the TFEST bit is 1.
— The RFE bit in the CiRFCR register is 0 and the RFEST bit is 1.

CAN0 Mailbox Interrupt Enable Register 1 (C0MIER1)

CAN1 Mailbox Interrupt Enable Register 1 (C1MIER1)

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7	TRMREQ	B'0	R/W	Transmit Mailbox Request Bit*2*4 The TRMREQ bit selects transmit modes shown in Table 47.12. When TRMREQ bit is set to "1", the corresponding mailbox is configured for transmission of a data frame or a remote frame. When TRMREQ bit is set to "0", the corresponding mailbox is not configured for transmission of a data frame or a remote frame. If the TRMREQ bit is changed from "1" to "0" to cancel the corresponding transmission request, either the TRMABT or SENTDATA bit is set to "1". When setting the TRMREQ bit to "1", do not set the RECREQ bit to "1". To change the configuration of a mailbox from reception to transmission, first abort the reception and then set bits NEWDATA and MSGLOST to "0" before changing to transmission. 0: Not configured for transmission 1: Configured for transmission
	—	B'0	R	Reserved bit (Registers CiMCTL0 to CiMCTL31) This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.
6	RECREQ	B'0	R/W	Receive Mailbox Request Bit*2*4*5 The RECREQ bit selects receive modes shown in Table 47.12. When the RECREQ bit is set to "1", the corresponding mailbox is configured for reception of a data frame or a remote frame. When the RECREQ bit is set to "0", the corresponding mailbox is not configured for reception of a data frame or a remote frame. Due to hardware protection the RECREQ bit cannot be set to "0" by writing "0" by a program during the following period. Hardware protection is started From the acceptance filter procedure. (the beginning of CRC field) Hardware protection is released For the mailbox that is specified to receive the incoming message, after the received data is stored into the mailbox or a CAN bus error occurs. (i.e. a maximum period of hardware protection is from the beginning of CRC field to the end of the 7th bit of EOF.) For the other mailboxes, after the acceptance filter procedure. If no mailbox is specified to receive the message, after the acceptance filter procedure. When setting the RECREQ bit to "1", do not set "1" to the TRMREQ bit. To change the configuration of a mailbox from transmission to reception, first abort the transmission and then set bits SENTDATA and TRMABT to "0" before changing to reception. 0: Not configured for reception 1: Configured for reception
5	—	B'0	R	Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.

Bit	Symbol	Initial Value	R/W	Description
4	ONESHOT	B'0	R/W	One-shot Enable Bit*3 The ONESHOT bit can be used in the following two ways, receive mode and transmit mode: One-Shot Receive Mode When the ONESHOT bit is set to "1" in receive mode (RECREQ bit = "1" and TRMREQ bit = "0"), the mailbox receives a message only one time. The mailbox does not behave as a receive mailbox after having received a message one time. The behavior of bits NEWDATA and INVALDATA is the same as in normal reception mode. In one-shot receive mode, the MSGLOST bit is not set to "1". To set the ONESHOT bit to "0", first write "0" to the RECREQ bit and ensure that it has been set to "0". One-Shot Transmit Mode When the ONESHOT bit is set to "1" in transmit mode (RECREQ bit = "0" and TRMREQ bit = "1"), the CAN module transmits a message only one time. The CAN module does not transmit the message again if a CAN bus error or CAN bus arbitration lost occurs. When transmission is completed, the SENTDATA bit is set to "1". If transmission is not completed due to a CAN bus error or CAN bus arbitration lost, the TRMABT bit is set to "1". Set the ONESHOT bit to "0" after the SENTDATA or TRMABT bit is set to "1". 0: One-shot reception or one-shot transmission disabled 1: One-shot reception or one-shot transmission enabled
	—	B'0	R	Reserved bit (Registers CiMCTL0 to CiMCTL31) This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.
3	—	B'0	R	Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.

Bit	Symbol	Initial Value	R/W	Description
2	TRMABT	B'0	R/W	Transmission Abort Complete Flag (Transmit mailbox setting enabled)*1*2 The TRMABT bit is set to "1" in the following cases: Following a transmission abort request, when the transmission abort is completed before starting transmission. Following a transmission abort request, when the CAN module detects CAN bus arbitration lost or a CAN bus error. In one-shot transmission mode (RECREQ bit = "0", TRMREQ bit = "1", and ONESHOT bit = "1"), when the CAN module detects CAN bus arbitration lost or a CAN bus error. The TRMABT bit is not set to "1" when data transmission is completed. In this case, the SENTDATA bit is set to "1". The TRMABT bit is set to "0" by writing "0" by a program. 0: Transmission has started, transmission abort failed because transmission is completed, or transmission abort is not requested 1: Transmission abort is completed
	MSGLOST	B'0	R/W	Message Lost Flag (Receive mailbox setting enabled)*1*2 The MSGLOST bit is set to "1" when the mailbox is overwritten or overrun by a new received message while the NEWDATA bit is "1". The MSGLOST bit is set to "1" at the end of the 6th bit of EOF. The MSGLOST bit is set to "0" by writing "0" by a program. In both overwrite and overrun modes, the MSGLOST bit is not set to "0" by writing "0" by a program during the 5 peripheral clock (clkp1) cycles following the 6th bit of EOF. 0: Message is not overwritten or overrun 1: Message is overwritten or overrun
1	TRMACTIVE	B'0	R	Transmission-in-Progress Status Flag (Transmit mailbox setting enabled) The TRMACTIVE bit is set to "1" when the corresponding mailbox of the CAN module begins transmitting a message. The TRMACTIVE is set to "0" when the CAN module has lost CAN bus arbitration, a CAN bus error occurs, or data transmission is completed. 0: Transmission is pending or transmission is not requested 1: From acceptance of transmission request to completion of transmission, or error/arbitration lost
	INVALDATA	B'0	R	Reception-in-Progress Status Flag (Receive mailbox setting enabled) After the completion of a message reception, the INVALDATA bit is set to "1" while the received message is being updated into the corresponding mailbox. The INVALDATA bit is set to "0" immediately after the message has been stored. If the mailbox is read while the INVALDATA bit is "1", the data is undefined. 0: Message valid 1: Message being updated

Bit	Symbol	Initial Value	R/W	Description
0	SENTDATA	B'0	R/W	Transmission Complete Flag (Transmit mailbox setting enabled)*1*2 The SENTDATA bit is set to "1" when data transmission from the corresponding mailbox is completed. The SENTDATA bit is set to "0" by writing "0" by a program. To set the SENTDATA bit to "0", first set the TRMREQ bit to "0". Bits SENTDATA and TRMREQ cannot be set to "0" simultaneously. To transmit a new message from the corresponding mailbox, set the SENTDATA bit to "0". 0: Transmission is not completed (pending) 1: Transmission is completed (success)
	NEWDATA	B'0	R/W	Reception Complete Flag (Receive mailbox setting enabled)*1*2 The NEWDATA bit is set to "1" when a new message is being stored or has been stored to the mailbox. The timing for setting this bit to "1" is simultaneous with the INVALDATA bit. The NEWDATA bit is set to "0" by writing "0" by a program. The NEWDATA bit is not set to "0" by writing "0" by a program while the related INVALDATA bit is "1". 0: No data has been received or "0" is written to the NEWDATA bit 1: A new message is being stored or has been stored to the mailbox

Notes:
1. Write "0" only. Writing "1" has no effect.
2. When writing "0" to bits NEWDATA, SENTDATA, MSGLOST, TRMABT, RECREQ, and TRMREQ by a program, use the MOV instruction to ensure that only the specified bit is set to "0" and the other bits are set to "1".
3. To enter one-shot receive mode, write "1" to the ONESHOT bit at the same time as setting the RECREQ bit to "1".
   To exit one-shot receive mode, write "0" to the ONESHOT bit after writing "0" to the RECREQ bit and confirming it has been set to "0".
   To enter one-shot transmit mode, write "1" to the ONESHOT bit at the same time as setting the TRMREQ bit to "1".
   To exit one-shot transmit mode, write "0" to the ONESHOT bit after the message has been transmitted or aborted.
4. Do not set both the RECREQ and TRMREQ bits to "1".
5. When setting the RECREQ bit to "0", set bits MSGLOST, NEWDATA, RECREQ to "0" simultaneously.

47.2.10 CANi Receive FIFO Control Register (CiRFCR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Write to the CiRFCR registers in CAN operation mode or CAN halt mode.

CAN0 Receive FIFO Control Register (C0RFCR)

CAN1 Receive FIFO Control Register (C1RFCR)

Bit:	7	6	5	4	3	2	1	0
	RFEST	RFWST	RFFST	RFMLF	RFUST			RFE
Initial value:	1	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

<After Reset: H'80>

Bit	Symbol	Initial Value	R/W	Description
7	RFEST	B'1	R	Receive FIFO Empty Status Flag The RFEST bit is set to "1" (no unread message in receive FIFO) when the number of unread messages in the receive FIFO is "0". The RFEST bit is set to "1" when the RFE bit is set to "0". The RFEST bit is set to "0" (unread message in receive FIFO) when the number of unread messages in the receive FIFO is one or more. 0: Unread message in receive FIFO 1: No unread message in receive FIFO
6	RFWST	B'0	R	Receive FIFO Buffer Warning Status Flag The RFWST bit is set to "1" (receive FIFO is buffer warning) when the number of unread messages in the receive FIFO is 3. The RFWST bit is "0" (receive FIFO is not buffer warning) when the number of unread messages in the receive FIFO is less than 3 or equal to 4. The RFWST bit is set to "0" when the RFE bit is "0". 0: Receive FIFO is not buffer warning 1: Receive FIFO is buffer warning (3 unread messages)
5	RFFST	B'0	R	Receive FIFO Full Status Flag The RFFST bit is set to "1" (receive FIFO is full) when the number of unread messages in the receive FIFO is 4. The RFFST bit is "0" (receive FIFO is not full) when the number of unread messages in the receive FIFO is less than 4. The RFFST bit is set to "0" when the RFE bit is "0". 0: Receive FIFO is not full 1: Receive FIFO full (4 unread messages)

Bit	Symbol	Initial Value	R/W	Description
4	RFMLF	B’0	R	Receive FIFO Message Lost Flag The RFMLF bit is set to "1" (receive FIFO message lost has occurred) when the receive FIFO receives a new message and the receive FIFO is full. The timing for setting this bit to "1" is at the end of the 6th bit of EOF. The RFMLF bit is set to "0" by writing "0" by a program (writing "1" has no effect). In both overwrite and overrun modes, the RFMLF bit cannot be set to "0" (receive FIFO message lost has not occurred) by writing "0" by a program due to hardware protection during the five cycles of peripheral clock (clkp1) following the 6th bit of EOF, if the receive FIFO is full and determined to receive the message. 0: No receive FIFO message lost has occurred 1: Receive FIFO message lost has occurred
3 to 1	RFUST	All 0	R	Receive FIFO Unread Message Number Status Flag The RFUST bit indicates the number of unread messages in the receive FIFO. The value of the RFUST bit is initialized to "000" when the RFE bit is set to "0". B’000: No unread message B’001: 1 unread message B’010: 2 unread messages B’011: 3 unread messages B’100: 4 unread messages B’101: Reserved B’110: Reserved B’111: Reserved
0	RFE	B’0	R/W	Receive FIFO Enable Bit When the RFE bit is set to "1", the receive FIFO is enabled. When this bit is set to "0", the receive FIFO is disabled for reception and becomes empty (RFEST bit = "1"). Do not set this bit to "1" in normal mailbox mode (MBM bit in the CiCTLR register = "0"). Due to hardware protection, the RFE bit is not set to "0" by writing "0" by a program during the following period: The hardware protection is started From the acceptance filter procedure (the beginning of CRC field) The hardware protection is released If the receive FIFO is specified to receive the incoming message, after the received data is stored into the receive FIFO or a CAN bus error occurs. (i.e. maximum period of hardware protection is from the beginning of CRC field to the end of 7th bit of EOF.) If the receive FIFO is not specified to receive the message, after the acceptance filter procedure. 0: Receive FIFO disabled 1: Receive FIFO enabled

Figure 47.2 shows the receive FIFO mailbox operation.

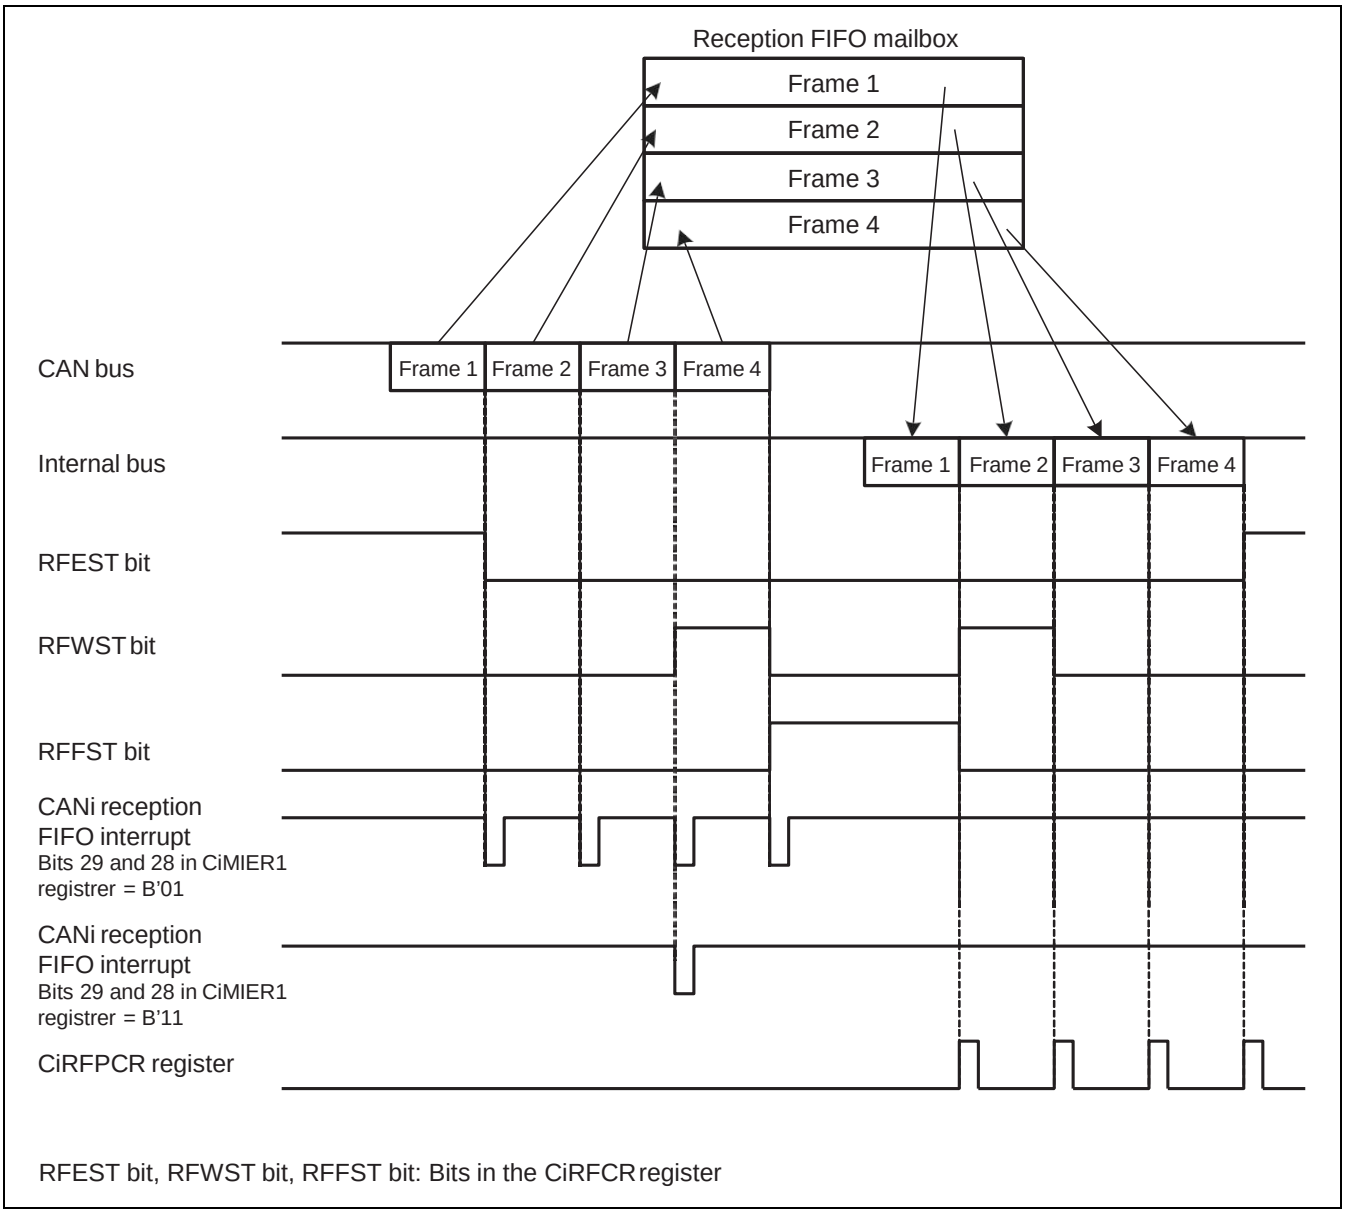

Figure 47.2 Receive FIFO Mailbox Operation
(Bits 29 and 28 in CiMIER1 Register = "01" and "11") (i = 0, 1)

47.2.11 CANi Receive FIFO Pointer Control Register (CiRFPCR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

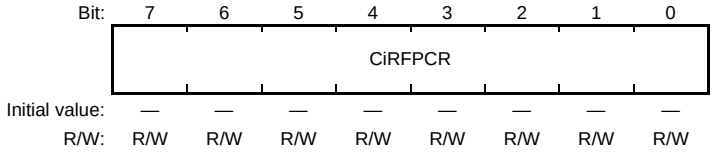
When the receive FIFO is not empty, write "H'FF" to the CiRFPCR register by a program to increment the CPU-side pointer for the receive FIFO to the next mailbox location.

Do not write to the CiRFPCR register when the RFE bit in the CiRFCR register is "0" (receive FIFO disabled).

Both the CAN-side pointer and the CPU-side pointer are incremented when a new message is received and the RFFST bit is "1" (receive FIFO is full) in overwrite mode. When the RFMLF bit is "1" in this condition, the CPU-side pointer cannot be incremented by writing to the CiRFPCR register by a program.

CAN0 Receive FIFO Pointer Control Register (C0RFPCR)

CAN1 Receive FIFO Pointer Control Register (C1RFPCR)



<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description

<After Reset: H'0500>

Bit	Symbol	Initial Value	R/W	Description
15	—	B'0	R	Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.
14	RECST	B'0	R	Receive Status Flag (receiver) The RECST bit is set to "1" when the CAN module performs as a receiver node. The RECST bit is set to "0" when the CAN module performs as a transmitter node or is in bus-idle state. 0: Bus idle or transmission in progress 1: Reception in progress
13	TRMST	B'0	R	Transmit Status Flag (transmitter) The TRMST bit is set to "1" when the CAN module performs as a transmitter node or is in the bus-off state. The TRMST bit is set to "0" when the CAN module performs as a receiver node or is in bus-idle state. 0: Bus idle or reception in progress 1: Transmission in progress or in bus-off state
12	BOST	B'0	R	Bus-Off Status Flag The BOST bit is set to "1" when the value of the CiTECR register exceeds 255 and the CAN module is in the bus-off state (TEC ≥ 256). The BOST bit is set to "0" when the CAN module is not in the bus-off state. 0: Not in bus-off state 1: In bus-off state
11	EPST	B'0	R	Error-Passive Status Flag The EPST bit is set to "1" when the value of the CiTECR or CiRECR register exceeds 127 and the CAN module is in error-passive state (128 ≤ TEC < 256 or 128 ≤ REC < 256). The EPST bit is set to "0" when the CAN module is not in the error-passive state. TEC indicates the value of the transmit error counter (CiTECR register) and REC indicates the value of the receive error counter (CiRECR register). 0: Not in error-passive state 1: In error-passive state

Bit	Symbol	Initial Value	R/W	Description
10	SLPST	B'1	R	CAN Sleep Status Flag The SLPST bit is set to "1" when the CAN module is in CAN sleep mode. The SLPST bit is set to "0" when the CAN module is not in CAN sleep mode. 0: Not in CAN sleep mode 1: In CAN sleep mode
9	HLTST	B'0	R	CAN Halt Status Flag The HLTST bit is set to "1" when the CAN module is in CAN halt mode. The HLTST bit is set to "0" when the CAN module is not in CAN halt mode. Even when the state is changed from CAN halt mode to CAN sleep mode, the HLTST bit remains "1". 0: Not in CAN halt mode 1: In CAN halt mode
8	RSTST	B'1	R	CAN Reset Status Flag The RSTST bit is set to "1" when the CAN module is in CAN reset mode. The RSTST bit is "0" when the CAN module is not in CAN reset mode. Even when the state is changed from CAN reset mode to CAN sleep mode, the RSTST bit remains "1". 0: Not in CAN reset mode 1: In CAN reset mode
7	EST	B'0	R	Error Status Flag The EST bit is "1" when at least one error is detected by the CiEIFR register regardless of the value of the CiEIER register. The EST bit is set to "0" when no error is detected by the CiEIFR register. 0: No error occurred 1: Error occurred
6	TABST	B'0	R	Transmission Abort Status Flag The TABST bit is set to "1" when at least one TRMABT bit in the CiMCTLj register is "1" regardless of the value of the CiMIER register. The TABST bit is set to "0" when all TRMABT bits are "0". 0: No mailbox with TRMABT bit = "1" 1: Mailbox(es) with TRMABT bit = "1"
5	FMLST	B'0	R	FIFO Mailbox Message Lost Status Flag The FMLST bit is set to "1" when the RFMLF bit in the CiRFCR register is "1" regardless of the value of the CiMIER register. The FMLST bit is set to "0" when the RFMLF bit is "0". 0: RFMLF bit = "0" 1: RFMLF bit = "1"
4	NMLST	B'0	R	Normal Mailbox Message Lost Status Flag The NMLST bit is set to "1" when at least one MSGLOST bit in the CiMCTLj register is "1" regardless of the value of the CiMIER register. The NMLST bit is set to "0" when all MSGLOST bit is "0". 0: No mailbox with MSGLOST bit = "1" 1: Mailbox(es) with MSGLOST bit = "1"
3	TFST	B'0	R	Transmit FIFO Status Flag The TFST bit is set to "1" when the transmit FIFO is not full. The TFST bit is set to "0" when the transmit FIFO is full. The TFST bit is set to "0" when normal mailbox mode is selected. 0: Transmit FIFO is full 1: Transmit FIFO is not full

Bit	Symbol	Initial Value	R/W	Description
2	RFST	B'0	R	Receive FIFO Status Flag The RFST bit is set to "1" when the receive FIFO is not empty. The RFST bit is set to "0" when the receive FIFO is empty. The RFST bit is set to "0" when normal mailbox mode is selected. 0: No message in receive FIFO 1: Message in receive FIFO
1	SDST	B'0	R	SENTDATA Status Flag The SDST bit is set to "1" when at least one SENTDATA bit in the CiMCTLj register is "1" regardless of the value of the CiMIER register. The SDST bit is set to "0" when all SENTDATA bits are "0". 0: No mailbox with SENTDATA bit = "1" 1: Mailbox(es) with SENTDATA bit = "1"
0	NDST	B'0	R	NEWDATA Status Flag The NDST bit is set to "1" when at least one NEWDATA bit in the CiMCTLj register is "1" regardless of the value of the CiMIER register. The NDST bit is set to "0" when all NEWDATA bits are "0". 0: No mailbox with NEWDATA bit = "1" 1: Mailbox(es) with NEWDATA bit = "1"

47.2.15 CANi Mailbox Search Mode Register (CiMSMR) (i = 0, 1)

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 2	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
1, 0	MBSM	All 0	R/W	Mailbox Search Mode Select Bits The MBSM bit selects the search mode for the mailbox search function. When the MBSM bit is "00", receive mailbox search mode is selected. In this mode, the search targets are the NEWDATA bit in the CiMCTLj register (j = 0 to 63) for the normal mailbox and the RFEST bit in the CiRFCR register. When the MBSM bit is "01", transmit mailbox search mode is selected. In this mode, targets the SENTDATA bit in the CiMCTLj register. When the MBSM bit is "10", message lost search mode is selected. In this mode, targets the MSGLOST bit in the CiMCTLj register for the normal mailbox and the RFMLF bit in the CiRFCR register. When the MBSM bit is "11", channel search mode is selected. In this mode, the search target is the CiCSSR register. Refer to section 47.2.17, CANi Channel Search Support Register (CiCSSR) (i = 0, 1). B’00: Receive mailbox search mode B’01: Transmit mailbox search mode B’10: Message lost search mode B’11: Channel search mode

47.2.16 CANi Mailbox Search Status Register (CiMSSR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CAN0 Mailbox Search Status Register (C0MSSR)

CAN1 Mailbox Search Status Register (C1MSSR)

Bit:	7	6	5	4	3	2	1	0
	SEST	—	MBNST					
Initial value:	1	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

<After Reset: H'80>

Bit	Symbol	Initial Value	R/W	Description
7	SEST	B'1	R	Search Result Status Bit The SEST bit is set to "1" when no corresponding mailbox is found after searching all mailboxes. For example, in transmit mailbox search mode, the SEST bit is set to "1" when no SENTDATA bit for mailboxes is "1". The SEST bit is set to "0" when at least one SENTDATA bit is "1". When the SEST bit is "1", the value of the MBNST bits is undefined. 0: Search result found 1: No search result
6	—	B'0	R	Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.
5 to 0	MBNST	All 0	R	Search Result Mailbox Number Status Bits The MBNST bit outputs the smallest mailbox number that is searched in each mode of the CiMSMR register. In receive mailbox, transmit mailbox, and message lost search modes, the value of the mailbox i.e., the search result to be output, is updated as described below: When the NEWDATA, SENTDATA or MSGLOST bit for the output mailbox is set to "0". When the NEWDATA, SENTDATA or MSGLOST bit for a higher-priority mailbox is set to "1". In receive mailbox search and message lost search modes, the receive FIFO (mailbox [60]) is output when the receive FIFO is not empty and there are no unread received messages or no lost messages in any of the normal mailboxes (mailboxes [0] to [55]). In transmit mailbox search mode, the transmit FIFO (mailbox [56]) is not output. Table 47.8 lists the behavior of MBNST bit in FIFO mailbox mode. In channel search mode, the MBNST bit outputs the corresponding channel number. After the CiMSSR register is read by a program, the next target channel number is output.

Table 47.8 Operation of MBNST Bit in FIFO Mailbox Mode

MBSM Bit	Mailbox [56] (Transmit FIFO)	Mailbox [60] (Receive FIFO)
"00"	Mailbox [56] is not output.	Mailbox [60] is output when no NEWDATA bit for the normal mailbox is set to "1" and the receive FIFO is not empty.
"01"		Mailbox [60] is not output.
"10"		Mailbox [60] is output when no MSGLOST bit for the normal mailbox is set to "1" and the RFMLF bit is set to "1" (receive FIFO message lost has occurred) in the receive FIFO.
"11"		Mailbox [60] is not output.

47.2.17 CANi Channel Search Support Register (CiCSSR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

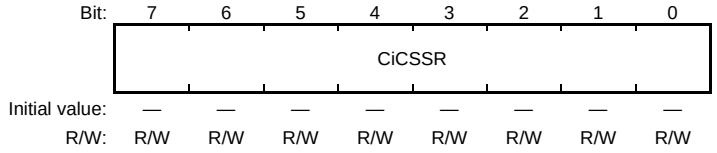
The bits in the CiCSSR register, which are set to "1", are encoded by an 8/3 encoder (the lower bit position, the higher priority) and output to the MBNST bits in the CiMSSR register.

The CiMSSR register outputs the updated value whenever the CiMSSR register is read by a program.

Write to the CiCSSR register only when the MBSM bit in the CiMSMR register is "11" (channel search mode). Write to this register in CAN operation mode or CAN halt mode.

CAN0 Channel Search Support Register (C0CSSR)

CAN1 Channel Search Support Register (C1CSSR)



<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
7 to 0	CiCSSR	Undefined	R/W	When the value for the channel search is input, the channel number is output to the CiMSSR register.

Figure 47.4 shows the write and read of registers CiCSSR and CiMSSR.

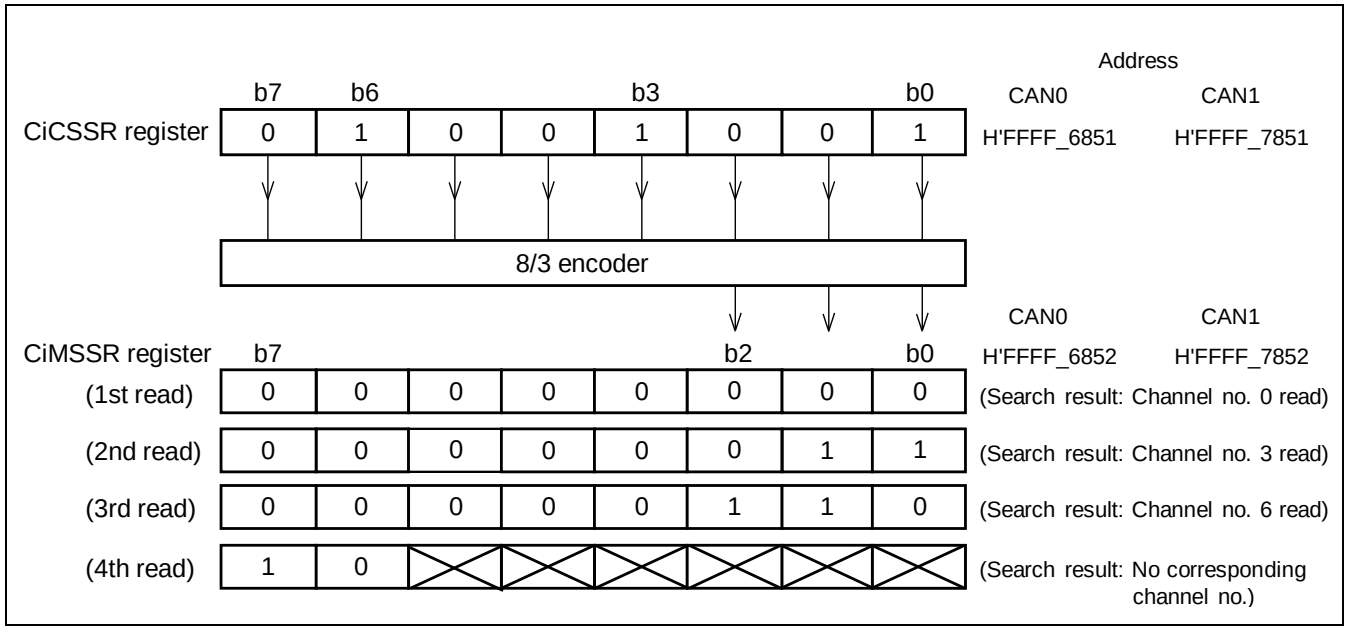


Figure 47.4 Write and Read of Registers CiCSSR and CiMSSR (i = 0, 1)

The value of the CiCSSR register is also updated whenever the CiMSSR register is read. When the CiCSSR register is read, the value before the 8/3 encoder conversion is read.

47.2.18 CANi Acceptance Filter Support Register (CiAFSR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The acceptance filter support unit (ASU) can be used for data table (8 bits × 256) search. In the data table, all standard IDs created by the user are set to be valid/invalid in bit units. When the CAFSR register is written with the 16-bit unit data including the SID bit in the CiMBj register (j = 0 to 63), in which a received ID is stored, a decoded row (byte offset) position and column (bit) position for data table search can be read. The ASU can be used for standard (11-bit) IDs only.

The ASU is enabled in the following cases:

- When the ID to receive cannot be masked by the acceptance filter.
  (Example) IDs to receive: H'078, H'087, H'111
- When there are too many IDs to receive and software filtering time is expected to be shortened.

Write to the CiAFSR register in CAN operation mode or CAN halt mode.

CAN0 Acceptance Filter Support Register (C0AFSR)

CAN1 Acceptance Filter Support Register (C1AFSR)

0	BEIE	B'0	R/W	Bus Error Interrupt Enable Bit When the BEIE bit is "0", no error interrupt request is generated even if the BEIF bit in the CiEIFR register is set to "1". When the BEIE bit is "1", an error interrupt request is generated if the BEIF bit is set to "1". 0: Bus error interrupt disabled 1: Bus error interrupt enabled

47.2.20 CANi Error Interrupt Factor Judge Register (CiEIFR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

If an event corresponding to each bit occurs, the corresponding bit in the CiEIFR register is set to "1" regardless of the setting of the CiEIER register.

To set each bit to "0", write "0" by a program. If the set timing occurs simultaneously with the clear timing by the program, the bit becomes "1".

When writing "0" to a single bit by a program, use the MOV instruction to ensure that only the specified bit is set to "0" and the other bits are set to "1". Writing "1" has no effect to these bit values.

CAN0 Error Interrupt Factor Judge Register (C0EIFR)

CAN1 Error Interrupt Factor Judge Register (C1EIFR)

Bit:	7	6	5	4	3	2	1	0
	BLIF	OLIF	ORIF	BORIF	BOEIF	EPIF	EWIF	BEIF
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7	BLIF	B'0	R/W	Bus Lock Detect Flag* The BLIF bit becomes 1 if 32 consecutive dominant bits are detected on the CAN bus while the CAN module is in CAN operation mode. After the BLIF bit becomes 1, bus lock can be detected again after either of the following conditions is satisfied: • After this bit is set to 0 from 1, recessive bits are detected (bus lock is resolved). • After this bit is set to 0 from 1, the CAN module enters CAN reset mode and then enters CAN operation mode again (internal reset). 0: No bus lock detected 1: Bus lock detected
6	OLIF	B'0	R/W	Overload Frame Transmission Detect Flag* The OLIF bit is set to "1" if the transmitting condition of an overload frame is detected when the CAN module performs transmission or reception. 0: No overload frame transmission detected 1: Overload frame transmission detected

Bit	Symbol	Initial Value	R/W	Description
5	ORIF	B'0	R/W	Receive Overrun Detect Flag* The ORIF bit is set to "1" when a receive overrun occurs. This bit is not to set to "1" in overwrite mode. In overwrite mode, a reception complete interrupt request is generated if an overwrite condition occurs and the ORIF bit is not set to "1". In normal mailbox mode, if an overrun occurs in any of mailboxes [0] to [63] in overrun mode, this bit is set to "1". In FIFO mailbox mode, if an overrun occurs in any of mailboxes [0] to [55] or the receive FIFO in overrun mode, this bit is set to "1". 0: No receive overrun detected 1: Receive overrun detected
4	BORIF	B'0	R/W	Bus-Off Recovery Detect Flag* The BORIF bit is set to "1" when the CAN module recovers from the bus-off state normally by detecting 11 consecutive bits 128 times in the following conditions: When the BOM bit in the CiCTLR register is "00". When the BOM bit is "10". When the BOM bit is "11". The BORIF bit is not set to "1" if the CAN module recovers from the bus-off state in the following conditions: When the CANM bit in the CiCTLR register is set to "01" or "11" (CAN reset mode). When the RBOC bit in the CiCTLR register is set to "1" (forcible return from bus-off). When the BOM bit is "01". When the BOM bit is "11" and the CANM bit is set to "10" (CAN halt mode) before normal recovery occurs. 0: No bus-off recovery detected 1: Bus-off recovery detected
3	BOEIF	B'0	R/W	Bus-Off Entry Detect Flag* The BOEIF bit is set to "1" when the CAN error state becomes bus-off (the TEC value exceeds 255). The BOEIF bit is also set to "1" when the BOM bit in the CiCTLR register is "01" (entry to CAN halt mode automatically at bus-off entry) and the CAN module becomes the bus-off state. 0: No bus-off entry detected 1: Bus-off entry detected
2	EPIF	B'0	R/W	Error Passive Detect Flag* The EPIF bit is set to "1" when the CAN error state becomes error-passive (the REC or TEC value exceeds 127). The EPIF bit is set to "1" only when the REC or TEC initially exceeds 127. Thus, if "0" is written to the EPIF bit by a program while the REC or TEC remains greater than 127, the EPIF bit is not set to "1" until the REC and TEC goes below 127 and then exceeds 127 again. 0: No error passive detected 1: Error passive detected

Bit	Symbol	Initial Value	R/W	Description
1	EWIF	B’0	R/W	Error Warning Detect Flag* The EWIF bit is set to "1" when the value of the receive error counter (REC) or transmit error counter (TEC) exceeds 95. The EWIF bit is set to "1" only when the REC or TEC initially exceeds 95. Thus, if "0" is written to the EWIF bit by a program while the REC or TEC remains greater than 95, the EWIF bit is not set to "1" until the REC and TEC goes below 95 and then exceeds 95 again. 0: No error warning detected 1: Error warning detected
0	BEIF	B’0	R/W	Bus Error Detect Flag* The BEIF bit is set to "1" when a bus error is detected. 0: No bus error detected 1: Bus error detected

Note: * Only "0" may be written to this bit. (Writing "1" has no effect.) When writing "0" to specific bits in software, use the MOV instruction and write "0" to each bit to be cleared to "0" and "1" to all other bits.

Table 47.9 lists the behavior of bits BOEIF and BORIF according to BOM bit setting value.

Table 47.9 Behavior of Bits BOEIF and BORIF according to BOM Bit Setting Value

BOM Bit	BOEIF Bit	BORIF Bit
B’00	Set to "1" on entry to the bus-off state.	Set to "1" on exit from the bus-off state.
B’01		Do not set to "1".
B’10		Set to "1" on exit from the bus-off state.
B’11		Set to "1" if normal bus-off recovery occurs before the CANM bit is set to "10" (CAN halt mode).

47.2.21 CANi Receive Error Count Register (CiRECR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

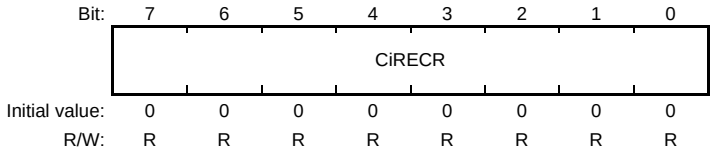
The CiRECR register indicates the value of the receive error counter.

For the increment/decrement conditions of the receive error counter, refer to the CAN Specifications (ISO11898-1).

The value in bus-off state is undefined.

CAN0 Receive Error Count Register (C0RECR)

CAN1 Receive Error Count Register (C1RECR)



<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 0	CiRECR	All 0	R	Receive Error Count Function The CiRECR register increments or decrements the counter value according to error status of the CAN module during reception.

47.2.22 CANi Transmit Error Count Register (CiTECR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The CiTECR register indicates the value of the transmit error counter.

For the increment/decrement conditions of the transmit error counter, refer to the CAN Specifications (ISO11898-1).

The value in bus-off state is undefined.

CAN0 Transmit Error Count Register (C0TECR)

CAN1 Transmit Error Count Register (C1TECR)

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 0	CiTECR	All 0	R	Transmit Error Count Function The CiTECR register increments or decrements the counter value according to error status of the CAN module during transmission.

47.2.23 CANi Error Code Store Register (CiECSR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The CiECSR register can be used to monitor whether an error has occurred on the CAN bus. Refer to the CAN Specifications (ISO11898-1) to check the generation conditions of each error.

To set each bit except the EDPM bit to "0", write "0" by a program. If the timing at which each bit is set to "1" and the timing at which "0" is written by a program are the same, the relevant bit is set to "1".

CAN0 Error Code Store Register (C0ECSR)

CAN1 Error Code Store Register (C1ECSR)

Bit:	7	6	5	4	3	2	1	0
	EDPM	ADEF	BE0F	BE1F	CEF	AEF	FEF	SEF
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7	EDPM	B'0	R/W	Error Display Mode Select Bit*1*2 The EDPM bit selects the output mode of the CiECSR register. When the EDPM bit is set to "0", the CiECSR register outputs the first error code. When the EDPM bit is set to "1", the CiECSR register outputs the accumulated error code. 0: Output of first detected error code 1: Output of accumulated error code
6	ADEF	B'0	R/W	ACK Delimiter Error Flag*3*4 The ADEF bit is set to "1" when a form error is detected with the ACK delimiter during transmission. 0: No ACK delimiter error detected 1: ACK delimiter error detected
5	BE0F	B'0	R/W	Bit Error (dominant) Flag*3*4 The BE0F bit is set to "1" when a dominant bit error is detected. 0: No bit error (dominant) detected 1: Bit error (dominant) detected
4	BE1F	B'0	R/W	Bit Error (recessive) Flag*3*4 The BE1F bit is set to "1" when a recessive bit error is detected. 0: No bit error (recessive) detected 1: Bit error (recessive) detected
3	CEF	B'0	R/W	CRC Error Flag*3*4 The CEF bit is set to "1" when a CRC error is detected. 0: No CRC error detected 1: CRC error detected

Bit	Symbol	Initial Value	R/W	Description
2	AEF	B'0	R/W	ACK Error Flag*3*4 The AEF bit is set to "1" when an ACK error is detected. 0: No ACK error detected 1: ACK error detected
1	FEF	B'0	R/W	Form Error Flag*3*4 The FEF bit is set to "1" when a form error is detected. 0: No form error detected 1: Form error detected
0	SEF	B'0	R/W	Stuff Error Flag*3*4 The SEF bit is set to "1" when a stuff error is detected. 0: No stuff error detected 1: Stuff error detected

Notes: 1. Write to the EDPM bit in CAN reset mode or CAN halt mode.
2. If more than one error condition is detected simultaneously, all related bits are set to "1".
3. Writing "1" has no effect to these bit values.
4. When writing "0" to bits SEF, FEF, AEF, CEF, BE1F, BE0F, and ADEF by a program, use the MOV instruction to ensure that only the specified bit is set to "0" and the other bits are set to "1".

47.2.24 CANi Time Stamp Register (CiTSR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

When the CiTSR register is read, the value of the time stamp counter (16-bit free-running counter) at that moment is read.

The value of the time stamp counter reference clock is a multiple of 1 bit time, as configured by the TSPS bit in the CiCTLR register.

The time stamp counter stops in CAN sleep mode and CAN halt mode, and is initialized in CAN reset mode.

The time stamp counter value is stored to TSL and TSH in the CiMBj register when a received message is stored in a receive mailbox.

47.2.25 CANi Test Control Register (CiTCR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Write to the CiTCR register in CAN halt mode only.

CAN0 Test Control Register (C0TCR)

CAN1 Test Control Register (C1TCR)

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	TSTM		TSTE
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
2, 1	TSTM	All 0	R/W	CAN Test Mode Select Bits The TSTM bit selects the CAN test mode. For details on the CAN test modes, see section 47.2.25 (1), Listen-Only Mode, section 47.2.25 (2), Self-Test Mode 0 (External Loop Back), and section 47.2.25 (3), Self-Test Mode 1 (Internal Loop Back). B’00: Other than CAN test mode B’01: Listen-only mode B’10: Self-test mode 0 (external loop back) B’11: Self-test mode 1 (internal loop back)
0	TSTE	B’0	R/W	CAN Test Mode Enable Bit When the TSTE bit is set to "0", CAN test mode is disabled. When the TSTE bit is set to "1", CAN test mode is enabled. 0: CAN test mode disabled 1: CAN test mode enabled

(1) Listen-Only Mode

The ISO 11898-1 recommends an optional bus monitoring mode. In listen-only mode, the CAN node is able to receive valid data frames and valid remote frames. It sends only recessive bits on the CAN bus, and the protocol controller is not required to send the ACK bit, overload flag, or active error flag.

Listen-only mode can be used for baud rate detection.

Do not request transmission from any mailboxes in this mode.

Figure 47.6 shows the connection when listen-only mode is selected.

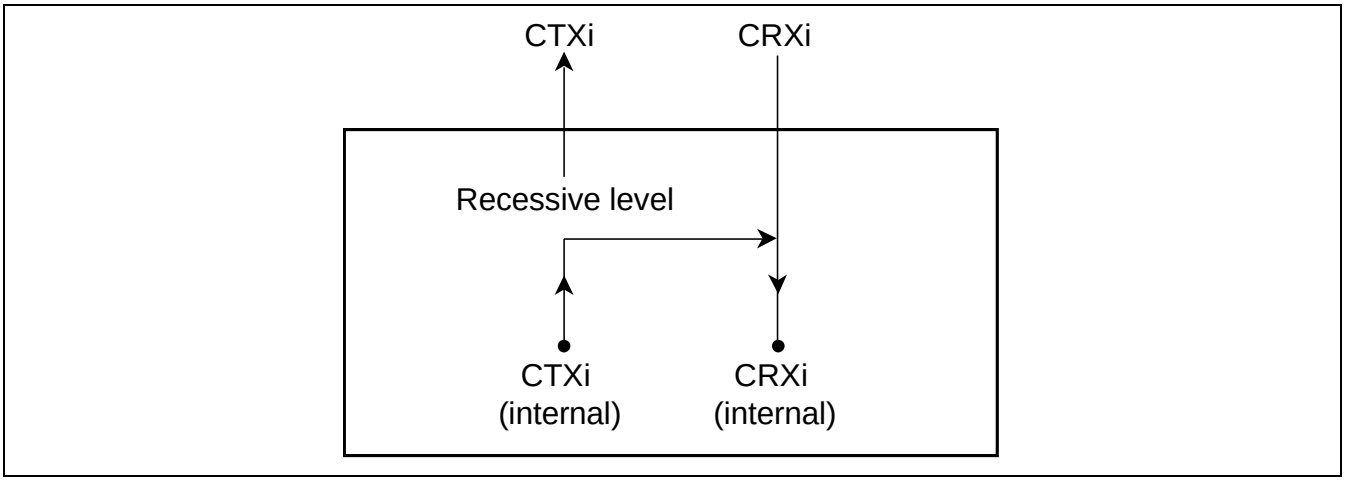

Figure 47.6 Connection when Listen-Only Mode is Selected

(2) Self-Test Mode 0 (External Loop Back)

Self-test mode 0 is provided for CAN transceiver tests.

In this mode, the protocol controller treats its own transmitted messages as messages received via the CAN transceiver and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

Connect the CANi_TX/CANi_RX pins to the transceiver.

Figure 47.7 shows the connection when self-test mode 0 is selected.

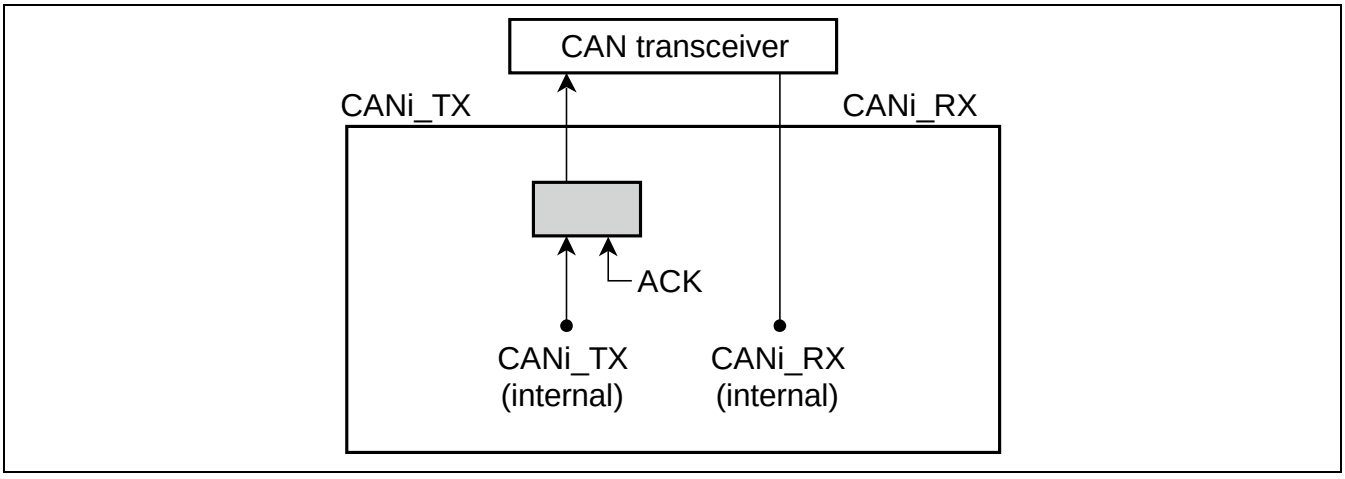

Figure 47.7 Connection when Self-Test Mode 0 is Selected

(3) Self-Test Mode 1 (Internal Loop Back)

Self-test mode 1 is provided for self-test functions.

In this mode, the protocol controller treats its transmitted messages as received messages and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

In self-test mode 1, the protocol controller performs an internal feedback from the internal CANi_TX pin to the internal CANi_RX pin. The input value of the external CANi_RX pin is ignored. The external CANi_TX pin outputs only recessive bits. The CANi_TX/CANi_RX pins do not need to be connected to the CAN bus or any external device.

Figure 47.8 shows the connection when self-test mode 1 is selected.

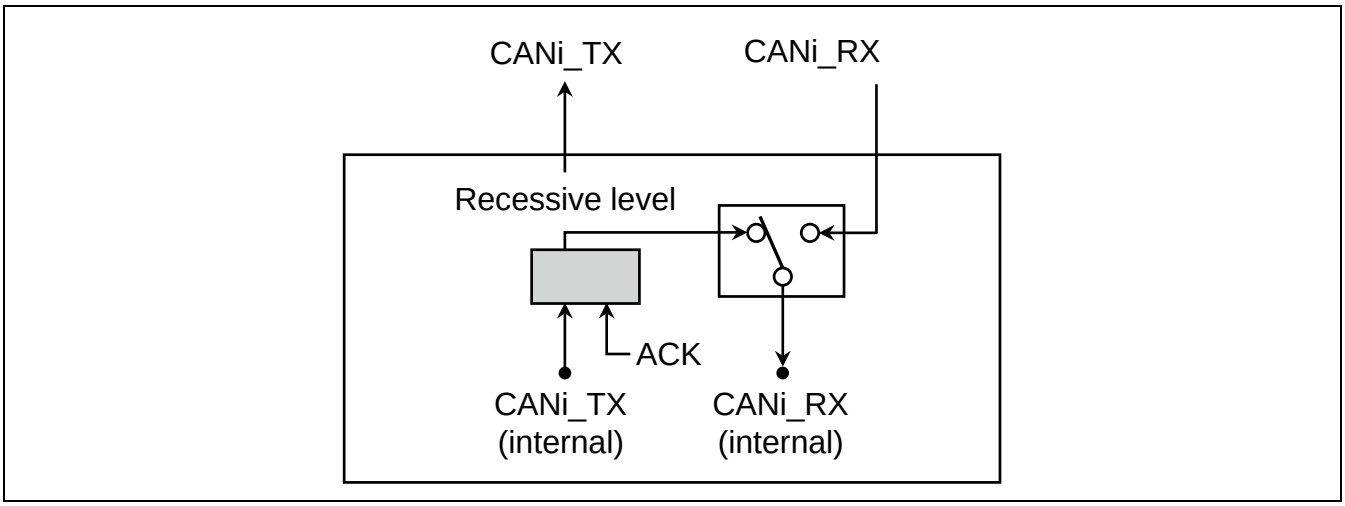

Figure 47.8 Connection when Self-Test Mode 1 is Selected

47.2.26 CANi Interrupt Status Register (CiISR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The CiISR register shows interrupt sources before masking by the CiIER register.

Bit	Symbol	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
5	ERSF	B'0	R	Error (ERS) Interrupt Status Bit*1 The ERSF bit shows the error interrupt source status. 0: ERS interrupt source not detected 1: ERS interrupt source detected
4	RXFF	B'0	R/W	Reception FIFO (RXF) Interrupt Status Bit*2 The RXFF bit shows the FIFO receive interrupt source status. 0: RXF interrupt source not detected 1: RXF interrupt source detected The RXFF is cleared to "0" by writing "0" to it by software. (writing "1" has no effect)
3	TXFF	B'0	R/W	Transmission FIFO (TXF) Interrupt Status Bit*3 The TXFF bit shows the FIFO transmit interrupt source status. 0: TXF interrupt source not detected 1: TXF interrupt source detected The TXFF is cleared to "0" by writing "0" to it by software. (writing "1" has no effect)
2	RXM0F	B'0	R	Mailbox 0 Successful Reception (RXM0) Interrupt Status Bit*4 The RXM0F bit shows the successful reception interrupt source status for mailbox 0. 0: RXM0 interrupt source not detected 1: RXM0 interrupt source detected
1	RXM1F	B'0	R	Mailbox 1 to 63 Successful Reception (RXM1) Interrupt Status Bit*5 The RXM1F bit shows the successful reception interrupt source status for mailboxes 1 to 63. 0: RXM1 interrupt source not detected 1: RXM1 interrupt source detected

Bit	Symbol	Initial Value	R/W	Description
0	TXMF	B'0	R	Mailbox 32 to 63 Successful Transmission (TXM) Interrupt Status Bit*6 The TXMF bit shows the successful transmission interrupt source status for mailboxes 32 to 63. 0: TXM interrupt source not detected 1: TXM interrupt source detected

Notes:
1. The ERSF bit is set to "1" when a bit in one of the CiEIFR[j] registers is set to "1" due to a communication error while the corresponding bit in the CiEIER[j] register is set to "1" (j = 0 to 7).
2. The RXFF bit is set to "1" when bit 6 or 5 in the CiRFCR register is set to "1" because of a reception FIFO full or warning condition due to the setting of CiMIER[61].
3. The TXFF bit is set to "1" when the transmission FIFO message count reaches the specified value due to the setting of CiMIER[57].
4. After the NEWDATA bit in CiMCTL0 is set to "1" at the end of a receive operation, the RXM0F bit is set to "1" if storing of the receive data is complete (corresponding INVALDATA bit value changed from "1" to "0") and the CiMIER0[0] bit has been set to "1".
5. After the NEWDATA bit in CiMCTLj is set to "1" at the end of a receive operation, the RXM1F bit is set to "1" if storing of the receive data is complete (corresponding INVALDATA bit value changed from "1" to "0") and the bit in CiMIER0 or CiMIER1 corresponding to mailbox j has the been set to "1" (j = 1 to 63).
6. The TXMF bit is set to "1" when the bit in the CiMIER1 register corresponding to mailbox j is set to "1" while the value of the SENTDATA bit in the CiMCTLj register is "1" following a successful reception (j = 32 to 63).

47.2.27 CANi Interrupt Enable Register (CiIER) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The CiIER register can be used by an application to cause some interrupts to be ignored while processing by an interrupt service routine is taking place. Each bit affects the individual interrupt source corresponding to it.

CAN0 Interrupt Enable Register (C0IER)

CAN1 Interrupt Enable Register (C1IER)

Bit:	7	6	5	4	3	2	1	0
	—	—	ERSIE	RXFIE	TXFIE	RXM 0IE	RXM 1IE	TXM IE
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
5	ERSIE	B'0	R/W	Error (ERS) Interrupt Enable Bit The ERSIE bit enables or disables the ERS interrupt controller. 0: ERS interrupt disabled 1: ERS interrupt enabled
4	RXFIE	B'0	R/W	Reception FIFO (RXF) Interrupt Enable Bit The RXFIE bit enables or disables the RXF interrupt controller. 0: RXF interrupt disabled 1: RXF interrupt enabled
3	TXFIE	B'0	R/W	Transmission FIFO (TXF) Interrupt Enable Bit The TXFIE bit enables or disables the TXF interrupt controller. 0: TXF interrupt disabled 1: TXF interrupt enabled
2	RXM0IE	B'0	R/W	Mailbox 0 Successful Reception (RXM0) Interrupt Enable Bit The RXM0IE bit enables or disables the RXM0 interrupt controller. 0: RXM0 interrupt disabled 1: RXM0 interrupt enabled
1	RXM1IE	B'0	R/W	Mailbox 1 to 63 Successful Reception (RXM1) Interrupt Enable Bit The RXM1IE bit enables or disables the RXM1 interrupt controller. 0: RXM1 interrupt disabled 1: RXM1 interrupt enabled
0	TXMIE	B'0	R/W	Mailbox 32 to 63 Successful Transmission (TXM) Interrupt Enable Bit The TXMIE bit enables or disables the TXM interrupt controller. 0: TXM interrupt disabled 1: TXM interrupt enabled

47.2.28 CANi Mailbox Search Mask Register (CiMBSMR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Write to the CiMBSMR register in CAN halt mode only.

CAN0 Mailbox Search Mask Register (C0MBSMR)

CAN1 Mailbox Search Mask Register (C1MBSMR)

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MB0SM
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
0	MB0SM	B'0	R/W	Mailbox 0 Search Mask Bit* When the MB0SM bit is set to "1", message box 0 is excluded from the search target for the CANi mailbox search status register.

Note: * The MB0SM bit is enabled in the search modes except channel search mode. In the RXM1 interrupt handling, this bit is usable to exclude message box 0 from the search target for the CiMSSR register in receive mailbox search mode.

47.2.29 CANi Parity Error Control Register (CiPECR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register controls the function of the parity mode and displays a parity error flag

Bit:	7	6	5	4	3	2	1	0
	PF	—	—	—	—	PIE	PME	PM
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R/W	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7	PF	B'0	R/W	Parity error flag *2 This bit is set to "1" when a parity error is detected. The bit has to be cleared by the program. As long as this bit is set no further parity error can be detected and the address value in the Parity Error Address Capture Register keeps the address for the first captured parity error. 0: Parity error is not detected 1: Parity error is detected
6 to 3	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
2	PIE	B'0	R/W	Parity error interrupt *1 This bit controls the parity error interrupt enable. When this bit is configured to "0", the parity error interrupt is disabled. When this bit is set to "1", the parity error interrupt is enabled. When a parity error interrupt is generated, the parity error flag (CANi Parity Error Control Register, bit 7) should be checked to determine the interrupt source. 0: Parity error interrupt is disabled 1: Parity error interrupt is enabled
1	PME	B'0	R/W	Parity enable bit This bit controls the Dual Port RAM parity functionality. When this bit is set to "0", parity checkers are disabled keeping the parity generators still active to store the correct parity bit for each byte when writing to the Dual Port RAM. When this bit is set to "1", parity checkers and parity generators are both active. 0: Parity checker off 1: Parity checker on

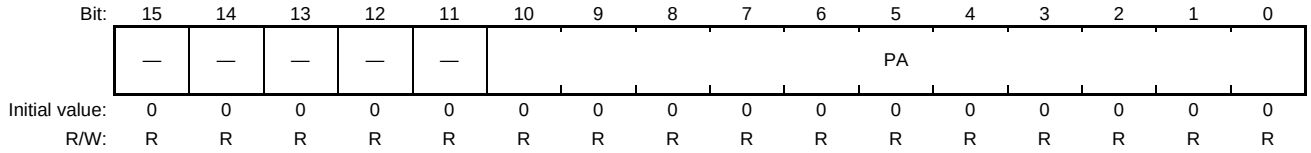
Bit	Symbol	Initial Value	R/W	Description
0	PM	B'0	R/W	Parity mode This bit controls the action of the CAN Module following the detection of a parity error. When this bit is programmed to "1" and a parity error is detected while in Operation Mode the CAN module forces the cancellation of a possible pending communication (either reception or transmission) and then enters Halt mode. When the pending communication is cancelled, the Reception Error Counter and Transmission Error Counter are initialized. If a parity error is detected while the CAN module is in its Reset or Halt mode no state transition will take place. In the case where CPU requests transition to Reset Mode at the same time as a parity error occurs then the CPU request to enter Reset Mode will have the highest priority. When this bit is set to "0", CAN module continues in Operation Mode and the pending communication is not canceled. Regardless of the setting of ParMode (PM) when a parity error occurs and ParModeEn (PME) bit is set to '1' (parity function enabled): • A parity error flag is set in bit 7 of the CAN Parity Error Control Register • A parity error interrupt is generated (providing the ParIntEn (PIE) bit is asserted) • The address where a parity error occurs is captured in the CANi Parity Error Capture Address Register. When parity error is detected 0: Continue operation mode 1: Go to Halt mode

Notes: 1. Do not write to this bit in Operation Mode
2. Write "0" only (writing "1" has no effect)
3. The software sequence required to set these bits is described in section 47.9, CPU is prevented from writing this bit in operation mode by H/W write protection.

47.2.30 CANi Parity Error Address Capture Register (CiPEACR) (i = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register displays the address where the parity error occurred.



<After Reset: H'0000>

Bit	Symbol	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
10 to 0	PA	All 0	R	Parity error captured address bits This register displays the address offset from a starting address of Mailbox 0 where parity error is detected. When a parity error is detected, the address in which the error occurred is captured in this register. Only the longword address is shown. The address is shown as below.

ParAddress value	Location
H'000 - H'00F	Mailbox 0*
H'010 – H'01F	Mailbox 1
H'020 – H'02F	Mailbox 2
...	…
H'3F0 – H'3FF	Mailbox 63
H'400 – H'41F	CiMKR 2 to 9
H'420 – H'427	FIFO ID 0 to 1
H'428 – H'42B	Mask Invalid 1
H'42C – H'42F	Interrupt enable 1
H'430 – H'433	CiMKR 0
H'434 – H'437	CiMKR 1
H'438 – H'43B	Mask Invalid 0
H'43C – H'43F	Interrupt enable 0

Note: * H'000 is the first byte of the mailbox 0.

Only the address related to the first parity error is reported. The program has to clear the ParFlag status to enable the capture of other locations leading to a parity error.

In case parity error is flagged at the same time from DPRAM CAN side parity checker and the DPRAM CPU side parity checker, the CPU side access address will be displayed in the parity error address capture register.

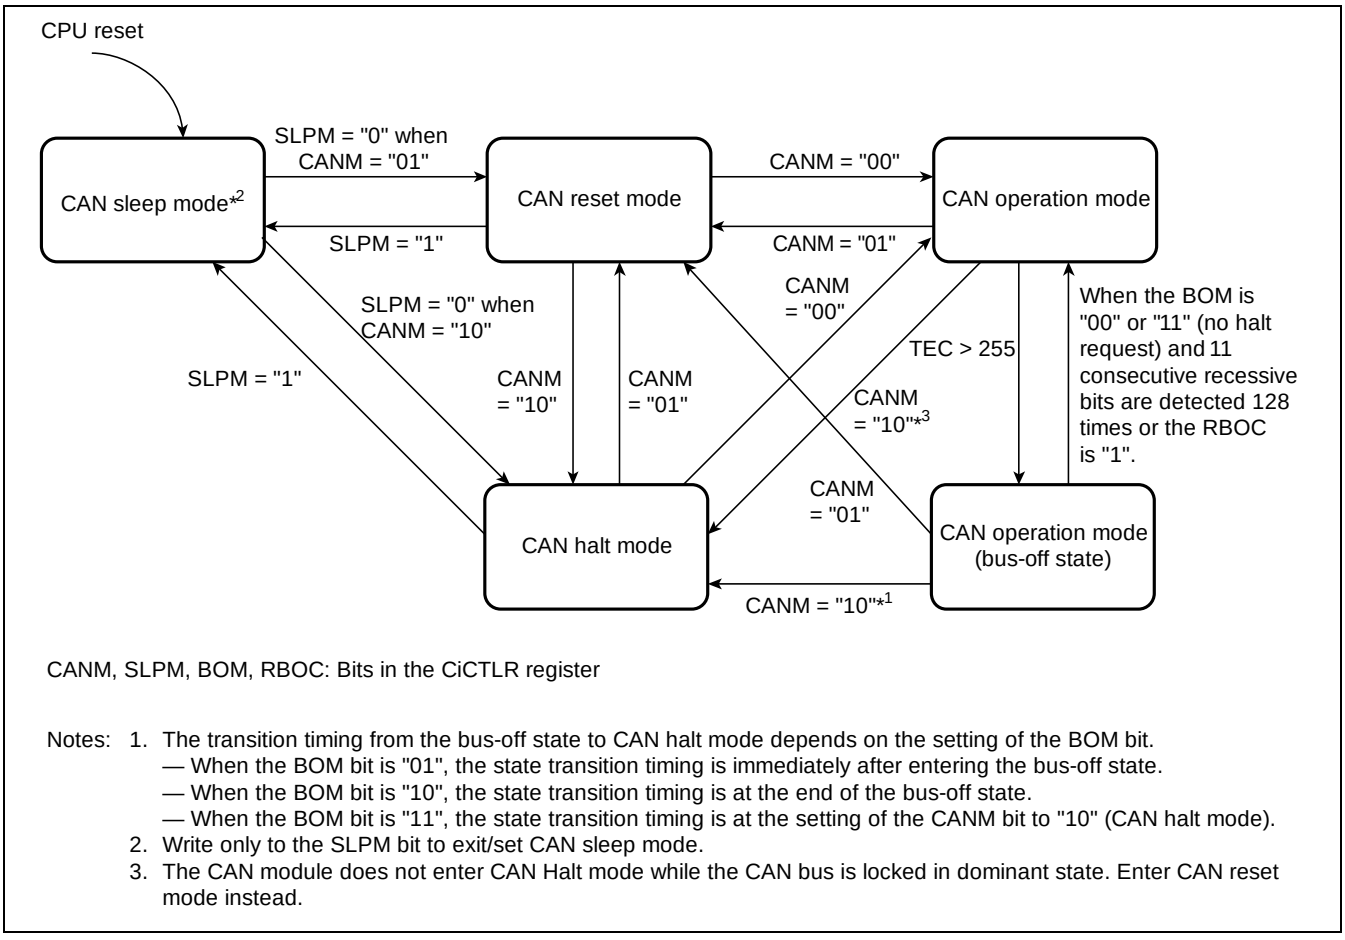
47.3 Operating Mode

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

The CAN module has the following four operating modes.

- CAN reset mode
- CAN halt mode
- CAN operation mode
- CAN sleep mode

Figure 47.9 shows the transition between CAN operating modes.



Notes: 1. The transition timing from the bus-off state to CAN halt mode depends on the setting of the BOM bit.
— When the BOM bit is "01", the state transition timing is immediately after entering the bus-off state.
— When the BOM bit is "10", the state transition timing is at the end of the bus-off state.
— When the BOM bit is "11", the state transition timing is at the setting of the CANM bit to "10" (CAN halt mode).
2. Write only to the SLPM bit to exit/set CAN sleep mode.
3. The CAN module does not enter CAN Halt mode while the CAN bus is locked in dominant state. Enter CAN reset mode instead.

Figure 47.9 Transition between CAN Operating Modes (i = 0, 1)

47.3.1 CAN Reset Mode

CAN reset mode is provided for CAN communication configuration.

When the CANM bit in the CiCTLR register is set to "01" or "11", the CAN module enters CAN reset mode. Then the RSTST bit in the CiSTR register is set to "1". Do not change the CANM bit until the RSTST bit is set to "1". Configure the CiBCR register before exiting CAN reset mode to any other modes.

The following registers are initialized to their reset values after entering CAN reset mode and their initialized values are retained during CAN reset mode:

- CiMCTLj register
- CiSTR register (except bits SLPST and TFST)
- CiEIFR register
- CiRECR register
- CiTECR register
- CiTSR register
- CiMSSR register
- CiMSMR register
- CiRFCR register
- CiTFCR register
- CiTCR register
- CiECSR register (except EDPM bit)
- CiISR register
- CiMBSMR register

The following registers retain their values after entering CAN reset mode.

- CiCLKR register
- CiCTLR register
- CiSTR register (bits SLPST and TFST)
- Registers CiMIER0 and CiMIER1
- CiEIER register
- CiBCR register
- CiCSSR register
- CiECSR register (EDPM bit only)
- CiMBj register
- Registers CiMKR0 to CiMKR9
- Registers CiFIDCR0 and CiFIDCR1
- Registers CiMKIVLR0 and CiMKIVLR1
- CiAFSR register
- CiRFPCR register
- CiTFPCR register
- CiIER register

47.3.2 CAN Halt Mode

CAN halt mode is used for mailbox configuration and test mode setting.

When the CANM bit in the CiCTLR register is set to "10", CAN halt mode is selected. Then the HLTST bit in the CiSTR register is set to "1". Do not change the CANM bit until the HLTST bit is set to "1".

Refer to Table 47.10, Operation in CAN Reset Mode and CAN Halt Mode regarding the state transition conditions when transmitting or receiving.

All registers except bits RSTST, HLTST, and SLPST in the CiSTR register remain unchanged when the CAN module enters CAN halt mode.

Do not change registers CiCLKR, CiCTLR (except bits CANM and SLPM), and CiEIER in CAN halt mode. The CiBCR register can be changed in CAN halt mode only when listen-only mode is selected to use for automatic bit rate detection.

Table 47.10 Operation in CAN Reset Mode and CAN Halt Mode

Mode	Receiver	Transmitter	Bus-Off
CAN reset mode	CAN module enters CAN reset mode without waiting for the end of message reception	CAN module enters CAN reset mode after waiting for the end of message transmission (1, 4)	CAN module enters CAN reset mode without waiting for the end of bus-off recovery
CAN halt mode	CAN module enters CAN halt mode after waiting for the end of message reception (2, 3)	CAN module enters CAN halt mode after waiting for the end of message transmission (1, 2, 4)	• When the BOM bit is "B'00" A halt request from a program will be acknowledged only after bus-off recovery • When the BOM bit is "B'01" CAN module automatically enters CAN halt mode without waiting for the end of bus-off recovery (regardless of a halt request from a program) • When the BOM bit is "B'10" CAN module automatically enters CAN halt mode after waiting for the end of bus-off recovery (regardless of a halt request from a program) • When the BOM bit is "B'11" CAN module enters CAN halt mode (without waiting for the end of bus-off recovery) if a halt is requested by a program during bus-off

BOM bit: Bit in the CiCTLR register (i = 0, 1)

Notes: 1. If several messages are requested to be transmitted, mode transition occurs after the completion of the first message transmission. When CAN reset mode is being requested during suspend transmission, mode transition occurs when the bus is idle, the next transmission ends, or the CAN module becomes a receiver.
2. If the CAN bus is locked in dominant state, the program can detect this state by monitoring the BLIF bit in the CiEIFR register. The CAN module does not enter CAN Halt mode while the CAN bus is locked in dominant state. Enter CAN reset mode instead.
3. If a CAN bus error occurs during reception after CAN halt mode is requested, the CAN module enters CAN halt mode. However, the CAN module does not enter CAN Halt mode when the CAN bus is locked in dominant state.
4. If a CAN bus error or arbitration lost occurs during transmission after CAN reset mode or CAN halt mode is requested, the CAN module enters the requested operating mode. However, the CAN module does not enter CAN Halt mode when the CAN bus is locked in dominant state.

47.3.3 CAN Sleep Mode

CAN sleep mode is used for reducing current consumption by stopping the clock supply to the CAN module. After MCU hardware reset or software reset, the CAN module starts from CAN sleep mode.

When the SLPM bit in the CiCTLR register is set to "1", the CAN module enters CAN sleep mode. Then the SLPST bit in the CiSTR register is set to "1". Do not change the value of the SLPM bit until the SLPST bit is set to "1". The other registers remain unchanged when the MCU enters CAN sleep mode.

Write to the SLPM bit in CAN reset mode and CAN halt mode. Do not change any registers (except the SLPM bit) during CAN sleep mode. Read operation is still allowed. When the SLPM bit is set to "0", the CAN module is released from CAN sleep mode. When the CAN module exits CAN sleep mode, the other registers remain unchanged.

47.3.4 CAN Operation Mode (Excluding Bus-Off State)

CAN operation mode is used for CAN communication.

When the CANM bit in the CiCTLR register is set to "B'00", the CAN module enters CAN operation mode.

Then bits RSTST and HLTST in the CiSTR register are set to "0". Do not change the value of the CANM bit until these bits are set to "0".

If 11 consecutive recessive bits are detected after entering CAN operation mode, the CAN module is in the following states:

- The CAN module becomes an active node on the network that enables transmission and reception of CAN messages.
- Error monitoring of the CAN bus, such as receive and transmit error counters, is performed.

During CAN operation mode, the CAN module may be in one of the following three sub-modes, depending on the status of the CAN bus:

- Idle mode: Transmission or reception is not being performed.
- Receive mode: A CAN message sent by another node is being received.
- Transmit mode: A CAN message is being transmitted. The CAN module may receive its own message simultaneously when self-test mode 0 (TSTM bit in the CiTCR register = "B'10") or self-test mode 1 (TSTM bit = "B'11") is selected.

Figure 47.10 shows the sub mode in CAN operation mode.

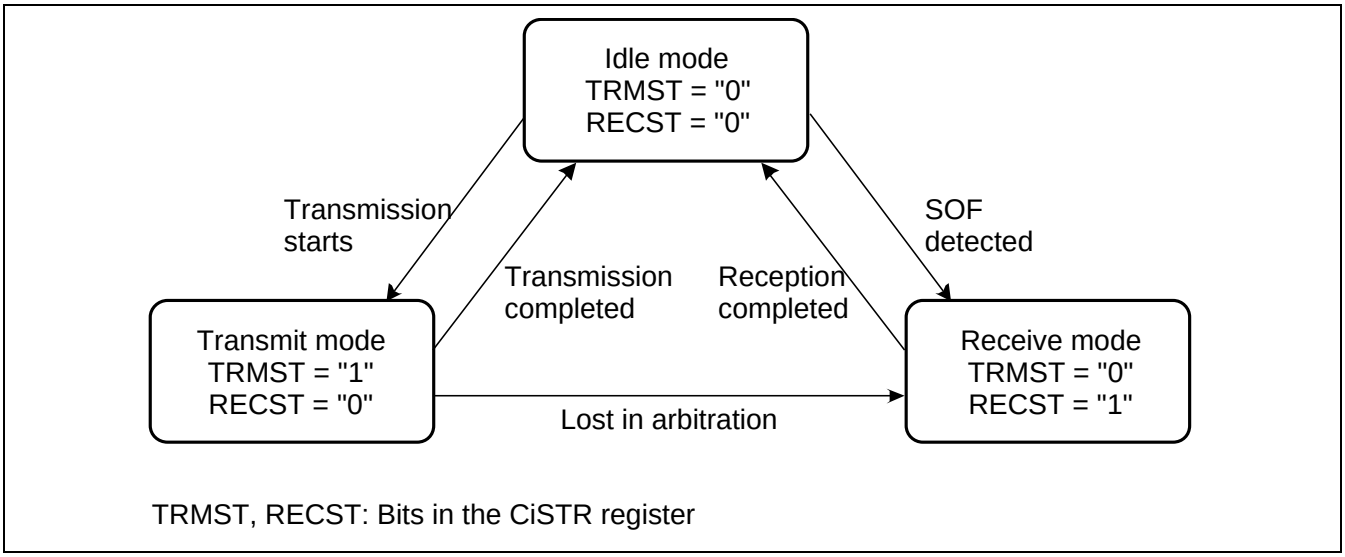


Figure 47.10 Sub Mode in CAN Operation Mode (i = 0, 1)

47.3.5 CAN Operation Mode (Bus-Off State)

The CAN module enters the bus-off state according to the increment/decrement rules for the transmit/error counters in the CAN Specifications.

The following cases apply when recovering from the bus-off state. When the CAN module is in bus-off state, the values of the associated registers, except registers CiSTR, CiEIFR, CiRECR, CiTECR and CiTSR, remain unchanged.

1. When the BOM bit in the CiCTLR register is "B'00" (normal mode)
   The CAN module enters the error-active state after it has completed the recovery from the bus-off state and CAN communication is enabled instantly. The BORIF bit in the CiEIFR register is set to "1" (bus-off recovery detected) at this time.
2. When the RBOC bit in the CiCTLR register is set to "1" (forcible return from bus-off)
   The CAN module enters the error-active state when it is in bus-off state and the RBOC bit is set to "1". CAN communication is enabled again after 11 consecutive recessive bits are detected. The BORIF bit is not set to "1" at this time.
3. When the BOM bit is "B'01" (entry to CAN halt mode automatically at bus-off entry)
   The CAN module enters CAN halt mode when it reaches the bus-off state. The BORIF bit is not set to "1" at this time.
4. When the BOM bit is "B'10" (entry to CAN halt mode automatically at bus-off end)
   The CAN module enters CAN halt mode when it has completed the recovery from bus-off. The BORIF bit is set to "1" at this time.
5. When the BOM bit is "B'11" (entry to CAN halt mode by a program) and the CANM bit in the CiCTLR register is set to "B'10" (CAN halt mode) during the bus-off state
   The CAN module enters CAN halt mode when it is in bus-off state and the CANM bit is set to "B'10" (CAN halt mode). The BORIF bit is not set to "1" at this time.
   If the CANM bit is not set to "B'10" during bus-off, the same behavior as (1) applies.

47.4 CAN Communication Speed Configuration

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

The following description explains about the CAN communication speed configuration.

47.4.1 CAN Clock Configuration

This MCU has a CAN clock selector. The CAN clock can be configured by setting the CCLKS bit in the CiCLKR register and the BRP bit in the CiBCR register.

Figure 47.11 shows the block diagram of CAN clock generator.

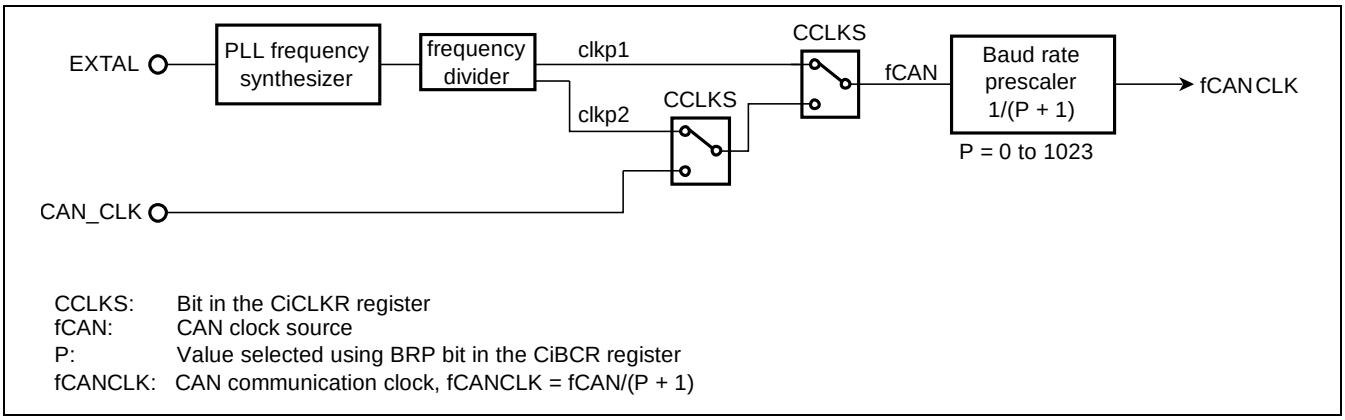

Figure 47.11 Block Diagram of CAN Clock Generator (i = 0, 1)

The CAN operating clock can be selected from the internal clock (clkp1, clkp2) from the CPG (PLL), and the external clock input to external pin (CAN_CLK).

In the initial state, clkp1 is selected. If an external clock input is to be selected, set the CiCLKR register (section 47.2.2) before accessing the CAN module. The range of frequencies that may be input as an external clock is 8 to 50 MHz.

47.4.2 Bit Timing Configuration

The bit time is a single bit time for transmitting/receiving a message and consists of the following three segments.

Figure 47.12 shows the bit timing.

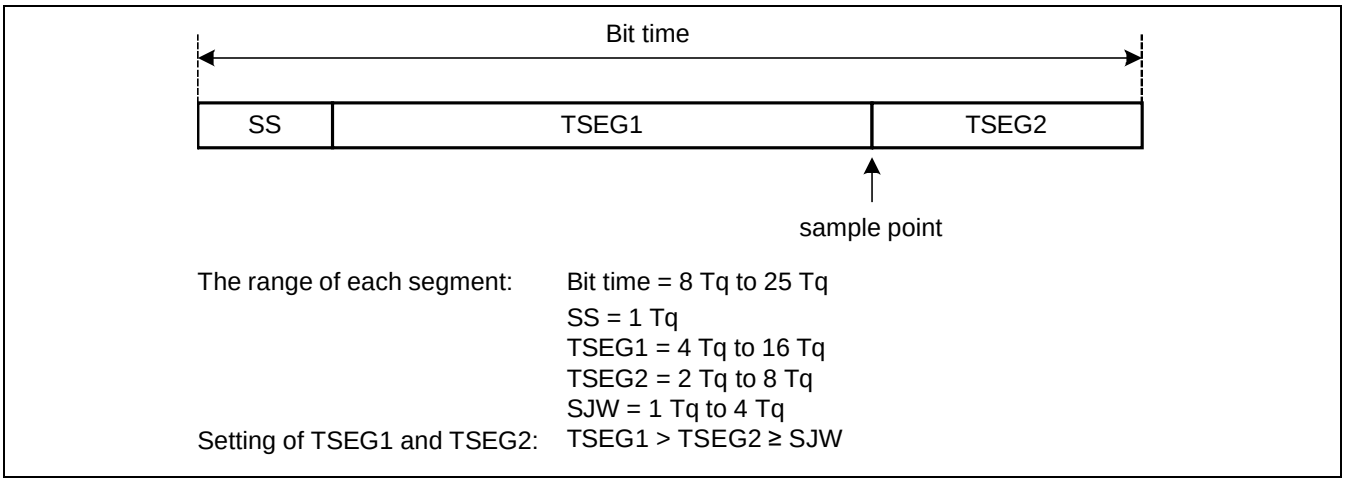

Figure 47.12 Bit Timing

47.4.3 Bit-rate

The bit rate depends on the division value of the fCAN (CAN clock source), the division value of the baud rate prescaler, and the number of Tq of one bit time.

$$\text{Bit rate [bps]} = \frac{fCAN}{\text{Baud rate prescaler division value}^* \times \text{number of Tq of one bit time}} = \frac{fCANCLK}{\text{Number of Tq of one bit time}}$$

Note: * Division value of the baud rate prescaler = P + 1 (P: 0 to 1023)
P: Setting value of the BRP bit in the CiBCR register (i = 0, 1)

Table 47.11 lists bit rate examples.

Table 47.11 Example of Bit-rate

fCAN	40 MHz		32 MHz		20 MHz		16 MHz	
Bit-rate	**No. of Tq**	**P + 1**	**No. of Tq**	**P + 1**	**No. of Tq**	**P + 1**	**No. of Tq**	**P + 1**

	H'FFFF_6420 +4 × n+1	H'FFFF_7420 +4 × n+1
	H'FFFF_6420 +4 × n+2	H'FFFF_7420 +4 × n+2
	H'FFFF_6420 +4 × n+3	H'FFFF_7420 +4 × n+3

CiFIDCRn register

Figure 47.15 Structure of CiFIDCRn register (i = 0, 1; n = 0, 1)

47.6 Acceptance Filtering and Masking Function

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

Acceptance filtering allows the user to receive messages with a specified range of multiple IDs for mailboxes. Registers CiMKR0 to CiMKR9 can perform masking of the standard ID and the extended ID of 29 bits.

- The CiMKR0 register corresponds to mailboxes [0] to [15].
- The CiMKR1 register corresponds to mailboxes [16] to [31].
- The CiMKR2 register corresponds to mailboxes [32] to [35].
- The CiMKR3 register corresponds to mailboxes [36] to [39].
- The CiMKR4 register corresponds to mailboxes [40] to [43].
- The CiMKR5 register corresponds to mailboxes [44] to [47].
- The CiMKR6 register corresponds to mailboxes [48] to [51].
- The CiMKR7 register corresponds to mailboxes [52] to [55].
- The CiMKR8 register corresponds to mailboxes [56] to [59] in normal mailbox mode and the receive FIFO mailboxes [60] to [63] in FIFO mailbox mode.
- The CiMKR9 register corresponds to mailboxes [60] to [63] in normal mailbox mode and the receive FIFO mailboxes [60] to [63] in FIFO mailbox mode.

Registers CiMKIVLR0 and CiMKIVLR1 disable acceptance filtering individually for each mailbox.

The IDE bit in the CiMBj register is enabled when the ID bit in the CiCTLR register is "B'10" (mixed ID mode).

The RTR bit in the CiMBj register selects a data frame or a remote frame.

In FIFO mailbox mode, normal mailboxes (mailboxes [0] to [55]) use the single corresponding register among registers CiMKR0 to CiMKR7 for acceptance filtering. Receive FIFO mailboxes (mailboxes [60] to [63]) use two registers CiMKR8 and CiMKR9 for the acceptance filtering.
Also, the receive FIFO uses two registers CiFIDCR0 and CiFIDCR1 for ID comparison. Bits EID, SID, RTR, and IDE in registers CiMB60 to CiMB63 for the receive FIFO are disabled. As acceptance filtering depends on the result of two ID-mask sets, two ranges of IDs can be received into the receive FIFO.
Registers CiMKIVLR0 and CiMKIVLR1 are disabled for the receive FIFO.
If both setting of standard ID and extended ID are set in the IDE bits in registers CiFIDCR0 and CiFIDCR1 individually, both ID formats are received.
If both setting of data frame and remote frame are set in the RTR bits in registers CiFIDCR0 and CiFIDCR1 individually, both data and remote frames are received.
When combination with two ranges of IDs is not necessary, set the same mask value and the same ID into both of the FIFO ID/mask register sets.

Figure 47.16 shows the correspondence of mask registers to mailboxes. Figure 47.17 shows the acceptance filtering.

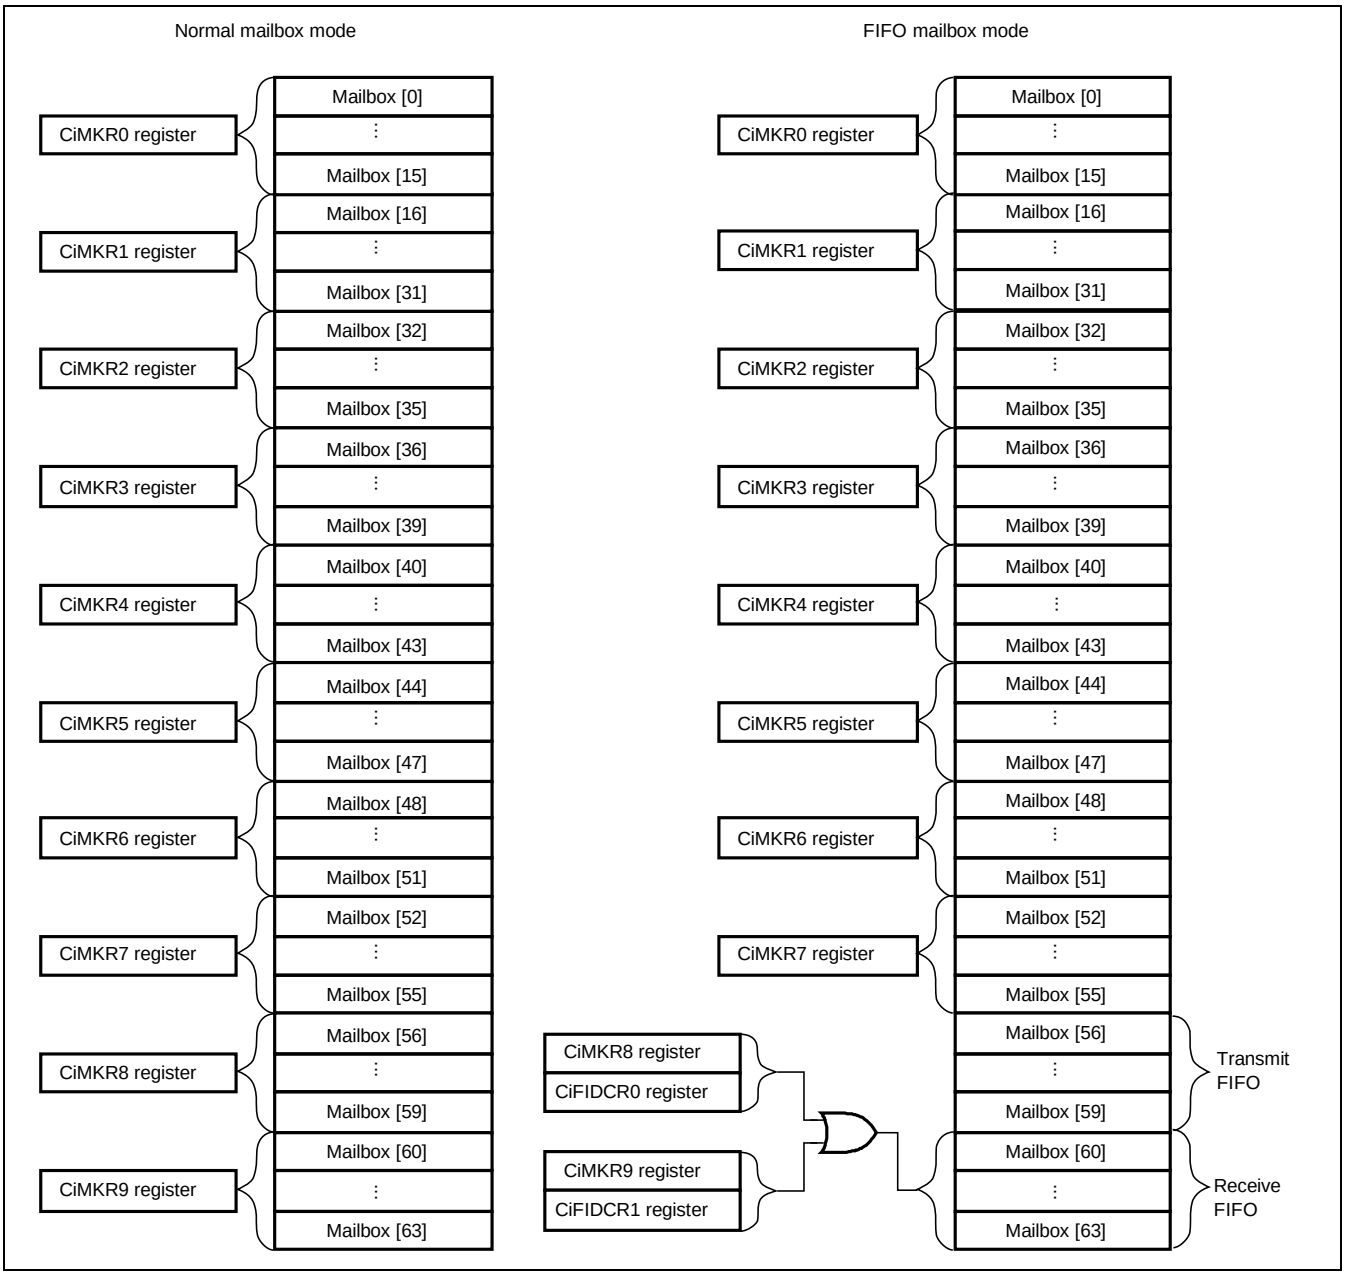

Figure 47.16 Correspondence of Mask Registers to Mailboxes (i = 0, 1)

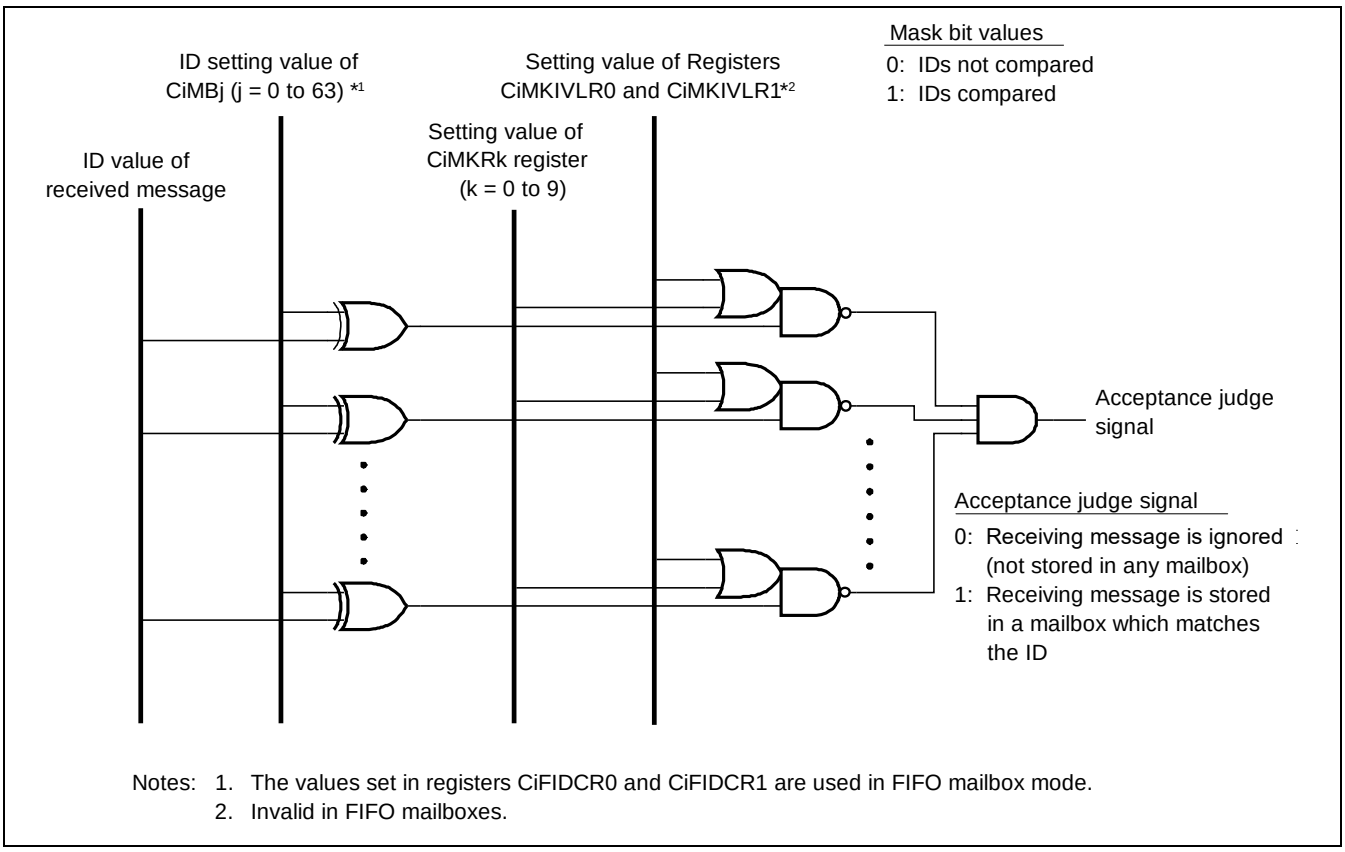

Notes: 1. The values set in registers CiFIDCR0 and CiFIDCR1 are used in FIFO mailbox mode.
2. Invalid in FIFO mailboxes.

Figure 47.17 Acceptance Filtering (i = 0, 1)

47.7 Reception and Transmission

RZ/G2H | RZ/G2M V1.3 | RZ/G2M V3.0 | RZ/G2N | RZ/G2E

Table 47.12 lists the CAN communication mode configuration.

Table 47.12 Configuration for CAN Reception Mode and Transmission Mode

TRMREQ	RECREQ	ONESHOT	Communication Mode of Mailbox
0	0	0	Mailbox disabled or transmission being aborted
0	0	1	Configurable only when transmission or reception from a mailbox (programmed in one-shot mode) is aborted.
0	1	0	Configured as a receive mailbox for a data frame or a remote frame.
0	1	1	Configured as a one-shot receive mailbox for a data frame or a remote frame.
1	0	0	Configured as a transmit mailbox for a data frame or a remote frame.
1	0	1	Configured as a one-shot transmit mailbox for a data frame or a remote frame.
1	1	0	Do not set.
1	1	1	Do not set.

Note: TRMREQ, RECREQ, ONESHOT: Bits in CiMCTLj register (i = 0, 1; j = 32 to 63)

When a mailbox is configured as a receive mailbox or a one-shot receive mailbox, note the following:

1. Before a mailbox is configured as a receive mailbox or a one-shot receive mailbox, set the CiMCTLj register to "H'00".
2. A received message is stored into the first mailbox that matches the condition according to the result of receive mode configuration and acceptance filtering. Upon deciding a mailbox which stores the received message, the mailbox with the smaller number has higher priority.
3. In CAN operation mode, when a CAN module transmits a message whose ID matches with the ID/mask set of a mailbox configured to receive messages, the CAN module never receives the transmitted data. In self-test mode, however, the CAN module may receive its transmitted data. In this case, the CAN module sends an ACK.

When configuring a mailbox as a transmit mailbox or a one-shot transmit mailbox, note the following:

1. Before a mailbox is configured as a transmit mailbox or one-shot transmit mailbox, ensure that the CiMCTLj register is "H'00" and that there is no pending abort process.

47.7.1 Reception

Figure 47.18 shows an operation example of data frame reception in overwrite mode.

This example shows the operation of overwriting the first message when the CAN module receives two consecutive CAN messages that matches the receiving conditions of the CiMCTLj register.

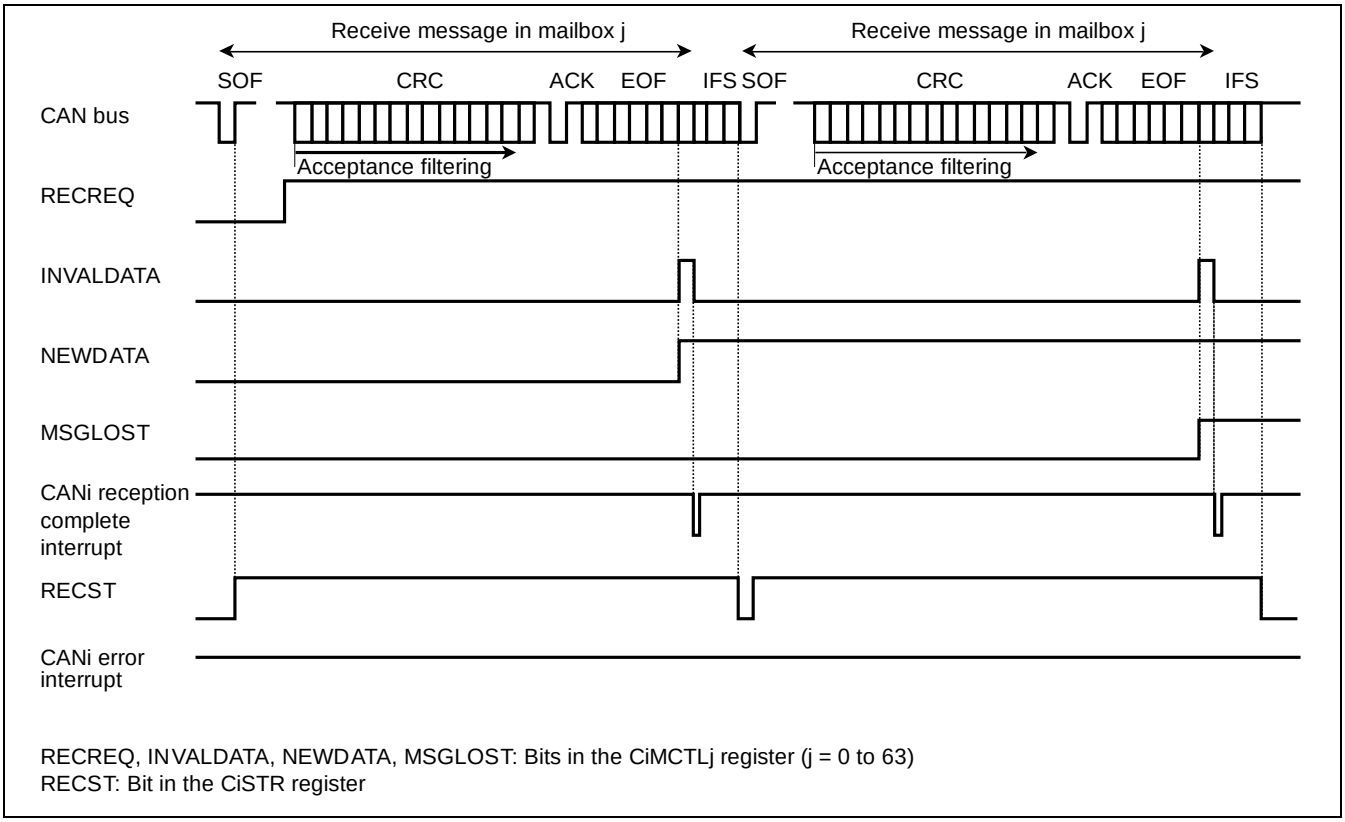

Figure 47.18 Operation Example of Data Frame Reception in Overwrite Mode (i = 0, 1)

1. When a SOF is detected on the CAN bus, the RECST bit in the CiSTR register is set to "1" (reception in progress) if the CAN module has no message ready to start transmission.
2. The acceptance filter procedure starts at the beginning of the CRC field to select the receive mailbox.
3. After a message has been received, the NEWDATA bit in the CiMCTLj register for the receive mailbox is set to "1" (new data being updated/stored in the mailbox). The INVALDATA bit in the CiMCTLj register is set to "1" (message is being updated) at the same time, and then the INVALDATA bit is set to "0" (message valid) again after the complete message is transferred to the mailbox.
4. When the interrupt enable bit in the CiMIER register for the receive mailbox is "1" (interrupt enabled), the CANi reception complete interrupt request is generated. This interrupt is generated when the INVALDATA bit is set to "0".
5. After reading the message from the mailbox, the NEWDATA bit needs to be set to "0" by a program.
6. In overwrite mode, if the next CAN message has been received into a mailbox whose NEWDATA bit is still set to "1", the MSGLOST bit in the CiMCTLj register is set to "1" (message has been overwritten). The new received message is transferred to the mailbox. The CANi reception complete interrupt request is generated the same as in 4.

Figure 47.19 shows the operation example of data frame reception in overrun mode. This example shows the operation of overrunning the second message when the CAN module receives two consecutive CAN messages that matches the receiving conditions of the CiMCTLj register.

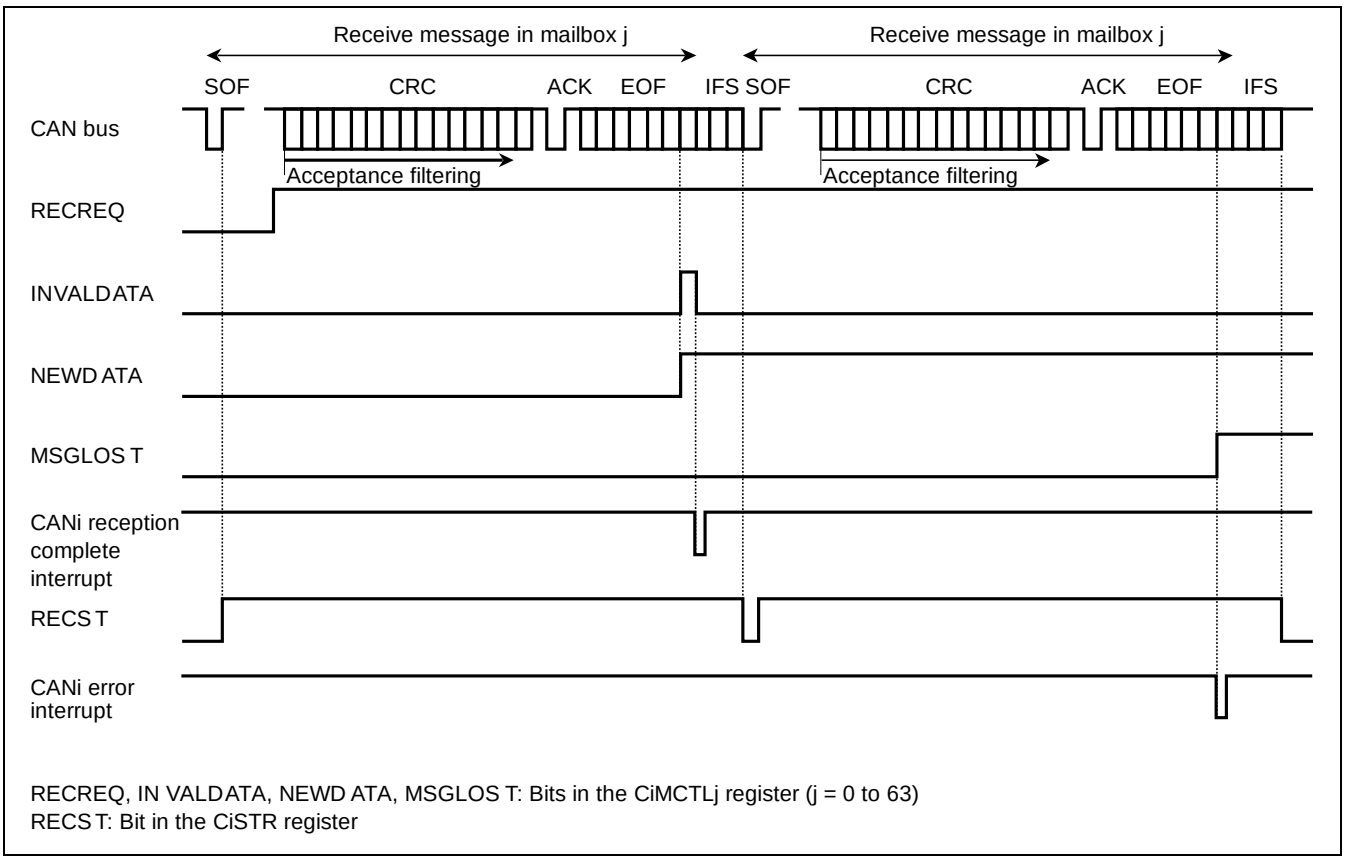

Figure 47.19 Operation Example of Data Frame Reception in Overrun Mode (i = 0, 1)

1. to 5. are the same as overwrite mode.

6. In overrun mode, if the next message has been received before the NEWDATA bit is set to "0", the MSGLOST bit in the CiMCTLj register is set to "1" (message has been overrun). The new received message is discarded and a CANi error interrupt request is generated if the corresponding interrupt enable bit in the CiEIER register is set to "1" (interrupt enabled).

47.7.2 Transmission

Figure 47.20 shows an operation example of data frame transmission.

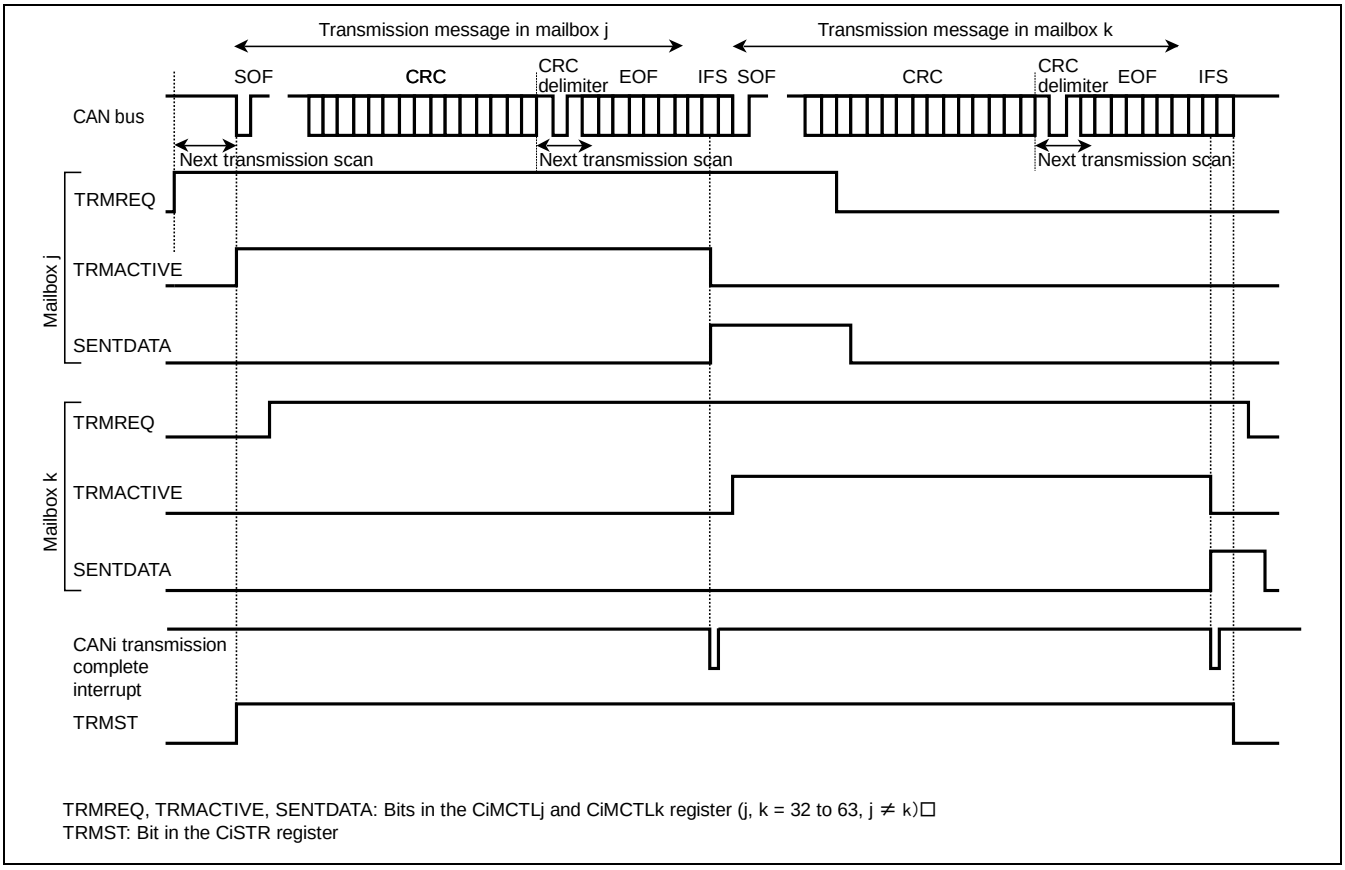

Figure 47.20 Operation Example of Data Frame Transmission (i = 0, 1)

1. When a TRMREQ bit in the CiMCTLj register is set to 1 (transmit mailbox) in bus-idle state, the mailbox scan procedure starts to decide the highest-priority mailbox for transmission. Once the transmit mailbox is decided, the TRMACTIVE bit in the CiMCTLj register is set to "1" (from when a transmission request is received until transmission is completed, or an error/arbitration lost has occurred), the TRMST bit in the CiSTR register is set to "1" (transmission in progress), and the CAN module starts transmission.*
2. If other TRMREQ bits are set, the transmission scan procedure starts with the CRC delimiter for the next transmission.
3. If transmission is completed without losing arbitration, the SENTDATA bit in the CiMCTLj register is set to "1" (transmission completed) and the TRMACTIVE bit is set to "0" (transmission is pending, or no transmission request). If the interrupt enable bit in the CiMIER register is "1" (interrupt enabled), the CANi transmission complete interrupt request is generated.
4. When requesting the next transmission from the same mailbox, set bits SENDTDATA and TRMREQ to "0", then set the TRMREQ bit to "1" after checking that bits SENDTDATA and TRMREQ have been set to "0".

Note: * If arbitration is lost after the CAN module starts transmission, the TRMACTIVE bit is set to "0". The transmission scan procedure is performed again to search for the highest-priority transmit mailbox from the beginning of the CRC delimiter. If an error occurs either during transmission or following the arbitration lost the transmission scan procedure is performed again from the start of the error delimiter to search for the highest-priority transmit mailbox.

47.8 CAN Interrupt

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

The CAN module provides the following CAN interrupts for each channel. Table 47.13 lists CAN interrupts.

- CANi reception complete interrupt (mailbox 0) [RXM0i]
- CANi reception complete interrupt (mailbox 1 to 63) [RXM1i]
- CANi transmission complete interrupt (mailbox 32 to 63) [TXMi]
- CANi reception FIFO interrupt [RXFi]
- CANi transmission FIFO interrupt [TXFi]
- CANi error interrupt [ERSi]

  There are eight types of interrupt sources for the CANi error interrupts. These sources can be determined by checking the CiEIFR register.
  - Bus error
  - Error-warning
  - Error-passive
  - Bus-off entry
  - Bus-off recovery
  - Receive overrun
  - Overload frame transmission
  - Bus lock

Table 47.13 CAN Interrupts

Module	Interrupt Symbol	Interrupt Source	Source Flag
CANi	ERSi	Bus lock detected	CiEIFR.BLIF
		Overload frame transmission detected	CiEIFR.OLIF
		Overrun detected	CiEIFR.ORIF
		Bus-off recovery detected	CiEIFR.BORIF
		Bus-off entry detected	CiEIFR.BOEIF
		Error-passive detected	CiEIFR.EPIF
		Error-warning detected	CiEIFR.EWIF
		Bus error detected	CiEIFR.BEIF
	RXFi	Receive FIFO message received (CiMIER1[29] = 0)	CiISR.RXFF
		Receive FIFO warning (CiMIER1[29] = 1)	
	TXFi	Transmit FIFO message transmission completed (CiMIER1[25] = 0)	CiISR.TXFF
		FIFO last message transmission completed (CiMIER1[25] = 1)	
	RXM0i	Mailbox 0 message received	CiMCTL0.NEWDATA
	RXM1i	Mailbox 1 to 63 message received	CiMCTL1.NEWDATA to CiMCTL63.NEWDATA
	TXMi	Mailbox 32 to 63 message transmission completed	CiMCTL32.SENTDATA to CiMCTL63.SENTDATA

Legend: i = 0, 1

(1) CANi reception complete interrupt (mailbox 0) [RXM0i]

After the CiMCTL0.NEWDATA bit is set by the completion of reception, if received data has been stored (the corresponding INVALDATA bit changes from "1" to "0"), the CiISR.RXM0F bit is set to "1" when CiMIER0[0] has been set to "1". When the mailbox 0 reception complete (RXM0) interrupt has been enabled, the RXM0 interrupt is requested to the interrupt controller.

To clear the RXM0 interrupt, clear the CiMCTL0.NEWDATA bit in the RXM0 interrupt handling routine. To change the CiIER.RXM0IE bit to disabled after having set the bit, make the change while no RXM0 interrupt is generated or during the RXM0 interrupt handling routine. This also applies to CiMIER0[0].

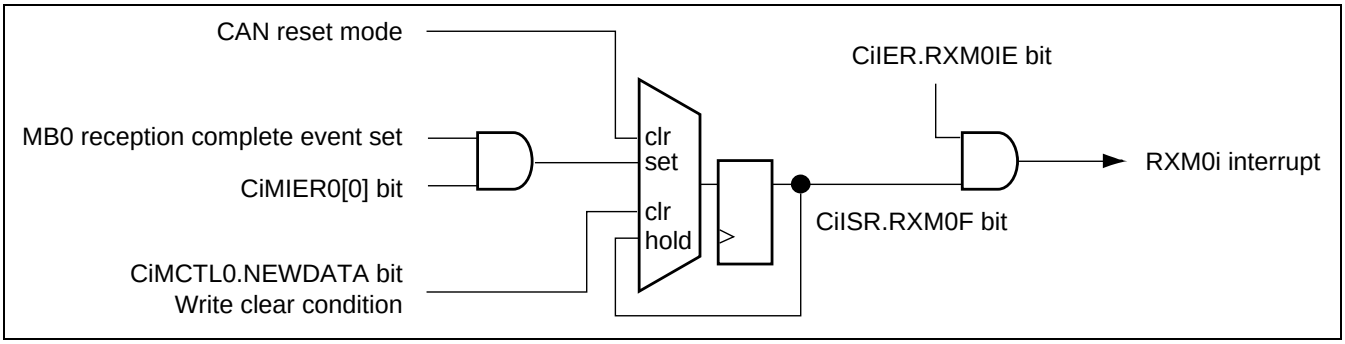

Figure 47.21 Block Diagram of CANi Reception Complete Interrupt (Mailbox 0) [RXM0i]

(2) CANi reception complete interrupt (mailbox 1 to 63) [RXM1i]

After the CiMCTLj.NEWDATA bit is set by the completion of reception, if received data has been stored (the corresponding INVALDATA bit changes from "1" to "0"), the CiISR.RXM1F bit is set to "1" when the CiMIER0 or CiMIER1 register bit corresponding to mailbox j has been set to "1". When the mailbox 1 to 63 reception complete (RXM1) interrupt has been enabled, the RXM1 interrupt is requested to the interrupt controller.

To clear the RXM1 interrupt, clear the CiMCTLj.NEWDATA bit in the RXM1 interrupt handling routine. To change the CiIER.RXM1IE bit to disabled after having set the bit, make the change while no RXM1 interrupt is generated or during the RXM1 interrupt handling routine. This also applies to CiMIER0[j] (j = 1 to 31) or CiMIER1[j-32] (j = 32 to 63).

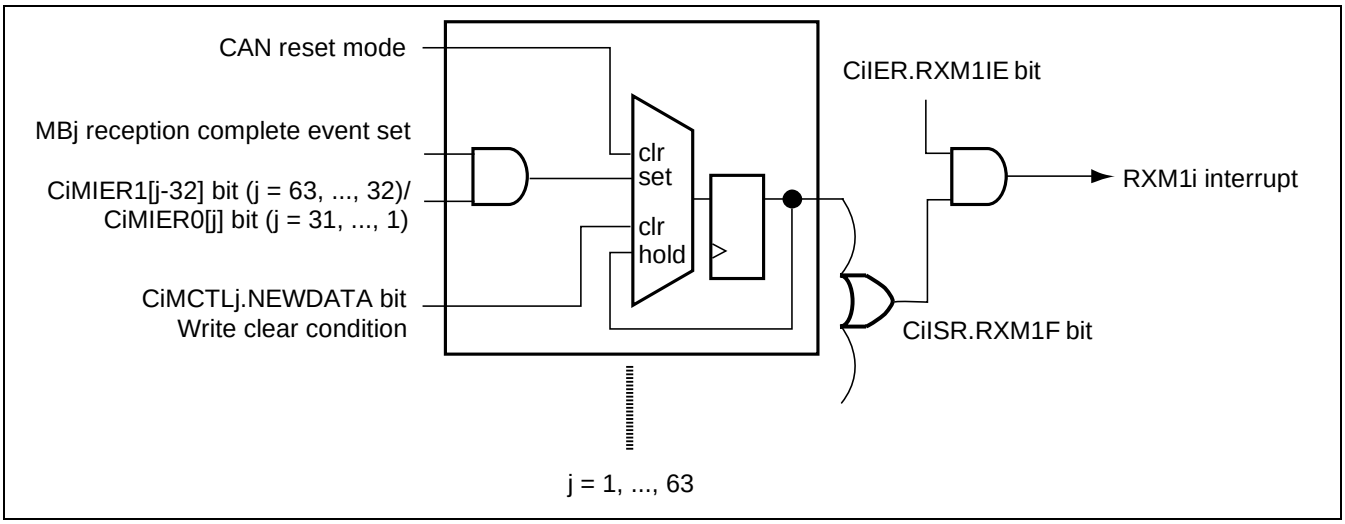

Figure 47.22 Block Diagram of CANi Reception Complete Interrupt (Mailbox 1 to 63) [RXM1i]

(3) CANi transmission complete interrupt (mailbox 32 to 63) [TXMi]

If the CiMCTLj.SENTDATA bit is set by the completion of transmission, the CiISR.TXMF bit is set to "1" when the CiMIER1 register bit corresponding to mailbox j has been set to "1". When the mailbox 32 to 63 transmission complete (TXM) interrupt has been enabled, the TXM interrupt is requested to the interrupt controller.

To clear the TXM interrupt, clear the CiMCTLj.SENTDATA bit in the TXM interrupt handling routine. To change the CiIER.TXMIE bit to disabled after having set the bit, make the change while no TXM interrupt is generated or during the TXM interrupt handling routine. This also applies to CiMIER1[j-32] (j = 32 to 63).

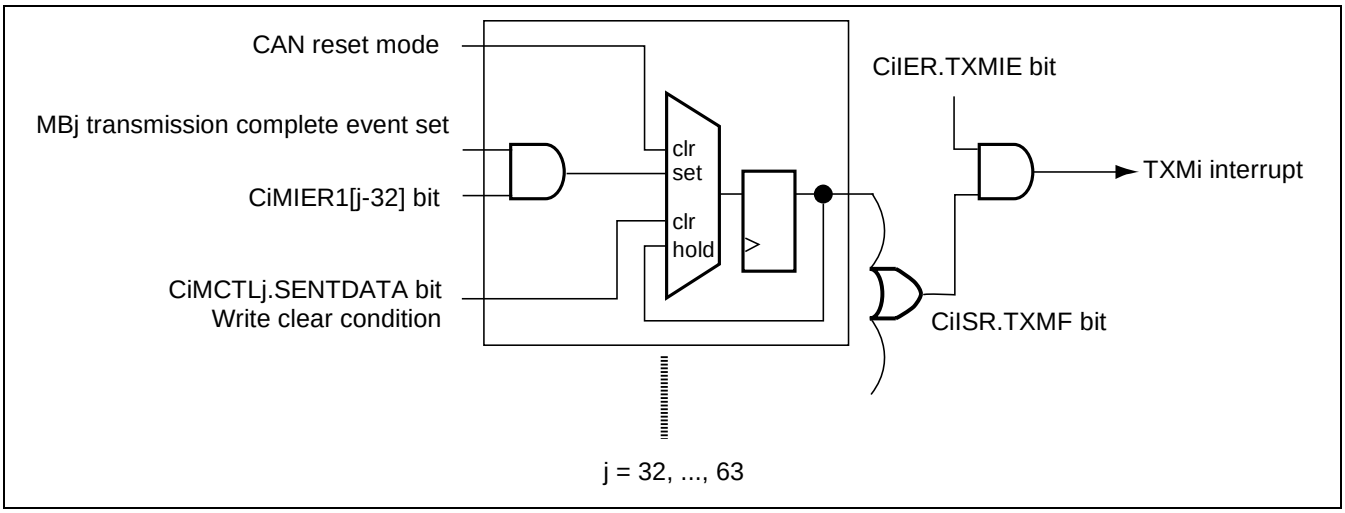

Figure 47.23 Block Diagram of CANi Transmission Complete Interrupt (Mailbox 32 to 63) [TXMi]

(4) CANi receive FIFO interrupt [RXFi]

If CiRFCR[6:5] are set by the reception of a receive FIFO message or by a warning with the settings of CiMIER1[29:28], the CiISR.RXFF bit is set to "1". When the receive FIFO (RXF) interrupt has been enabled with the CiIER.RXFIE bit, the RXF interrupt is requested to the interrupt controller.

To clear the RXF interrupt, clear the CiISR.RXFF bit in the RXF interrupt handling routine. To change the CiIER.RXFIE bit to disabled after having set the bit, make the change while no RXF interrupt is generated or during the RXF interrupt handling routine. This also applies to CiMIER1[28].

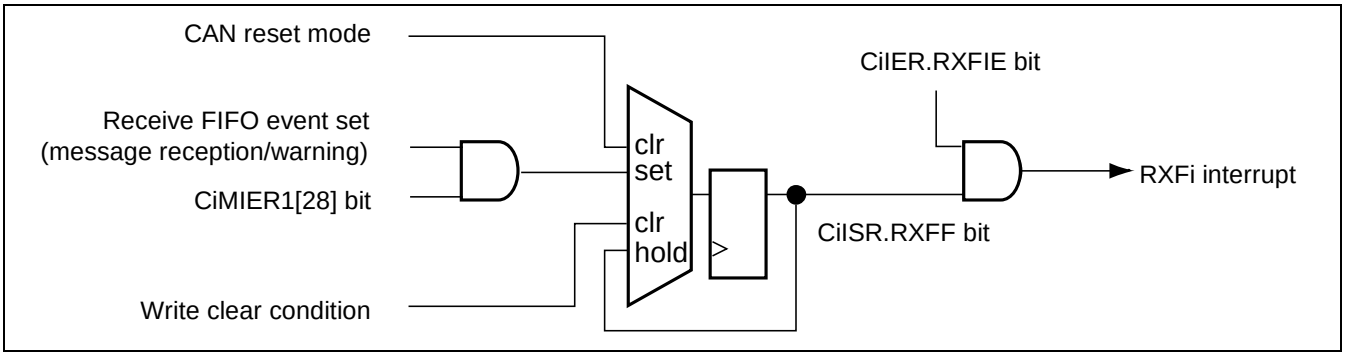

Figure 47.24 Block Diagram of CANi Receive FIFO Interrupt [RXFi]

(5) CANi transmit FIFO interrupt [TXFi]

When the transmission of a transmit FIFO message is counted for the specified number of times with the settings of CiMIER1 [25:24], the CiISR.TXFF bit is set to "1". When the transmit FIFO (TXF) interrupt has been enabled with the CiIER.TXFIE bit, the TXF interrupt is requested to the interrupt controller.

To clear the TXF interrupt, clear the CiISR.TXFF bit in the TXF interrupt handling routine. To change the CiIER.TXFIE bit to disabled after having set the bit, make the change while no TXF interrupt is generated or during the TXF interrupt handling routine. This also applies to CiMIER1[24].

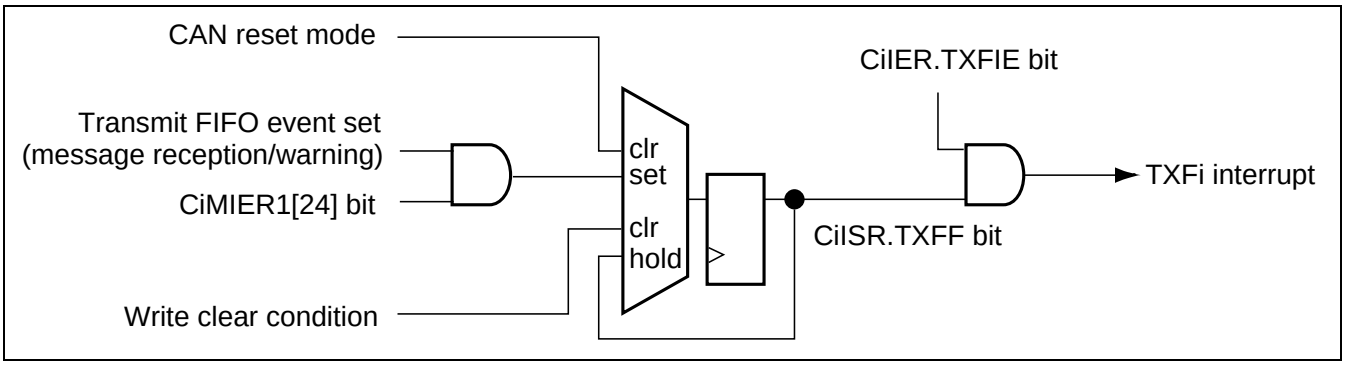

Figure 47.25 Block Diagram of CANi Transmit FIFO Interrupt [TXFi]

(6) CANi error interrupt [ERSi]

If CiEIFR[j] is set by a communication error, the CiISR.ERSF bit is set to "1" when the corresponding CiEIER[j] has been set to "1". When the error (ERS) interrupt has been enabled with the CiIER.ERSIE bit, the ERS interrupt is requested to the interrupt controller.

To clear the ERS interrupt, clear each CiEIFR[j] register bit in the ERS interrupt handling routine. To change the CiIER.ERSIE bit to disabled after having set the bit, make the change while no ERS interrupt is generated or during the ERS interrupt handling routine. This also applies to CiEIER[j] (j = 7 to 0).

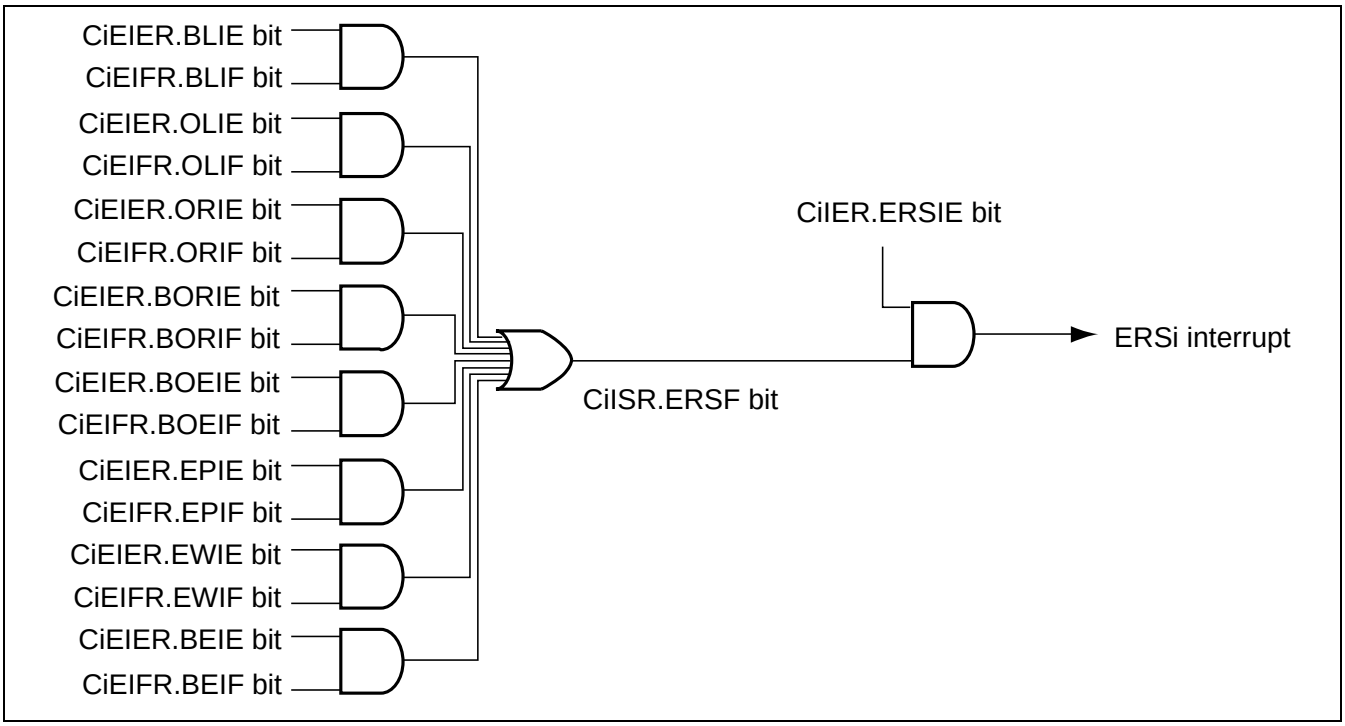

Figure 47.26 Block Diagram of CANi Error Interrupt [ERSi]

47.9 CAN module can support Parity Check

RZ/G2H | RZ/G2M V1.3 | RZ/G2M V3.0 | RZ/G2N | RZ/G2E

47.9.1 Overview

The Parity bit generator for an Even Parity check is a simple XOR of each bit. Exclusive or (XOR) is represented by "^" as follows.

parity[0] = ^DataBus[7:0]

parity[1] = ^DataBus[15:8]

parity[2] = ^DataBus[23:16]

parity[3] = ^DataBus[31:24]

The Parity error detection for an Even Parity check is a simple XOR of each bit including the Parity bit. In case the result is equal to the Data Byte no error is generated. The detection logic is only working during read access for the selected byte.

parity_error[0] = { ^DataBus[7:0]} ^ parity[0]

parity_error[1] = { ^DataBus[15:8]} ^ parity[1]

parity_error[2] = { ^DataBus[23:16]} ^ parity[2]

parity_error[3] = { ^DataBus[31:24]} ^ parity[3]

Each memory location in the DPRAM consists of 36 bits. 32 bits are used for storage of user data. For each byte of a longword memory location a parity bit is allocated. The value of this parity bit is calculated by the parity generation logic for each byte and both data byte and parity bit are stored in memory during the same write access. The alignment of data bytes and corresponding parity bits in each memory location is shown in the following diagram:

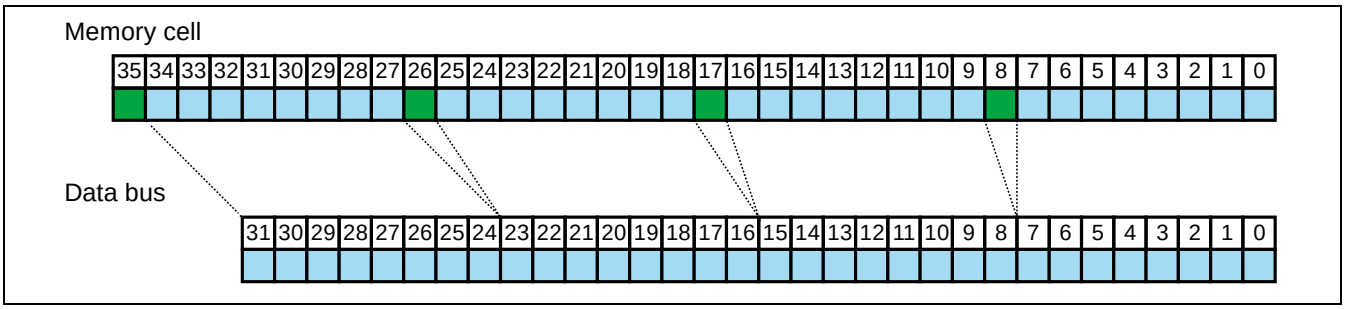

Figure 47.27 Parity bit alignment

47.9.2 Recommend Usage

In order to use this function, refer to 47.2.29 (Parity Error Control Register (CiPECR) (i = 0, 1)) to know how to enable this function.

47.9.3 Failure Control

When parity error detected, an interrupt request is issued to Interrupt handle is obtained.

48. CAN-FD

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

This section contains a generic description of the CANFD interface (RS-CANFD).

The first part of this section describes all specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of RS-CANFD.

48.1 Overview

48.1.1 Functional Overview

Table 48.1 shows the RS-CANFD module specifications. Figure 48.1 shows the RS-CANFD module block diagram.

Table 48.1 RS-CANFD Module Specifications

Item	Specification
Number of channels	
Protocol	ISO11898-1 compliant Use of CAN FD frames can be selected by switching the interface modes.
Communication speed	Classical CAN mode: Maximum 1 Mbps Communication speed (CANm bit time clock) = $\frac{1}{\text{CANm bit time}}$ CANm bit time = CANmTq × Tq count per bit CANmTq = $\frac{\text{(BRP[9:0] bits in the RSCFDnCmCFG register + 1)}}{\text{fCAN}}$ fCAN: Frequency of CAN clock (selected by the DCS bit in the RSCFDnGCFG register) CAN FD mode: Normal bit rate: 1 Mbps (max.), Data bit rate: 8 Mbps (max.) Communication speed (CANm normal bit time clock) = $\frac{1}{\text{CANm normal bit time}}$ Communication speed (CANm data bit time clock) = $\frac{1}{\text{CANm data bit time}}$ CANm normal bit time = CANmTq(N) × Tq count per normal bit CANm data bit time = CANmTq(D) × Tq count per normal bit CANmTq(N) = $\frac{\text{(NBRP[9:0] bits in RSCFDnCFDCmNCFG register + 1)}}{\text{fCAN}}$ CANmTq(D) = $\frac{\text{(DBRP[7:0] bits in RSCFDnCFDCmDCFGregister + 1)}}{\text{fCAN}}$ fCAN: Frequency of CAN clock (selected by the DCS bit in the RSCFDnCFDGCFG register) m = 0 or 1 Tq: Time quantum

Item	Specification
Buffer	• Individual buffers: 32 buffers (16 buffers × 2 channels) Transmit buffer: 16 buffers per channel Transmit FIFO: 3 FIFO per channel Transmit queue: Signle queue per channel (shared with the transmit buffer; up to 16 buffers allocated) • Shared buffers: 128 buffers for all channels Receive buffer: 32 buffers Receive FIFO: 8 FIFO (up to 128 buffers allocated to each) Transmit/receive FIFO buffer: 3 FIFO buffers per channel (up to 128 buffers allocated to each) • ECC included
Reception function	• Receives data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be received. • Sets interrupt enable/disable for each FIFO. • Mirror function (reception of messages transmitted from the own CAN node) • Timestamp function (to record message reception time as a 16-bit timer value)
Reception filter function	• Selects receive messages according to 1 receive rule. • Sets the number of receive rules (0 to 128) for each channel. • Acceptance filter processing: Sets ID and mask for each receive rule. • DLC filter processing: Enables DLC filter check for each acceptance rule.
Receive message transfer function	• Routing function Transfers receive messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Receive buffer, receive FIFO buffer, and/or transmit/receive FIFO buffer • Label addition function Stores label information together with a message in a receive buffer and FIFO buffer.
Transmission function	• Transmits data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be transmitted. • Sets interrupt enable/disable for each transmit buffer and transmit/receive FIFO buffer. • Selects ID priority transmission or transmit buffer number priority transmission. • Transmit request can be aborted (possible to confirm with a flag) • One-shot transmission function
Interval transmission function	Transmit messages at configurable intervals (transmit mode or gateway mode of transmit/receive FIFO buffers)
Transmit queue function	Transmits all stored messages according to the ID priority.
Transmit history function	Stores the history information of transmission-completed messages Adds the timestamp to the history information (records the 16-bit timer value for the message transmission time).
Gateway function	Transmits a received message automatically.
Bus off recovery mode selection	Selects the method for returning from bus off state. • ISO11898-1 compliant • Automatic entry to channel halt mode at bus-off entry • Automatic entry to channel halt mode at bus-off end • Transition to channel standby mode by program request • Transition to the error-active state by program request (forcible return from the bus off state)

Item	Specification
Error status monitoring	• Monitors CAN protocol errors (stuff error, form error, ACK error, CRC error, bit error, ACK delimiter error, and bus dominant lock). • Detects error status transitions (error warning, error passive, bus off entry, and bus off recovery) • Reads the error counter. • Monitors DLC errors.
Interrupt source	• Global Interrupts (2 sources) Receive FIFO interrupt Global error interrupt • Channel interrupts (3 sources/channel) CANm transmit interrupt (m = 0 or 1) CANm transmit complete interrupt CANm transmit abort interrupt CANm transmit/receive FIFO transmit complete interrupt (in transmit mode, gateway mode) CANm transmit history interrupt CANm transmit queue interrupt CANm transmit/receive FIFO receive complete interrupt (in receive mode, gateway mode) CANm error interrupt
CAN stop mode	Reduces power consumption by stopping clock supply to the RS-CANFD module.
CAN clock source	Selects the clkc or the clk_xincan. As for the range of operating frequency, see section 48.16.1.3, Setting Communication Speed.
Test function	Test function for user evaluation • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback) • Limited operation mode • RAM test (read/write test) • Inter-channel communication test [CRC error test is available]

48.1.2 Interface Mode

RS-CANFD has the following two interface modes.

- Classical CAN mode: Only classical CAN frames are handled.
- CAN FD mode: both the classical CAN frames and CAN FD frames are handled.

Two modes use different register maps with the same base address, and the register maps are switched by switching the modes.

Interface modes can be switched using the RCMC bit in the RSCFDnCFDGRMCFG register.

48.2 Block Diagram

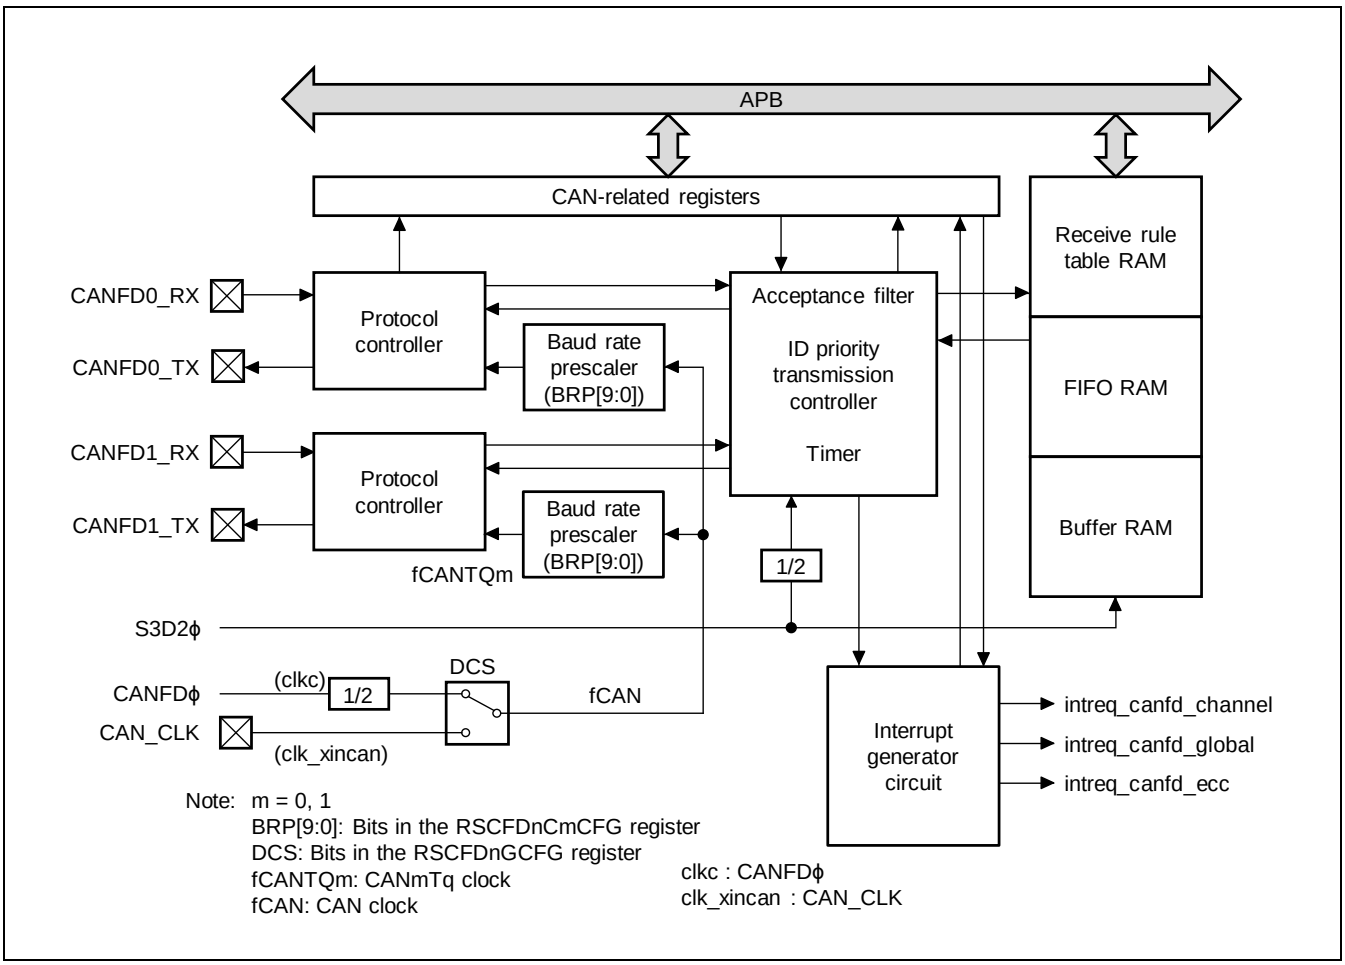

Figure 48.1 RS-CANFD Module Block Diagram (in classical CAN mode)

In CAN FD mode, the specification of the clock to be input to the baud rate prescaler and protocol controller is different from that of the clock in classical CAN mode. Refer to section 48.16.1.3, Setting Communication Speed.

CANFDϕ must be set as 80 (MHz).

48.3 External Pins

Table 48.2 shows the CAN module pin.

Pin switching is required for pins which are multiplexed with other Function. For details, see section 8, Pin Function Controller (PFC).

Table 48.2 Pin Configuration

				Second Generation RZ/G Series Products			
Name	**Abbreviation**	**I/O**	**Function**	**RZ/G2H**	**RZ/G2M V1.3 RZ/G2M V3.0**	**RZ/G2N**	**RZ/G2E**
CANFDi_RX	—	Input	Pins for receiving data	√	√	√	√
CANFDi_TX	—	Output	Pins for transmitting data	√	√	√	√
CAN_CLK	—	Input	Input pin used for external clock input.	√	√	√	√

Legend: i = 0 and 1

48.4 Connected module

Table 48.3 Connected module

Module name	Connected module name	function of the related module
CANFD	AXI	Register access of CPU
	CPG	Clock output
	PFC	Selection of external pins
	Module Standby	Clock stop control
	Software Reset	Soft reset execution
	INTC	Interruption
	SYS-DMAC	DMA transmission

48.5 Features of RS-CANFD

RS-CANFD has two interface modes (classical CAN mode and CAN FD mode), and uses different registers in each mode. The different register names RSCFDnXXX and RSCFDnCFDXXX are used in the different interface modes (XXX can be any character). In this document, the registers common to the two modes are indicated as RSCFDn(CFD)XXX.

Table 48.4 Index

Index	Meaning
n	Throughout this section, the individual RS-CANFD units are generically indicated by the index “n” (n = 0); for example, RSCFDn(CFD)GCTR is the global control register of the RSCFDn unit.
m	Throughout this section, the individual channels of RS-CANFD units are generically indicated by the index “m” (m = 0, 1); for example, RSCFDn(CFD)CmSTS is the channel m status register.
j	The individual registers associated with receive rule table are generically indicated by the index “j” (j = 0 to 15); for example, RSCFDn(CFD)GAFLIDj is the receive rule ID register.
k	The individual transmit/receive FIFO buffers are generically indicated by the index “k” (k = 0 to [channel m × 3 + 2]); for example, RSCFDn(CFD)CFCCk is the transmit/receive FIFO buffer configuration/control register.
x	The individual receive FIFO buffers in the RS-CANFD units are identified by the index “x” (x = 0 to 7): for example, RSCFDn(CFD)RFSTSx is the receive FIFO buffer status register.
d	The individual transmit/receive FIFO buffers are generically indicated by the index “d” (d = 0 to 1 in classical CAN mode, and d = 0 to 15 in CAN FD mode); for example, RSCFDn(CFD)CFDFd_k is the transmit/receive FIFO buffer data field register.
q	The individual receive buffers are generically indicated by the index “q” (q = 0 to [channel m × 16 + 15]); for example, RSCFDn(CFD)RMIDq is the receive buffer ID register.
p	The individual transmit buffers are generically indicated by the index “p” (p = 0 to [channel m × 16 + 15]; for example, RSCFDn(CFD)TMCp is the transmit buffer control register.
b	The individual transmit and receive buffers are generically indicated by the index “b” (b = 0 to 1 in classical CAN mode, and b = 0 to 4 in CAN FD mode); for example, RSCFDn(CFD)RMDFb_q is the receive buffer data field register.
r	The individual RAM tests for CAN are generically indicated by the index “r” (r = 0 to 63); for example, RSCFDn(CFD)RPGACCr is the RAM test page access register.
y	The registers not covered above are indicated by the letter “y” (y = 0); for example, RSCFDn(CFD)RMNDy is a receive buffer new data register.

Note: The Function and descriptions of registers in this section are for the RS-CANFDs that has 2 channels (m = 0, 1). When referring to information with indices, regard the index values as the ones corresponding to your target product. Also, note that, if the value of an index exceeds the range described in this section due to your target product, write the value after reset when writing to bits outside the index range.

48.5.1 Register Base Address

RSCFDn base addresses are listed in the following table.

RSCFDn register addresses are given as offsets from the base addresses in general.

Table 48.5 Register Base Address

Base Address Name	Base Address
<RSCFD0_base>	H'E66C_0000

48.6 Registers Configuration (classical CAN mode)

48.6.1 List of Registers

Table 48.6 lists the RS-CANFD registers used in classical CAN mode.

For details about <RSCFDn_base>, see section 48.5.1, Register Base Address.

Table 48.6 Registers

48.7 Register Description (classical CAN mode)

48.7.1 Details of Interface Mode Related Registers

48.7.1.1 RSCFDnCFDGRMCFG - Global Interface Mode Select Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGRMCFG register can be read/written in 32-bit units

RSCFDnCFDGRMCFGL, RSCFDnCFDGRMCFGH registers can be read/written in 16-bit units

RSCFDnCFDGRMCFGLL, RSCFDnCFDGRMCFGLH, RSCFDnCFDGRMCFGHL, RSCFDnCFDGRMCFGHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGRMCFG: <RSCFDn_base> + H'04FC

RSCFDnCFDGRMCFGL: <RSCFDn_base> + H'04FC,
RSCFDnCFDGRMCFGH: <RSCFDn_base> + H'04FE

RSCFDnCFDGRMCFGLL: <RSCFDn_base> + H'04FC,
RSCFDnCFDGRMCFGLH: <RSCFDn_base> + H'04FD,
RSCFDnCFDGRMCFGHL: <RSCFDn_base> + H'04FE,
RSCFDnCFDGRMCFGHH: <RSCFDn_base> + H'04FF

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RCMC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
0	RCMC	B'0	R/W	Interface Mode Select Setting this bit to 0 places the CANFD into classical CAN mode. To place the RS-CANFD module from CAN FD mode to classical CAN mode, modify the RSCFDnCFDGRMCFG register after setting the post-reset values to all the registers and bits that are solely assigned to the register map used in CAN FD mode. 0: Classical CAN mode 1: CAN FD mode

Modify the RSCFDnCFDGRMCFG register only in global reset mode. Also set the register before setting any other RS-CANFD register.

48.7.2 Details of Channel Related Registers

48.7.2.1 RSCFDnCmCFG — Channel Configuration Register (m = 0, 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCmCFG register can be read/written in 32-bit units

RSCFDnCmCFGL, RSCFDnCmCFGH registers can be read/written in 16-bit units

RSCFDnCmCFGLL, RSCFDnCmCFGLH, RSCFDnCmCFGHL, RSCFDnCmCFGHH registers can be read/written in 8-bit units

Address: RSCFDnCmCFG: <RSCFDn_base> + H'0000 + (H'10 × m)

RSCFDnCmCFGL: <RSCFDn_base> + H'0000 + (H'10 × m),
RSCFDnCmCFGH: <RSCFDn_base> + H'0002 + (H'10 × m)

RSCFDnCmCFGLL: <RSCFDn_base> + H'0000 + (H'10 × m),
RSCFDnCmCFGLH: <RSCFDn_base> + H'0001 + (H'10 × m),
RSCFDnCmCFGHL: <RSCFDn_base> + H'0002 + (H'10 × m),
RSCFDnCmCFGHH: <RSCFDn_base> + H'0003 + (H'10 × m)

Value after reset: H’0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	SJW[1:0]		—	TSEG2[2:0]			TSEG1[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
25, 24	SJW[1:0]	B’00	R/W	Resynchronization Jump Width Control These bits are used to specify a Tq value for the resynchronization jump width. Allowed values are 1 Tq to 4 Tq, inclusive. Set a value less than or equal to the value of the TSEG2 bits. B’00: 1 Tq B’01: 2 Tq B’10: 3 Tq B’11: 4 Tq
23	Reserved	B’0	R	This bit is read as the value after reset. The write value should be the value after reset.

Bit	Bit Name	Initial Value	R/W	Description
22 to 20	TSEG2[2:0]	B'000	R/W	Time Segment 2 Control These bits are used to specify a Tq value for the length of phase segment 2 (PHASE_SEG2). Allowed values are 2 Tq to 8 Tq, inclusive. Set a value smaller than the value of the TSEG1 bits. B'000: Setting prohibited B'001: 2 Tq B'010: 3 Tq B'011: 4 Tq B'100: 5 Tq B'101: 6 Tq B'110: 7 Tq B'111: 8 Tq
19 to 16	TSEG1[3:0]	B'0000	R/W	Time Segment 1 Control These bits are used to specify a Tq value for the total length of the propagation segment (PROP_SEG) and phase segment 1 (PHASE_SEG1). Allowed values are 4 Tq to 16 Tq, inclusive. B'0000: Setting prohibited B'0001: Setting prohibited B'0010: Setting prohibited B'0011: 4 Tq B'0100: 5 Tq B'0101: 6 Tq B'0110: 7 Tq B'0111: 8 Tq B'1000: 9 Tq B'1001: 10 Tq B'1010: 11 Tq B'1011: 12 Tq B'1100: 13 Tq B'1101: 14 Tq B'1110: 15 Tq B'1111: 16 Tq
15 to 10	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
9 to 0	BRP[9:0]	H'000	R/W	Prescaler Division Ratio Set The CANmTq clock (fCANTQm) is calculated by dividing the CAN clock (fCAN) by the baud rate prescaler, ((BRP[9:0]) + 1). One clock cycle of the CANmTq clock is 1 Time Quantum (Tq). When these bits are set to P (0 to 1023), the baud rate prescaler divides fCAN by P + 1.

Modify the RSCFDnCmCFG register in channel reset mode or channel halt mode. Set this register in channel reset mode before shifting to channel communication mode or channel wait mode. For a description of the bit timing parameters and settings, see section 48.16.1, Initial Settings.

48.7.2.2 RSCFDnCmCTR — Channel Control Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCmCTR register can be read/written in 32-bit units

RSCFDnCmCTRL, RSCFDnCmCTRH registers can be read/written in 16-bit units

RSCFDnCmCTRLL, RSCFDnCmCTRLH, RSCFDnCmCTRHL, RSCFDnCmCTRHH registers can be read/written in 8-bit units

Address: RSCFDnCmCTR: <RSCFDn_base> + H'0004 + (H'10 × m)

Bit	Bit Name	Initial Value	R/W	Description
31	Reserved	B'0	R	This bit is read as the value after reset. The write value should be the value after reset.
30	CRCT	B'0	R/W	CRC Error Test Enable This bit is used to test the CRC generator circuit in the RS-CANFD module. Setting this bit to 1 allows the first bit in the ID field to be reversed when a message is received. Due to the bit reversal, the CRC calculation result does not agree with the correct CRC value of the received frame. A CRC error is thus detected (the CERR bit in the RSCFDnCmERFL register is 1). Note the following when using this function: • This function is available when the CTME bit in the RSCFDnCmCTR register is 1 (communication test mode enabled). • Communicating with another CAN node is impossible. Use the function in the inter-channel communication test (the CmICBCE bit in the RSCFDnGTSTCFG register is 1). • Bit reversal in the ID field may violate the bit stuffing rule. In this case, a stuff error is detected instead of a CRC error. Modify this bit only in channel standby mode. In channel standby mode, this bit is 0. 0: The first bit in the receive ID field is not reversed. 1: The first bit in the receive ID field is reversed.

Bit	Bit Name	Initial Value	R/W	Description
29 to 27	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
26, 25	CTMS[1:0]	B'00	R/W	Communication Test Mode Select These bits are used to select a communication test mode. Modify these bits only in channel halt mode. These bits are set to 0 in channel reset mode. B'00: Standard test mode B'01: Listen-only mode B'10: Self-test mode 0 (external loopback mode) B'11: Self-test mode 1 (internal loopback mode)
24	CTME	B'0	R/W	Communication Test Mode Enable Setting this bit to 1 enables communication test mode. Modify these bits in channel halt mode. This bit is set to 0 in channel reset mode. 0: Communication test mode is disabled. 1: Communication test mode is enabled.
23	ERRD	B'0	R/W	Error Display Mode Select This bit is used to control the display mode of bits 14 to 8 in the RSCFDnCmERFL register. When this bit is clear to 0, only the flags of the first error event are set to 1. If two or more errors occur in the first error event, all the flags of the detected errors are set to 1. When this bit is set to 1, all the flags of errors that have occurred are set to 1 regardless of the error occurrence order. Modify this bit only in channel reset mode or channel halt mode. 0: Error flags are displayed only for the first error information after bits 14 to 8 in RSCFDnCmERFL are all cleared. 1: Error flags for all error information are displayed.

Bit	Bit Name	Initial Value	R/W	Description
22, 21	BOM[1:0]	B’00	R/W	Bus Off Recovery Mode Select These bits are used to select the bus off recovery mode of the RS-CANFD module. When the BOM[1:0] bits are set to B'00, return from the bus off state to the error active state is compliant with the CAN specifications. That is, the RS-CANFD module reenters the CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. A bus off recovery interrupt request is generated at the time of return from the bus off state. Even if the CHMDC[1:0] bits are set to B'10 (channel halt mode) before recessive bits are detected 128 times, the RS-CANFD module does not transition to channel halt mode until recessive bits are detected 128 times. When the module reaches the bus off state when the BOM[1:0] bits are set to B'01, the CHMDC[1:0] bits in the RSCFDnCmCTR register (m = 0 or 1) are set to B'10 and the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated and the TEC[7:0] and REC[7:0] bits in the RSCFDnCmSTS register are cleared to H'00. When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to B'10, the CHMDC[1:0] bits are set to B'10 and the RS-CANFD module transitions to channel halt mode after return from the bus off state (11 consecutive recessive bits are detected 128 times). A bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to H'00. When the BOM[1:0] bits are set to B'11 and the CHMDC[1:0] bits are set to B'10 while the RS-CANFD module is in the bus off state, the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to H'00. However, if 11 consecutive recessive bits are detected 128 times and the RS-CANFD module has recovered to the error active state from the bus off state before the CHMDC[1:0] bits are set to B'10, a bus off recovery interrupt request is generated. If a program writes to the CHMDC[1:0] bit at the same time as the RS-CANFD module transition to channel halt mode (at bus off entry when the BOM[1:0] bits are B'01 or at bus off end when the BOM[1:0] bits are B'10), the program’s writing takes precedence. Modify the BOM[1:0] bits only in channel reset mode. B’00: ISO11898-1 compliant B’01: Entry to channel halt mode automatically at bus-off entry B’10: Entry to channel halt mode automatically at bus-off end B’11: Entry to channel halt mode (in bus-off state) by program request
20 to 17	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
16	TAIE	B’0	R/W	Transmit Abort Interrupt Enable When transmit abort of the transmit buffer is completed with the TAIE bit set to 1, an interrupt request is generated. Modify this bit only in channel reset mode. 0: Transmit abort interrupt is disabled. 1: Transmit abort interrupt is enabled.

Bit	Bit Name	Initial Value	R/W	Description
15	ALIE	B'0	R/W	Arbitration Lost Interrupt Enable When the ALF flag in the RSCFDnCmERFL register is set to 1 with the ALIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Arbitration lost interrupt is disabled. 1: Arbitration lost interrupt is enabled.
14	BLIE	B'0	R/W	Bus Lock Interrupt Enable When the BLF flag in the RSCFDnCmERFL register is set to 1 with the BLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Bus lock interrupt is disabled. 1: Bus lock interrupt is enabled.
13	OLIE	B'0	R/W	Overload Frame Transmit Interrupt Enable When the OVLF flag in the RSCFDnCmERFL register is set to 1 with the OLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Overload frame transmit interrupt is disabled. 1: Overload frame transmit interrupt is enabled.
12	BORIE	B'0	R/W	Bus Off Recovery Interrupt Enable When the BORF flag in the RSCFDnCmERFL register is set to 1 with the BORIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Bus off recovery interrupt is disabled. 1: Bus off recovery interrupt is enabled.
11	BOEIE	B'0	R/W	Bus Off Entry Interrupt Enable When the BOEF flag in the RSCFDnCmERFL register is set to 1 with the BOEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Bus off entry interrupt is disabled. 1: Bus off entry interrupt is enabled.
10	EPIE	B'0	R/W	Error Passive Interrupt Enable When the EPF flag in the RSCFDnCmERFL register is set to 1 with the EPIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Error passive interrupt is disabled. 1: Error passive interrupt is enabled.
9	EWIE	B'0	R/W	Error Warning Interrupt Enable When the EWF flag in the RSCFDnCmERFL register is set to 1 with the EWIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Error warning interrupt is disabled. 1: Error warning interrupt is enabled.
8	BEIE	B'0	R/W	Bus Error Interrupt Enable When the BEF flag in the RSCFDnCmERFL register is set to 1 with the BEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Bus error interrupt is disabled. 1: Bus error interrupt is enabled.
7 to 4	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.

Bit	Bit Name	Initial Value	R/W	Description
3	RTBO	B’0	R/W	Forcible Return from Bus-off Setting this bit to 1 in the bus off state forcibly returns the state from the bus off state to the error active state. This bit is automatically cleared to 0. Setting this bit to 1 clears the TEC[7:0] and REC[7:0] bits in the RSCFDnCmSTS register to H'00 and also clears the BOSTS flag in the RSCFDnCmSTS register to 0 (not in bus off state). The other registers remain unchanged. No bus off recovery interrupt request is generated upon return from the bus off state in this case. Use this bit only when the BOM[1:0] bits in the RSCFDnCmCTR are B'00 (ISO11898-1 compliant). A delay of up to 1 CAN bit time occurs after the RTBO bit is set to 1 until the RS-CANFD module transitions to the error active state. Set this bit to 1 in channel communication mode.
2	CSLPR	B’1	R/W	Channel Stop Mode Setting this bit to 1 places the channel into channel stop mode. Clearing this bit to 0 makes the channel exit channel stop mode. This bit should not be modified in channel communication mode or channel wait mode. 0: Other than channel stop mode 1: Channel stop mode
1, 0	CHMDC[1:0]	B’01	R/W	Mode Select These bits are used to select a channel mode (channel communication mode, channel reset mode, or channel halt mode). For details, see section 48.11.2, Channel Modes. Setting the CSLPR bit to 1 in channel reset mode allows transition to channel stop mode. Do not set the CHMDC[1:0] bits to B'11. When the RS-CANFD module has automatically transitioned to channel halt mode based on the setting of the BOM[1:0] bits, the CHMDC[1:0] bits automatically become B'10. B’00: Channel communication mode B’01: Channel reset mode B’10: Channel halt mode B’11: Setting prohibited

48.7.2.3 RSCFDnCmSTS — Channel Status Register (m = 0 or 1)

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	TEC[7:0]	H'00	R	The transmit error counter (TEC) can be read. These bits contain the transmit error counter value. For transmit error counter increment/decrement conditions, see the CAN specification (ISO11898-1). These bits are cleared to 0 in channel reset mode.
23 to 16	REC[7:0]	H'00	R	The receive error counter (REC) can be read. These bits contain the receive error counter value. For receive error counter increment/decrement conditions, see the CAN specifications (ISO11898-1). These bits are cleared to 0 in channel reset mode.
15 to 8	Reserved	All 0	R	These bits are read as the value after reset.
7	COMSTS	B'0	R	Communication Status Flag This bit indicates that communication is ready. This flag becomes 1 when the RS-CANFD module has detected 11 consecutive recessive bits after it has transitioned from channel reset mode or channel halt mode to channel communication mode. This flag is cleared to 0 in channel reset mode or channel halt mode. 0: Communication is not ready. 1: Communication is ready.

Bit	Bit Name	Initial Value	R/W	Description
6	RECSTS	B'0	R	Receive Status Flag This flag is set to 1 when reception has started, and is cleared to 0 when the bus has become idle or transmission has started. 0: Bus idle, in transmission or bus off state 1: In reception
5	TRMSTS	B'0	R	Transmit Status Flag This flag is set to 1 when transmission has started, and is cleared to 0 when the bus has become idle or reception has started. This flag remains 1 in the bus off state. 0: Bus idle or in reception 1: In transmission or bus off state
4	BOSTS	B'0	R	Bus Off Status Flag This flag is set to 1 when the bus off state (TEC[7:0] > 255) is entered. It is cleared to 0 when the RS-CANFD module has exited the bus off state. 0: Not in bus off state 1: In bus off state
3	EPSTS	B'0	R	Error Passive Status Flag This flag is set to 1 when the RS-CANFD module has entered the error passive state ((128 ≤ TEC[7:0] ≤ 255) or (128 ≤ REC[7:0])), It is cleared to 0 when the RS-CANFD module has exited the error passive state or has entered channel reset mode. 0: Not in error passive state 1: In error passive state
2	CSLPSTS	B'1	R	Channel Stop Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to channel stop mode, and is cleared to 0 when the RS-CANFD module has returned from channel stop mode. 0: Not in channel stop mode 1: In channel stop mode
1	CHLTSTS	B'0	R	Channel Halt Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to channel halt mode, and is cleared to 0 when the RS-CANFD module has returned from channel halt mode. 0: Not in channel halt mode 1: In channel halt mode
0	CRSTSTS	B'1	R	Channel Reset Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to channel reset mode, and is cleared to 0 when the RS-CANFD module has transitioned to channel communication mode or channel halt mode. This flag remains 1 when the RS-CANFD module transitions from channel reset mode to channel stop mode. 0: Not in channel reset mode 1: In channel reset mode

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31	Reserved	B'0	R	When read, the value after reset is returned. When writing to this bit, write the value after reset.
30 to 16	CRCREG [14:0]	H'0000	R	CRC Calculation Data When the CTME bit in the RSCFDnCmCTR register is set to 1 (communication test mode is enabled), the CRC value calculated based on the transmit or receive message can be read. When the CTME bit is set to 0 (communication test mode is disabled), these bits are always read as 0.
15	Reserved	B'0	R	When read, the value after reset is returned. When writing to this bit, write the value after reset.
14	ADERR	B'0	R/W*	ACK Delimiter Error Flag This flag is set to 1 when a form error has been detected in the ACK delimiter during transmission. 0: No ACK delimiter error is detected. 1: ACK delimiter error is detected.
13	B0ERR	B'0	R/W*	Dominant Bit Error Flag This flag is set to 1 when a recessive bit has been detected though a dominant bit was transmitted. 0: No dominant bit error is detected. 1: Dominant bit error is detected.

Bit	Bit Name	Initial Value	R/W	Description
12	B1ERR	B'0	R/W*	Recessive Bit Error Flag This flag is set to 1 when a dominant bit has been detected though a recessive bit was transmitted. 0: No recessive bit error is detected. 1: Recessive bit error is detected.
11	CERR	B'0	R/W*	CRC Error Flag This flag is set to 1 when a CRC error has been detected. 0: No CRC error is detected. 1: CRC error is detected.
10	AERR	B'0	R/W*	ACK Error Flag This flag is set to 1 when an ACK error has been detected. 0: No ACK error is detected. 1: ACK error is detected.
9	FERR	B'0	R/W*	Form Error Flag This flag is set to 1 when a form error has been detected. 0: No form error is detected. 1: Form error is detected.
8	SERR	B'0	R/W*	Stuff Error Flag This flag is set to 1 when a stuff error has been detected. 0: No stuff error is detected. 1: Stuff error is detected.
7	ALF	B'0	R/W*	Arbitration-lost Flag This flag is set to 1 when an arbitration-lost has been detected. 0: No arbitration-lost is detected. 1: Arbitration-lost is detected.
6	BLF	B'0	R/W*	Bus Lock Flag This flag is set to 1 when 32 consecutive dominant bits have been detected on the CAN bus in channel communication mode. After that, detection of a dominant lock is restarted when either of the following conditions is met. • A recessive bit is detected after the BLF bit has been cleared from 1 to 0. • The RS-CANFD module transitions to channel reset mode and returns to channel communication mode after the BLF bit has been cleared from 1 to 0. 0: No channel bus lock is detected. 1: Channel bus is lock detected.
5	OVLF	B'0	R/W*	Overload Flag This flag is set to 1 when the overload frame transmit condition has been detected when performing reception or transmission. 0: No overload is detected. 1: Overload is detected.

Bit	Bit Name	Initial Value	R/W	Description
4	BORF	B’0	R/W*	Bus Off Recovery Flag This flag is set to 1 when 11 consecutive recessive bits have been detected 128 times and the RS-CANFD module returns from the bus off state. However, this flag is not set to 1 if the RS-CANFD module returns from the bus off state in any of the following ways before 11 consecutive recessive bits are detected 128 times. • The CHMDC[1:0] bits in the RSCFDnCmCTR register are set to B'01 (channel reset mode). • The RTBO bit in the RSCFDnCmCTR register is set to 1 (forcible return from the bus off state is made). • The BOM[1:0] bits in the RSCFDnCmCTR register are set to B'01 (transition to channel halt mode at bus off entry). • The CHMDC[1:0] bits in the RSCFDnCmCTR register are set to B'10 (channel halt mode) before 11 consecutive recessive bits are detected 128 times with the BOM[1:0] bits set to B'11 (transition to channel halt mode upon a request from the program during bus off). 0: No bus off recovery is detected. 1: Bus off recovery is detected.
3	BOEF	B’0	R/W*	Bus Off Entry Flag This flag is set to 1 when the bus off state is reached (TEC[7:0] value > 255). This flag is also set to 1 if the bus off state is reached when the BOM[1:0] bits in the RSCFDnCmCTR register (m = 0 or 1) set to B'01 (transition to channel halt mode at bus off entry). 0: No bus off entry is detected. 1: Bus off entry is detected.
2	EPF	B’0	R/W*	Error Passive Flag This flag becomes 1 when the error passive state is reached (REC[7:0] or TEC[7:0] value > 127).This flag becomes 1 only when the REC[7:0] or TEC[7:0] value first exceeds 127. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 127, this bit is not set to 1 until both REC[7:0] and TEC[7:0] values become 127 or less and then the REC[7:0] or TEC[7:0] value exceeds 127 again. 0: No error passive is detected. 1: Error passive is detected.
1	EWF	B’0	R/W*	Error Warning Flag This flag is set to 1 only when the REC[7:0] or TEC[7:0] value first exceeds 95. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 95, this bit is not set to 1 until both REC[7:0] and TEC[7:0] values become 95 or less and then the REC[7:0] or TEC[7:0] value exceeds 95 again. 0: No error warning is detected. 1: Error warning is detected.
0	BEF	B’0	R/W*	Bus Error Flag This flag is set to 1 when any one of the ADERR, B0ERR, B1ERR, CERR, AERR, FERR, and SERR flags in the RSCFDnCmERFL register is set to 1. 0: No channel bus error is detected. 1: Channel bus error is detected.

Note: To clear the flag of this register to 0, use a store instruction to write “0” to the given flag and “1” to the other flags.

See the CAN specification (ISO11898-1) for a description of error occurrence conditions. To clear each flag of this register, the program must write a 0 to the corresponding bit. These flags cannot be set to 1 by the program. If any of these flags is set to 0 at the same time that the program writes 0 to the flag, the flag is still set to 1. The channel reset mode transition clears all of these flags to 0.

If the ERRD bit in the RSCFDnCmCTR register is set to 0 (ie, only the flags for the first error event are displayed) and an error related to bits 14 to 8 of RSCFDnCmERFL is detected, the flag bits are only set by the error event if bits 14 to 8 were all 0 at the when time the error occurred.

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	ITRCP[15:0]	H'0000	R/W	Interval Timer Prescaler Set These bits are used to set a clock source division value of the interval timer for FIFO buffers. See section 48.13.3.1, Interval Transmission Function. When these bits are set to M, the pclk is divided by M. Setting H'0000 is prohibited when the interval timer is in use.
15 to 13	TSBTCS[2:0]	B'000	R/W	Timestamp Clock Source Select When the TSSS bit is 1, these bits are used to select the channel of the bit time clock that will be the clock source of the timestamp counter. B'000: Channel 0 bit time clock B'001: Channel 1 bit time clock B'010: Setting prohibited B'011: Setting prohibited B'100: Setting prohibited B'101: Setting prohibited B'110: Setting prohibited B'111: Setting prohibited
12	TSSS	0	R/W	Timestamp Source Select This bit is used to select a clock source of the timestamp counter. 0: pclk/2*1 1: Bit time clock

Bit	Bit Name	Initial Value	R/W	Description
11 to 8	TSP[3:0]	B'0000	R/W	Timestamp Clock Source Division A clock obtained by dividing the clock source selected with the TSBTCS[2:0] bits and TSSS bit according to the TSP[3:0] bits is used as the timestamp counter count source. B'0000: Not divided B'0001: Divided by 2 B'0010: Divided by 4 B'0011: Divided by 8 B'0100: Divided by 16 B'0101: Divided by 32 B'0110: Divided by 64 B'0111: Divided by 128 B'1000: Divided by 256 B'1001: Divided by 512 B'1010: Divided by 1024 B'1011: Divided by 2048 B'1100: Divided by 4096 B'1101: Divided by 8192 B'1110: Divided by 16384 B'1111: Divided by 32768
7	TMTSCE	B'0	R/W	Transmit Timestamp Enable Setting this bit to 1 can store the timestamp of the transmission-completed message into the transmit history buffer. The timestamp is stored in the TMTS[15:0] bits in the RSCFDnTHLACCm register. 0: Transmit timestamp is disabled. 1: Transmit timestamp is enabled.
6	EEFE	B'0	R/W	ECC Error Flag Enable Setting this bit to 1 sets the EEFm bit in the RSCFDnGERFL register to 1 if an ECC2 bit error is detected as a result of a transmit priority selection. Here, the message in which the ECC2 bit error is detected is not transmitted. 0: ECC error flag is disabled. 1: ECC error flag is enabled.
5	Reserved	B'0	R	When read, the value after reset is returned. When writing to this bit, write the value after reset.
4	DCS	B'0	R/W	CAN Clock Source Select*2 When this bit is set to 0, clkc is used as the clock source of the CAN clock (fCAN). When this bit is set to 1, clk_xincan is used as the clock source of the CAN clock (fCAN). For the CAN clock frequency settings, see section 48.16.1.3, Setting Communication Speed. 0: clkc 1: clk_xincan
3	MME	B'0	R/W	Mirror Function Enable Setting this bit to 1 makes the mirror function available. 0: Mirror function is disabled. 1: Mirror function is enabled.

Bit	Bit Name	Initial Value	R/W	Description
2	DRE	B’0	R/W	DLC Replacement Enable When the DRE bit is set to 1, the DLC value of the receive rule is stored in the buffer instead of the DLC value of the received message after the DLC value has passed through the DLC filter. In this case, a value of H'00 is stored in each data byte beyond the DLC value of the receive rule. The DLC replacement function is only available when the DCE bit is set to 1 (DLC check is enabled). 0: DLC replacement is disabled. 1: DLC replacement is enabled.
1	DCE	B’0	R/W	DLC Check Enable Setting this bit to 1 makes the DLC check function available. When disabling the DLC check function, set the GAFLDLC[3:0] bits in the RSCFDnGAFLP0_j register to B'0000 before clearing the DCE bit in the RSCFDnGCFG register to 0. 0: DLC check is disabled. 1: DLC check is enabled.
0	TPRI	B’0	R/W	Transmit Priority Select This bit is used to set the transmit priority. When this bit is set to 0, ID priority is selected and the transmit priority complies with the CAN bus arbitration rule (ISO11898-1 specifications). When this bit is set to 1, transmit buffer number priority is selected and the lowest transmit buffer number of those has the highest priority. While the transmit queue is in use, this bit should be set to 0. 0: ID priority 1: Transmit buffer number priority

Notes: 1. When specifying pclk/2 as the timestamp counter count source, set bits TSBTCS[2:0] to B'000.
2. For the CAN clock frequency settings, see section 48.16.1.3, Setting Communication Speed.

Modify the RSCFDnGCFG register only in global reset mode.

48.7.3.2 RSCFDnGCTR — Global Control Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGCTR register can be read/written in 32-bit units

RSCFDnGCTRL, RSCFDnGCTRH registers can be read/written in 16-bit units

RSCFDnGCTRLL, RSCFDnGCTRLH, RSCFDnGCTRHL, RSCFDnGCTRHH registers can be read/written in 8-bit units

Address: RSCFDnGCTR: <RSCFDn_base> + H'0088

RSCFDnGCTRL: <RSCFDn_base> + H'0088, RSCFDnGCTRH: <RSCFDn_base> + H'008A

RSCFDnGCTRLL: <RSCFDn_base> + H'0088, RSCFDnGCTRLH: <RSCFDn_base> + H'0089, RSCFDnGCTRHL: <RSCFDn_base> + H'008A, RSCFDnGCTRHH: <RSCFDn_base> + H'008B

Value after reset: H'0000_0005

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	THLEIE	MEIE	DEIE	—	—	—	—	—	GSLPR	GMDC[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1
R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
16	TSRST	B'0	R/W	Timestamp Counter Reset This bit is used to reset the timestamp counter. When this bit is set to 1, the RSCFDnGTSC register is cleared to H'0000. This bit is always read as 0.
15 to 11	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
10	THLEIE	B'0	R/W	Transmit History Buffer Overflow Interrupt Enable When the THLEIE bit is set to 1 and the THLES flag in the RSCFDnGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode. 0: Transmit history buffer overflow interrupt is disabled. 1: Transmit history buffer overflow interrupt is enabled.
9	MEIE	B'0	R/W	FIFO Message Lost Interrupt Enable When the MEIE bit is set to 1 and the MES flag in the RSCFDnGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode. 0: FIFO message lost interrupt is disabled. 1: FIFO message lost interrupt is enabled.

Bit	Bit Name	Initial Value	R/W	Description
8	DEIE	B’0	R/W	DLC Error Interrupt Enable When the DEIE bit is set to 1 and the DEF flag in the RSCFDnGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode. 0: DLC error interrupt is disabled. 1: DLC error interrupt is enabled.
7 to 3	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	GSLPR	B’1	R/W	Global Stop Mode Setting this bit to 1 places the RS-CANFD module into global stop mode. Clearing this bit to 0 makes the RS-CANFD module leave from global stop mode. This bit should not be modified in global operating mode or global test mode. 0: Other than global stop mode 1: Global stop mode
1, 0	GMDC[1:0]	B’01	R/W	Global Mode Select These bits are used to select the mode of entire RS-CANFD module (global operating mode, global reset mode, or global test mode). For details, see section 48.11.1, Global Modes. Setting the GSLPR bit to 1 when in global reset mode places the RS-CANFD module into global stop mode. B’00: Global operating mode B’01: Global reset mode B’10: Global test mode B’11: Setting prohibited

48.7.3.3 RSCFDnGSTS — Global Status Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGSTS register can be read only in 32-bit units

RSCFDnGSTSL, RSCFDnGSTSH registers can be read only in 16-bit units

RSCFDnGSTSLL, RSCFDnGSTSLH, RSCFDnGSTSHL, RSCFDnGSTSHH registers can be read only in 8-bit units

Address: RSCFDnGSTS: <RSCFDn_base> + H'008C

RSCFDnGSTSL: <RSCFDn_base> + H'008C, RSCFDnGSTSH: <RSCFDn_base> + H'008E

RSCFDnGSTSLL: <RSCFDn_base> + H'008C, RSCFDnGSTSLH: <RSCFDn_base> + H'008D, RSCFDnGSTSHL: <RSCFDn_base> + H'008E, RSCFDnGSTSHH: <RSCFDn_base> + H'008F

Value after reset: H'0000_000D

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	GRAMINIT	GSLPSTS	GHLTSTS	GRSTSTS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	Reserved	All 0	R	When read, the value after reset is returned.
3	GRAMINIT	B’1	R	CAN RAM Initialization Status Flag This flag indicates the initialization status of the CAN RAM. This flag is set to 1 after the MCU has been reset, and is cleared to 0 when CAN RAM initialization is completed. 0: CAN RAM initialization is completed. 1: CAN RAM initialization is ongoing.
2	GSLPSTS	B’1	R	Global Stop Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to global stop mode, and is cleared to 0 when the RS-CANFD module has returned from global stop mode. 0: Not in global stop mode 1: In global stop mode
1	GHLTSTS	B’0	R	Global Test Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to global test mode, and is cleared to 0 when the RS-CANFD module has exited global test mode. 0: Not in global test mode 1: In global test mode

Bit	Bit Name	Initial Value	R/W	Description
0	GRSTSTS	B’1	R	Global Reset Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to global reset mode, and is cleared to 0 when the RS-CANFD module has exited global reset mode. This flag remains 1 even when the RS-CANFD module has transitioned from global reset mode to global stop mode. 0: Not in global reset mode 1: In global reset mode

48.7.3.4 RSCFDnGERFL — Global Error Flag Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGERFL register can be read/written in 32-bit units

RSCFDnGERFLL, RSCFDnGERFLH registers can be read/written in 16-bit units

RSCFDnGERFLLL, RSCFDnGERFLLH, RSCFDnGERFLHL, RSCFDnGERFLHH registers can be read/written in 8-bit units

Address: RSCFDnGERFL: <RSCFDn_base> + H'0090

RSCFDnGERFLL: <RSCFDn_base> + H'0090, RSCFDnGERFLH: <RSCFDn_base> + H'0092

RSCFDnGERFLLL: <RSCFDn_base> + H'0090, RSCFDnGERFLLH: <RSCFDn_base> + H'0091, RSCFDnGERFLHL: <RSCFDn_base> + H'0092, RSCFDnGERFLHH: <RSCFDn_base> + H'0093

Value after reset: H’0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EEF1	EEF0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*	R/W*

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	THLES	MES	DEF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
17	EEF1	B’0	R/W	ECC Error Flag for Channel 1 The EEF1 flag is set to 1 disabling message transmission if an ECC2 bit error is detected in transmit priority selection of channel 1 when the EEFE bit in the RSCFDnGCFG register is 1. The program must write 0 to the corresponding flag to be cleared. The program can clear this flag by writing 0 to this bit. 0: No 2-bit ECC error has occurred in transmit priority selection. 1: A 2-bit ECC error has occurred in transmit priority selection.

Bit	Bit Name	Initial Value	R/W	Description
16	EEF0	B'0	R/W	ECC Error Flag for channel 0 The EEF0 flag is set to 1 disabling message transmission if an ECC2 bit error is detected in transmit priority selection of channel 0 when the EEFE bit in the RSCFDnGCFG register is 1. The program must write 0 to the corresponding flag to be cleared. The program can clear this flag by writing 0 to this bit. 0: No 2-bit ECC error has occurred in transmit priority selection. 1: A 2-bit ECC error has occurred in transmit priority selection.
15 to 3	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	THLES	B'0	R	Transmit History Buffer Overflow Status Flag The THLES flag is set to 1 when any one of the THLELT flags in the RSCFDnTHLSTSm register (m = 0, 1) is set to 1. This flag is cleared to 0 when the THLELT flags of all channels are set to 0. 0: No transmit history buffer overflow has occurred. 1: A transmit history buffer overflow has occurred.
1	MES	B'0	R	FIFO Message Lost Status Flag The MES flag is set to 1 when any one of the RFMLT flags in the RSCFDnRFSTSx register (x = 0 to 7) or the CFMLT flags in the RSCFDnCFSTSk register (k = 0 to 5) is set to 1. This flag is cleared to 0 when all RFMLT flags and CFMLT flags are set to 0. 0: No FIFO message lost error has occurred. 1: A FIFO message lost error has occurred.
0	DEF	B'0	R/W	DLC Error Flag The DEF flag is set to 1 when an error has been detected during the DLC check. The program can clear this flag by writing 0 to this bit. 0: No DLC error has occurred. 1: A DLC error has occurred.

Note: To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1".

All flags in the RSCFDnGERFL register are cleared to 0 in global reset mode.

48.7.3.5 RSCFDnGTSC — Global Timestamp Counter Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGTSC register can be read only in 32-bit units.
RSCFDnGTSCL, RSCFDnGTSCH registers can be read only in 16-bit units.

Address: RSCFDnGTSC: <RSCFDn_base> + H'0094
RSCFDnGTSCL: <RSCFDn_base> + H'0094, RSCFDnGTSCH: <RSCFDn_base> + H'0096

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Reserved	All 0	R	These bits are read as the value after reset.
15 to 0	TS[15:0]	H'0000	R	Timestamp Value The timestamp counter value can be read. Counter Value: H'0000 to H'FFFF When the TS[15:0] bits are read, the read value shows the timestamp counter (16-bit free-running counter) value at that time. When the SOF is detected, the TS[15:0] value is captured and later stored in the receive buffer or the FIFO buffer. When the TMTSCE bit in the RSCFDnGCFG register is 1, the TS[15:0] value is stored in the transmit history buffer. The timestamp counter is initialized in global reset mode. The timestamp counter starts and stops counting differently, depending on the count source. • When the TSSS bit in the RSCFDnGCFG register is 0 (pclk): The timestamp counter starts counting when the RS-CANFD module has transitioned to global operating mode. This counter stops counting when the RS-CANFD module has transitioned to global stop mode or global test mode. • When the TSSS bit is 1 (CANm bit time clock): The timestamp counter starts counting when the corresponding channel has transitioned to channel communication mode. This counter stops counting when the corresponding channel has transitioned to channel reset mode or channel halt mode.

48.7.3.6 RSCFDnGTINTSTS0 — Global TX Interrupt Status Register 0

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGTINTSTS0 register can be read only in 32-bit units

RSCFDnGTINTSTS0L, RSCFDnGTINTSTS0H registers can be read only in 16-bit units

RSCFDnGTINTSTS0LL, RSCFDnGTINTSTS0LH, RSCFDnGTINTSTS0HL, RSCFDnGTINTSTS0HH registers can be read only in 8-bit units

Address: RSCFDnGTINTSTS0: <RSCFDn_base> + H'0460

RSCFDnGTINTSTS0L: <RSCFDn_base> + H'0460, RSCFDnGTINTSTS0H: <RSCFDn_base> + H'0462

RSCFDnGTINTSTS0LL: <RSCFDn_base> + H'0460, RSCFDnGTINTSTS0LH: <RSCFDn_base> + H'0461, RSCFDnGTINTSTS0HL: <RSCFDn_base> + H'0462, RSCFDnGTINTSTS0HH: <RSCFDn_base> + H'0463

Value after reset: H'0000_0000

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R*	R*	R*	R*	R*	R	R	R	R*	R*	R*	R*	R*

Note: * This bit is automatically cleared in the global reset or channel reset mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	Reserved	All 0	R	These bits are read as the value after reset.
12	THIF1	B'0	R	Channel 1 Transmit History Interrupt Status Flag When the THLIE bit in the RSCFDnTHLCCm register is set to 1 (transmit history interrupt enabled) and the THLIF bit in the RSCFDnTHLSTSm register is set to 1 (transmit history interrupt request), this bit is set to 1. When the THLIF bit in the RSCFDnTHLSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the THLIE bit is cleared to 0. 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
11	CFTIF1	B'0	R	Channel 1 Transmit/receive FIFO Transmit Interrupt Status Flag When the CFTXIE bit in the RSCFDnCFCCk register is set to 1 (transmit/receive FIFO transmit interrupt enabled) and the CFTXIF bit in the RSCFDnCFSTSk register is set to 1 (transmit/receive FIFO transmit interrupt request), this bit is set to 1. When the CFTXIF bit is cleared to 0 under the conditions that this bit can be set to 1, this bit is cleared to 0. This flag is also cleared to 0 when the CFTXIE bit is cleared to 0. 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.

Bit	Bit Name	Initial Value	R/W	Description
10	TQIF1	B'0	R	Channel 1 Transmit Queue Interrupt Status Flag When the TXQIE bit in the RSCFDnTXQCCm register is set to 1 (transmit queue interrupt enabled) and the TXQIF bit in the RSCFDnTXQSTSm register is set to 1 (transmit queue interrupt request), this bit is set to 1. When the TXQIF bit (transmit queue interrupt request) in the RSCFDnTXQSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the TXQIE bit is cleared to 0. 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
9	TAIF1	B'0	R	Channel 1 Transmit Buffer Abort Interrupt Status Flag This bit is set to 1 when the TAIE bit in the RSCFDnCmCTR register is 1 (transmit abort interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnTMSTSp register are set to B'01 (transmit abort completed). This flag is cleared to 0 when the TMTRF[1:0] flags are cleared to B'00 after the transmit abort is completed. 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.
8	TSIF1	B'0	R	Channel 1 Transmit Buffer Interrupt Status Flag This bit is set to 1 when the TMIEp bit in the RSCFDnTMIECy register is set to 1 (transmit buffer interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnTMSTSp register are set to B'10 (transmit completed without abort request) or B'11 (transmit completed with abort request). When the TMTRF[1:0] flags are cleared to B'00 under the condition that this bit can be set to 1, this flag is cleared to 0. In addition, clearing the TMIEp bit to 0 also clears this flag to 0. 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.
7 to 5	Reserved	All 0	R	These bits are read as the value after reset.
4	THIF0	B'0	R	Channel 0 Transmit History Interrupt Status Flag When the THLIE bit in the RSCFDnTHLCCm register is set to 1 (transmit history interrupt enabled) and the THLIF bit in the RSCFDnTHLSTSm register is set to 1 (transmit history interrupt request), this bit is set to 1. When the THLIF bit in the RSCFDnTHLSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the THLIE bit is cleared to 0. 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
3	CFTIF0	B'0	R	Channel 0 Transmit/receive FIFO Transmit Interrupt Status Flag When the CFTXIE bit in the RSCFDnCFCCk register is set to 1 (transmit/receive FIFO transmit interrupt enabled) and the CFTXIF bit in the RSCFDnCFSTSk register is set to 1 (transmit/receive FIFO transmit interrupt request), this bit is set to 1. When the CFTXIF bit is cleared to 0 under the conditions that this bit can be set to 1, this bit is cleared to 0. This flag is also cleared to 0 when the CFTXIE bit is cleared to 0. 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.

Bit	Bit Name	Initial Value	R/W	Description
2	TQIF0	B’0	R	Channel 0 Transmit Queue Interrupt Status Flag When the TXQIE bit in the RSCFDnTXQCCm register is set to 1 (transmit queue interrupt enabled) and the TXQIF bit in the RSCFDnTXQSTSm register is set to 1 (transmit queue interrupt request), this bit is set to 1. When the TXQIF bit (transmit queue interrupt request) in the RSCFDnTXQSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the TXQIE bit is cleared to 0. 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
1	TAIF0	B’0	R	Channel 0 Transmit Buffer Abort Interrupt Status Flag This bit is set to 1 when the TAIE bit in the RSCFDnCmCTR register is 1 (transmit abort interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnTMSTSp register are set to B'01 (transmit abort completed). This flag is cleared to 0 when the TMTRF[1:0] flags are cleared to B'00 after the transmit abort is completed. 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.
0	TSIF0	B’0	R	Channel 0 Transmit Buffer Interrupt Status Flag This bit is set to 1 when the TMIEp bit in the RSCFDnTMIECy register is set to 1 (transmit buffer interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnTMSTSp register are set to B'10 (transmit completed without abort request) or B'11 (transmit completed with abort request). When the TMTRF[1:0] flags are cleared to B'00 under the condition that this bit can be set to 1, this flag is cleared to 0. In addition, clearing the TMIEp bit to 0 also clears this flag to 0. 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.

48.7.3.7 RSCFDnGTINTSTS1 — Global TX Interrupt Status Register 1

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGTINTSTS1 register can be read only in 32-bit units

RSCFDnGTINTSTS1L, RSCFDnGTINTSTS1H registers can be read only in 16-bit units

RSCFDnGTINTSTS1LL, RSCFDnGTINTSTS1LH, RSCFDnGTINTSTS1HL, RSCFDnGTINTSTS1HH registers can be read only in 8-bit units

Address: RSCFDnGTINTSTS1: <RSCFDn_base> + H'0464

RSCFDnGTINTSTS1L: <RSCFDn_base> + H'0460, RSCFDnGTINTSTS0H: <RSCFDn_base> + H'0466

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 0	R	Reserved bits These bits are read as the value after reset. The write value should be the value after reset.

48.7.4 Details of Receive Rule Related Registers

48.7.4.1 RSCFDnGAFLECTR — Receive Rule Entry Control Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGAFLECTR register can be read/written in 32-bit units

RSCFDnGAFLECTRL, RSCFDnGAFLECTRH registers can be read/written in 16-bit units

RSCFDnGAFLECTRLL, RSCFDnGAFLECTRLH, RSCFDnGAFLECTRHL, RSCFDnGAFLECTRHH registers can be read/written in 8-bit units

Address: RSCFDnGAFLECTR: <RSCFDn_base> + H'0098

RSCFDnGAFLECTRL: <RSCFDn_base> + H'0098, RSCFDnGAFLECTRH: <RSCFDn_base> + H'009A

RSCFDnGAFLECTRLL: <RSCFDn_base> + H'0098, RSCFDnGAFLECTRLH: <RSCFDn_base> + H'0099, RSCFDnGAFLECTRHL: <RSCFDn_base> + H'009A, RSCFDnGAFLECTRHH: <RSCFDn_base> + H'009B

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	AFLDAE	—	—	—	AFLPN[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
8	AFLDAE	B'0	R/W	Receive Rule Table Write Enable Setting this bit to 0 disables the write to the receive rule table. After writes to the receive rule table are completed, set this bit to 0 to disable the write to the table. The receive rule table can be read regardless of the value of this bit. Set the AFLDAE bit to 1 only in global reset mode. 0: Receive rule table write is disabled. 1: Receive rule table write is enabled.
7 to 5	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
4 to 0	AFLPN[4:0]	B'0_0000	R/W	Receive Rule Table Page Number Configuration These bits are used to set the page number of the receive rule table. Sixteen receive rules can be set per page. A page number can be selected from a range of page 0 (B'0_0000) to page 23 (B'1_0111). Set these bits to a value within the range of B'0_0000 to B'1_0111.

48.7.4.2 RSCFDnGAFLCFG0 — Receive Rule Configuration Register 0

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGAFLCFG0 register can be read/written in 32-bit units

RSCFDnGAFLCFG0L, RSCFDnGAFLCFG0H registers can be read/written in 16-bit units

RSCFDnGAFLCFG0LL, RSCFDnGAFLCFG0LH, RSCFDnGAFLCFG0HL, RSCFDnGAFLCFG0HH registers can be read/written in 8-bit units

Address: RSCFDnGAFLCFG0: <RSCFDn_base> + H'009C

RSCFDnGAFLCFG0L: <RSCFDn_base> + H'009C, RSCFDnGAFLCFG0H: <RSCFDn_base> + H'009E

RSCFDnGAFLCFG0LL: <RSCFDn_base> + H'009C, RSCFDnGAFLCFG0LH: <RSCFDn_base> + H'009D, RSCFDnGAFLCFG0HL: <RSCFDn_base> + H'009E, RSCFDnGAFLCFG0HH: <RSCFDn_base> + H'009F

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RNC0[7:0]								RNC1[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	RNC0[7:0]	H'00	R/W	Number of Rules for Channel 0 These bits are used to set the number of rules to be registered in the channel 0 receive rule table. Set these bits to a value within the range of H'00 to H'80.
23 to 16	RNC1[7:0]	H'00	R/W	Number of Rules for Channel 1 These bits are used to set the number of rules to be registered in the channel 1 receive rule table. Set these bits to a value within the range of H'00 to H'80.
15 to 0	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.

Modify the RSCFDnGAFLCFG0 register only in global reset mode.

Up to 64 × (number of channels) rules can be registered in the receive rule table as the entire unit. The number of receive rules per channel should meet the following conditions.

The maximum number of rules per channel is 128.

The total of the number of rules allocated to each channel is not larger than the number of rules that can be registered in the entire unit.

48.7.4.3 RSCFDnGAFLCFG1 — Receive Rule Configuration Register 1

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGAFLCFG1 register can be read/written in 32-bit units

RSCFDnGAFLCFG1L, RSCFDnGAFLCFG1H registers can be read/written in 16-bit units

RSCFDnGAFLCFG1LL, RSCFDnGAFLCFG1LH, RSCFDnGAFLCFG1HL, RSCFDnGAFLCFG1HH registers can be read/written in 8-bit units

Address: RSCFDnGAFLCFG1: <RSCFDn_base> + H'00A0

RSCFDnGAFLCFG1L: <RSCFDn_base> + H'00A0, RSCFDnGAFLCFG1H: <RSCFDn_base> + H'00A2

RSCFDnGAFLCFG1LL: <RSCFDn_base> + H'00A0, RSCFDnGAFLCFG1LH: <RSCFDn_base> + H'00A1, RSCFDnGAFLCFG1HL: <RSCFDn_base> + H'00A2, RSCFDnGAFLCFG1HH: <RSCFDn_base> + H'00A3

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.

Modify the RSCFDnGAFLCFG1 register only in global reset mode.

48.7.4.4 RSCFDnGAFLIDj — Receive Rule ID Register (j = 0 to 15)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGAFLIDj register can be read/written in 32-bit units

RSCFDnGAFLIDjL, RSCFDnGAFLIDjH registers can be read/written in 16-bit units

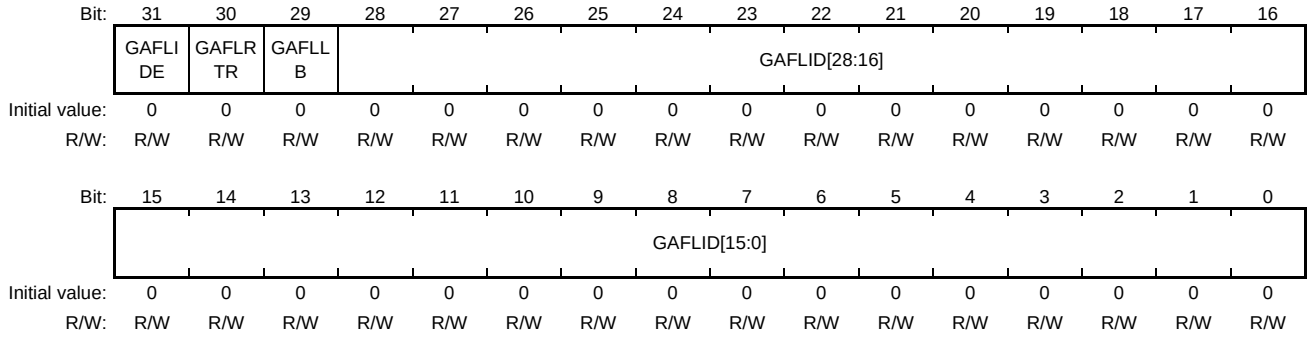
RSCFDnGAFLIDjLL, RSCFDnGAFLIDjLH, RSCFDnGAFLIDjHL, RSCFDnGAFLIDjHH registers can be read/written in 8-bit units

Address: RSCFDnGAFLIDj: <RSCFDn_base> + H'0500 + (H'10 × j)

RSCFDnGAFLIDjL: <RSCFDn_base> + H'0500 + (H'10 × j),
RSCFDnGAFLIDjH: <RSCFDn_base> + H'0502 + (H'10 × j)

RSCFDnGAFLIDjLL: <RSCFDn_base> + H'0500 + (H'10 × j),
RSCFDnGAFLIDjLH: <RSCFDn_base> + H'0501 + (H'10 × j),
RSCFDnGAFLIDjHL: <RSCFDn_base> + H'0502 + (H'10 × j),
RSCFDnGAFLIDjHH: <RSCFDn_base> + H'0503 + (H'10 × j)

Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31	GAFLIDE	B'0	R/W	IDE Select This bit is used to select the ID format (standard ID or extended ID) of the receive rule. This bit is compared with the IDE bit in the received message during the acceptance filter processing. 0: Standard ID 1: Extended ID
30	GAFLRTR	B'0	R/W	RTR Select This bit is used to select the frame format (data frame or remote frame) of the receive rule. This bit is compared with the RTR bit in the received message during the acceptance filter processing. 0: Data frame 1: Remote frame
29	GAFLLB	B'0	R/W	Receive Rule Target Message Select When this bit is set to 0, data processing using the receive rule is performed when receiving messages transmitted from another CAN node. When this bit is set to 1 when the mirror function is used, data processing using the receive rule is performed when the CAN node is receiving its own transmitted messages. 0: When a message transmitted from another CAN node is received 1: When the own transmitted message is received

Bit	Bit Name	Initial Value	R/W	Description
28 to 0	GAFLID[28:0]	H'0000_0000	R/W	ID Set These bits are used to set the ID field of the receive rule. The ID value set by these bits is compared with the ID of the received message during the acceptance filter processing. For the standard ID, set the ID in bits 10 to 0 and set bits 28 to 11 to 0.

Modify the RSCFDnGAFLIDj register when the AFLDAE bit in the RSCFDnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

48.7.4.5 RSCFDnGAFLMj — Receive Rule Mask Register (j = 0 to 15)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGAFLMj register can be read/written in 32-bit units

RSCFDnGAFLMjL, RSCFDnGAFLMjH registers can be read/written in 16-bit units

RSCFDnGAFLMjLL, RSCFDnGAFLMjLH, RSCFDnGAFLMjHL, RSCFDnGAFLMjHH registers can be read/written in 8-bit units

Address: RSCFDnGAFLMj: <RSCFDn_base> + H'0504 + (H'10 × j)

RSCFDnGAFLMjL: <RSCFDn_base> + H'0504 + (H'10 × j),
RSCFDnGAFLMjH: <RSCFDn_base> + H'0506 + (H'10 × j)

RSCFDnGAFLMjLL: <RSCFDn_base> + H'0504 + (H'10 × j),
RSCFDnGAFLMjLH: <RSCFDn_base> + H'0505 + (H'10 × j),
RSCFDnGAFLMjHL: <RSCFDn_base> + H'0506 + (H'10 × j),
RSCFDnGAFLMjHH: <RSCFDn_base> + H'0507 + (H'10 × j)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLIDEM	GAFLRTRM	—	GAFLIDM[28:16]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GAFLIDM[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	GAFLIDEM	B'0	R/W	IDE Mask When this bit is set to 1, filter processing is performed only for messages of the ID format specified by the GAFLIDE bit in the RSCFDnGAFLIDj register. When this bit is cleared to 0, the IDs of all the receive messages and the specified IDs are regarded as matched. To set the GAFLIDEM bit to 0, set the GAFLIDM[28:0] bits to all 0 at the same time. 0: The IDE bit is not compared. 1: The IDE bit is compared.
30	GAFLRTRM	B'0	R/W	RTR Mask This bit is used to mask the RTR bit of the receive rule. 0: The RTR bit is not compared. 1: The RTR bit is compared
29	Reserved	B'0	R	This bit is read as the value after reset. The write value should be the value after reset.
28 to 0	GAFLIDM [28:0]	H'0000_0000	R/W	ID Mask These bits are used to mask the corresponding ID bit of the receive rule. 0: The corresponding ID bit is not compared. 1: The corresponding ID bit is compared.

Modify the RSCFDnGAFLMj register when the AFLDAE bit in the RSCFDnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

48.7.4.6 RSCFDnGAFLP0_j — Receive Rule Pointer 0 Register (j = 0 to 15)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGAFLP0_j register can be read/written in 32-bit units

RSCFDnGAFLP0_jL, RSCFDnGAFLP0_jH registers can be read/written in 16-bit units

RSCFDnGAFLP0_jLL, RSCFDnGAFLP0_jLH, RSCFDnGAFLP0_jHL, RSCFDnGAFLP0_jHH registers can be read/written in 8-bit units

Address: RSCFDnGAFLP0_j: <RSCFDn_base> + H'0508 + (H'10 × j)

RSCFDnGAFLP0_jL: <RSCFDn_base> + H'0508 + (H'10 × j),
RSCFDnGAFLP0_jH: <RSCFDn_base> + H'050A + (H'10 × j)

RSCFDnGAFLP0_jLL: <RSCFDn_base> + H'0508 + (H'10 × j),
RSCFDnGAFLP0_jLH: <RSCFDn_base> + H'0509 + (H'10 × j),
RSCFDnGAFLP0_jHL: <RSCFDn_base> + H'050A + (H'10 × j),
RSCFDnGAFLP0_jHH: <RSCFDn_base> + H'050B + (H'10 × j)

Value after reset: H’0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLDLC[3:0]				GAFLPTR[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GAFLRMV	GAFLRMDP[6:0]							—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	GAFLDLC [3:0]	B’0000	R/W	Receive Rule DLC These bits are used to set the minimum data length necessary for receiving messages. If the data length of a message that is being filtered is equal to or larger than the value set by the GAFLDLC[3:0] bits, the message passes the DLC check. Setting these bits to B'0000 disables the DLC check function allowing messages with any data length to pass the DLC check. B’0000: DLC check is disabled. B’0001: 1 data byte B’0010: 2 data bytes B’0011: 3 data bytes B’0100: 4 data bytes B’0101: 5 data bytes B’0110: 6 data bytes B’0111: 7 data bytes B’1XXX: 8 data bytes
27 to 16	GAFLPTR [11:0]	H'000	R/W	Receive Rule Label These bits are used to set a 12-bit label to be attached to messages that have passed through the filter. A label is attached when a message is stored in the receive buffer or the FIFO buffer. Set the 12-bit label information.

Bit	Bit Name	Initial Value	R/W	Description
15	GAFLRMV	B'0	R/W	Receive Buffer Enable When this bit is set to 1, receive messages that have passed through the filter are stored in the receive buffer selected by the GAFLRMDP[6:0] bits. 0: No receive buffer is used. 1: A receive buffer is used.
14 to 8	GAFLRMDP [6:0]	H'00	R/W	Receive Buffer Number Select These bits are used to select the number of the receive buffer that stores receive messages that have passed through the filter when the GAFLRMV bit is set to 1. Set these bits to a value smaller than the value set by the NRXMB[7:0] bits in the RSCFDnRMNB register.
7 to 0	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.

Modify the RSCFDnGAFLP0_j register when the AFLDAE bit in the RSCFDnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

48.7.4.7 RSCFDnGAFLP1_j — Receive Rule Pointer 1 Register (j = 0 to 15)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGAFLP1_j register can be read/written in 32-bit units

RSCFDnGAFLP1_jL, RSCFDnGAFLP1_jH registers can be read/written in 16-bit units

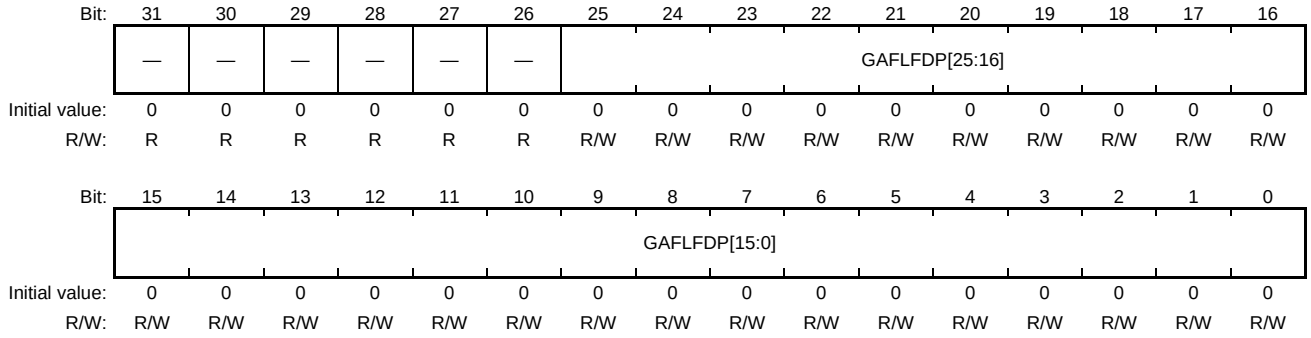
RSCFDnGAFLP1_jLL, RSCFDnGAFLP1_jLH, RSCFDnGAFLP1_jHL, RSCFDnGAFLP1_jHH registers can be read/written in 8-bit units

Address: RSCFDnGAFLP1_j: <RSCFDn_base> + H'050C + (H'10 × j)

RSCFDnGAFLP1_jL: <RSCFDn_base> + H'050C + (H'10 × j),
RSCFDnGAFLP1_jH: <RSCFDn_base> + H'050E + (H'10 × j)

RSCFDnGAFLP1_jLL: <RSCFDn_base> + H'050C + (H'10 × j),
RSCFDnGAFLP1_jLH: <RSCFDn_base> + H'050D + (H'10 × j),
RSCFDnGAFLP1_jHL: <RSCFDn_base> + H'050E + (H'10 × j),
RSCFDnGAFLP1_jHH: <RSCFDn_base> + H'050F + (H'10 × j)

Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31 to 26	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
25 to 8	GAFLFDP [25:8]	H'0_0000	R/W	Transmit/Receive FIFO Buffer k Select (Bit position –8 = target transmit/receive FIFO buffer number k) 0: Transmit/receive FIFO buffer is not selected. 1: Transmit/receive FIFO buffer is selected.
7 to 0	GAFLFDP [7:0]	H'00	R/W	Receive FIFO Buffer x Select (Bit position = target receive FIFO buffer number x) 0: Receive FIFO buffer is not selected. 1: Receive FIFO buffer is selected.

Modify the RSCFDnGAFLP1_j register when the AFLDAE bit in the RSCFDnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLFDP[25:0] Bits

These bits are used to specify FIFO buffers that store receive messages that have passed through the filter. Up to eight FIFO buffers are selectable. However, when the GAFLRMV bit in the RSCFDnGAFLP0_j register is set to 1 (a message is stored in the receive buffer), up to seven FIFO buffers can be selected. Only receive FIFO buffers and the transmit/receive FIFO buffer for which the CFM[1:0] bits in the RSCFDnCFCC register are set to B'00 (receive mode) or B'10 (gateway mode) are selectable.

48.7.5 Details of Receive Buffer Related Registers

48.7.5.1 RSCFDnRMNB - Receive Buffer Number Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnRMNB register can be read/written in 32-bit units

RSCFDnRMNBL, RSCFDnRMNBH registers can be read/written in 16-bit units

RSCFDnRMNBLL, RSCFDnRMNBLH, RSCFDnRMNBHL, RSCFDnRMNBHH registers can be read/written in 8-bit units

Address: RSCFDnRMNB: <RSCFDn_base> + H'00A4

RSCFDnRMNBL: <RSCFDn_base> + H'00A4, RSCFDnRMNBH: <RSCFDn_base> + H'00A6

RSCFDnRMNBLL: <RSCFDn_base> + H'00A4, RSCFDnRMNBLH: <RSCFDn_base> + H'00A5, RSCFDnRMNBHL: <RSCFDn_base> + H'00A6, RSCFDnRMNBHH: <RSCFDn_base> + H'00A7

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	NRXMB[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
7 to 0	NRXMB[7:0]	H'00	R/W	Receive Buffer Number Configuration These bits are used to set the total number of receive buffers of the RS-CANFD module. The maximum value is 16 × (number of channels). Setting these bits all to 0 makes receive buffers unavailable. Set a value of 0 to 96.

Modify the RSCFDnRMNB register only in global reset mode.

48.7.5.2 RSCFDnRMNDy — Receive Buffer New Data Register (y = 0)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnRMNDy register can be read/written in 32-bit units

RSCFDnRMNDyL, RSCFDnRMNDyH registers can be read/written in 16-bit units

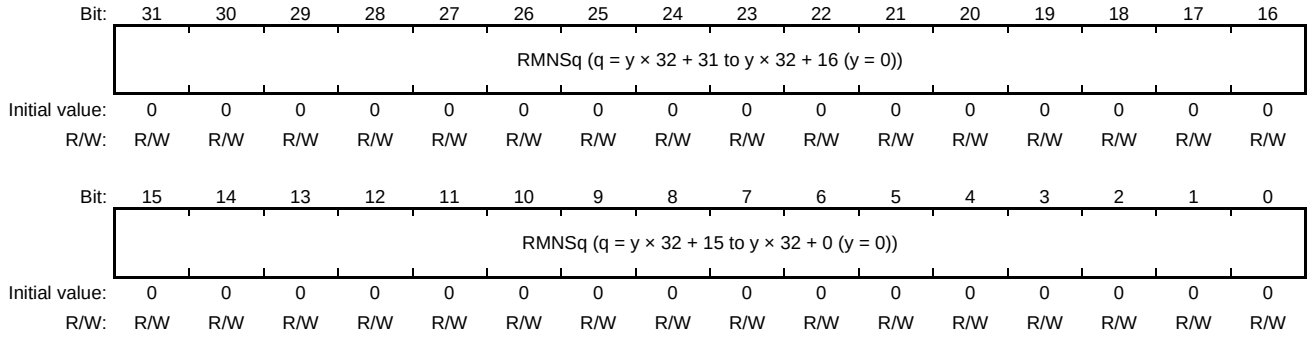
RSCFDnRMNDyLL, RSCFDnRMNDyLH, RSCFDnRMNDyHL, RSCFDnRMNDyHH registers can be read/written in 8-bit units

Address: RSCFDnRMNDy: <RSCFDn_base> + H'00A8 + (H'04 × y)

RSCFDnRMNDyL: <RSCFDn_base> + H'00A8 + (H'04 × y),
RSCFDnRMNDyH: <RSCFDn_base> + H'00AA + (H'04 × y)

RSCFDnRMNDyLL: <RSCFDn_base> + H'00A8 + (H'04 × y),
RSCFDnRMNDyLH: <RSCFDn_base> + H'00A9 + (H'04 × y),
RSCFDnRMNDyHL: <RSCFDn_base> + H'00AA + (H'04 × y),
RSCFDnRMNDyHH: <RSCFDn_base> + H'00AB + (H'04 × y)

Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RMNSq	H'0000_0000	R/W	Receive Buffer Receive Complete Flag q (q = y × 32 + 31 to y × 32 + 0) 0: There is no new message in receive buffer q. 1: There is a new message in receive buffer q.

Write 0 to the RSCFDnRMNDy register in global operating mode or global test mode.

RMNSq Flags (q = 0 to 31)

Each RMNS flag is set to 1 when the processing for storing a message in the corresponding receive buffer starts.

To clear a flag to 0, the program must write 0 to the flag. Use a store instruction to write “0” to the flag and “1” to other flags. These bits cannot be set to 0 while a message is being stored. It takes ten clock cycles of pclk to store a message.

These flags are cleared to 0 in global reset mode.

48.7.5.3 RSCFDnRMIDq — Receive Buffer ID Register (q = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnRMIDq register can be read only in 32-bit units

RSCFDnRMIDqL, RSCFDnRMIDqH registers can be read only in 16-bit units

RSCFDnRMIDqLL, RSCFDnRMIDqLH, RSCFDnRMIDqHL, RSCFDnRMIDqHH registers can be read only in 8-bit units

Address: RSCFDnRMIDq: <RSCFDn_base> + H'0600 + (H'10 × q)

RSCFDnRMIDqL: <RSCFDn_base> + H'0600 + (H'10 × q),
RSCFDnRMIDqH: <RSCFDn_base> + H'0602 + (H'10 × q)

RSCFDnRMIDqLL: <RSCFDn_base> + H'0600 + (H'10 × q),
RSCFDnRMIDqLH: <RSCFDn_base> + H'0601 + (H'10 × q),
RSCFDnRMIDqHL: <RSCFDn_base> + H'0602 + (H'10 × q),
RSCFDnRMIDqHH: <RSCFDn_base> + H'0603 + (H'10 × q)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMIDE	RMRTR	—	RMID[28:16]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description
31	RMIDE	B'0	R	Receive Buffer IDE This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive buffer. 0: Standard ID 1: Extended ID
30	RMRTR	B'0	R	Receive Buffer RTR This bit indicates the frame format (data frame or remote frame) of the message stored in the receive buffer. 0: Data frame 1: Remote frame
29	Reserved	B'0	R	This bit is read as the value after reset.
28 to 0	RMID[28:0]	H'0000_0000	R	Receive Buffer ID Data These bits contain the standard ID or extended ID of the received message. Read bits 10 to 0 for standard ID. Bits 28 to 11 are read as 0.

48.7.5.4 RSCFDnRMPTRq — Receive Buffer Pointer Register (q = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnRMPTRq register can be read only in 32-bit units

RSCFDnRMPTRqL, RSCFDnRMPTRqH registers can be read only in 16-bit units

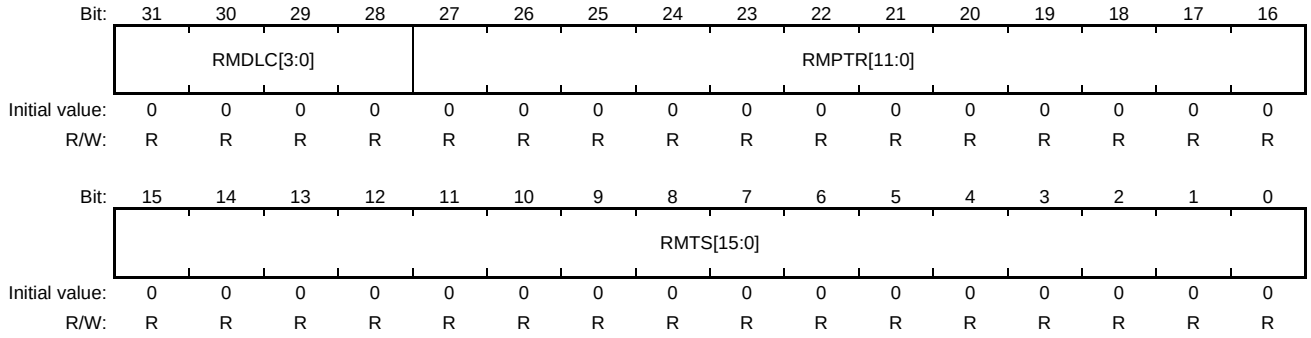
RSCFDnRMPTRqLL, RSCFDnRMPTRqLH, RSCFDnRMPTRqHL, RSCFDnRMPTRqHH registers can be read only in 8-bit units

Address: RSCFDnRMPTRq: <RSCFDn_base> + H'0604 + (H'10 × q)

RSCFDnRMPTRqL: <RSCFDn_base> + H'0604 + (H'10 × q),
RSCFDnRMPTRqH: <RSCFDn_base> + H'0606 + (H'10 × q)

RSCFDnRMPTRqLL: <RSCFDn_base> + H'0604 + (H'10 × q),
RSCFDnRMPTRqLH: <RSCFDn_base> + H'0605 + (H'10 × q),
RSCFDnRMPTRqHL: <RSCFDn_base> + H'0606 + (H'10 × q),
RSCFDnRMPTRqHH: <RSCFDn_base> + H'0607 + (H'10 × q)

Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31 to 28	RMDLC[3:0]	B'0000	R	Receive Buffer DLC Data These bits indicate the data length of the message stored in the receive buffer. B'0000: 0 data bytes B'0001: 1 data byte B'0010: 2 data bytes B'0011: 3 data bytes B'0100: 4 data bytes B'0101: 5 data bytes B'0110: 6 data bytes B'0111: 7 data bytes B'1XXX: 8 data bytes
27 to 16	RMPTR[11:0]	H'000	R	Receive Buffer Label Data These bits indicate the label information of the message stored in the receive buffer.
15 to 0	RMTS[15:0]	H'0000	R	Receive Buffer Timestamp Data These bits indicate the timestamp value of the message stored in the receive buffer.

48.7.5.5 RSCFDnRMDF0_q — Receive Buffer Data Field 0 Register (q = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnRMDF0_q register can be read only in 32-bit units

RSCFDnRMDF0_qL, RSCFDnRMDF0_qH registers can be read only in 16-bit units

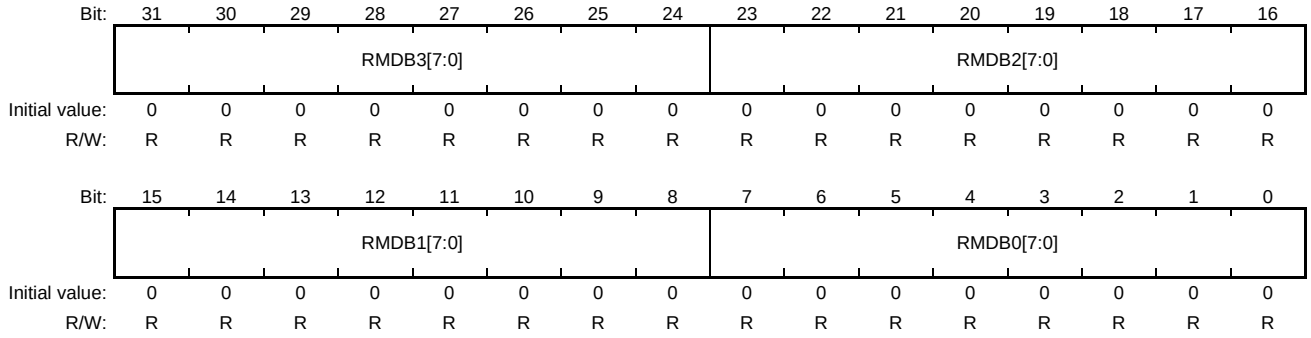
RSCFDnRMDF0_qLL, RSCFDnRMDF0_qLH, RSCFDnRMDF0_qHL, RSCFDnRMDF0_qHH registers can be read only in 8-bit units

Address: RSCFDnRMDF0_q: <RSCFDn_base> + H'0608 + (H'10 × q)

RSCFDnRMDF0_qL: <RSCFDn_base> + H'0608 + (H'10 × q),
RSCFDnRMDF0_qH: <RSCFDn_base> + H'060A + (H'10 × q)

RSCFDnRMDF0_qLL: <RSCFDn_base> + H'0608 + (H'10 × q),
RSCFDnRMDF0_qLH: <RSCFDn_base> + H'0609 + (H'10 × q),
RSCFDnRMDF0_qHL: <RSCFDn_base> + H'060A + (H'10 × q),
RSCFDnRMDF0_qHH: <RSCFDn_base> + H'060B + (H'10 × q)

Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	RMDB3[7:0]	H'00	R	Receive Buffer Data Byte 3
23 to 16	RMDB2[7:0]	H'00	R	Receive Buffer Data Byte 2
15 to 8	RMDB1[7:0]	H'00	R	Receive Buffer Data Byte 1
7 to 0	RMDB0[7:0]	H'00	R	Receive Buffer Data Byte 0 Data for a message stored in the receive buffer can be read.

When the RMDLC[3:0] value in the RSCFDnRMPTRq register is smaller than B'1000, data bytes for which no data is set are read as H'00.

48.7.5.6 RSCFDnRMDF1_q — Receive Buffer Data Field 1 Register (q = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnRMDF1_q register can be read only in 32-bit units

RSCFDnRMDF1_qL, RSCFDnRMDF1_qH register can be read only in 16-bit units

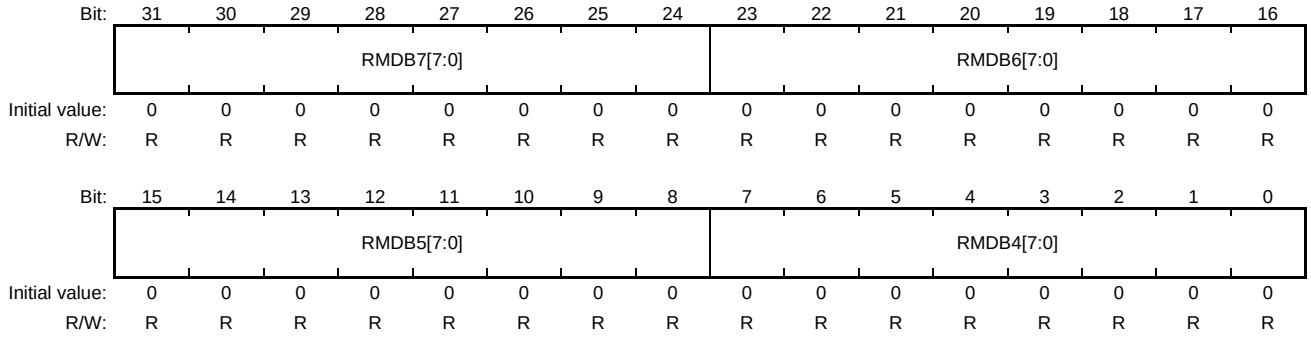
RSCFDnRMDF1_qLL, RSCFDnRMDF1_qLH, RSCFDnRMDF1_qHL, RSCFDnRMDF1_qHH registers can be read only in 8-bit units

Address: RSCFDnRMDF1_q: <RSCFDn_base> + H'060C + (H'10 × q)

RSCFDnRMDF1_qL: <RSCFDn_base> + H'060C + (H'10 × q),
RSCFDnRMDF1_qH: <RSCFDn_base> + H'060E + (H'10 × q)

RSCFDnRMDF1_qLL: <RSCFDn_base> + H'060C + (H'10 × q),
RSCFDnRMDF1_qLH: <RSCFDn_base> + H'060D + (H'10 × q),
RSCFDnRMDF1_qHL: <RSCFDn_base> + H'060E + (H'10 × q),
RSCFDnRMDF1_qHH: <RSCFDn_base> + H'060F + (H'10 × q)

Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	RMDB7[7:0]	H'00	R	Receive Buffer Data Byte 7
23 to 16	RMDB6[7:0]	H'00	R	Receive Buffer Data Byte 6
15 to 8	RMDB5[7:0]	H'00	R	Receive Buffer Data Byte 5
7 to 0	RMDB4[7:0]	H'00	R	Receive Buffer Data Byte 4 Data for a message stored in the receive buffer can be read.

When the RMDLC[3:0] value in the RSCFDnRMPTRq register is smaller than B'1000, data bytes for which no data is set are read as H'00.

48.7.6 Details of Receive FIFO Buffer Related Registers

48.7.6.1 RSCFDnRFCCx — Receive FIFO Buffer Configuration and Control Register (x = 0 to 7)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnRFCCx register can be read/written in 32-bit units

RSCFDnRFCCxL, RSCFDnRFCCxH registers can be read/written in 16-bit units

RSCFDnRFCCxLL, RSCFDnRFCCxLH, RSCFDnRFCCxHL, RSCFDnRFCCxHH registers can be read/written in 8-bit units

Address: RSCFDnRFCCx: <RSCFDn_base> + H'00B8 + (H'04 × x)

RSCFDnRFCCxL: <RSCFDn_base> + H'00B8 + (H'04 × x),
RSCFDnRFCCxH: <RSCFDn_base> + H'00BA + (H'04 × x)

RSCFDnRFCCxLL: <RSCFDn_base> + H'00B8 + (H'04 × x),
RSCFDnRFCCxLH: <RSCFDn_base> + H'00B9 + (H'04 × x),
RSCFDnRFCCxHL: <RSCFDn_base> + H'00BA + (H'04 × x),
RSCFDnRFCCxHH: <RSCFDn_base> + H'00BB + (H'04 × x)

Value after reset: H’0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFIGCV[2:0]			RFIM	—	RFDC[2:0]			—	—	—	—	—	—	RFIE	RFE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
15 to 13	RFIGCV[2:0]	B’000	R/W	Receive FIFO Interrupt Request Timing Select These bits are used to specify the number of received messages for generating a receive FIFO interrupt request when the RFIM bit is set to 0 with a fraction for the total number of buffers (the setting of RFDC[2:0]). When the RFDC[2:0] bits are set to B'001 (4 messages), set the RFIGCV[2:0] bits to B'001, B'011, B'101, or B'111. Modify these bits only in global reset mode. B’000: When FIFO is 1/8 full. B’001: When FIFO is 2/8 full. B’010: When FIFO is 3/8 full. B’011: When FIFO is 4/8 full. B’100: When FIFO is 5/8 full. B’101: When FIFO is 6/8 full. B’110: When FIFO is 7/8 full. B’111: When FIFO is full.

Bit	Bit Name	Initial Value	R/W	Description
12	RFIM	B’0	R/W	Receive FIFO Interrupt Source Select This bit is used to select a FIFO interrupt source. Modify this bit only in global reset mode. 0: An interrupt occurs when the condition set by the RFIGCV[2:0] bits is met. 1: An interrupt occurs each time a message has been received.
11	Reserved	B’0	R	This bit is read as the value after reset. The write value should be the value after reset.
10 to 8	RFDC[2:0]	B’000	R/W	Receive FIFO Buffer Depth Configuration These bits are used to select the number of messages that can be stored in a single receive FIFO buffer. When these bits are set to B'000, no receive FIFO buffer should be used. Modify these bits only in global reset mode. B’000: 0 messages B’001: 4 messages B’010: 8 messages B’011: 16 messages B’100: 32 messages B’101: 48 messages B’110: 64 messages B’111: 128 messages
7 to 2	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
1	RFIE	B’0	R/W	Receive FIFO Interrupt Enable Setting the RFIE bit to 1 enables receive FIFO interrupts. Modify this bit when the RFE bit set to 0 (no receive FIFO buffer is used). 0: Receive FIFO interrupt is disabled. 1: Receive FIFO interrupt is enabled.
0	RFE	B’0	R/W	Receive FIFO Buffer Enable Setting the RFE bit to 1 makes receive FIFO buffers available. Clearing this bit to 0 sets the RFEMP flag in the RSCFDnRFSTSx register to 1 (buffer empty). Modify this bit in global operating mode or global test mode. 0: No receive FIFO buffer is used. 1: Receive FIFO buffers are used.

48.7.6.2 RSCFDnRFSTSx — Receive FIFO Buffer Status Register (x = 0 to 7)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnRFSTSx register can be read/written in 32-bit units

RSCFDnRFSTSxL, RSCFDnRFSTSxH registers can be read/written in 16-bit units

RSCFDnRFSTSxLL, RSCFDnRFSTSxLH, RSCFDnRFSTSxHL, RSCFDnRFSTSxHH registers can be read/written in 8-bit units

Address: RSCFDnRFSTSx: <RSCFDn_base> + H'00D8 + (H'04 × x)

RSCFDnRFSTSxL: <RSCFDn_base> + H'00D8 + (H'04 × x),
RSCFDnRFSTSxH: <RSCFDn_base> + H'00DA + (H'04 × x)

RSCFDnRFSTSxLL: <RSCFDn_base> + H'00D8 + (H'04 × x),
RSCFDnRFSTSxLH: <RSCFDn_base> + H'00D9 + (H'04 × x),
RSCFDnRFSTSxHL: <RSCFDn_base> + H'00DA + (H'04 × x),
RSCFDnRFSTSxHH: <RSCFDn_base> + H'00DB + (H'04 × x)

Value after reset: H'0000_0001

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFMC[7:0]								—	—	—	—	RFIF	RFMLT	RFFLL	RFEMP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R	R

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Reserved	All 0	R	These bits are read as the value after reset. When writing to these bits, write the value after reset.
15 to 8	RFMC[7:0]	H'00	R	Receive FIFO Unread Message Counter This flag indicates the number of unread messages in the receive FIFO buffer. This flag becomes H'00 when the RFE bit in the RSCFDnRFCCx register is set to 0.
7 to 4	Reserved	All 0	R	These bits are read as the value after reset. When writing to these bits, write the value after reset.
3	RFIF	B'0	R/W*	Receive FIFO Interrupt Request Flag This flag is set to 1 when the receive FIFO interrupt request generation conditions set by the RFIGCV[2:0] bits and the RFIM bit in the RSCFDnRFCCx register are met. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”. 0: No receive FIFO interrupt request is present. 1: A receive FIFO interrupt request is present.

Bit	Bit Name	Initial Value	R/W	Description
2	RFMLT	B'0	R/W*	Receive FIFO Message Lost Flag This flag is set to 1 when an attempt is made to store a new message while the receive FIFO buffer is full. In this case, the new message is discarded. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: No receive FIFO message is lost. 1: A receive FIFO message is lost.
1	RFFLL	B'0	R	Receive FIFO Buffer Full Status Flag This flag is set to 1 when the number of messages stored in the receive FIFO buffer matches the FIFO buffer depth set by the RFDC[2:0] bits in the RSCFDnRFCCx register. If the number of messages stored in the receive FIFO buffer becomes smaller than the FIFO buffer depth set by the RFDC[2:0] bits, this flag is cleared to 0. This flag is also cleared to 0 when the RFE bit in the RSCFDnRFCCx register is set to 0 (no receive FIFO buffer is used) or in global reset mode. 0: The receive FIFO buffer is not full. 1: The receive FIFO buffer is full.
0	RFEMP	B'1	R	Receive FIFO Buffer Empty Status Flag This flag is set to 1 when all messages in the receive FIFO buffer have been read. This flag is also set to 1 when the RFE bit in the RSCFDnRFCCx register is 0 or in global reset mode. This flag is cleared to 0 when even a single received message has been stored in the receive FIFO buffer. 0: The receive FIFO buffer contains unread message. 1: The receive FIFO buffer contains no unread message (buffer empty).

Note: To clear the RFMLT or RFIF flag to 0, use a store instruction to write "0" to the given flag and "1" to the other flags.

48.7.6.3 RSCFDnRFPCTRx — Receive FIFO Buffer Pointer Control Register (x = 0 to 7)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnRFPCTRx register can only be written in 32-bit units

RSCFDnRFPCTRxL, RSCFDnRFPCTRxH registers can only be written in 16-bit units

RSCFDnRFPCTRxLL, RSCFDnRFPCTRxLH, RSCFDnRFPCTRxHL, RSCFDnRFPCTRxHH registers can only be written in 8-bit units

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	Reserved	All 0	R	The write value should be the value after reset.
7 to 0	RFPC[7:0]	H'00	W	Receive FIFO Pointer Control When the RFPC[7:0] bits are set to H'FF, the read pointer moves to the next unread message in the receive FIFO buffer. At this time, the RFMC[7:0] (receive FIFO unread message counter) value in the RSCFDnRFSTSx register is decremented. Read the RSCFDnRFIDx, RSCFDnRFPTRx, RSCFDnRFDF0_x, and RSCFDnRFDF1_x registers to read messages in the receive FIFO buffer, and then write H'FF to the RFPC[7:0] bits. When writing H'FF to these bits, make sure that the RFE bit in the RSCFDnRFCCx register is set to 1 (receive FIFO buffers are used) and the RFEMP flag in the RSCFDnRFSTSx register is 0 (the receive FIFO buffer contains unread messages).

R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	CFITT[7:0]	H'00	R/W	Set a message transmission interval. These bits are used to set a message transmission interval when transmitting messages continuously from a transmit/receive FIFO buffer whose CFM[1:0] bits are set to B'01 (transmit mode) or B'10 (gateway mode). Clear the CFE bit to 0 (no transmit/receive FIFO buffer is used) before modifying the CFITT[7:0] bits. Set Value: H'00 to H'FF

Bit	Bit Name	Initial Value	R/W	Description
23 to 20	CFTML[3:0]	H'0	R/W	Transmit Buffer Link Configuration These bits are used to set the number of transmit buffer on the channel which will be linked to transmit/receive FIFO buffer k when the CFM[1:0] bits are set to B'01 (transmit mode) or B'10 (gateway mode). There are three transmit/receive FIFO buffers per channel, so channel number m of FIFO buffer k is calculated as m = k/3 (integer division). The actual assigned transmit buffer number p linked to FIFO buffer k will be ((16 × m) + CFTML[3:0]). See Table 48.7 and Table 48.8, as for the relationship between transmit/receive FIFO buffer k and transmit buffer p. Setting the CFDC[2:0] bits to B'001 or more enables the setting of the CFTML[3:0] bits. Do not link to any transmit buffer which is already allocated to a transmit queue on the identical channel or to another transmit/receive FIFO buffer. Modify these bits only in global reset mode.
19	CFITR	B’0	R/W	Transmit/Receive FIFO Interval Timer Resolution This bit is enabled when the CFITSS bit is 0. When this bit is 0, the interval timer clock source is the pclk/2 clock divided by the value of the ITRCP[15:0] bits in the RSCFDnGCFG register. When this bit is 1, the interval timer clock source is the pclk/2 clock divided by (the value of the ITRCP[15:0] bits in the RSCFDnGCFG register × 10). Modify this bit while the CFE bit is set to 0 (no transmit/receive FIFO buffer is used). 0: Clock dividing pclk/2 by (ITRCP[15:0] bits) 1: Clock dividing pclk/2 by (ITRCP[15:0] bits × 10)
18	CFITSS	B’0	R/W	Transmit/Receive FIFO Interval Timer Clock Source Select When this bit is 0, the clock selected by the CFITR bit is the count source of the interval timer. When this bit is 1, the bit time clock of the channel to which the FIFO is linked is the count source of the interval timer. Modify this bit while the CFE bit is set to 0 (no transmit/receive FIFO buffer is used). 0: Interval timer clock source selected by the CFITR bit 1: Interval timer clock source is the bit time clock for the channel to which the FIFO is linked.
17, 16	CFM[1:0]	B’00	R/W	Transmit/Receive FIFO Mode Select These bits are used to select transmit/receive FIFO mode. Modify these bits only in global reset mode. B’00: Receive mode B’01: Transmit mode B’10: Gateway mode B’11: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	CFIGCV[2:0]	B’000	R/W	Transmit/Receive FIFO Receive Interrupt Request Timing Select These bits are used to specify the number of received messages for generating a transmit/receive FIFO receive interrupt request when the CFM[1:0] bits are set to B'00 (receive mode) or B'10 (gateway mode) and the CFIM bit is set to 0 with a fraction for the total number of buffers (the setting of CFDC[2:0]). When the CFDC[2:0] bits are set to B'001 (4 messages), set the CFIGCV[2:0] bits to B'001, B'011, B'101, or B'111. Modify these bits only in global reset mode. B’000: When FIFO is 1/8 full. B’001: When FIFO is 2/8 full. B’010: When FIFO is 3/8 full. B’011: When FIFO is 4/8 full. B’100: When FIFO is 5/8 full. B’101: When FIFO is 6/8 full. B’110: When FIFO is 7/8 full. B’111: When FIFO is full.
12	CFIM	B’0	R/W	Transmit/Receive FIFO Interrupt Source Select This bit is used to select a transmit/receive FIFO interrupt source. Modify this bit only in global reset mode. 0: • Receive mode/gateway mode When the number of received messages has met the condition set by the CFIGCV[2:0] bits, a FIFO receive interrupt request is generated. • Transmit mode/gateway mode When the buffer becomes empty upon completion of message transmission, a FIFO transmit interrupt request is generated. 1: • Receive mode/gateway mode A FIFO receive interrupt request is generated each time a message has been received. • Transmit mode/gateway mode A FIFO transmit interrupt request is generated each time a message has been transmitted.
11	Reserved	B’0	R	This bit is read as the value after reset. The write value should be the value after reset.
10 to 8	CFDC[2:0]	B’000	R/W	Transmit/Receive FIFO Buffer Depth Configuration These bits are used to set the number of messages that can be stored in a single transmit/receive FIFO buffer. When these bits are set to B'000, do not use a transmit/receive FIFO buffer. Modify these bits only in global reset mode. B’000: 0 messages B’001: 4 messages B’010: 8 messages B’011: 16 messages B’100: 32 messages B’101: 48 messages B’110: 64 messages B’111: 128 messages

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
2	CFTXIE	B'0	R/W	Transmit/Receive FIFO Transmit Interrupt Enable When this bit is set to 1 and the CFTXIF flag in the RSCFDnCFSTSk register is set to 1, a transmit/receive FIFO transmit interrupt request is generated. Modify this bit with the CFE bit set to 0 (no transmit/receive FIFO buffer is used). 0: Transmit/receive FIFO transmit interrupt is disabled. 1: Transmit/receive FIFO transmit interrupt is enabled.
1	CFRXIE	B'0	R/W	Transmit/Receive FIFO Receive Interrupt Enable When this bit is set to 1 and the CFRXIF flag in the RSCFDnCFSTSk register is set to 1, a transmit/receive FIFO receive interrupt request is generated. Modify this bit with the CFE bit set to 0. 0: Transmit/receive FIFO receive interrupt is disabled. 1: Transmit/receive FIFO receive interrupt is enabled.
0	CFE	B'0	R/W	Transmit/Receive FIFO Buffer Enable Setting this bit to 1 makes transmit/receive FIFO buffers available. When this bit is set to 0 in transmit mode or gateway mode, if a message in the transmit/receive FIFO buffer is being transmitted or will be transmitted next, the transmit/receive FIFO buffer becomes empty after completion of transmission of that message, or upon detection of a CAN bus error, or arbitration-lost. In other cases or in receive mode, the transmit/receive FIFO buffer becomes empty immediately. This bit is cleared to 0 when the following conditions are met. • Receive mode: Global reset mode • Transmit mode or gateway mode: Channel reset mode Modify this bit in the following mode. • Receive mode: Global operating mode or global test mode • Transmit mode or gateway mode: Channel communication mode or channel halt mode First set all the other bits in the RSCFDnCFCCk register and then set this bit to 1 using another instruction. 0: No transmit/receive FIFO buffer is used. 1: Transmit/receive FIFO buffers are used.

R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W*	R	R

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Reserved	All 0	R	These bits are read as the value after reset. When writing to these bits, write the value after reset.
15 to 8	CFMC[7:0]	H'00	R	Transmit/Receive FIFO Message Counter The number of messages stored in the transmit/receive FIFO buffer. The CFMC[7:0] bits indicate the following values that depend on the setting of the CFM[1:0] bits in the RSCFDnCFCCk register. • When CFM[1:0] value is B'01 (transmit mode): Number of untransmitted messages in the buffer • When CFM[1:0] value is B'00 (receive mode): Number of unread received messages in the buffer • When CFM[1:0] value is B'10 (gateway mode): Number of untransmitted received messages in the buffer These bits are cleared to 0 when any of the following conditions is met. • When CFM[1:0] value is B'00: In global reset mode • When CFM[1:0] value is B'01 or B'10: In channel reset mode
7 to 5	Reserved	All 0	R	These bits are read as the value after reset. When writing to these bits, write the value after reset.

Bit	Bit Name	Initial Value	R/W	Description
4	CFTXIF	B’0	R/W*	Transmit/Receive FIFO Transmit Interrupt Request Flag The CFTXIF flag is set to 1 when any of the following conditions is met. • When the CFM[1:0] bits are set to B'01 or B'10, and the factor selected by the CFIM bit in the RSCFDnCFCCk register occurs The CFTXIF flag is cleared to 0 when any of the following conditions is met. • When 0 is written to the CFTXIF flag • When the CFM[1:0] bits are set to B'00: In global reset mode • When the CFM[1:0] bits are set to B'01 or B'10: In channel reset mode Write 0 to this flag in global operating mode or global test mode. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: No transmit/receive FIFO transmit interrupt request is present. 1: A transmit/receive FIFO transmit interrupt request is present.
3	CFRXIF	B’0	R/W*	Transmit/Receive FIFO Receive Interrupt Request Flag The CFRXIF flag is set to 1 when any of the following conditions is met. • When the CFM[1:0] bits are set to B'00 or B'10, and the factor selected by the CFIM bit in the RSCFDnCFCCk register occurs The CFRXIF flag is cleared to 0 when any of the following conditions is met. • When 0 is written to the CFRXIF flag • When the CFM[1:0] bits are set to B'00: In global reset mode • When the CFM[1:0] bits are set to B'01 or B'10: In channel reset mode Write 0 to this flag in global operating mode or global test mode. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: No transmit/receive FIFO receive interrupt request is present. 1: A transmit/receive FIFO receive interrupt request is present.

Bit	Bit Name	Initial Value	R/W	Description
2	CFMLT	B'0	R/W*	Transmit/Receive FIFO Message Lost Flag The CFMLT flag is set to 1 when any of the following conditions is met. • When an attempt is made to store a new message while the transmit/receive FIFO buffer is full. In this case, the new message is discarded. The CFMLT flag is cleared to 0 when any of the following conditions is met. • When 0 is written to the CFMLT flag • When the CFM[1:0] bits are set to B'00: In global reset mode • When the CFM[1:0] bits are set to B'01 or B'10: In channel reset mode Write 0 to this flag in global operating mode or global test mode To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: No transmit/receive FIFO message is lost. 1: A transmit/receive FIFO message is lost.
1	CFFLL	B'0	R	Transmit/Receive FIFO Buffer Full Status Flag The CFFLL flag is set to 1 when any of the following conditions is met. • When the number of messages stored in the transmit/receive FIFO buffer matches the FIFO buffer depth set by the CFDC[2:0] bits in the RSCFDnCFCCk register. The CFMLT flag is cleared to 0 when any of the following conditions is met. • When the number of messages stored in the transmit/receive FIFO buffer becomes smaller than the FIFO buffer depth set by the CFDC[2:0] bits. • When the CFE bit in the RSCFDnCFCCk register is 0 (no transmit/receive FIFO buffer is used): When not in the transmit abort • When the CFM[1:0] bits are set to B'00: In global reset mode • When the CFM[1:0] bits are set to B'01 or B'10: In channel reset mode 0: The transmit/receive FIFO buffer is not full. 1: The transmit/receive FIFO buffer is full.

Bit	Bit Name	Initial Value	R/W	Description
0	CFEMP	B’1	R	Transmit/Receive FIFO Buffer Empty Status Flag The CFEMP flag is set to 1 when any of the following conditions is met. • When the CFM[1:0] bits are set to B'00: All messages have been read, or in global reset mode • When the CFM[1:0] bits are set to B'01 or B'10: All messages have been transmitted, or in channel reset mode • When the CFE bit is 0 (no transmit/receive FIFO buffer is used): Not in the transmit abort The CFEMP flag is cleared to 0 when any of the following conditions is met. • When the CFM[1:0] bits are set to B'00 or B'10: At least one received message has been stored in the transmit/receive FIFO buffer. • When the CFM[1:0] bits are set to B'01: A value of H'FF has been written to the RSCFDnCFPCTRk register after data was written to the RSCFDnCFIDk, RSCFDnCFPTRk, RSCFDnCFDF0_k, and RSCFDnCFDF1_k registers. 0: The transmit/receive FIFO buffer contains messages. 1: The transmit/receive FIFO buffer contains no message (buffer empty).

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	Reserved	All 0	R	The write value should be the value after reset.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	CFPC[7:0]	H'00	W	Transmit/Receive FIFO Pointer Control • Receive mode (CFM[1:0] value in the RSCFDnCFCCk register is B'00): Writing H'FF to the CFPC[7:0] bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value (transmit/receive FIFO message counter) in the RSCFDnCFSTSk register is decremented. Read the RSCFDnCFIDk, RSCFDnCFPTRk, RSCFDnCFDF0_k, and RSCFDnCFDF1_k registers to read messages from the transmit/receive FIFO buffer, and then write H'FF to the CFPC[7:0] bits. When writing H'FF to these bits, make sure that the CFE bit in the RSCFDnCFCCk register is set to 1 (transmit/receive FIFO buffers are used) and the CFEMP flag in the RSCFDnCFSTSk register is 0 (the transmit/receive FIFO buffer contains messages). • Transmit mode (CFM[1:0] value in the RSCFDnCFCCk register is B'01): Writing H'FF to the CFPC[7:0] bits stores the data written to the RSCFDnCFIDk, RSCFDnCFPTRk, RSCFDnCFDF0_k, and RSCFDnCFDF1_k registers in the transmit/receive FIFO buffer and moves the write pointer to the next stage of the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value is incremented. Write transmit messages to the RSCFDnCFIDk, RSCFDnCFPTRk, RSCFDnCFDF0_k, and RSCFDnCFDF1_k registers before writing H'FF to the CFPC[7:0] bits. When writing H'FF to these bits, make sure that the CFE bit in the RSCFDnCFCCk register is set to 1 and the CFFLL flag in the RSCFDnCFSTSk register is 0 (the transmit/receive FIFO buffer is not full). • Gateway mode (CFM[1:0] value in the RSCFDnCFCCk register is B'10): Setting prohibited

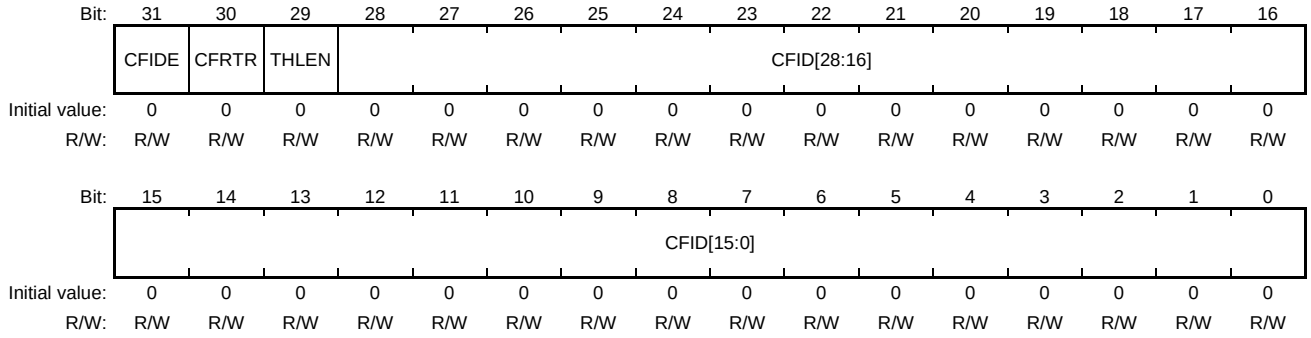
Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31	CFIDE	B'0	R/W	Transmit/Receive FIFO Buffer IDE This bit indicates the ID format (standard ID or extended ID) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is B'00. When the CFM[1:0] value is B'01, these bits are used to set the ID format of the message to be transmitted from the transmit/receive FIFO buffer. 0: Standard ID 1: Extended ID
30	CFRTR	B'0	R/W	Transmit/Receive FIFO Buffer RTR This bit indicates the data format (data frame or remote frame) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is B'00. When the CFM[1:0] value is B'01, this bit is used to set the data format of the message to be transmitted from the transmit/receive FIFO buffer. 0: Data frame 1: Remote frame

Bit	Bit Name	Initial Value	R/W	Description
29	THLEN	B’0	R/W	Transmit History Data Store Enable When this bit is set to 1, the transmit history data (label information, buffer number, and buffer type) of transmit messages is stored in the transmit history buffer after transmission is completed. This bit is enabled when the CFM[1:0] value is B'01 (transmit mode). 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.
28 to 0	CFID[28:0]	H’0000_0000	R/W	Transmit/Receive FIFO Buffer ID Data • When CFM[1:0] value is B'01 (transmit mode): Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11. • When CFM[1:0] value is B'00 (receive mode): Standard ID or extended ID in the received message can be read. For standard ID, read bits 10 to 0. Bits 28 to 11 are read as 0.

This register is writable only when the CFM[1:0] value in the RSCFDnCFCCk register is B'01 (transmit mode). This register is readable only when the CFM[1:0] value is B'00 (receive mode). This register should not be read or written when the CFM[1:0] value is B'10 (gateway mode).

The RSCFDnCFTISTS register is cleared to H'0000_0000 in global reset mode.

48.7.9 Details of Transmit Buffer Related Registers

48.7.9.1 RSCFDnTMCp — Transmit Buffer Control Register (p = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnTMCp register can be read/written in 8-bit units

Address: RSCFDnTMCp: <RSCFDn_base> + H'0250 + (H'01 × p)

Value after reset: H'00

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	TMOM	TMTAR	TMTR
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W*	R/W*	R/W*

Note: * The only effective value for writing to this bit is 1, which sets the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
2	TMOM	B'0	R/W*	One-Shot Transmission Enable Setting this bit to 1 enables one-shot transmission. When transmission fails, retransmission defined in the CAN protocol is not performed. Modify the TMOM bit when the TMTRM flag in the RSCFDnTMSTSp register is set to 0. Set the TMOM bit to 1 together with the TMTR bit. 0: One-shot transmission is disabled. 1: One-shot transmission is enabled.
1	TMTAR	B'0	R/W*	Transmit Abort Request Setting this bit to 1 generates a transmit abort request for the message stored in the transmit buffer. However, a message that is being transmitted or one that will be transmitted next cannot be aborted. The TMTAR bit can be set to 1 when TMTR bit is 1. The TMTAR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit. Transmission has been completed. Transmit abort has been completed. An error or arbitration loss has been detected. If this bit becomes 0 at the same time as the program writes 1 to this bit, this bit becomes 0. 0: Transmit abort is not requested. 1: Transmit abort is requested.

Bit	Bit Name	Initial Value	R/W	Description
0	TMTR	B'0	R/W*	Transmit Request Setting this bit to 1 transmits the message stored in the transmit buffer. The TMTR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit. Transmission has been completed. Transmit abort has been completed after the TMTAR bit was set to 1. An error or arbitration-lost has been detected with the TMOM bit set to 1. Set the TMTR bit to 1 when the value of TMTRF[1:0] in the RSCFDnTMSTSp register is B'00. 0: Transmission is not requested. 1: Transmission is requested.

When the RSCFDnTMCp register meets any of the following conditions, set it to H'00.

The RSCFDnTMCp register corresponds to the transmit buffer number selected by the CFTML[3:0] bits in the RSCFDnCFCCk register (p = m × 16 + the value of CFTML[3:0] bits).

The RSCFDnTMCp register corresponds to the transmit buffer allocated to the transmit queue by the TXQDC[3:0] bits in the RSCFDnTXQCCm (m = 0 or 1) register (p = (m × 16 + 15) to (m × 16 + 15 – the value of TXQDC[3:0] bits)).

Bits in the RSCFDnTMCp register are all cleared to 0 in channel reset mode. Modify the RSCFDnTMCp register in channel communication mode or channel halt mode.

48.7.9.2 RSCFDnTMSTSp — Transmit Buffer Status Register (p = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnTMSTSp register can be read/written in 8-bit units

Address: RSCFDnTMSTSp: <RSCFDn_base> + H'02D0 + (H'01 × p)

Value after reset: H'00

Bit:	7	6	5	4	3	2	1	0
	—	—	—	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
4	TMTARM	B'0	R	Transmit Buffer Transmit Abort Request Status Flag The TMTARM flag is set to 1 when the TMTAR bit in the RSCFDnTMCp register is set to 1. The TMTARM flag is set to 0 when the TMTAR bit in the RSCFDnTMCp register is set to 0. 0: No transmit abort request is present. 1: A transmit abort request is present.
3	TMTRM	B'0	R	Transmit Buffer Transmit Request Status Flag The TMTRM flag is set to 1 when the TMTR bit in the RSCFDnTMCp register is set to 1. The TMTRM flag is set to 0 when the TMTR bit in the RSCFDnTMCp register is set to 0. 0: No transmit request is present. 1: A transmit request is present.
2, 1	TMTRF[1:0]	B'00	R/W	Transmit Buffer Transmit Result Status Flag This flag indicates the result of transmission from the transmit buffer. B'00: Transmission is in progress or no transmit request is present. B'01: Transmission from the transmit buffer was aborted. B'10: Transmission has been completed with the TMTAR bit in the RSCFDnTMCp register set to 0 (transmit abort is not requested). B'11: Transmission has been completed with the TMTAR bit in the RSCFDnTMCp register set to 1 (transmit abort is requested). Write B'00 to the TMTRF[1:0] flag in channel communication mode or channel halt mode. Do not write any value other than B'00 to this flag.
0	TMTSTS	B'0	R	Transmit Buffer Transmit Status Flag This flag is set to 1 when transmission from the transmit buffer starts, and is cleared to 0 when transmission from the transmit buffer has been completed or terminated due to a bus error or arbitration lost. 0: Transmission is not in progress. 1: Transmission is in progress.

The RSCFDnTMSTSp register is cleared to all 0 in channel reset mode.

48.7.9.3 RSCFDnTMIDp — Transmit Buffer ID Register (p = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnTMIDp register can be read/written in 32-bit units

RSCFDnTMIDpL, RSCFDnTMIDpH registers can be read/written in 16-bit units

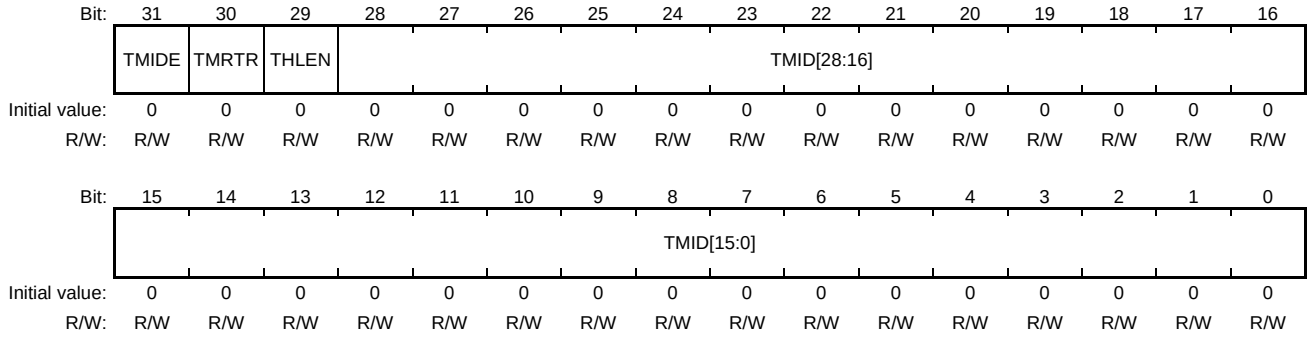
RSCFDnTMIDpLL, RSCFDnTMIDpLH, RSCFDnTMIDpHL, RSCFDnTMIDpHH registers can be read/written in 8-bit units

Address: RSCFDnTMIDp: <RSCFDn_base> + H'1000 + (H'10 × p)

RSCFDnTMIDpL: <RSCFDn_base> + H'1000 + (H'10 × p),
RSCFDnTMIDpH: <RSCFDn_base> + H'1002 + (H'10 × p)

RSCFDnTMIDpLL: <RSCFDn_base> + H'1000 + (H'10 × p),
RSCFDnTMIDpLH: <RSCFDn_base> + H'1001 + (H'10 × p),
RSCFDnTMIDpHL: <RSCFDn_base> + H'1002 + (H'10 × p),
RSCFDnTMIDpHH: <RSCFDn_base> + H'1003 + (H'10 × p)

Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31	TMIDE	B'0	R/W	Transmit Buffer IDE This bit is used to set the ID format of the message to be transmitted from the transmit buffer. 0: Standard ID 1: Extended ID
30	TMRTR	B'0	R/W	Transmit Buffer RTR This bit is used to set the data format of the message to be transmitted from the transmit buffer. 0: Data frame 1: Remote frame
29	THLEN	B'0	R/W	Transmit History Data Store Enable With this bit set to 1, the transmit history data of the message transmitted (label information, buffer number, and buffer type; if the TMTSCE bit in the RSCFDnGCFG register is 1, timestamp is also included) is stored in the transmit history buffer after transmission is completed. 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.

Bit	Bit Name	Initial Value	R/W	Description
28 to 0	TMID[28:0]	H'0000_0000	R/W	Transmit Buffer ID Data These bits are used to set the ID of the message to be transmitted from the transmit buffer. Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11.

Modify this register when the TMTRM bit in the corresponding RSCFDnTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write data to this register. If this register is allocated to the transmit queue, only write data to a transmit buffer p (p = m × 16 + 15) for the corresponding channel.

48.7.9.4 RSCFDnTMPTRp — Transmit Buffer Pointer Register (p = 0 to 31)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TMTARSTSp	H'0000_0000	R	Transmit Buffer Transmit Abort Request Status Flag p (p = y × 32 + 31 to y × 32 + 0) 0: No transmit abort request is present. 1: A transmit abort request is present.

TMTARSTSp Flags (p = 0 to 31)

These flags indicate the status of the TMTAR bit in the RSCFDnTMCp register.

When the TMTAR bit is set to 1 (transmit abort is requested), the corresponding TMTARSTSp flag is set to 1.

The corresponding TMTARSTSp flag is cleared to 0 when the TMTAR bit is set to 0 (transmit abort is not requested) or in channel reset mode.

Table 48.13 shows the bit assignment.

RSCFDnTXQCCmHL: <RSCFDn_base> + H'03A2 + (H'04 × m),
RSCFDnTXQCCmHH: <RSCFDn_base> + H'03A3 + (H'04 × m)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	TXQIM	TXQIE	TXQDC[3:0]				—	—	—	—	—	—	—	TXQE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
13	TXQIM	0	R/W	Transmit Queue Interrupt Source Select This bit is used to select a transmit queue interrupt source. Modify this bit in channel reset mode. 0: When the transmit queue becomes empty upon completion of message transmission, a transmit queue interrupt request is generated. 1: A transmit queue interrupt request is generated each time a message has been transmitted.
12	TXQIE	0	R/W	Transmit Queue Interrupt Enable When the TXQIE bit is set to 1 and the source selected by the TXQIM bit occurs, an interrupt request is generated. Set the TXQE bit to 0 before modifying the TXQIE bit. 0: Transmit queue interrupt is disabled. 1: Transmit queue interrupt is enabled.

Bit	Bit Name	Initial Value	R/W	Description
11 to 8	TXQDC[3:0]	B’0000	R/W	Transmit Queue Depth Configuration These bits are used to specify the number of transmit buffers to be allocated to the transmit queues. Transmit buffers are allocated to transmit queues in descending order of buffer number, that is, from (m × 16 + 15) to (m × 16 + 0). For examples of how buffer allocation is done, see Figure 48.9. Modify these bits only in channel reset mode. Setting these bits to g (g = 2 to 15) makes the (g + 1)-buffer transmit queue available. Setting these bits to 0 disables the transmit queue. Setting these bits to 1 is prohibited.
7 to 1	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	TXQE	B’0	R/W	Transmit Queue Enable Setting this bit to 1 makes the transmit queue available. Modify this bit in channel communication mode or channel halt mode. This bit is cleared to 0 in channel reset mode. Before setting the TXQE bit to 1, set the TXQDC[3:0] bits to B'0010 or more. 0: The transmit queue is not used. 1: The transmit queue is used.

48.7.11.2 RSCFDnTXQSTSm — Transmit Queue Status Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnTXQSTSm register can be read/written in 32-bit units

RSCFDnTXQSTSmL, RSCFDnTXQSTSmH registers can be read/written in 16-bit units

RSCFDnTXQSTSmLL, RSCFDnTXQSTSmLH, RSCFDnTXQSTSmHL, RSCFDnTXQSTSmHH registers can be read/written in 8-bit units

Address: RSCFDnTXQSTSm: <RSCFDn_base> + H'03C0 + (H'04 × m)

RSCFDnTXQSTSmL: <RSCFDn_base> + H'03C0 + (H'04 × m),
RSCFDnTXQSTSmH: <RSCFDn_base> + H'03C2 + (H'04 × m)

RSCFDnTXQSTSmLL: <RSCFDn_base> + H'03C0 + (H'04 × m),
RSCFDnTXQSTSmLH: <RSCFDn_base> + H'03C1 + (H'04 × m),
RSCFDnTXQSTSmHL: <RSCFDn_base> + H'03C2 + (H'04 × m),
RSCFDnTXQSTSmHH: <RSCFDn_base> + H'03C3 + (H'04 × m)

Value after reset: H'0000_0001

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQIF	TXQFLL	TXQEMP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*	R	R

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
12 to 8	Reserved	All 0	R	When read, an undefined value is returned. When writing to these bits, write the value after reset.
7 to 3	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	TXQIF	B'0	R/W*	Transmit Queue Interrupt Request Flag The TXQIF flag is set to 1 when the event specified by the TXQIM bit in the RSCFDnTXQCCm register has occurred. The TXQIF flag is cleared to 0 in channel reset mode or by writing 0 to this flag. This flag is not cleared to 0 by setting the TXQE bit in the RSCFDnTXQCCm register to 0 (the transmit queue is not used). 0: No transmit queue interrupt request is present. 1: A transmit queue interrupt request is present.

Bit	Bit Name	Initial Value	R/W	Description
1	TXQFLL	B'0	R	Transmit Queue Full Status Flag The TXQFLL flag is set to 1 when the number of messages set for the transmit queue matches the transmit queue depth set by the TXQDC[3:0] bits in the RSCFDnTXQCCm register. This flag is cleared to 0 in any of the following cases. • The number of messages set for the transmit queue is smaller than the transmit queue depth set by the TXQDC[3:0] bits. • In channel reset mode 0: The transmit queue is not full. 1: The transmit queue is full.
0	TXQEMP	B'1	R	Transmit Queue Empty Status Flag The TXQEMP flag is cleared to 0 when even a single message is set for the transmit queue. This flag is set to 1 in any of the following cases. • The TXQE bit is set to 0 (the transmit queue is not used). • The transmit queue becomes empty. • In channel reset mode 0: The transmit queue contains messages. 1: The transmit queue contains no message (transmit queue empty).

48.7.11.3 RSCFDnTXQPCTRm — Transmit Queue Pointer Control Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnTXQPCTRm registers can only be written in 32-bit units

RSCFDnTXQPCTRmL, RSCFDnTXQPCTRmH registers can only be written in 16-bit units

RSCFDnTXQPCTRmLL, RSCFDnTXQPCTRmLH, RSCFDnTXQPCTRmHL, RSCFDnTXQPCTRmHH registers can only be written in 8-bit units

Address: RSCFDnTXQPCTRm: <RSCFDn_base> + H'03E0 + (H'04 × m)

RSCFDnTXQPCTRmL: <RSCFDn_base> + H'03E0 + (H'04 × m),
RSCFDnTXQPCTRmH: <RSCFDn_base> + H'03E2 + (H'04 × m)

RSCFDnTXQPCTRmLL: <RSCFDn_base> + H'03E0 + (H'04 × m),
RSCFDnTXQPCTRmLH: <RSCFDn_base> + H'03E1 + (H'04 × m),
RSCFDnTXQPCTRmHL: <RSCFDn_base> + H'03E2 + (H'04 × m),
RSCFDnTXQPCTRmHH: <RSCFDn_base> + H'03RZ/G2E + (H'04 × m)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	TXQPC[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	Reserved	All 0	R	The write value should be the value after reset.
7 to 0	TXQPC[7:0]	H'00	W	Transmit Queue Pointer Control Writing H'FF to the TXQPC[7:0] bits moves the write pointer to the next transmit queue buffer and generates a transmit request of the message. Write transmit messages to the RSCFDnTMIDp, RSCFDnTMPTRp, RSCFDnTMDF0_p, and RSCFDnTMDF1_p registers (p = 15, 31) before writing H'FF to the TXQPC[7:0] bits. When writing H'FF to these bits, make sure that the TXQE bit in the RSCFDnTXQCCm register is set to 1 (the transmit queue is used) and the TXQFLL flag in the RSCFDnTXQSTSm register is 0 (the transmit queue is not full).

48.7.12 Details of Transmit History Related Registers

48.7.12.1 RSCFDnTHLCCm — Transmit History Configuration and Control Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

12 to 8	THLMC[4:0]	B'0_0000	R	Transmit History Buffer Unread Data Counter These bits indicate the number of unread data sets stored in the transmit history buffer.
7 to 4	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	THLIF	B'0	R/W*	Transmit History Interrupt Request Flag The THLIF flag is set to 1 when the interrupt source specified with the THLIM bit in the RSCFDnTHLCCm register occurs. This flag is cleared to 0 in channel reset mode or by the program writing 0 to this flag. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: No transmit history interrupt request is present. 1: A transmit history interrupt request is present.

Bit	Bit Name	Initial Value	R/W	Description
2	THLELT	B'0	R/W*	Transmit History Buffer Overflow Flag The THLELT flag is set to 1 when an attempt is made to store new transmit history data while the transmit history buffer is full. In this case, the new data is discarded. This flag becomes 0 in channel reset mode or by the program writing 0 to this flag. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: Transmit history buffer overflow has not occurred. 1: Transmit history buffer overflow has occurred.
1	THLFLL	B'0	R	Transmit History Buffer Full Status Flag The THLFLL flag is set to 1 when 16 data sets have been stored in the transmit history buffer, and is cleared to 0 when the number of data sets stored in the transmit history buffer has decreased to less than 16. This bit is also cleared to 0 in channel reset mode or when the THLE bit in the RSCFDnTHLCCm register is set to 0 (transmit history buffer is not used). 0: Transmit history buffer is not full. 1: Transmit history buffer is full.
0	THLEMP	B'1	R	Transmit History Buffer Empty Status Flag The THLEMP flag is cleared to 0 when even a single set of transmit history data has been stored in the transmit history buffer. This flag is set to 1 when all the data in the transmit history buffer has been read. This flag is also set to 1 in channel reset mode or when the THLE bit in the RSCFDnTHLCCm register is set to 0 (transmit history buffer is not used). 0: Transmit history buffer contains unread data. 1: Transmit history buffer contains no unread data (buffer empty).

Note: To clear THLIF or THLELT flag to 0, the program must write 0. When writing, use a store instruction to write "0" to the given flag and "1" to other flags.

48.7.12.3 RSCFDnTHLPCTRm — Transmit History Pointer Control Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	syouuRZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnTHLPCTRm register can only be written in 32-bit units

RSCFDnTHLPCTRmL, RSCFDnTHLPCTRmH registers can only be written in 16-bit units

RSCFDnTHLPCTRmLL, RSCFDnTHLPCTRmLH, RSCFDnTHLPCTRmHL, RSCFDnTHLPCTRmHH registers can only be written in 8-bit units

Address: RSCFDnTHLPCTRm: <RSCFDn_base> + H'0440 + (H'04 × m)

RSCFDnTHLPCTRmL: <RSCFDn_base> + H'0440 + (H'04 × m),
RSCFDnTHLPCTRmH: <RSCFDn_base> + H'0442 + (H'04 × m)

RSCFDnTHLPCTRmLL: <RSCFDn_base> + H'0440 + (H'04 × m),
RSCFDnTHLPCTRmLH: <RSCFDn_base> + H'0441 + (H'04 × m),
RSCFDnTHLPCTRmHL: <RSCFDn_base> + H'0442 + (H'04 × m),
RSCFDnTHLPCTRmHH: <RSCFDn_base> + H'0443 + (H'04 × m)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	THLPC[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	Reserved	All 0	R	When writing to these bits, write the value after reset.
7 to 0	THLPC[7:0]	H'00	W	Transmit History List Pointer Control When the THLPC[7:0] bits are set to H'FF, the read pointer moves to the next data in the transmit history buffer. At this time, the THLMC[4:0] (transmit history buffer unread data counter) value in the RSCFDnTHLSTSm register is decremented. Write H'FF to the THLPC[7:0] bits after reading from the RSCFDnTHLACCm register. When writing H'FF to these bits, make sure that the THLE bit in the RSCFDnTHLCCm register is set to 1 (transmit history buffer is used) and the THLEMP flag in the RSCFDnTHLSTSm register is 0.

48.7.12.4 RSCFDnTHLACCm — Transmit History Access Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnTHLACCm register can be read only in 32-bit units

RSCFDnTHLACCmL, RSCFDnTHLACCmH registers can be read only in 16-bit units

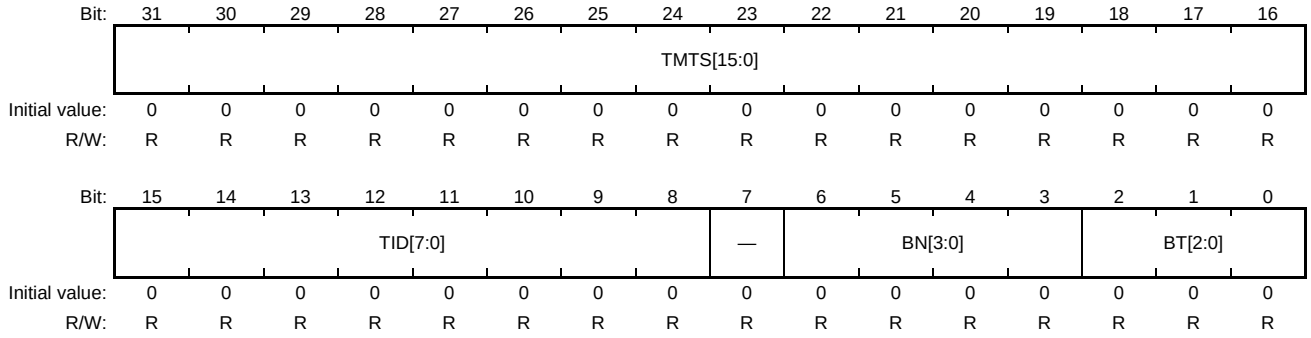
RSCFDnTHLACCmLL, RSCFDnTHLACCmLH, RSCFDnTHLACCmHL, RSCFDnTHLACCmHH registers can be read only in 8-bit units

Address: RSCFDnTHLACCm: <RSCFDn_base> + H'1800 + (H'04 × m)

RSCFDnTHLACCmL: <RSCFDn_base> + H'1800 + (H'04 × m),
RSCFDnTHLACCmH: <RSCFDn_base> + H'1802 + (H'04 × m)

RSCFDnTHLACCmLL: <RSCFDn_base> + H'1800 + (H'04 × m),
RSCFDnTHLACCmLH: <RSCFDn_base> + H'1801 + (H'04 × m),
RSCFDnTHLACCmHL: <RSCFDn_base> + H'1802 + (H'04 × m),
RSCFDnTHLACCmHH: <RSCFDn_base> + H'1803 + (H'04 × m)

Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	TMTS[15:0]	H'0000	R	Timestamp Data These bits indicate the timestamp value of the transmit history data stored in the transmit history buffer when the TMTSCE bit in the RSCFDnGCFG register is 1. These bits are always read as 0 when the TMTSCE bit is 0.
15 to 8	TID[7:0]	H'00	R	Label Data These bits indicate the label information of transmit history data stored in the transmit history buffer.
7	Reserved	B'0	R	When read, the value after reset is returned.
6 to 3	BN[3:0]	B'0000	R	Buffer Number Data These bits indicate the transmit source buffer number in the transmit history data stored in the transmit history buffer.
2 to 0	BT[2:0]	B'000	R	Buffer Type Data These bits indicate the type of the transmit source buffer in the transmit history data stored in the transmit history buffer. B'001: Transmit buffer B'010: Transmit/receive FIFO buffer B'100: Transmit queue

48.7.13 Details of Test Related Registers

48.7.13.1 RSCFDnGTSTCFG — Global Test Configuration Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGTSTCFG register can be read/written in 32-bit units

RSCFDnGTSTCFGL, RSCFDnGTSTCFGH registers can be read/written in 16-bit units

RSCFDnGTSTCFGLL, RSCFDnGTSTCFGLH, RSCFDnGTSTCFGHL, RSCFDnGTSTCFGHH registers can be read/written in 8-bit units

Address: RSCFDnGTSTCFG: <RSCFDn_base> + H'0468

RSCFDnGTSTCFGL: <RSCFDn_base> + H'0468, RSCFDnGTSTCFGH: <RSCFDn_base> + H'046A

RSCFDnGTSTCFGLL: <RSCFDn_base> + H'0468, RSCFDnGTSTCFGLH: <RSCFDn_base> + H'0469, RSCFDnGTSTCFGHL: <RSCFDn_base> + H'046A, RSCFDnGTSTCFGHH: <RSCFDn_base> + H'046B

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	RTMPS[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	C1ICBCE	C0ICBCE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
22 to 16	RTMPS[6:0]	H'00	R/W	RAM Test Page Configuration These bits are used to set the RAM test target page number for RAM test. Set a value in the range of H'00 to H'38, inclusive.
15 to 2	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
1	C1ICBCE	B'0	R/W	CAN1 Inter-Channel Communication Test Enable Setting this bit to 1 enables the channel 1 inter-channel communication test. 0: CAN1 inter-channel communication test is disabled. 1: CAN1 inter-channel communication test is enabled.
0	C0ICBCE	B'0	R/W	CAN0 Inter-Channel Communication Test Enable Setting this bit to 1 enables the channel 0 inter-channel communication test. 0: CAN0 inter-channel communication test is disabled. 1: CAN0 inter-channel communication test is enabled.

Modify the RSCFDnGTSTCFG register only in global test mode.

48.7.13.2 RSCFDnGTSTCTR — Global Test Control Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGTSTCTR register can be read/written in 32-bit units

RSCFDnGTSTCTRL, RSCFDnGTSTCTRH registers can be read/written in 16-bit units

RSCFDnGTSTCTRLL, RSCFDnGTSTCTRLH, RSCFDnGTSTCTRHL, RSCFDnGTSTCTRHH registers can be read/written in 8-bit units

Address: RSCFDnGTSTCTR: <RSCFDn_base> + H'046C

RSCFDnGTSTCTRL: <RSCFDn_base> + H'046C, RSCFDnGTSTCTRH: <RSCFDn_base> + H'046E

RSCFDnGTSTCTRLL: <RSCFDn_base> + H'046C, RSCFDnGTSTCTRLH: <RSCFDn_base> + H'046D, RSCFDnGTSTCTRHL: <RSCFDn_base> + H'046E, RSCFDnGTSTCTRHH: <RSCFDn_base> + H'046F

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	RTME	—	ICBCTME
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	RTME	B'0	R/W	RAM Test Enable Setting this bit to 1 enables the RAM test. Modify this bit only in global test mode. 1. Set the GMDC[1:0] bits in the RSCFDnGCTR register to B'10 (Global test mode). 2. Set the RTME bit to 1. 3. Check that the RTME bit is set to 1. 0: RAM test is disabled. 1: RAM test is enabled.
1	Reserved	B'0	R	When read, the value after reset is returned. When writing to this bit, write the value after reset.
0	ICBCTME	B'0	R/W	Communication Test between Channels Enable When this bit is set to 1, a communication test is enabled between the channels for which the CmICBCE bit (m = 0 or 1) in the RSCFDnGTSTCFG register has been set to 1. Modify the ICBCTME bit only in global test mode. 0: Communication test between channels disabled 1: Communication test between channels enabled

48.7.13.3 RSCFDnGLOCKK — Global Lock Key Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnGLOCKK register can be written only in 32-bit units
RSCFDnGLOCKKL, RSCFDnGLOCKKH registers can be written only in 16-bit units

Address: RSCFDnGLOCKK: <RSCFDn_base> + H'047C
RSCFDnGLOCKKL: <RSCFDn_base> + H'047C, RSCFDnGLOCKKH: <RSCFDn_base> + H'047E

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LOCK[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*

Note: * Writing to these bits is effective only when the RS-CANFD module is in global test mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Reserved	All 0	R	When writing to these bits, write the value after reset.
15 to 0	LOCK[15:0]	H'0000	W*	Lock Key Writing the protection release data to the LOCK[15:0] bits in succession enables writing 1 to the RTME bit in the RSCFDnGTSTCTR register. After the protection has been released, writing to the I/O register area (<RSCFDn_base> + H'0000 to <RSCFDn_base> + H'04FF) of the CAN (except the RAM) enables the protection again. Reading from the I/O register area of the CAN or reading from/writing to other areas does not enable the protection.

The RSCFDnGLOCKK register releases protection of special test bits and is write only.

For the protection release data, see section 48.16.4.2, Procedure for Releasing the Protection.

48.7.13.4 RSCFDnRPGACCr — RAM Test Page Access Register (r = 0 to 63)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnRPGACCr register can be read/written in 32-bit units

RSCFDnRPGACCrL, RSCFDnRPGACCrH registers can be read/written in 16-bit units

RSCFDnRPGACCrLL, RSCFDnRPGACCrLH, RSCFDnRPGACCrHL, RSCFDnRPGACCrHH registers can be read/written in 8-bit units

Address: RSCFDnRPGACCr: <RSCFDn_base> + H'1900 + (H'04 × r)

RSCFDnRPGACCrL: <RSCFDn_base> + H'1900 + (H'04 × r),
RSCFDnRPGACCrH: <RSCFDn_base> + H'1902 + (H'04 × r)

RSCFDnRPGACCrLL: <RSCFDn_base> + H'1900 + (H'04 × r),
RSCFDnRPGACCrLH: <RSCFDn_base> + H'1901 + (H'04 × r),
RSCFDnRPGACCrHL: <RSCFDn_base> + H'1902 + (H'04 × r),
RSCFDnRPGACCrHH: <RSCFDn_base> + H'1903 + (H'04 × r)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RDTA[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDTA[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDTA[31:0]	H'0000_0000	R/W	RAM Data Test Access Data can be read and written in RSCAN RAM. These bits are read as 0. The write value should be 0.

Modify the RSCFDnRPGACCr register in global test mode with the RTME bit in the RSCFDnGTSTCTR register set to 1 (RAM test is enabled).

The RSCFDnRPGACCr register is readable and writable when the RTME bit is set to 1.

48.8 Registers Configuration (CAN FD mode)

This section describes all RS-CANFD registers used in CAN FD mode.

48.8.1 List of Registers

Table 48.16 lists the RS-CANFD registers used in CAN FD mode.

For details about <RSCFDn_base>, see section 48.5.1, Register Base Address.

48.9 Register Description (CAN FD mode)

48.9.1 Details of Interface Mode Related Registers

48.9.1.1 RSCFDnCFDGRMCFG — Global Interface Mode Select Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGRMCFG register can be read/written in 32-bit units

RSCFDnCFDGRMCFGL, RSCFDnCFDGRMCFGH registers can be read/written in 16-bit units

RSCFDnCFDGRMCFGLL, RSCFDnCFDGRMCFGLH, RSCFDnCFDGRMCFGHL, RSCFDnCFDGRMCFGHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGRMCFG: <RSCFDn_base> + H'04FC

RSCFDnCFDGRMCFGL: <RSCFDn_base> + H'04FC,
RSCFDnCFDGRMCFGH: <RSCFDn_base> + H'04FE

RSCFDnCFDGRMCFGLL: <RSCFDn_base> + H'04FC,
RSCFDnCFDGRMCFGLH: <RSCFDn_base> + H'04FD,
RSCFDnCFDGRMCFGHL: <RSCFDn_base> + H'04FE,
RSCFDnCFDGRMCFGHH: <RSCFDn_base> + H'04FF

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RCMC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
0	RCMC	B'0	R/W	Interface Mode Select Setting this bit to 1 places the CANFD into CAN FD mode. To place the RS-CANFD module from classical CAN mode to CAN FD mode, modify the RSCFDnCFDGRMCFG register after setting the post-reset values to all the registers and bits that are solely assigned to the register map used in classical CAN mode. 0: Classical CAN mode 1: CAN FD mode

Modify the RSCFDnCFDGRMCFG register only in global reset mode. Also set the register before setting any other RS-CANFD register.

48.9.2 Details of Channel Related Registers

48.9.2.1 RSCFDnCFDCmNCFG — Channel Normal Bit Rate Configuration Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDCmNCFG register can be read/written in 32-bit units

RSCFDnCFDCmNCFGL, RSCFDnCFDCmNCFGH registers can be read/written in 16-bit units

RSCFDnCFDCmNCFGLL, RSCFDnCFDCmNCFGLH, RSCFDnCFDCmNCFGHL, RSCFDnCFDCmNCFGHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmNCFG: <RSCFDn_base> + H'0000 + (H'10 × m)

RSCFDnCFDCmNCFGL: <RSCFDn_base> + H'0000 + (H'10 × m),
RSCFDnCFDCmNCFGH: <RSCFDn_base> + H'0002 + (H'10 × m)

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
28 to 24	NTSEG2[4:0]	B'0_0000	R/W	Normal Bit Rate Time Segment 2 Control These bits are used to specify a Tq value for the length of phase segment 2 (PHASE_SEG2) for normal bit rate. Allowed values are 2 Tq to 32 Tq, inclusive. Set a value smaller than the value of the NTSEG1[6:0] bits. B'0_0000: Setting prohibited B'0_0001: 2 Tq : : B'1_1110: 31 Tq B'1_1111: 32 Tq
23	Reserved	B'0	R	This bit is read as the value after reset. The write value should be the value after reset.

Bit	Bit Name	Initial Value	R/W	Description
22 to 16	NTSEG1[6:0]	B'000_0000	R/W	Normal Bit Rate Time Segment 1 Control These bits are used to specify a Tq value for the total length of the propagation segment (PROP_SEG) and phase segment 1 (PHASE_SEG1) for normal bit rate. Allowed values are 4 Tq to 128 Tq, inclusive. B'000_0000: Setting prohibited B'000_0001: Setting prohibited B'000_0010: Setting prohibited B'000_0011: 4 Tq : : B'111_1110: 127 Tq B'111_1111: 128 Tq
15 to 11	NSJW[4:0]	B'0_0000	R/W	Normal Bit Rate Resynchronization Jump Width Control These bits are used to specify a Tq value for the resynchronization jump width for normal bit rate. Allowed values are 1 Tq to 32 Tq, inclusive. Set a value less than or equal to the value of the NTSEG2[4:0] bits. B'0_0000: 1 Tq B'0_0001: 2 Tq B'0_0010: 3 Tq : : B'1_1110: 31 Tq B'1_1111: 32 Tq
10	Reserved	B'0	R	This bit is read as the value after reset. The write value should be the value after reset.
9 to 0	NBRP[9:0]	H'000	R/W	Normal Bit Rate Prescaler Division Ratio Set The CANmTq(N) clock (fCANTQ(N)m) is calculated by dividing the CAN clock (fCAN) by the normal bit rate prescaler, ((NBRP[9:0]) + 1). One clock cycle of the CANmTq(N) clock is 1 Time Quantum (Tq). When these bits are set to P (0 to 1023), the normal bit rate prescaler divides fCAN by P + 1.

Modify the RSCFDnCFDCmNCFG register in channel reset mode or channel halt mode. Set this register in channel reset mode before shifting to channel communication mode or channel wait mode. For a description of the bit timing parameters and settings, see section 48.16.1, Initial Settings.

48.9.2.2 RSCFDnCFDCmCTR — Channel Control Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDCmCTR register can be read/written in 32-bit units

RSCFDnCFDCmCTRL, RSCFDnCFDCmCTRH registers can be read/written in 16-bit units

RSCFDnCFDCmCTRLL, RSCFDnCFDCmCTRLH, RSCFDnCFDCmCTRHL, RSCFDnCFDCmCTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmCTR: <RSCFDn_base> + H'0004 + (H'10 × m)

RSCFDnCFDCmCTRL: <RSCFDn_base> + H'0004 + (H'10 × m),
RSCFDnCFDCmCTRH: <RSCFDn_base> + H'0006 + (H'10 × m)

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	ROM	B’0	R/W	Limited Operation Mode Enable This bit is used to enable the limited operation mode when the ROM and CTME bits in the RSCFDnCFDCmCTR register are set to 1. Use the limited operation mode only when the CTMS[1:0] bits in the SCFDnCFDCmCTR register are B'00 (standard test mode). Modify this bit only in channel halt mode. This bit is set to 0 in channel reset mode. 0: Limited operation mode is disabled. 1: Limited operation mode is enabled.

Bit	Bit Name	Initial Value	R/W	Description
30	CRCT	B’0	R/W	CRC Error Test Enable This bit is used to test the CRC generator circuit in the RS-CANFD module. Setting this bit to 1 allows the first bit in the ID field to be reversed when a message is received. Due to the bit reversal, the CRC calculation result does not agree with the correct CRC value of the received frame. A CRC error is thus detected (the CERR bit in the RSCFDnCFDCmERFL register is 1). Note the following when using this function: • This function is available when the CTME bit in the RSCFDnCFDCmCTR register is 1 (communication test mode enabled). • Communicating with another CAN node is impossible. Use the function in the inter-channel communication test (the CmICBCE bit in the RSCFDnCFDGTSTCFG register is 1). • Bit reversal in the ID field may violate the bit stuffing rule. In this case, a stuff error is detected instead of a CRC error. Modify this bit only in channel halt mode. This bit is set to 0 in channel reset mode. 0: The first bit in the receive ID field is not reversed. 1: The first bit in the receive ID field is reversed.
29 to 27	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
26, 25	CTMS[1:0]	B’00	R/W	Communication Test Mode Select These bits are used to select a communication test mode. Modify these bits only in channel halt mode. These bits are set to 0 in channel reset mode. B’00: Standard test mode B’01: Listen-only mode B’10: Self-test mode 0 (external loopback mode) B’11: Self-test mode 1 (internal loopback mode)
24	CTME	B’0	R/W	Communication Test Mode Enable Setting this bit to 1 enables communication test mode. Modify these bits in channel halt mode. This bit is set to 0 in channel reset mode. 0: Communication test mode is disabled. 1: Communication test mode is enabled.
23	ERRD	B’0	R/W	Error Display Mode Select This bit is used to control the display mode of bits 14 to 8 in the RSCFDnCFDCmERFL register. When this bit is clear to 0, only the flags of the first error event are set to 1. If two or more errors occur in the first error event, all the flags of the detected errors are set to 1. When this bit is set to 1, all the flags of errors that have occurred are set to 1 regardless of the error occurrence order. Modify this bit only in channel reset mode or channel halt mode. 0: Error flags are displayed only for the first error information after bits 14 to 8 in RSCFDnCFDCmERFL are all cleared. 1: Error flags for all error information are displayed.

Bit	Bit Name	Initial Value	R/W	Description
22, 21	BOM[1:0]	B’00	R/W	Bus Off Recovery Mode Select These bits are used to select the bus off recovery mode of the RS-CANFD module. When the BOM[1:0] bits are set to B'00, return from the bus off state to the error active state is compliant with the CAN specifications. That is, the RS-CANFD module reenters the CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. A bus off recovery interrupt request is generated at the time of return from the bus off state. Even if the CHMDC[1:0] bits are set to B'10 (channel halt mode) before recessive bits are detected 128 times, the RS-CANFD module does not transition to channel halt mode until recessive bits are detected 128 times. When the module reaches the bus off state when the BOM[1:0] bits are set to B'01, the CHMDC[1:0] bits in the RSCFDnCFDCmCTR register (m = 0 or 1) are set to B'10 and the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated and the TEC[7:0] and REC[7:0] bits in the RSCFDnCFDCmSTS register are cleared to H'00. When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to B'10, the CHMDC[1:0] bits are set to B'10 and the RS-CANFD module transitions to channel halt mode after return from the bus off state (11 consecutive recessive bits are detected 128 times). A bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to H'00. When the BOM[1:0] bits are set to B'11 and the CHMDC[1:0] bits are set to B'10 while the RS-CANFD module is in the bus off state, the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to H'00. However, if 11 consecutive recessive bits are detected 128 times and the RS-CANFD module has recovered to the error active state from the bus off state before the CHMDC[1:0] bits are set to B'10, a bus off recovery interrupt request is generated. If a program writes to the CHMDC[1:0] bit at the same time as the RS-CANFD module transition to channel halt mode (at bus off entry when the BOM[1:0] bits are B'01 or at bus off end when the BOM[1:0] bits are B'10), the program’s writing takes precedence. Modify the BOM[1:0] bits only in channel reset mode. B’00: ISO11898-1 compliant B’01: Entry to channel halt mode automatically at bus-off entry B’10: Entry to channel halt mode automatically at bus-off end B’11: Entry to channel halt mode (in bus-off state) by program request
20	Reserved	B’0	R	This bit is read as the value after reset. The write value should be the value after reset.
19	TDCVFIE	B’0	R/W	Transmit Delay Correction Violation Interrupt Enable When the TDCVF flag in the RSCFDnCFDCmFDSTS register is set to 1 with the TDCVFIE bit set to 1, an interrupt request is generated. Modify this bit only in channel reset mode. 0: Transmit delay correction violation interrupt is disabled. 1: Transmit delay correction violation interrupt is enabled.

Bit	Bit Name	Initial Value	R/W	Description
18	SOCOIE	B'0	R/W	Communication Success Occurrence Counter Overflow Interrupt Enable When the SOCO flag in the RSCFDnCFDCmFDSTS register is set to 1 with the SOCOIE bit set to 1, an interrupt request is generated. Modify this bit only in channel reset mode. 0: Communication success occurrence counter overflow interrupt is disabled. 1: Communication success occurrence counter overflow interrupt is enabled.
17	EOCOIE	B'0	R/W	Error Occurrence Counter Overflow Interrupt Enable When the EOCO flag in the RSCFDnCFDCmFDSTS register is set to 1 with the EOCOIE bit set to 1, an interrupt request is generated. Modify this bit only in channel reset mode. 0: Error occurrence counter overflow interrupt is disabled. 1: Error occurrence counter overflow interrupt is enabled.
16	TAIE	B'0	R/W	Transmit Abort Interrupt Enable When transmit abort of the transmit buffer is completed with the TAIE bit set to 1, an interrupt request is generated. Modify this bit only in channel reset mode. 0: Transmit abort interrupt is disabled. 1: Transmit abort interrupt is enabled.
15	ALIE	B'0	R/W	Arbitration Lost Interrupt Enable When the ALF flag in the RSCFDnCFDCmERFL register is set to 1 with the ALIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Arbitration lost interrupt is disabled. 1: Arbitration lost interrupt is enabled.
14	BLIE	B'0	R/W	Bus Lock Interrupt Enable When the BLF flag in the RSCFDnCFDCmERFL register is set to 1 with the BLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Bus lock interrupt is disabled. 1: Bus lock interrupt is enabled.
13	OLIE	B'0	R/W	Overload Frame Transmit Interrupt Enable When the OVLF flag in the RSCFDnCFDCmERFL register is set to 1 with the OLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Overload frame transmit interrupt is disabled. 1: Overload frame transmit interrupt is enabled.
12	BORIE	B'0	R/W	Bus Off Recovery Interrupt Enable When the BORF flag in the RSCFDnCFDCmERFL register is set to 1 with the BORIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Bus off recovery interrupt is disabled. 1: Bus off recovery interrupt is enabled.
11	BOEIE	B'0	R/W	Bus Off Entry Interrupt Enable When the BOEF flag in the RSCFDnCFDCmERFL register is set to 1 with the BOEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Bus off entry interrupt is disabled. 1: Bus off entry interrupt is enabled.

Bit	Bit Name	Initial Value	R/W	Description
10	EPIE	B’0	R/W	Error Passive Interrupt Enable When the EPF flag in the RSCFDnCFDCmERFL register is set to 1 with the EPIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Error passive interrupt is disabled. 1: Error passive interrupt is enabled.
9	EWIE	B’0	R/W	Error Warning Interrupt Enable When the EWF flag in the RSCFDnCFDCmERFL register is set to 1 with the EWIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Error warning interrupt is disabled. 1: Error warning interrupt is enabled.
8	BEIE	B’0	R/W	Bus Error Interrupt Enable When the BEF flag in the RSCFDnCFDCmERFL register is set to 1 with the BEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode. 0: Bus error interrupt is disabled. 1: Bus error interrupt is enabled.
7 to 4	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
3	RTBO	B’0	R/W	Forcible Return from Bus-off Setting this bit to 1 in the bus off state forcibly returns the state from the bus off state to the error active state. This bit is automatically cleared to 0. Setting this bit to 1 clears the TEC[7:0] and REC[7:0] bits in the RSCFDnCFDCmSTS register to H'00 and also clears the BOSTS flag in the RSCFDnCFDCmSTS register to 0 (not in bus off state). The other registers remain unchanged. No bus off recovery interrupt request is generated upon return from the bus off state in this case. Use this bit only when the BOM[1:0] bits in the RSCFDnCFDCmCTR are B'00 (ISO11898-1 compliant). A delay of up to 1 CAN bit time occurs after the RTBO bit is set to 1 until the RS-CANFD module transitions to the error active state. Set this bit to 1 in channel communication mode.
2	CSLPR	B’1	R/W	Channel Stop Mode Setting this bit to 1 places the channel into channel stop mode. Clearing this bit to 0 makes the channel exit channel stop mode. This bit should not be modified in channel communication mode or channel wait mode. 0: Other than channel stop mode 1: Channel stop mode
1, 0	CHMDC[1:0]	B’01	R/W	Mode Select These bits are used to select a channel mode (channel communication mode, channel reset mode, or channel halt mode). For details, see section 48.11.2, Channel Modes. Setting the CSLPR bit to 1 in channel reset mode allows transition to channel stop mode. Do not set the CHMDC[1:0] bits to B'11. When the RS-CANFD module has automatically transitioned to channel halt mode based on the setting of the BOM[1:0] bits, the CHMDC[1:0] bits automatically become B'10. B’00: Channel communication mode B’01: Channel reset mode B’10: Channel halt mode B’11: Setting prohibited

R/W:	R	R	R	R	R	R	R	R/W*	R	R	R	R	R	R	R	R

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	TEC[7:0]	H'00	R	The transmit error counter (TEC) can be read. These bits contain the transmit error counter value. For transmit error counter increment/decrement conditions, see the CAN specification (ISO11898-1). These bits are cleared to 0 in channel reset mode.
23 to 16	REC[7:0]	H'00	R	The receive error counter (REC) can be read. These bits contain the receive error counter value. For receive error counter increment/decrement conditions, see the CAN specifications (ISO11898-1). These bits are cleared to 0 in channel reset mode.
15 to 9	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.

Bit	Bit Name	Initial Value	R/W	Description
8	ESIF	B'0	R/W*	Error State Indicate Flag This flag becomes 1 when the recessive ESI bit has been detected in the message that has been normally received. In loopback mode or mirror mode, a message transmitted from the own CAN node is considered as a received message. To clear this flag to 0, the program must write 0 to the flag; this flag cannot be set to 1 by a program. If the timing when this flag becomes 1 and the program writes 0 to this flag is the same, the flag will become 1. This flag is cleared to 0 in channel reset mode. 0: No CAN FD message that the ESI bit is recessive has been received. 1: At least one CAN FD message that the ESI bit is recessive has been received.
7	COMSTS	B'0	R	Communication Status Flag This bit indicates that communication is ready. This flag becomes 1 when the RS-CANFD module has detected 11 consecutive recessive bits after it has transitioned from channel reset mode or channel halt mode to channel communication mode. This flag is cleared to 0 in channel reset mode or channel halt mode. 0: Communication is not ready. 1: Communication is ready.
6	RECSTS	B'0	R	Receive Status Flag This flag is set to 1 when reception has started, and is cleared to 0 when the bus has become idle or transmission has started. 0: Bus idle, in transmission or bus off state 1: In reception
5	TRMSTS	B'0	R	Transmit Status Flag This flag is set to 1 when transmission has started, and is cleared to 0 when the bus has become idle or reception has started. This flag remains 1 in the bus off state. 0: Bus idle or in reception 1: In transmission or bus off state
4	BOSTS	B'0	R	Bus Off Status Flag This flag is set to 1 when the bus off state (TEC[7:0] > 255) is entered. It is cleared to 0 when the RS-CANFD module has exited the bus off state. 0: Not in bus off state 1: In bus off state
3	EPSTS	B'0	R	Error Passive Status Flag This flag is set to 1 when the RS-CANFD module has entered the error passive state ((128 ≤ TEC[7:0] ≤ 255) or (128 ≤ REC[7:0])), It is cleared to 0 when the RS-CANFD module has exited the error passive state or has entered channel reset mode. 0: Not in error passive state 1: In error passive state
2	CSLPSTS	B'1	R	Channel Stop Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to channel stop mode, and is cleared to 0 when the RS-CANFD module has returned from channel stop mode. 0: Not in channel stop mode 1: In channel stop mode

Bit	Bit Name	Initial Value	R/W	Description
1	CHLTSTS	B'0	R	Channel Halt Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to channel halt mode, and is cleared to 0 when the RS-CANFD module has returned from channel halt mode. 0: Not in channel halt mode 1: In channel halt mode
0	CRSTSTS	B'1	R	Channel Reset Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to channel reset mode, and is cleared to 0 when the RS-CANFD module has transitioned to channel communication mode or channel halt mode. This flag remains 1 when the RS-CANFD module transitions from channel reset mode to channel stop mode. 0: Not in channel reset mode 1: In channel reset mode

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31	Reserved	B'0	R	When read, the value after reset is returned. When writing to this bit, write the value after reset.
30 to 16	CRCREG [14:0]	H'0000	R	CRC Calculation Data (15-bit CRC length) When the CTME bit in the RSCFDnCFDCmCTR register is set to 1 (communication test mode is enabled), if the transmit or receive message is in the classical CAN frame (15-bit CRC length), this flag is updated and the CRC value calculated based on the transmit or receive message can be read. When the CAN FD frame is transmitted or received, the CRCREG[20:0] bits in the RSCFDnCFDCmFDCRC register are updated. When the CTME bit is set to 0 (communication test mode is disabled), these bits are always read as 0.
15	Reserved	B'0	R	When read, the value after reset is returned. When writing to this bit, write the value after reset.
14	ADERR	B'0	R/W	ACK Delimiter Error Flag This flag is set to 1 when a form error has been detected in the ACK delimiter during transmission. 0: No ACK delimiter error is detected. 1: ACK delimiter error is detected.

Bit	Bit Name	Initial Value	R/W	Description
13	B0ERR	B'0	R/W	Dominant Bit Error Flag This flag is set to 1 when a recessive bit has been detected though a dominant bit was transmitted. 0: No dominant bit error is detected. 1: Dominant bit error is detected.
12	B1ERR	B'0	R/W	Recessive Bit Error Flag This flag is set to 1 when a dominant bit has been detected though a recessive bit was transmitted. 0: No recessive bit error is detected. 1: Recessive bit error is detected.
11	CERR	B'0	R/W	CRC Error Flag This flag is set to 1 when a CRC error has been detected. 0: No CRC error is detected. 1: CRC error is detected.
10	AERR	B'0	R/W	ACK Error Flag This flag is set to 1 when an ACK error has been detected. 0: No ACK error is detected. 1: ACK error is detected.
9	FERR	B'0	R/W	Form Error Flag This flag is set to 1 when a form error has been detected. 0: No form error is detected. 1: Form error is detected.
8	SERR	B'0	R/W	Stuff Error Flag This flag is set to 1 when a stuff error has been detected. 0: No stuff error is detected. 1: Stuff error is detected.
7	ALF	B'0	R/W	Arbitration-lost Flag This flag is set to 1 when an arbitration-lost has been detected. 0: No arbitration-lost is detected. 1: Arbitration-lost is detected.
6	BLF	B'0	R/W	Bus Lock Flag This flag is set to 1 when 32 consecutive dominant bits have been detected on the CAN bus in channel communication mode. After that, detection of a dominant lock is restarted when either of the following conditions is met. • A recessive bit is detected after the BLF bit has been cleared from 1 to 0. • The RS-CANFD module transitions to channel reset mode and returns to channel communication mode after the BLF bit has been cleared from 1 to 0. 0: No channel bus is detected. 1: Channel bus is detected.
5	OVLF	B'0	R/W	Overload Flag This flag is set to 1 when the overload frame transmit condition has been detected when performing reception or transmission. 0: No overload is detected. 1: Overload is detected.

Bit	Bit Name	Initial Value	R/W	Description
4	BORF	B’0	R/W	Bus Off Recovery Flag This flag is set to 1 when 11 consecutive recessive bits have been detected 128 times and the RS-CANFD module returns from the bus off state. However, this flag is not set to 1 if the RS-CANFD module returns from the bus off state in any of the following ways before 11 consecutive recessive bits are detected 128 times. • The CHMDC[1:0] bits in the RSCFDnCFDCmCTR register are set to B'01 (channel reset mode). • The RTBO bit in the RSCFDnCFDCmCTR register is set to 1 (forcible return from the bus off state is made). • The BOM[1:0] bits in the RSCFDnCFDCmCTR register are set to B'01 (transition to channel halt mode at bus off entry). • The CHMDC[1:0] bits in the RSCFDnCFDCmCTR register are set to B'10 (channel halt mode) before 11 consecutive recessive bits are detected 128 times with the BOM[1:0] bits set to B'11 (transition to channel halt mode upon a request from the program during bus off). 0: No bus off recovery is detected. 1: Bus off recovery is detected.
3	BOEF	B’0	R/W	Bus Off Entry Flag This flag is set to 1 when the bus off state is reached (TEC[7:0] value > 255). This flag is also set to 1 if the bus off state is reached when the BOM[1:0] bits in the RSCFDnCFDCmCTR register (m = 0 or 1) set to B'01 (transition to channel halt mode at bus off entry). 0: No bus off entry is detected. 1: Bus off entry is detected.
2	EPF	B’0	R/W	Error Passive Flag This flag becomes 1 when the error passive state is reached (REC[7:0] or TEC[7:0] value > 127).This flag becomes 1 only when the REC[7:0] or TEC[7:0] value first exceeds 127. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 127, this bit is not set to 1 until both REC[7:0] and TEC[7:0] values become 127 or less and then the REC[7:0] or TEC[7:0] value exceeds 127 again. 0: No error passive is detected. 1: Error passive is detected.
1	EWF	B’0	R/W	Error Warning Flag This flag is set to 1 only when the REC[7:0] or TEC[7:0] value first exceeds 95. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 95, this bit is not set to 1 until both REC[7:0] and TEC[7:0] values become 95 or less and then the REC[7:0] or TEC[7:0] value exceeds 95 again. 0: No error warning is detected. 1: Error warning is detected.
0	BEF	B’0	R/W	Bus Error Flag This flag is set to 1 when any one of the ADERR, B0ERR, B1ERR, CERR, AERR, FERR, and SERR flags in the RSCFDnCFDCmERFL register is set to 1. 0: No channel bus error is detected. 1: Channel bus error is detected.

Note: To clear the flag of this register to 0, use a store instruction to write “0” to the given flag and “1” to the other flags.

See the CAN specification (ISO11898-1) for a description of error occurrence conditions. To clear each flag of this register, the program must write a 0 to the corresponding bit. These flags cannot be set to 1 by the program. If any of these flags is set to 0 at the same time that the program writes 0 to the flag, the flag is still set to 1. The channel reset mode transition clears all of these flags to 0.

If the ERRD bit in the RSCFDnCFDCmCTR register is set to 0 (ie, only the flags for the first error event are displayed) and an error related to bits 14 to 8 of RSCFDnCFDCmERFL is detected, the flag bits are only set by the error event if bits 14 to 8 were all 0 at the when time the error occurred.

Allowed values are 1 Tq to 8 Tq, inclusive. Set a value less than or equal to the value of the DTSEG2[2:0] bits. B'000: 1 Tq B'001: 2 Tq B'010: 3 Tq B'011: 4 Tq B'100: 5 Tq B'101: 6 Tq B'110: 7 Tq B'111: 8 Tq
23	Reserved	B'0	R	This bit is read as the value after reset. The write value should be the value after reset.

Bit	Bit Name	Initial Value	R/W	Description
22 to 20	DTSEG2[2:0]	B'000	R/W	Data Bit Rate Time Segment 2 Control These bits are used to specify a Tq value for the length of phase segment 2 (PHASE_SEG2) for data bit rate. Allowed values are 2 Tq to 8 Tq, inclusive. Set a value smaller than the value of the DTSEG1[3:0] bits. B'000: Setting prohibited B'001: 2 Tq B'010: 3 Tq B'011: 4 Tq B'100: 5 Tq B'101: 6 Tq B'110: 7 Tq B'111: 8 Tq
19 to 16	DTSEG1[3:0]	B'0000	R/W	Data Bit Rate Time Segment 1 Control These bits are used to specify a Tq value for the total length of the propagation segment (PROP_SEG) and phase segment 1 (PHASE_SEG1) for data bit rate. Allowed values are 2 Tq to 16 Tq, inclusive. B'0000: Setting prohibited B'0001: 2 Tq B'0010: 3 Tq B'0011: 4 Tq B'0100: 5 Tq B'0101: 6 Tq B'0110: 7 Tq B'0111: 8 Tq B'1000: 9 Tq B'1001: 10 Tq B'1010: 11 Tq B'1011: 12 Tq B'1100: 13 Tq B'1101: 14 Tq B'1110: 15 Tq B'1111: 16 Tq
15 to 8	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
7 to 0	DBRP[7:0]	H'00	R/W	Data Bit Rate Prescaler Division Ratio Set The CANmTq(D) clock (fCANTQ(D)m) is calculated by dividing the CAN clock (fCAN) by the data bit rate prescaler, ((DBRP[7:0]) + 1). One clock cycle of the CANmTq(D) clock is 1 Time Quantum (Tq).

Modify the RSCFDnCFDCmDCFG register in channel reset mode or channel halt mode. Set this register in channel reset mode before shifting to channel communication mode or channel halt mode. If the classical CAN frame is only used, set the same value to the RSCFDnCFDCmDCFG register as the set value in the RSCFDnCFDCmNCFG register. For a description of the bit timing parameters and settings, see section 48.16.1, Initial Settings.

R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
27	TMME	B'0	R/W	Transmit Buffer Merge Mode Enable When this bit is set to 1, a transmit buffer merge mode is enabled. Modify this bit only in channel reset mode or channel halt mode. 0: The transmit buffer merge mode is disabled. 1: The transmit buffer merge mode is enabled.
26	GWBRS	B'0	R/W	Gateway BRS Set This bit is used to set the BRS bit in the CAN FD frame which is transmitted by the gateway function when the GWEN bit is 1. Write 0 to this bit when the GWFDF bit is cleared to 0. Modify this bit only in channel reset mode. 0: The BRS bit in the receive frame is cleared to 0 and transmitted. 1: The BRS bit in the receive frame is set to 1 and transmitted.
25	GWFDF	B'0	R/W	Gateway FDF Set This bit is used to set the FDF bit in the CAN FD frame which is transmitted by the gateway function when the GWEN bit is 1. Modify this bit only in channel reset mode. 0: The receive frame is transmitted as the classical CAN frame. 1: The receive frame is transmitted as the CAN FD frame.

Bit	Bit Name	Initial Value	R/W	Description
24	GWEN	B’0	R/W	CAN-CAN FD Gateway Enable This bit is used to control operation of the transmit/receive FIFO buffer that the CFM[1:0] bits in the RSCFDnCFDCFCCk register are set to B'10 (gateway mode). Setting this bit to 1 enables the CAN-CAN FD gateway and transmission by the format which is different from that received by the gateway function. The receive frame is replaced according to the settings of GWFDF and GWBRS bits. When the DLC value of the received classical CAN frame is equal to or larger than B'1001 and the GWFDF bit is 1 (CAN FD frame), the DLC value is replaced with B'1000. When this bit is 1, do not route the following frames by the gateway function. • CAN FD frame of which payload length is longer than 8 bytes • Remote frame Modify this bit only in channel reset mode. Table 48.21 shows the format and setting of the transmit/receive frame when the CAN-CAN FD gateway is enabled. 0: The CAN-CAN FD gateway is disabled. 1: The CAN-CAN FD gateway is enabled.
23	Reserved	B’0	R	This bit is read as the value after reset. The write value should be the value after reset.
22 to 16	TDCO[6:0]	H'00	R/W	Transmit Delay Correction Offset Set These bits are used to set the SSP offset value. The usage of the value depends on the TDCOC bit in the RSCFDnCFDCmFDCFG register. When the TDCOC bit is 0, the result of transmit delay correction is equal to the sum of the values of the measured delay and the TDCO[6:0] bits (it is rounded down to Tq which is the approximate integer). When the TDCOC bit is 1, the result of transmit delay correction is equal to the value of the TDCO[6:0] bits. The SSP offset value is the set value of TDCO[6:0] bits + 1. Modify these bits only in channel reset mode or channel halt mode.
15 to 11	Reserved	All 0	R	This bit is read as the value after reset. The write value should be the value after reset.
10	ESIC	B’0	R/W	Error State Indicate Mode Select When this bit is set to 1 and a channel is error-active, the ESI bit value that has been set in the transmit/receive FIFO buffer or the transmit buffer (the CFESI bit in the RSCFDnCFDCFFDCSTSk register or the TMESI bit in the RSCFDnCFDTMFDCTRp register) is transmitted as the ESI bit value in the transmit message. When a channel is error-passive or the ESIC bit is 0, the channel status is transmitted as the ESI bit value. Modify this bit only in channel reset mode or channel halt mode. See Table 48.22. 0: The error state of a channel is always transmitted as the ESI bit for the frame. 1: When a channel is not error-passive, the error state of the message buffer is transmitted as the ESI bit for the frame. When a channel is error-passive, the error state of the channel is transmitted as the ESI bit for the frame.

Bit	Bit Name	Initial Value	R/W	Description
9	TDCE	B’0	R/W	Transmit Delay Correction Enable When this bit is set to 1, transmit delay correction is enabled. Modify this bit only in channel reset mode or channel halt mode. 0: Transmit delay correction is disabled. 1: Transmit delay correction is enabled.
8	TDCOC	B’0	R/W	Transmit Delay Correction Measurement Select When this bit is cleared to 0, the SSP position is defined by the sum of the measured delay and the SSP offset value (fixed value). When this bit is set to 1, the SSP position is only defined by the SSP offset value. Modify this bit only in channel reset mode or channel halt mode. 0: Measurement and offset 1: Offset only
7 to 3	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
2 to 0	EOCCFG[2:0]	B’000	R/W	Error Occurrence Count Method Select These bits are used to select the frame format and transmit/receive direction when a CAN bus error is counted by an error occurrence counter. Modify these bits only in channel reset mode or channel halt mode. B’000: All transmit and receive messages B’001: All transmit messages B’010: All receive messages B’011: Setting prohibited B’100: Only the data phase of the transmitted or received CAN FD message B’101: Only the data phase of the transmitted CAN FD message B’110: Only the data phase of the received CAN FD message B’111: Setting prohibited

Table 48.21 Operation when the CAN-CAN FD Gateway is Enabled

Receive Frame				Transmit Frame		
Format	**BRS Bit**	**Receive DLC Value**	**GWFDF Bit**	**Format**	**BRS Bit**	**Transmit DLC Value**
Classical CAN	None	DLC ≤ “B'1000”	B’0	Classical CAN	None	Not replaced
		DLC > “B'1000”				
CAN FD	Optional	DLC ≤ “B'1000”				
Classical CAN	None	DLC ≤ “B'1000”	B’1	CAN FD	Depends on the setting of the GWBRS bit	Not replaced
		DLC > “B'1000”				Replaced with B'1000
CAN FD	Optional	DLC ≤ “B'1000”				Not replaced

Table 48.22 Transmit ESI Value

ESIC Bit	Channel Status	Transmit ESI Value
B'0	Error-active	0 (A node is error-active.)
	Error-passive	1 (A node is error-passive.)
B'1	Error-active	The ESI bit value that has been set in the transmit/receive FIFO buffer or the transmit buffer (the CFESI bit in the RSCFDnCFDCFFDCSTSk register or the TMESI bit in the RSCFDnCFDTMFDCTRp register)
	Error-passive	1 (A node is error-passive.)

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	SOC[7:0]	H'00	R	Communication Success Occurrence Counter These bits indicate a value of the communication success occurrence counter. This counter is incremented when reception or transmission of a message completed without any errors. When this counter reaches H'FF, updating is stopped. In loopback mode, this counter is incremented twice. These bits are cleared to 0 when 1 is written to the SOCCLR bit in the RSCFDnCFDCmCTR register. In channel reset mode, these bits are cleared to 0.
23 to 16	EOC[7:0]	H'00	R	Error Occurrence Counter These bits indicate a value of the error occurrence counter. This counter is incremented when an error occurs according to the condition that has been set for the EOCCFG[2:0] bits in the RSCFDnCFDCmFDCFG register. When this counter reaches H'FF, updating is stopped. These bits are cleared to 0 when 1 is written to the EOCCLR bit in the RSCFDnCFDCmCTR register. In channel reset mode, these bits are cleared to 0.
15 to 10	Reserved	All 0	R	These bits are read as the value after reset.

Bit	Bit Name	Initial Value	R/W	Description
9	SOCO	B'0	R/W	Communication Success Occurrence Counter Overflow Flag This bit indicates that an overflow was generated in the communication success occurrence counter. When the SOC[7:0] bits reached H'FF and reception or transmission of a message completed, this bit is set to 1. In channel reset mode, this bit is cleared to 0. 0: An overflow is not generated in the communication success occurrence counter. 1: An overflow is generated in the communication success occurrence counter.
8	EOCO	B'0	R/W	Error Occurrence Counter Overflow Flag This bit indicates that an overflow was generated in the error occurrence counter. When the SOC[7:0] bits reached H'FF and a CAN bus error was detected under the condition that has been set for the EOCCFG[2:0] bits in the RSCFDnCFDCmFDCFG register, this bit is set to 1. In channel reset mode, this bit is cleared to 0. 0: An overflow is not generated in the error occurrence counter. 1: An overflow is generated in the error occurrence counter.
7	TDCVF	B'0	R/W	Transmit Delay Correction Violation Flag This bit indicates violation of transmit delay correction. The transmit data is compared to the receive CAN bus level that has been delayed due to the loop delay of a transceiver. This delay changes depending on the physical factor such as a temperature. Since the TDCR[6:0] flags are updated in each message, the temporary maximum delay cannot be checked. This bit is set to 1 when the maximum transmit delay correction exceeds 3-CANm bit time – 2 Tq (the CANm bit time and Tq are values of the data bit rate). In channel reset mode, this bit is cleared to 0. 0: Transmit delay correction violation does not occur. 1: Transmit delay correction violation occurs.
6 to 0	TDCR[6:0]	H'00	R	Transmit Delay Correction Result Status These bits indicate the transmit delay correction result with a multiple of the CAN clock (fCAN). The result depends on the setting of the TDCOC and TDCO[6:0] bits in the CFDCmFDCFG register. In channel reset mode, these bits are cleared to 0.

48.9.2.9 RSCFDnCFDCmFDCRC — Channel CAN FD CRC Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDCmFDCRC register can be read only in 32-bit units

RSCFDnCFDCmFDCRCL, RSCFDnCFDCmFDCRCH registers can be read only in 16-bit units

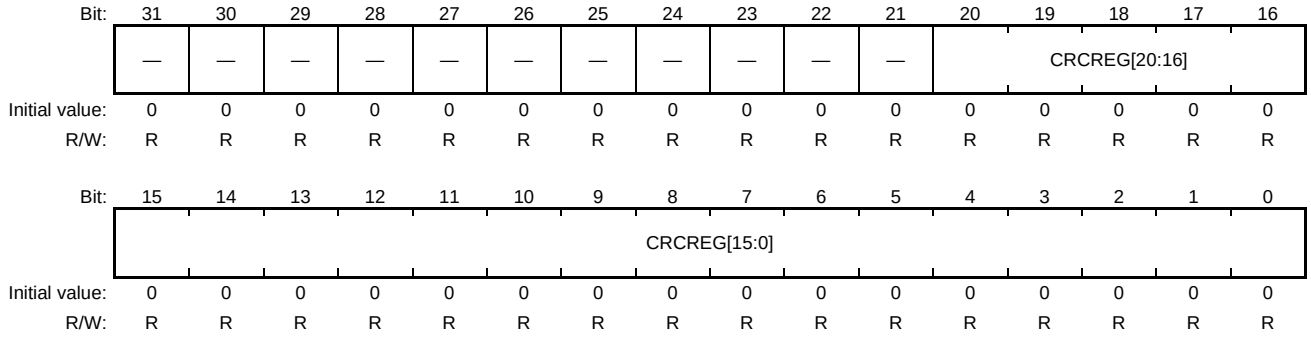
RSCFDnCFDCmFDCRCLL, RSCFDnCFDCmFDCRCLH, RSCFDnCFDCmFDCRCHL, RSCFDnCFDCmFDCRCHH registers can be read only in 8-bit units

Address: RSCFDnCFDCmFDCRC: <RSCFDn_base> + H'0510 + (H'20 × m)

RSCFDnCFDCmFDCRCL: <RSCFDn_base> + H'0510 + (H'20 × m),
RSCFDnCFDCmFDCRCH: <RSCFDn_base> + H'0512 + (H'20 × m)

RSCFDnCFDCmFDCRCLL: <RSCFDn_base> + H'0510 + (H'20 × m),
RSCFDnCFDCmFDCRCLH: <RSCFDn_base> + H'0511 + (H'20 × m),
RSCFDnCFDCmFDCRCHL: <RSCFDn_base> + H'0512 + (H'20 × m),
RSCFDnCFDCmFDCRCHH: <RSCFDn_base> + H'0513 + (H'20 × m)

Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31 to 21	Reserved	All 0	R	Reserved These bits are read as 0. The write value should be 0.
20 to 0	CRCREG [20:0]	H'00_0000	R	CRC Calculation Data (17-bit or 21-bit CRC length) When the CTME bit in the RSCFDnCFDCmCTR register is set to 1 (communication test mode is enabled), if the transmit or receive message is in the CAN FD frame (17-bit or 21-bit CRC length), these flags are updated and the CRC value calculated based on the transmit or receive message can be read. When the message has the 17-bit CRC length, bits 20 to 17 are always read as 0. When the classical CAN frame is transmitted or received, the CRCREG[14:0] bits in the RSCFDnCFDCmERFL register are updated. When the CTME bit is cleared to 0 (communication test mode is disabled), these bits are always read as 0.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	ITRCP[15:0]	H'0000	R/W	Interval Timer Prescaler Set These bits are used to set a clock source division value of the interval timer for FIFO buffers. See section 48.13.3.1, Interval Transmission Function. When these bits are set to M, the pclk is divided by M. Setting H'0000 is prohibited when the interval timer is in use.
15 to 13	TSBTCS[2:0]	B'000	R/W	Timestamp Clock Source Select When the TSSS bit is 1, these bits are used to select the channel of the normal bit time clock that will be the clock source of the timestamp counter. However, do not select the channel which handles the CAN FD frame. B'000: Channel 0 bit time clock B'001: Channel 1 bit time clock B'010: Setting prohibited B'011: Setting prohibited B'100: Setting prohibited B'101: Setting prohibited B'110: Setting prohibited B'111: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
12	TSSS	B’0	R/W	Timestamp Source Select This bit is used to select a clock source of the timestamp counter. If there is no channel which handles the classical CAN frame only, select pclk. 0: pclk/2*1 1: Normal bit time clock
11 to 8	TSP[3:0]	B’0000	R/W	Timestamp Clock Source Division A clock obtained by dividing the clock source selected with the TSBTCS[2:0] bits and TSSS bit according to the TSP[3:0] bits is used as the timestamp counter count source. B’0000: Not divided B’0001: Divided by 2 B’0010: Divided by 4 B’0011: Divided by 8 B’0100: Divided by 16 B’0101: Divided by 32 B’0110: Divided by 64 B’0111: Divided by 128 B’1000: Divided by 256 B’1001: Divided by 512 B’1010: Divided by 1024 B’1011: Divided by 2048 B’1100: Divided by 4096 B’1101: Divided by 8192 B’1110: Divided by 16384 B’1111: Divided by 32768
7, 6	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
5	CMPOC	B’0	R/W	Payload Overflow Mode Select This bit is used to select the operation when the payload length of the received message exceeds the size for storing the payload in the storage buffer. When this bit is 0, the received message that the payload overflows is not stored in the buffer. When this bit is 1, the received message that the payload overflows is stored in the buffer. The payload which exceeds the size for storing the payload in the buffer is truncated. The size for storing the payload in the buffer is specified with the following bits. • Receive buffer: RMPLS[1:0] bits in the RSCFDnCFDRMNB register • Receive FIFO buffer: RFPLS[2:0] bits in the RSCFDnCFDRFCCx register • Transmit/receive FIFO buffer: CFPLS[2:0] bits in the RSCFDnCFDCFCCk register 0: Messages are not stored. 1: Messages are stored and the payload which exceeds the buffer size is truncated.

Bit	Bit Name	Initial Value	R/W	Description
4	DCS	B'0	R/W	CAN Clock Source Select*2 When this bit is set to 0, clkc is used as the clock source of the CAN clock (fCAN). When this bit is set to 1, clk_xincan is used as the clock source of the CAN clock (fCAN). For the CAN clock frequency settings, see section 48.16.1.3, Setting Communication Speed. 0: clkc 1: clk_xincan
3	MME	B'0	R/W	Mirror Function Enable Setting this bit to 1 makes the mirror function available. 0: Mirror function is disabled. 1: Mirror function is enabled.
2	DRE	B'0	R/W	DLC Replacement Enable When the DRE bit is set to 1, the DLC value of the receive rule is stored in the buffer instead of the DLC value of the received message after the DLC value has passed through the DLC filter. In this case, a value of H'00 is stored in each data byte beyond the DLC value of the receive rule. The DLC replacement function is only available when the DCE bit is set to 1 (DLC check is enabled). 0: DLC replacement is disabled. 1: DLC replacement is enabled.
1	DCE	B'0	R/W	DLC Check Enable Setting this bit to 1 makes the DLC check function available. When disabling the DLC check function, set the GAFLDLC[3:0] bits in the RSCFDnCFDGAFLP0_j register to B'0000 before clearing the DCE bit in the RSCFDnCFDGCFG register to 0. 0: DLC check is disabled. 1: DLC check is enabled.
0	TPRI	B'0	R/W	Transmit Priority Select This bit is used to set the transmit priority. When this bit is set to 0, ID priority is selected and the transmit priority complies with the CAN bus arbitration rule (ISO11898-1 specifications). When this bit is set to 1, transmit buffer number priority is selected and the lowest transmit buffer number of those has the highest priority. While the transmit queue is in use, this bit should be set to 0. 0: ID priority 1: Transmit buffer number priority

Notes: 1. When specifying pclk/2 as the timestamp counter count source, set bits TSBTCS[2:0] to B'000.
2. For the CAN clock frequency settings, see section 48.16.1.3, Setting Communication Speed.

Modify the RSCFDnCFDGCFG register only in global reset mode.

48.9.3.2 RSCFDnCFDGCTR — Global Control Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGCTR register can be read/written in 32-bit units

RSCFDnCFDGCTRL, RSCFDnCFDGCTRH registers can be read/written in 16-bit units

RSCFDnCFDGCTRLL, RSCFDnCFDGCTRLH, RSCFDnCFDGCTRHL, RSCFDnCFDGCTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGCTR: <RSCFDn_base> + H'0088

RSCFDnCFDGCTRL: <RSCFDn_base> + H'0088, RSCFDnCFDGCTRH: <RSCFDn_base> + H'008A

RSCFDnCFDGCTRLL: <RSCFDn_base> + H'0088, RSCFDnCFDGCTRLH: <RSCFDn_base> + H'0089, RSCFDnCFDGCTRHL: <RSCFDn_base> + H'008A, RSCFDnCFDGCTRHH: <RSCFDn_base> + H'008B

Value after reset: H'0000_0005

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CMPOFIE	THLEIE	MEIE	DEIE	—	—	—	—	—	GSLPR	GMDC[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
16	TSRST	B'0	R/W	Timestamp Counter Reset This bit is used to reset the timestamp counter. When this bit is set to 1, the RSCFDnCFDGTSC register is cleared to H'0000. This bit is always read as 0.
15 to 12	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
11	CMPOFIE	B'0	R/W	Payload Overflow Interrupt Enable When the CMPOFIE bit is set to 1 and the CMPOF flag in the RSCFDnCFDGERFL register becomes 1, an interrupt request is generated. Modify this bit only in global reset mode. 0: Payload overflow interrupt is disabled. 1: Payload overflow interrupt is enabled.
10	THLEIE	B'0	R/W	Transmit History Buffer Overflow Interrupt Enable When the THLEIE bit is set to 1 and the THLES flag in the RSCFDnCFDGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode. 0: Transmit history buffer overflow interrupt is disabled. 1: Transmit history buffer overflow interrupt is enabled.

Bit	Bit Name	Initial Value	R/W	Description
9	MEIE	B'0	R/W	FIFO Message Lost Interrupt Enable When the MEIE bit is set to 1 and the MES flag in the RSCFDnCFDGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode. 0: FIFO message lost interrupt is disabled. 1: FIFO message lost interrupt is enabled.
8	DEIE	B'0	R/W	DLC Error Interrupt Enable When the DEIE bit is set to 1 and the DEF flag in the RSCFDnCFDGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode. 0: DLC error interrupt is disabled. 1: DLC error interrupt is enabled.
7 to 3	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	GSLPR	B'1	R/W	Global Stop Mode Setting this bit to 1 places the RS-CANFD module into global stop mode. Clearing this bit to 0 makes the RS-CANFD module leave from global stop mode. This bit should not be modified in global operating mode or global test mode. 0: Not in global stop mode 1: In global stop mode
1, 0	GMDC[1:0]	B'01	R/W	Global Mode Select These bits are used to select the mode of entire RS-CANFD module (global operating mode, global reset mode, or global test mode). For details, see section 48.11.1, Global Modes. Setting the GSLPR bit to 1 when in global reset mode places the RS-CANFD module into global stop mode. B'00: Global operating mode B'01: Global reset mode B'10: Global test mode B'11: Setting prohibited

48.9.3.3 RSCFDnCFDGSTS — Global Status Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGSTS register can be read only in 32-bit units

RSCFDnCFDGSTSL, RSCFDnCFDGSTSH registers can be read only in 16-bit units

RSCFDnCFDGSTSLL, RSCFDnCFDGSTSLH, RSCFDnCFDGSTSHL, RSCFDnCFDGSTSHH registers can be read only in 8-bit units

Address: RSCFDnCFDGSTS: <RSCFDn_base> + H'008C

RSCFDnCFDGSTSL: <RSCFDn_base> + H'008C, RSCFDnCFDGSTSH: <RSCFDn_base> + H'008E

RSCFDnCFDGSTSLL: <RSCFDn_base> + H'008C, RSCFDnCFDGSTSLH: <RSCFDn_base> + H'008D, RSCFDnCFDGSTSHL: <RSCFDn_base> + H'008E, RSCFDnCFDGSTSHH: <RSCFDn_base> + H'008F

Value after reset: H'0000_000D

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	Reserved	All 0	R	When read, the value after reset is returned.
3	GRAMINIT	B’1	R	CAN RAM Initialization Status Flag This flag indicates the initialization status of the CAN RAM. This flag is set to 1 after the MCU has been reset, and is cleared to 0 when CAN RAM initialization is completed. 0: CAN RAM initialization is completed. 1: CAN RAM initialization is ongoing.
2	GSLPSTS	B’1	R	Global Stop Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to global stop mode, and is cleared to 0 when the RS-CANFD module has returned from global stop mode. 0: Not in global stop mode 1: In global stop mode
1	GHLTSTS	B’0	R	Global Test Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to global test mode, and is cleared to 0 when the RS-CANFD module has exited global test mode. 0: Not in global test mode 1: In global test mode

Bit	Bit Name	Initial Value	R/W	Description
0	GRSTSTS	B'1	R	Global Reset Status Flag This flag is set to 1 when the RS-CANFD module has transitioned to global reset mode, and is cleared to 0 when the RS-CANFD module has exited global reset mode. This flag remains 1 even when the RS-CANFD module has transitioned from global reset mode to global stop mode. 0: Not in global reset mode 1: In global reset mode

48.9.3.4 RSCFDnCFDGERFL — Global Error Flag Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGERFL register can be read/written in 32-bit units

RSCFDnCFDGERFLL, RSCFDnCFDGERFLH registers can be read/written in 16-bit units

RSCFDnCFDGERFLLL, RSCFDnCFDGERFLLH, RSCFDnCFDGERFLHL, RSCFDnCFDGERFLHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGERFL: <RSCFDn_base> + H'0090

RSCFDnCFDGERFLL: <RSCFDn_base> + H'0090, RSCFDnCFDGERFLH: <RSCFDn_base> + H'0092

RSCFDnCFDGERFLLL: <RSCFDn_base> + H'0090, RSCFDnCFDGERFLLH: <RSCFDn_base> + H'0091, RSCFDnCFDGERFLHL: <RSCFDn_base> + H'0092, RSCFDnCFDGERFLHH: <RSCFDn_base> + H'0093

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EEF1	EEF0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*	R/W*

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CMPOF	THLES	MES	DEF
Initial value:	0	0	—	—	—	—	—	—	0	0	—	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W*	R	R	R/W*

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
17	EEF1	B'0	R/W	ECC Error Flag for Channel 1 The EEF1 flag is set to 1 disabling message transmission if an ECC2 bit error is detected in transmit priority selection of channel 1. To clear this flag to 0, the program must write 0 to the flag. 0: No 2-bit ECC error has occurred in transmit priority selection. 1: A 2-bit ECC error has occurred in transmit priority selection.
16	EEF0	B'0	R/W	ECC Error Flag for Channel 0 The EEF0 flag is set to 1 disabling message transmission if an ECC2 bit error is detected in transmit priority selection of channel 0. To clear this flag to 0, the program must write 0 to the flag. 0: No 2-bit ECC error has occurred in transmit priority selection. 1: A 2-bit ECC error has occurred in transmit priority selection.
15, 14	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
13 to 8	Reserved	Undefined	R	When read, an undefined value is returned. When writing to these bits, write the value after reset.
7, 6	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
5	Reserved	Undefined	R	When read, an undefined value is returned. When writing to this bit, write the value after reset.

Bit	Bit Name	Initial Value	R/W	Description
4	Reserved	B'0	R	When read, the value after reset is returned. When writing to this bit, write the value after reset.
3	CMPOF	B'0	R/W	Payload Overflow Flag If a payload overflow occurs in channel m (m = 0 or 1), the CMPOF flag is set to 1. To clear this flag to 0, the program must write 0 to the flag. 0: No payload overflow occurs. 1: A payload overflow occurs.
2	THLES	B'0	R	Transmit History Buffer Overflow Status Flag The THLES flag is set to 1 when any one of the THLELT flags in the RSCFDnCFDTHLSTSm register (m = 0, 1) is set to 1. This flag is cleared to 0 when the THLELT flags of all channels are set to 0. 0: No transmit history buffer overflow has occurred. 1: A transmit history buffer overflow has occurred.
1	MES	B'0	R	FIFO Message Lost Status Flag The MES flag is set to 1 when any one of the RFMLT flags in the RSCFDnCFDRFSTSx register (x = 0 to 7) or the CFMLT flags in the RSCFDnCFDCFSTSk register (k = 0 to 5) is set to 1. This flag is cleared to 0 when all RFMLT flags and CFMLT flags are set to 0. 0: No FIFO message lost error has occurred. 1: A FIFO message lost error has occurred.
0	DEF	B'0	R/W	DLC Error Flag The DEF flag is set to 1 when an error has been detected during the DLC check. The program can clear this flag by writing 0 to this bit. 0: No DLC error has occurred. 1: A DLC error has occurred.

Note: To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1".

All flags in the RSCFDnCFDGERFL register are cleared to 0 in global reset mode.

48.9.3.5 RSCFDnCFDGTSC — Global Timestamp Counter Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGTSC register can be read only in 32-bit units

RSCFDnCFDGTSCL, RSCFDnCFDGTSCH registers can be read only in 16-bit units

Address: RSCFDnCFDGTSC: <RSCFDn_base> + H'0094

RSCFDnCFDGTSCL: <RSCFDn_base> + H'0094, RSCFDnCFDGTSCH: <RSCFDn_base> + H'0096

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Reserved	All 0	R	These bits are read as the value after reset.
15 to 0	TS[15:0]	H'0000	R	Timestamp Value The timestamp counter value can be read. Counter Value: H'0000 to H'FFFF When the TS[15:0] bits are read, the read value shows the timestamp counter (16-bit free-running counter) value at that time. When the SOF is detected, the TS[15:0] value is captured and later stored in the receive buffer or the FIFO buffer. When the TMTSCE bit in the RSCFDnGCFG register is 1, the TS[15:0] value is stored in the transmit history buffer. The timestamp counter is initialized in global reset mode. The timestamp counter starts and stops counting differently, depending on the count source. • When the TSSS bit in the RSCFDnCFDGCFG register is 0 (pclk): The timestamp counter starts counting when the RS-CANFD module has transitioned to global operating mode. This counter stops counting when the RS-CANFD module has transitioned to global stop mode or global test mode. • When the TSSS bit is 1 (CANm normal bit time clock): The timestamp counter starts counting when the corresponding channel has transitioned to channel communication mode. This counter stops counting when the corresponding channel has transitioned to channel reset mode or channel halt mode.

48.9.3.6 RSCFDnCFDGTINTSTS0 — Global TX Interrupt Status Register 0

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGTINTSTS0 register can be read only in 32-bit units

RSCFDnCFDGTINTSTS0L, RSCFDnCFDGTINTSTS0H registers can be read only in 16-bit units

RSCFDnCFDGTINTSTS0LL, RSCFDnCFDGTINTSTS0LH, RSCFDnCFDGTINTSTS0HL, RSCFDnCFDGTINTSTS0HH registers can be read only in 8-bit units

Address: RSCFDnCFDGTINTSTS0: <RSCFDn_base> + H'0460

RSCFDnCFDGTINTSTS0L: <RSCFDn_base> + H'0460,
RSCFDnCFDGTINTSTS0H: <RSCFDn_base> + H'0462

R/W:	R	R	R	R*	R*	R*	R*	R*	R	R	R	R*	R*	R*	R*	R*

Note: * This bit is automatically cleared in the global reset or channel reset mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	Reserved	All 0	R	These bits are read as the value after reset.
12	THIF1	B'0	R	Channel 1 Transmit History Interrupt Status Flag When the THLIE bit in the RSCFDnCFDTHLCCm register is set to 1 (transmit history interrupt enabled) and the THLIF bit in the RSCFDnCFDTHLSTSm register is set to 1 (transmit history interrupt request), this bit is set to 1. When the THLIF bit in the RSCFDnCFDTHLSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the THLIE bit is cleared to 0. 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
11	CFTIF1	B'0	R	Channel 1 Transmit/receive FIFO Transmit Interrupt Status Flag When the CFTXIE bit in the RSCFDnCFDCFCCk register is set to 1 (transmit/receive FIFO transmit interrupt enabled) and the CFTXIF bit in the RSCFDnCFDCFSTSk register is set to 1 (transmit/receive FIFO transmit interrupt request), this bit is set to 1. When the CFTXIF bit is cleared to 0 under the conditions that this bit can be set to 1, this bit is cleared to 0. This flag is also cleared to 0 when the CFTXIE bit is cleared to 0. 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.

Bit	Bit Name	Initial Value	R/W	Description
10	TQIF1	B'0	R	Channel 1 Transmit Queue Interrupt Status Flag When the TXQIE bit in the RSCFDnTXQCCm register is set to 1 (transmit queue interrupt enabled) and the TXQIF bit in the RSCFDnCFDTXQSTSm register is set to 1 (transmit queue interrupt request), this bit is set to 1. When the TXQIF bit (transmit queue interrupt request) in the RSCFDnCFDTXQSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the TXQIE bit is cleared to 0. 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
9	TAIF1	B'0	R	Channel 1 Transmit Buffer Abort Interrupt Status Flag This bit is set to 1 when the TAIE bit in the RSCFDnCFDCmCTR register is 1 (transmit abort interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnCFDTMSTSp register are set to B'01 (transmit abort completed). This flag is cleared to 0 when the TMTRF[1:0] flags are cleared to B'00 after the transmit abort is completed. 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.
8	TSIF1	B'0	R	Channel 1 Transmit Buffer Interrupt Status Flag This bit is set to 1 when the TMIEp bit in the RSCFDnCFDTMIECy register is set to 1 (transmit buffer interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnCFDTMSTSp register are set to B'10 (transmit completed without abort request) or B'11 (transmit completed with abort request). When the TMTRF[1:0] flags are cleared to B'00 under the condition that this bit can be set to 1, this flag is cleared to 0. In addition, clearing the TMIEp bit to 0 also clears this flag to 0. 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.
7 to 5	Reserved	All 0	R	These bits are read as the value after reset.
4	THIF0	B'0	R	Channel 0 Transmit History Interrupt Status Flag When the THLIE bit in the RSCFDnCFDTHLCCm register is set to 1 (transmit history interrupt enabled) and the THLIF bit in the RSCFDnCFDTHLSTSm register is set to 1 (transmit history interrupt request), this bit is set to 1. When the THLIF bit in the RSCFDnCFDTHLSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the THLIE bit is cleared to 0. 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
3	CFTIF0	B'0	R	Channel 0 Transmit/receive FIFO Transmit Interrupt Status Flag When the CFTXIE bit in the RSCFDnCFDCFCCk register is set to 1 (transmit/receive FIFO transmit interrupt enabled) and the CFTXIF bit in the RSCFDnCFDCFSTSk register is set to 1 (transmit/receive FIFO transmit interrupt request), this bit is set to 1. When the CFTXIF bit is cleared to 0 under the conditions that this bit can be set to 1, this bit is cleared to 0. This flag is also cleared to 0 when the CFTXIE bit is cleared to 0. 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.

Bit	Bit Name	Initial Value	R/W	Description
2	TQIF0	B'0	R	Channel 0 Transmit Queue Interrupt Status Flag When the TXQIE bit in the RSCFDnCFDTXQCCm register is set to 1 (transmit queue interrupt enabled) and the TXQIF bit in the RSCFDnCFDTXQSTSm register is set to 1 (transmit queue interrupt request), this bit is set to 1. When the TXQIF bit (transmit queue interrupt request) in the RSCFDnCFDTXQSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the TXQIE bit is cleared to 0. 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
1	TAIF0	B'0	R	Channel 0 Transmit Buffer Abort Interrupt Status Flag This bit is set to 1 when the TAIE bit in the RSCFDnCFDCmCTR register is 1 (transmit abort interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnCFDTMSTSp register are set to B'01 (transmit abort completed). This flag is cleared to 0 when the TMTRF[1:0] flags are cleared to B'00 after the transmit abort is completed. 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.
0	TSIF0	B'0	R	Channel 0 Transmit Buffer Interrupt Status Flag This bit is set to 1 when the TMIEp bit in the RSCFDnCFDTMIECy register is set to 1 (transmit buffer interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnCFDTMSTSp register are set to B'10 (transmit completed without abort request) or B'11 (transmit completed with abort request). When the TMTRF[1:0] flags are cleared to B'00 under the condition that this bit can be set to 1, this flag is cleared to 0. In addition, clearing the TMIEp bit to 0 also clears this flag to 0. 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.

48.9.3.7 RSCFDnCFDGTINTSTS1 — Global TX Interrupt Status Register 1

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
8	AFLDAE	B'0	R/W	Receive Rule Table Write Enable Setting this bit to 0 disables the write to the receive rule table. After writes to the receive rule table are completed, set this bit to 0 to disable the write to the table. The receive rule table can be read regardless of the value of this bit. Set the AFLDAE bit to 1 only in global reset mode. 0: Receive rule table write is disabled. 1: Receive rule table write is enabled.
7 to 5	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
4 to 0	AFLPN[4:0]	B'0_0000	R/W	Receive Rule Table Page Number Configuration These bits are used to set the page number of the receive rule table. Sixteen receive rules can be set per page. A page number can be selected from a range of page 0 (B'0_0000) to page 23 (B'1_0111). Set these bits to a value within the range of B'0_0000 to B'1_0111.

48.9.4.2 RSCFDnCFDGAFLCFG0 — Receive Rule Configuration Register 0

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGAFLCFG0 register can be read/written in 32-bit units

RSCFDnCFDGAFLCFG0L, RSCFDnCFDGAFLCFG0H registers can be read/written in 16-bit units

RSCFDnCFDGAFLCFG0LL, RSCFDnCFDGAFLCFG0LH, RSCFDnCFDGAFLCFG0HL, RSCFDnCFDGAFLCFG0HH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLCFG0: <RSCFDn_base> + H'009C

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	RNC0[7:0]	H'00	R/W	Number of Rules for Channel 0 These bits are used to set the number of rules to be registered in the channel 0 receive rule table. Set these bits to a value within the range of H'00 to H'80.
23 to 16	RNC1[7:0]	H'00	R/W	Number of Rules for Channel 1 These bits are used to set the number of rules to be registered in the channel 1receive rule table. Set these bits to a value within the range of H'00 to H'80.
15 to 0	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.

Modify the RSCFDnCFDGAFLCFG0 register only in global reset mode.

Up to 64 × (number of channels) rules can be registered in the receive rule table as the entire unit. The number of receive rules per channel should meet the following conditions.

- The maximum number of rules per channel is 128.
- The total of the number of rules allocated to each channel is not larger than the number of rules that can be registered in the entire unit.

48.9.4.3 RSCFDnCFDGAFLCFG1 — Receive Rule Configuration Register 1

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

48.9.4.4 RSCFDnCFDGAFLIDj — Receive Rule ID Register (j = 0 to 15)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGAFLIDj register can be read/written in 32-bit units

RSCFDnCFDGAFLIDjL, RSCFDnCFDGAFLIDjH registers can be read/written in 16-bit units

RSCFDnCFDGAFLIDjLL, RSCFDnCFDGAFLIDjLH, RSCFDnCFDGAFLIDjHL, RSCFDnCFDGAFLIDjHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLIDj: <RSCFDn_base> + H'1000 + (H'10 × j)

RSCFDnCFDGAFLIDjL: <RSCFDn_base> + H'1000 + (H'10 × j),
RSCFDnCFDGAFLIDjH: <RSCFDn_base> + H'1002 + (H'10 × j)

RSCFDnCFDGAFLIDjLL: <RSCFDn_base> + H'1000 + (H'10 × j),
RSCFDnCFDGAFLIDjLH: <RSCFDn_base> + H'1001 + (H'10 × j),
RSCFDnCFDGAFLIDjHL: <RSCFDn_base> + H'1002 + (H'10 × j),
RSCFDnCFDGAFLIDjHH: <RSCFDn_base> + H'1003 + (H'10 × j)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLIDE	GAFLRTR	GAFLLB	GAFLID[28:16]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GAFLID[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	GAFLIDE	B'0	R/W	IDE Select This bit is used to select the ID format (standard ID or extended ID) of the receive rule. This bit is compared with the IDE bit in the received message during the acceptance filter processing. 0: Standard ID 1: Extended ID
30	GAFLRTR	B'0	R/W	RTR Select This bit is used to select the frame format (data frame or remote frame) of the receive rule. This bit is compared with the RTR bit in the received message during the acceptance filter processing. 0: Data frame 1: Remote frame
29	GAFLLB	B'0	R/W	Receive Rule Target Message Select When this bit is set to 0, data processing using the receive rule is performed when receiving messages transmitted from another CAN node. When this bit is set to 1 when the mirror function is used, data processing using the receive rule is performed when the CAN node is receiving its own transmitted messages. 0: When a message transmitted from another CAN node is received 1: When the own transmitted message is received

Bit	Bit Name	Initial Value	R/W	Description
28 to 0	GAFLID[28:0]	H'0000_0000	R/W	ID Set These bits are used to set the ID field of the receive rule. The ID value set by these bits is compared with the ID of the received message during the acceptance filter processing. For the standard ID, set the ID in bits 10 to 0 and set bits 28 to 11 to 0.

Modify the RSCFDnCFDGAFLIDj register when the AFLDAE bit in the RSCFDnCFDGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

48.9.4.5 RSCFDnCFDGAFLMj — Receive Rule Mask Register (j = 0 to 15)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGAFLMj register can be read/written in 32-bit units

RSCFDnCFDGAFLMjL, RSCFDnCFDGAFLMjH registers can be read/written in 16-bit units

RSCFDnCFDGAFLMjLL, RSCFDnCFDGAFLMjLH, RSCFDnCFDGAFLMjHL, RSCFDnCFDGAFLMjHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLMj: <RSCFDn_base> + H'1004 + (H'10 × j)

RSCFDnCFDGAFLMjL: <RSCFDn_base> + H'1004 + (H'10 × j),
RSCFDnCFDGAFLMjH: <RSCFDn_base> + H'1006 + (H'10 × j)

RSCFDnCFDGAFLMjLL: <RSCFDn_base> + H'1004 + (H'10 × j),
RSCFDnCFDGAFLMjLH: <RSCFDn_base> + H'1005 + (H'10 × j),
RSCFDnCFDGAFLMjHL: <RSCFDn_base> + H'1006 + (H'10 × j),
RSCFDnCFDGAFLMjHH: <RSCFDn_base> + H'1007 + (H'10 × j)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLIDEM	GAFLRTRM	—	GAFLIDM[28:16]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GAFLIDM[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	GAFLIDEM	B'0	R/W	IDE Mask When this bit is set to 1, filter processing is performed only for messages of the ID format specified by the GAFLIDE bit in the RSCFDnCFDGAFLIDj register. When this bit is cleared to 0, the IDs of all the receive messages and the specified IDs are regarded as matched. To set the GAFLIDEM bit to 0, set the GAFLIDM[28:0] bits to all 0 at the same time. 0: The IDE bit is not compared. 1: The IDE bit is compared.
30	GAFLRTRM	B'0	R/W	RTR Mask This bit is used to mask the RTR bit of the receive rule. 0: The RTR bit is not compared. 1: The RTR bit is compared
29	Reserved	B'0	R	This bit is read as the value after reset. The write value should be the value after reset.
28 to 0	GAFLIDM [28:0]	H'0000_0000	R/W	ID Mask These bits are used to mask the corresponding ID bit of the receive rule. 0: The corresponding ID bit is not compared. 1: The corresponding ID bit is compared.

Modify the RSCFDnCFDGAFLMj register when the AFLDAE bit in the RSCFDnCFDGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

48.9.4.6 RSCFDnCFDGAFLP0_j — Receive Rule Pointer 0 Register (j = 0 to 15)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGAFLP0_j register can be read/written in 32-bit units

RSCFDnCFDGAFLP0_jL, RSCFDnCFDGAFLP0_jH registers can be read/written in 16-bit units

RSCFDnCFDGAFLP0_jLL, RSCFDnCFDGAFLP0_jLH, RSCFDnCFDGAFLP0_jHL, RSCFDnCFDGAFLP0_jHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLP0_j: <RSCFDn_base> + H'1008 + (H'10 × j)

RSCFDnCFDGAFLP0_jL: <RSCFDn_base> + H'1008 + (H'10 × j),
RSCFDnCFDGAFLP0_jH: <RSCFDn_base> + H'100A + (H'10 × j)

RSCFDnCFDGAFLP0_jLL: <RSCFDn_base> + H'1008 + (H'10 × j),
RSCFDnCFDGAFLP0_jLH: <RSCFDn_base> + H'1009 + (H'10 × j),
RSCFDnCFDGAFLP0_jHL: <RSCFDn_base> + H'100A + (H'10 × j),
RSCFDnCFDGAFLP0_jHH: <RSCFDn_base> + H'100B + (H'10 × j)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLDLC[3:0]				GAFLPTR[11:0]

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	GAFLDLC [3:0]	B’0000	R/W	Receive Rule DLC These bits are used to set the minimum data length necessary for receiving messages. If the data length of a message that is being filtered is equal to or larger than the value set by the GAFLDLC[3:0] bits, the message passes the DLC check. Setting these bits to B'0000 disables the DLC check function allowing messages with any data length to pass the DLC check.

	Classical CAN Frame	CAN FD Frame
B’0000:	0 data bytes	
B’0001:	1 data byte	
B’0010:	2 data bytes	
B’0011:	3 data bytes	
B’0100:	4 data bytes	
B’0101:	5 data bytes	
B’0110:	6 data bytes	
B’0111:	7 data bytes	
B’1000:	8 data bytes	
B’1001:	8 data bytes	12 data bytes
B’1010:		16 data bytes
B’1011:		20 data bytes
B’1100:		24 data bytes
B’1101:		32 data bytes
B’1110:		48 data bytes
B’1111:		64 data bytes

27 to 16	GAFLPTR [11:0]	H'000	R/W	Receive Rule Label Set the 12-bit label information. These bits are used to set a 12-bit label to be attached to messages that have passed through the filter. A label is attached when a message is stored in the receive buffer or the FIFO buffer.
15	GAFLRMV	B’0	R/W	Receive Buffer Enable When this bit is set to 1, receive messages that have passed through the filter are stored in the receive buffer selected by the GAFLRMDP[6:0] bits. 0: No receive buffer is used. 1: A receive buffer is used.
14 to 8	GAFLRMDP [6:0]	H'00	R/W	Receive Buffer Number Select Set the receive buffer number to store receive messages. These bits are used to select the number of the receive buffer that stores receive messages that have passed through the filter when the GAFLRMV bit is set to 1. Set these bits to a value smaller than the value set by the NRXMB[7:0] bits in the RSCFDnCFDRMNB register.
7 to 0	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.

Modify the RSCFDnCFDGAFLP0_j register when the AFLDAE bit in the RSCFDnCFDGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

48.9.4.7 RSCFDnCFDGAFLP1_j — Receive Rule Pointer 1 Register (j = 0 to 15)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDGAFLP1_j register can be read/written in 32-bit units

RSCFDnCFDGAFLP1_jL, RSCFDnCFDGAFLP1_jH registers can be read/written in 16-bit units

RSCFDnCFDGAFLP1_jLL, RSCFDnCFDGAFLP1_jLH, RSCFDnCFDGAFLP1_jHL, RSCFDnCFDGAFLP1_jHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLP1_j: <RSCFDn_base> + H'100C + (H'10 × j)

RSCFDnCFDGAFLP1_jL: <RSCFDn_base> + H'100C + (H'10 × j),
RSCFDnCFDGAFLP1_jH: <RSCFDn_base> + H'100E + (H'10 × j)

RSCFDnCFDGAFLP1_jLL: <RSCFDn_base> + H'100C + (H'10 × j),
RSCFDnCFDGAFLP1_jLH: <RSCFDn_base> + H'100D + (H'10 × j),
RSCFDnCFDGAFLP1_jHL: <RSCFDn_base> + H'100E + (H'10 × j),
RSCFDnCFDGAFLP1_jHH: <RSCFDn_base> + H'100F + (H'10 × j)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GAFLFDP[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
25 to 16	GAFLFDP [25:16]	H'000	R/W	Transmit/Receive FIFO Buffer k Select (Bit position – 8 = target transmit/receive FIFO buffer number k) 0: Transmit/receive FIFO buffer is not selected. 1: Transmit/receive FIFO buffer is selected.
15 to 0	GAFLFDP [15:0]	H'0000	R/W	Receive FIFO Buffer x Select (Bit position = target receive FIFO buffer number x) 0: Receive FIFO buffer is not selected. 1: Receive FIFO buffer is selected.

Modify the RSCFDnCFDGAFLP1_j register when the AFLDAE bit in the RSCFDnCFDGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLFDP[25:0] Bits

These bits are used to specify FIFO buffers that store receive messages that have passed through the filter. Up to eight FIFO buffers are selectable. However, when the GAFLRMV bit in the RSCFDnCFDGAFLP0_j register is set to 1 (a message is stored in the receive buffer), up to seven FIFO buffers can be selected. Only receive FIFO buffers and the transmit/receive FIFO buffer for which the CFM[1:0] bits in the RSCFDnCFDCFCCk register are set to B'00 (receive mode) or B'10 (gateway mode) are selectable.

48.9.5 Details of Receive Buffer Related Registers

48.9.5.1 RSCFDnCFDRMNB — Receive Buffer Number Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDRMNB register can be read/written in 32-bit units

RSCFDnCFDRMNBL, RSCFDnCFDRMNBH registers can be read/written in 16-bit units

RSCFDnCFDRMNBLL, RSCFDnCFDRMNBLH, RSCFDnCFDRMNBHL, RSCFDnCFDRMNBHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRMNB: <RSCFDn_base> + H'00A4

RSCFDnCFDRMNBL: <RSCFDn_base> + H'00A4, RSCFDnCFDRMNBH: <RSCFDn_base> + H'00A6

RSCFDnCFDRMNBLL: <RSCFDn_base> + H'00A4, RSCFDnCFDRMNBLH: <RSCFDn_base> + H'00A5, RSCFDnCFDRMNBHL: <RSCFDn_base> + H'00A6, RSCFDnCFDRMNBHH: <RSCFDn_base> + H'00A7

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RMNSq	H'0000_0000	R/W	Receive Buffer Receive Complete Flag q (q = y × 32 + 31 to y × 32 + 0) 0: There is no new message in receive buffer q. 1: There is a new message in receive buffer q.

Write 0 to the RSCFDnCFDRMNDy register in global operating mode or global test mode.

RMNSq Flags (q = 0 to 31)

Each RMNS flag is set to 1 when the processing for storing a message in the corresponding receive buffer starts.

To clear a flag to 0, the program must write 0 to the flag. Use a store instruction to write “0” to the flag and “1” to other flags. These bits cannot be cleared to 0 while a message is being stored. Time for storing a message differs depending on the size for storing the payload in the receive buffer; it takes 12 clock cycles of pclk when the RMPLS[1:0] bits in the RSCFDnCFDRMNB register are B'00 (8 bytes) and 18 clock cycles of pclk when the RMPLS[1:0] bits are B'11 (20 bytes) (two clock cycles of pclk for four bytes of the size for storing the payload).

These flags are cleared to 0 in global reset mode.

48.9.5.3 RSCFDnCFDRMIDq — Receive Buffer ID Register (q = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDRMIDq register can be read only in 32-bit units

RSCFDnCFDRMIDqL, RSCFDnCFDRMIDqH registers can be read only in 16-bit units

RSCFDnCFDRMIDqLL, RSCFDnCFDRMIDqLH, RSCFDnCFDRMIDqHL, RSCFDnCFDRMIDqHH registers can be read only in 8-bit units

Address: RSCFDnCFDRMIDq: <RSCFDn_base> + H'2000 + (H'20 × q)

RSCFDnCFDRMIDqL: <RSCFDn_base> + H'2000 + (H'20 × q),
RSCFDnCFDRMIDqH: <RSCFDn_base> + H'2002 + (H'20 × q)

RSCFDnCFDRMIDqLL: <RSCFDn_base> + H'2000 + (H'20 × q),

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	Reserved	All 0	R	These bits are read as the value after reset.
2	RMFDF	B'0	R	FDF This bit indicates the FD format (classical CAN frame or CAN FD frame) of the message stored in the receive buffer. 0: Classical CAN frame 1: CAN FD frame
1	RMBRS	B'0	R	BRS When the RMFDF bit is 1, this bit indicates the BRS bit value of the message stored in the receive buffer. When the RMFDF bit is 0, this bit is always read as 0. 0: The bit rate in the data area is not changed. 1: The bit rate in the data area is changed.
0	RMESI	B'0	R	ESI When the RMFDF bit is 1, this bit indicates the ESI bit value of the message stored in the receive buffer. When the RMFDF bit is 0, this bit is always read as 0. 0: Error-active node 1: Error-passive node

48.9.5.6 RSCFDnCFDRMDFb_q — Receive Buffer Data Field b Register (b = 0 to 4, q = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDRMDFb_q register can be read only in 32-bit units

RSCFDnCFDRMDFb_qL, RSCFDnCFDRMDFb_qH registers can be read only in 16-bit units

RSCFDnCFDRMDFb_qLL, RSCFDnCFDRMDFb_qLH, RSCFDnCFDRMDFb_qHL, RSCFDnCFDRMDFb_qHH registers can be read only in 8-bit units

Address: RSCFDnCFDRMDFb_q: <RSCFDn_base> + H'200C + (H'04 × b) + (H'20 × q)

RSCFDnCFDRMDFb_qL: <RSCFDn_base> + H'200C + (H'04 × b) + (H'20 × q),
RSCFDnCFDRMDFb_qH: <RSCFDn_base> + H'200E + (H'04 × b) + (H'20 × q)

RSCFDnCFDRMDFb_qLL: <RSCFDn_base> + H'200C + (H'04 × b) + (H'20 × q),
RSCFDnCFDRMDFb_qLH: <RSCFDn_base> + H'200D + (H'04 × b) + (H'20 × q),
RSCFDnCFDRMDFb_qHL: <RSCFDn_base> + H'200E + (H'04 × b) + (H'20 × q),
RSCFDnCFDRMDFb_qHH: <RSCFDn_base> + H'200F + (H'04 × b) + (H'20 × q)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMDB4 × b + 3 [7:0]								RMDB4 × b + 2 [7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RMDB4 × b + 1 [7:0]								RMDB4 × b + 0 [7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	RMDB4 × b + 3 [7:0]	H'00	R	Receive Buffer Data Byte 4 × b + 3
23 to 16	RMDB4 × b + 2 [7:0]	H'00	R	Receive Buffer Data Byte 4 × b + 2
15 to 8	RMDB4 × b + 1 [7:0]	H'00	R	Receive Buffer Data Byte 4 × b + 1
7 to 0	RMDB4 × b + 0 [7:0]	H'00	R	Receive Buffer Data Byte 4 × b + 0 Data for a message stored in the receive buffer can be read.

When the RMDLC[3:0] bit values in the RSCFDnCFDRMPTRq register are smaller than the size for storing the payload in the receive buffer, data bytes for which no data is set are read as H'00.

The size for storing the payload in the receive buffer is specified with the RMPLS[1:0] bits in the RSCFDnCFDRMNB register. The RSCFDnCFDRMDFb_q register corresponding to the area which exceeds the specified size must not be read or written.

48.9.6 Details of Receive FIFO Buffer Related Registers

48.9.6.1 RSCFDnCFDRFCCx — Receive FIFO Buffer Configuration and Control Register (x = 0 to 7)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDRFCCx register can be read/written in 32-bit units

RSCFDnCFDRFCCxL, RSCFDnCFDRFCCxH registers can be read/written in 16-bit units

RSCFDnCFDRFCCxLL, RSCFDnCFDRFCCxLH, RSCFDnCFDRFCCxHL, RSCFDnCFDRFCCxHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRFCCx: <RSCFDn_base> + H'00B8 + (H'04 × x)

R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
15 to 13	RFIGCV[2:0]	B'000	R/W	Receive FIFO Interrupt Request Timing Select These bits are used to specify the number of received messages for generating a receive FIFO interrupt request when the RFIM bit is set to 0 with a fraction for the total number of buffers (the setting of RFDC[2:0]). When the RFDC[2:0] bits are set to B'001 (4 messages), set the RFIGCV[2:0] bits to B'001, B'011, B'101, or B'111. Modify these bits only in global reset mode. B'000: When FIFO is 1/8 full. B'001: When FIFO is 2/8 full. B'010: When FIFO is 3/8 full. B'011: When FIFO is 4/8 full. B'100: When FIFO is 5/8 full. B'101: When FIFO is 6/8 full. B'110: When FIFO is 7/8 full. B'111: When FIFO is full.

Bit	Bit Name	Initial Value	R/W	Description
12	RFIM	B’0	R/W	Receive FIFO Interrupt Source Select This bit is used to select a FIFO interrupt source. Modify this bit only in global reset mode. 0: An interrupt occurs when the condition set by the RFIGCV[2:0] bits is met. 1: An interrupt occurs each time a message has been received.
11	Reserved	B’0	R	This bit is read as the value after reset. The write value should be the value after reset.
10 to 8	RFDC[2:0]	B’000	R/W	Receive FIFO Buffer Depth Configuration These bits are used to select the number of messages that can be stored in a single receive FIFO buffer. When these bits are set to B'000, no receive FIFO buffer should be used. Modify these bits only in global reset mode. B’000: 0 messages B’001: 4 messages B’010: 8 messages B’011: 16 messages B’100: 32 messages B’101: 48 messages B’110: 64 messages B’111: 128 messages
7	Reserved	B’0	R	This bit is read as the value after reset. The write value should be the value after reset.
6 to 4	RFPLS[2:0]	B’000	R/W	Receive FIFO Buffer Payload Storing Size Select These bits are used to select the upper-limited size of the payload which can be stored in the receive FIFO buffer. Modify these bits only in global reset mode. B’000: 8 bytes B’001: 12 bytes B’010: 16 bytes B’011: 20 bytes B’100: 24 bytes B’101: 32 bytes B’110: 48 bytes B’111: 64 bytes
3, 2	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
1	RFIE	B’0	R/W	Receive FIFO Interrupt Enable Setting the RFIE bit to 1 enables receive FIFO interrupts. Modify this bit when the RFE bit set to 0 (no receive FIFO buffer is used). 0: Receive FIFO interrupt is disabled. 1: Receive FIFO interrupt is enabled.
0	RFE	B’0	R/W	Receive FIFO Buffer Enable Setting the RFE bit to 1 makes receive FIFO buffers available. Clearing this bit to 0 sets the RFEMP flag in the RSCFDnCFDRFSTSx register to 1 (buffer empty). Modify this bit in global operating mode or global test mode. 0: No receive FIFO buffer is used. 1: Receive FIFO buffers are used.

48.9.6.2 RSCFDnCFDRFSTSx — Receive FIFO Buffer Status Register (x = 0 to 7)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFMC[7:0]								—	—	—	—	RFIF	RFMLT	RFFLL	RFEMP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R	R

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Reserved	All 0	R	These bits are read as the value after reset. When writing to these bits, write the value after reset.
15 to 8	RFMC[7:0]	H'00	R	Receive FIFO Unread Message Counter This flag indicates the number of unread messages in the receive FIFO buffer. This flag becomes H'00 when the RFE bit in the RSCFDnCFDRFCCx register is set to 0.
7 to 4	Reserved	All 0	R	These bits are read as the value after reset. When writing to these bits, write the value after reset.
3	RFIF	B'0	R/W	Receive FIFO Interrupt Request Flag This flag is set to 1 when the receive FIFO interrupt request generation conditions set by the RFIGCV[2:0] bits and the RFIM bit in the RSCFDnCFDRFCCx register are met. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”. 0: No receive FIFO interrupt request is present. 1: A receive FIFO interrupt request is present.

Bit	Bit Name	Initial Value	R/W	Description
2	RFMLT	B'0	R/W	Receive FIFO Message Lost Flag This flag is set to 1 when an attempt is made to store a new message while the receive FIFO buffer is full. In this case, the new message is discarded. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: No receive FIFO message is lost. 1: A receive FIFO message is lost.
1	RFFLL	B'0	R	Receive FIFO Buffer Full Status Flag This flag is set to 1 when the number of messages stored in the receive FIFO buffer matches the FIFO buffer depth set by the RFDC[2:0] bits in the RSCFDnCFDRFCCx register. If the number of messages stored in the receive FIFO buffer becomes smaller than the FIFO buffer depth set by the RFDC[2:0] bits, this flag is cleared to 0. This flag is also cleared to 0 when the RFE bit in the RSCFDnCFDRFCCx register is set to 0 (no receive FIFO buffer is used) or in global reset mode. 0: The receive FIFO buffer is not full. 1: The receive FIFO buffer is full.
0	RFEMP	B'1	R	Receive FIFO Buffer Empty Status Flag This flag is set to 1 when all messages in the receive FIFO buffer have been read. This flag is also set to 1 when the RFE bit in the RSCFDnCFDRFCCx register is 0 or in global reset mode. This flag is cleared to 0 when even a single received message has been stored in the receive FIFO buffer. 0: The receive FIFO buffer contains unread message. 1: The receive FIFO buffer contains no unread message (buffer empty).

Note: To clear the RFMLT or RFIF flag to 0, use a store instruction to write "0" to the given flag and "1" to the other flags.

48.9.6.3 RSCFDnCFDRFPCTRx — Receive FIFO Buffer Pointer Control Register (x = 0 to 7)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDRFPCTRx register can only be written in 32-bit units

RSCFDnCFDRFPCTRxL, RSCFDnCFDRFPCTRxH registers can only be written in 16-bit units

RSCFDnCFDRFPCTRxLL, RSCFDnCFDRFPCTRxLH, RSCFDnCFDRFPCTRxHL, RSCFDnCFDRFPCTRxHH registers can only be written in 8-bit units

Address: RSCFDnCFDRFPCTRx: <RSCFDn_base> + H'00F8 + (H'04 × x)

RSCFDnCFDRFPCTRxL: <RSCFDn_base> + H'00F8 + (H'04 × x),

RSCFDnCFDRFPCTRxLL: <RSCFDn_base> + H'00F8 + (H'04 × x),

RSCFDnCFDRFPCTRxLH: <RSCFDn_base> + H'00F9 + (H'04 × x),

RSCFDnCFDRFPCTRxHL: <RSCFDn_base> + H'00FA + (H'04 × x),

RSCFDnCFDRFPCTRxHH: <RSCFDn_base> + H'00FB + (H'04 × x)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RFPC[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	Reserved	All 0	R	The write value should be the value after reset.
7 to 0	RFPC[7:0]	H'00	W	Receive FIFO Pointer Control When the RFPC[7:0] bits are set to H'FF, the read pointer moves to the next unread message in the receive FIFO buffer. At this time, the RFMC[7:0] (receive FIFO unread message counter) value in the RSCFDnCFDRFSTSx register is decremented. Read the RSCFDnCFDRFIDx, RSCFDnCFDRFPTRx, RSCFDnCFDRFFDSTSx, and RSCFDnCFDRFDFd_x registers to read messages in the receive FIFO buffer, and then write H'FF to the RFPC[7:0] bits. When writing H'FF to these bits, make sure that the RFE bit in the RSCFDnCFDRFCCx register is set to 1 (receive FIFO buffers are used) and the RFEMP flag in the RSCFDnCFDRFSTSx register is 0 (the receive FIFO buffer contains unread messages).

When the RFDMAEx bit in the RSCFDnCFDCDTCT register is 1 (the DMA transfer request is enabled), this register must not be written.

48.9.6.4 RSCFDnCFDRFIDx — Receive FIFO Buffer Access ID Register (x = 0 to 7)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to24	RFDB4 × d + 3 [7:0]	H'00	R	Receive FIFO Buffer Data Byte 4 × d + 3
23 to 16	RFDB4 × d + 2 [7:0]	H'00	R	Receive FIFO Buffer Data Byte 4 × d + 2
15 to 8	RFDB4 × d + 1 [7:0]	H'00	R	Receive FIFO Buffer Data Byte 4 × d + 1
7 to 0	RFDB4 × d + 0 [7:0]	H'00	R	Receive FIFO Buffer Data Byte 4 × d + 0 Data for a message stored in the receive FIFO buffer can be read.

When the RFDLC[3:0] bit values in the RSCFDnCFDRFPTRx register are smaller than the size for storing the payload in the receive FIFO buffer, data bytes for which no data is set are read as H'00.

The size for storing the payload in the receive FIFO buffer is specified with the RFPLS[2:0] bits in the RSCFDnCFDRFCCx register. The RSCFDnCFDRFDFd_x register corresponding to the area which exceeds the specified size must not be read or written.

48.9.7 Details of Transmit/Receive FIFO Buffer Related Registers

48.9.7.1 RSCFDnCFDCFCCk — Transmit/receive FIFO Buffer Configuration and Control Register k (k = 0 to 5)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDCFCCk register can be read/written in 32-bit units

RSCFDnCFDCFCCkL, RSCFDnCFDCFCCkH registers can be read/written in 16-bit units

RSCFDnCFDCFCCkLL, RSCFDnCFDCFCCkLH, RSCFDnCFDCFCCkHL, RSCFDnCFDCFCCkHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCFCCk: <RSCFDn_base> + H'0118 + (H'04 × k)

RSCFDnCFDCFCCkL: <RSCFDn_base> + H'0118 + (H'04 × k),

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	CFITT[7:0]	H'00	R/W	Set a message transmission interval. These bits are used to set a message transmission interval when transmitting messages continuously from a transmit/receive FIFO buffer whose CFM[1:0] bits are set to B'01 (transmit mode) or B'10 (gateway mode). Clear the CFE bit to 0 (no transmit/receive FIFO buffer is used) before modifying the CFITT[7:0] bits. Set Value: H'00 to H'FF

Bit	Bit Name	Initial Value	R/W	Description
23 to 20	CFTML[3:0]	H'0	R/W	Transmit Buffer Link Configuration These bits are used to set the number of transmit buffer on the channel which will be linked to transmit/receive FIFO buffer k when the CFM[1:0] bits are set to B'01 (transmit mode) or B'10 (gateway mode). There are three transmit/receive FIFO buffers per channel, so channel number m of FIFO buffer k is calculated as m = k/3 (integer division). The actual assigned transmit buffer number p linked to FIFO buffer k will be ((16 × m) + CFTML[3:0]). See Table 48.17 and Table 48.18, as for the relationship between transmit/receive FIFO buffer k and transmit buffer p. Setting the CFDC[2:0] bits to B'001 or more enables the setting of the CFTML[3:0] bits. Do not link to any transmit buffer which is already allocated to a transmit queue on the identical channel or to another transmit/receive FIFO buffer. Modify these bits only in global reset mode.
19	CFITR	B’0	R/W	Transmit/Receive FIFO Interval Timer Resolution This bit is enabled when the CFITSS bit is 0. When this bit is 0, the interval timer clock source is the pclk/2 clock divided by the value of the ITRCP[15:0] bits in the RSCFDnCFDGCFG register. When this bit is 1, the interval timer clock source is the pclk/2 clock divided by (the value of the ITRCP[15:0] bits in the RSCFDnCFDGCFG register × 10). Modify this bit while the CFE bit is set to 0 (no transmit/receive FIFO buffer is used). 0: Clock dividing pclk/2 by (ITRCP[15:0] bits) 1: Clock dividing pclk/2 by (ITRCP[15:0] bits × 10)
18	CFITSS	B’0	R/W	Transmit/Receive FIFO Interval Timer Clock Source Select When this bit is 0, the clock selected by the CFITR bit is the count source of the interval timer. When this bit is 1, the normal bit time clock of the channel to which the FIFO is linked is the count source of the interval timer. Use this bit only for a channel which does not handle the CAN FD frame. Modify this bit while the CFE bit is cleared to 0 (no transmit/receive FIFO buffer is used). 0: Interval timer clock source selected by the CFITR bit 1: Interval timer clock source is the normal bit time clock for the channel to which the FIFO is linked.
17, 16	CFM[1:0]	B’00	R/W	Transmit/Receive FIFO Mode Select These bits are used to select transmit/receive FIFO mode. Modify these bits only in global reset mode. B’00: Receive mode B’01: Transmit mode B’10: Gateway mode B’11: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	CFIGCV[2:0]	B’000	R/W	Transmit/Receive FIFO Receive Interrupt Request Timing Select These bits are used to specify the number of received messages for generating a transmit/receive FIFO receive interrupt request when the CFM[1:0] bits are set to B'00 (receive mode) or B'10 (gateway mode) and the CFIM bit is set to 0 with a fraction for the total number of buffers (the setting of CFDC[2:0]). When the CFDC[2:0] bits are set to B'001 (4 messages), set the CFIGCV[2:0] bits to B'001, B'011, B'101, or B'111. Modify these bits only in global reset mode. B’000: When FIFO is 1/8 full. B’001: When FIFO is 2/8 full. B’010: When FIFO is 3/8 full. B’011: When FIFO is 4/8 full. B’100: When FIFO is 5/8 full. B’101: When FIFO is 6/8 full. B’110: When FIFO is 7/8 full. B’111: When FIFO is full.
12	CFIM	B’0	R/W	Transmit/Receive FIFO Interrupt Source Select This bit is used to select a transmit/receive FIFO interrupt source. Modify this bit only in global reset mode. 0: • Receive mode/gateway mode When the number of received messages has met the condition set by the CFIGCV[2:0] bits, a FIFO receive interrupt request is generated. • Transmit mode/gateway mode When the buffer becomes empty upon completion of message transmission, a FIFO transmit interrupt request is generated. 1: • Receive mode/gateway mode A FIFO receive interrupt request is generated each time a message has been received. • Transmit mode/gateway mode A FIFO transmit interrupt request is generated each time a message has been transmitted.
11	Reserved	B’0	R	This bit is read as the value after reset. The write value should be the value after reset.
10 to 8	CFDC[2:0]	B’000	R/W	Transmit/Receive FIFO Buffer Depth Configuration These bits are used to set the number of messages that can be stored in a single transmit/receive FIFO buffer. When these bits are set to B'000, do not use a transmit/receive FIFO buffer. Modify these bits only in global reset mode. B’000: 0 messages B’001: 4 messages B’010: 8 messages B’011: 16 messages B’100: 32 messages B’101: 48 messages B’110: 64 messages B’111: 128 messages

Bit	Bit Name	Initial Value	R/W	Description
7	Reserved	B'0	R	This bit is read as the value after reset. The write value should be the value after reset.
6 to 4	CFPLS[2:0]	B'000	R/W	Transmit/Receive FIFO Buffer Payload Storing Size Select These bits are used to select the upper-limited size of the payload which can be stored in the transmit/receive FIFO buffer. Modify these bits only in global reset mode. B'000: 8 bytes B'001: 12 bytes B'010: 16 bytes B'011: 20 bytes B'100: 24 bytes B'101: 32 bytes B'110: 48 bytes B'111: 64 bytes
3	Reserved	B'0	R	This bit is read as the value after reset. The write value should be the value after reset.
2	CFTXIE	B'0	R/W	Transmit/Receive FIFO Transmit Interrupt Enable When this bit is set to 1 and the CFTXIF flag in the RSCFDnCFDCFSTSk register is set to 1, a transmit/receive FIFO transmit interrupt request is generated. Modify this bit with the CFE bit set to 0 (no transmit/receive FIFO buffer is used). 0: Transmit/receive FIFO transmit interrupt is disabled. 1: Transmit/receive FIFO transmit interrupt is enabled.
1	CFRXIE	B'0	R/W	Transmit/Receive FIFO Receive Interrupt Enable When this bit is set to 1 and the CFRXIF flag in the RSCFDnCFDCFSTSk register is set to 1, a transmit/receive FIFO receive interrupt request is generated. Modify this bit with the CFE bit set to 0. 0: Transmit/receive FIFO receive interrupt is disabled. 1: Transmit/receive FIFO receive interrupt is enabled.
0	CFE	B'0	R/W	Transmit/Receive FIFO Buffer Enable Setting this bit to 1 makes transmit/receive FIFO buffers available. When this bit is set to 0 in transmit mode or gateway mode, if a message in the transmit/receive FIFO buffer is being transmitted or will be transmitted next, the transmit/receive FIFO buffer becomes empty after completion of transmission of that message, or upon detection of a CAN bus error, or arbitration-lost. In other cases or in receive mode, the transmit/receive FIFO buffer becomes empty immediately. This bit is cleared to 0 when the following conditions are met. • Receive mode: Global reset mode • Transmit mode or gateway mode: Channel reset mode Modify this bit in the following mode. • Receive mode: Global operating mode or global test mode • Transmit mode or gateway mode: Channel communication mode or channel halt mode First set all the other bits in the RSCFDnCFDCFCCk register and then set this bit to 1 using another instruction. 0: No transmit/receive FIFO buffer is used. 1: Transmit/receive FIFO buffers are used.

R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W*	R	R

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Reserved	All 0	R	These bits are read as the value after reset. When writing to these bits, write the value after reset.
15 to 8	CFMC[7:0]	H'00	R	Transmit/Receive FIFO Message Counter The number of messages stored in the transmit/receive FIFO buffer. The CFMC[7:0] bits indicate the following values that depend on the setting of the CFM[1:0] bits in the RSCFDnCFDCFCCk register. • When CFM[1:0] value is B'01 (transmit mode): Number of untransmitted messages in the buffer • When CFM[1:0] value is B'00 (receive mode): Number of unread received messages in the buffer • When CFM[1:0] value is B'10 (gateway mode): Number of untransmitted received messages in the buffer These bits are cleared to 0 when any of the following conditions is met. • When CFM[1:0] value is B'00: In global reset mode • When CFM[1:0] value is B'01 or B'10: In channel reset mode

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	Reserved	All 0	R	These bits are read as the value after reset. When writing to these bits, write the value after reset.
4	CFTXIF	B’0	R/W	Transmit/Receive FIFO Transmit Interrupt Request Flag The CFTXIF flag is set to 1 when any of the following conditions is met. • When the CFM[1:0] bits are set to B'01 or B'10, and the factor selected by the CFIM bit in the RSCFDnCFDCFCCk register occurs The CFTXIF flag is cleared to 0 when any of the following conditions is met. • When 0 is written to the CFTXIF flag • When the CFM[1:0] bits are set to B'00: In global reset mode • When the CFM[1:0] bits are set to B'01 or B'10: In channel reset mode Write 0 to this flag in global operating mode or global test mode. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: No transmit/receive FIFO transmit interrupt request is present. 1: A transmit/receive FIFO transmit interrupt request is present.
3	CFRXIF	B’0	R/W	Transmit/Receive FIFO Receive Interrupt Request Flag The CFRXIF flag is set to 1 when any of the following conditions is met. • When the CFM[1:0] bits are set to B'00 or B'10, and the factor selected by the CFIM bit in the RSCFDnCFDCFCCk register occurs The CFRXIF flag is cleared to 0 when any of the following conditions is met. • When 0 is written to the CFRXIF flag • When the CFM[1:0] bits are set to B'00: In global reset mode • When the CFM[1:0] bits are set to B'01 or B'10: In channel reset mode Write 0 to this flag in global operating mode or global test mode. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: No transmit/receive FIFO receive interrupt request is present. 1: A transmit/receive FIFO receive interrupt request is present.

Bit	Bit Name	Initial Value	R/W	Description
2	CFMLT	B’0	R/W	Transmit/Receive FIFO Message Lost Flag The CFMLT flag is set to 1 when any of the following conditions is met. • When an attempt is made to store a new message while the transmit/receive FIFO buffer is full. In this case, the new message is discarded. The CFMLT flag is cleared to 0 when any of the following conditions is met. • When 0 is written to the CFMLT flag • When the CFM[1:0] bits are set to B'00: In global reset mode • When the CFM[1:0] bits are set to B'01 or B'10: In channel reset mode Write 0 to this flag in global operating mode or global test mode To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: No transmit/receive FIFO message is lost. 1: A transmit/receive FIFO message is lost.
1	CFFLL	B’0	R	Transmit/Receive FIFO Buffer Full Status Flag The CFFLL flag is set to 1 when any of the following conditions is met. • When the number of messages stored in the transmit/receive FIFO buffer matches the FIFO buffer depth set by the CFDC[2:0] bits in the RSCFDnCFDCFCCk register. The CFMLT flag is cleared to 0 when any of the following conditions is met. • When the number of messages stored in the transmit/receive FIFO buffer becomes smaller than the FIFO buffer depth set by the CFDC[2:0] bits. • When the CFE bit in the RSCFDnCFDCFCCk register is 0 (no transmit/receive FIFO buffer is used): When not in the transmit abort • When the CFM[1:0] bits are set to B'00: In global reset mode • When the CFM[1:0] bits are set to B'01 or B'10: In channel reset mode 0: The transmit/receive FIFO buffer is not full. 1: The transmit/receive FIFO buffer is full.

Bit	Bit Name	Initial Value	R/W	Description
0	CFEMP	B’1	R	Transmit/Receive FIFO Buffer Empty Status Flag The CFEMP flag is set to 1 when any of the following conditions is met. • When the CFM[1:0] bits are set to B'00: All messages have been read, or in global reset mode • When the CFM[1:0] bits are set to B'01 or B'10: All messages have been transmitted, or in channel reset mode • When the CFE bit is 0 (no transmit/receive FIFO buffer is used): Not in the transmit abort The CFEMP flag is cleared to 0 when any of the following conditions is met. • When the CFM[1:0] bits are set to B'00 or B'10: At least one received message has been stored in the transmit/receive FIFO buffer. • When the CFM[1:0] bits are set to B'01: A value of H'FF has been written to the RSCFDnCFDCFPCTRk register after data was written to the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDFd_k registers. 0: The transmit/receive FIFO buffer contains messages. 1: The transmit/receive FIFO buffer contains no message (buffer empty).

Note: To clear the CFTXIF, CFRXIF, or CFMLT flag to 0, the program must write 0 to the flag. Use a store instruction to write “0” to the flag and “1” to other flags.

48.9.7.3 RSCFDnCFDCFPCTRk — Transmit/receive FIFO Buffer Pointer Control Register (k = 0 to 5)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CFPC[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	Reserved	All 0	R	The write value should be the value after reset.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	CFPC[7:0]	H'00	W	Transmit/Receive FIFO Pointer Control • Receive mode (CFM[1:0] value in the RSCFDnCFDCFCCk register is B'00): Writing H'FF to the CFPC[7:0] bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value (transmit/receive FIFO message counter) in the RSCFDnCFDCFSTSk register is decremented. Read the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDFd_k registers to read messages from the transmit/receive FIFO buffer, and then write H'FF to the CFPC[7:0] bits. When writing H'FF to these bits, make sure that the CFE bit in the RSCFDnCFDCFCCk register is set to 1 (transmit/receive FIFO buffers are used) and the CFEMP flag in the RSCFDnCFDCFSTSk register is 0 (the transmit/receive FIFO buffer contains messages). • Transmit mode (CFM[1:0] value in the RSCFDnCFDCFCCk register is B'01): Writing H'FF to the CFPC[7:0] bits stores the data written to the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDFd_k registers in the transmit/receive FIFO buffer and moves the write pointer to the next stage of the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value is incremented. Write transmit messages to the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDFd_k registers before writing H'FF to the CFPC[7:0] bits. When writing H'FF to these bits, make sure that the CFE bit in the RSCFDnCFDCFCCk register is set to 1 and the CFFLL flag in the RSCFDnCFDCFSTSk register is 0 (the transmit/receive FIFO buffer is not full). • Gateway mode (CFM[1:0] value in the RSCFDnCFDCFCCk register is B'10): Setting prohibited

When the corresponding transmit/receive FIFO buffer is the first transmit/receive FIFO buffer which has been assigned to channel m (k = 3 × m) and the CFDMAEm bit in the RSCFDnCFDCDTCT register is 1 (the DMA transfer request is enabled), this register must not be written.

Bit	Bit Name	Initial Value	R/W	Description
31	CFIDE	B'0	R/W	Transmit/Receive FIFO Buffer IDE This bit indicates the ID format (standard ID or extended ID) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is B'00. When the CFM[1:0] value is B'01, these bits are used to set the ID format of the message to be transmitted from the transmit/receive FIFO buffer. 0: Standard ID 1: Extended ID

Bit	Bit Name	Initial Value	R/W	Description
30	CFRTR	B’0	R/W	Transmit/Receive FIFO Buffer RTR/RRS When the CFM[1:0] bits are B'00 and the received message is in the classical CAN frame, this bit indicates the data format (data frame or remote frame) of the received message stored in the transmit/receive FIFO buffer. When the received message is in the CAN FD frame, this bit indicates the RRS bit value of the message. When the CFM[1:0] bits are B'01, this bit is used to set the data format of the message transmitted from the transmit/receive FIFO buffer. When the CFFDF bit in the RSCFDnCFDCFFDCSTSk register is 1 (CAN FD frame), this bit must be cleared to 0. • When the CFM[1:0] bits are B'01 (transmit mode): — When the transmit message is in the classical CAN frame: 0: Data frame 1: Remote frame — When the transmit message is in the CAN FD frame: Write 0 to this bit. • When the CFM[1:0] bits are B'00 (receive mode): — When the received message is in the classical CAN frame: 0: Data frame 1: Remote frame — When the received message is in the CAN FD frame: The RRS bit value of the received message is read.
29	THLEN	B’0	R/W	Transmit History Data Store Enable When this bit is set to 1, the transmit history data (label information, buffer number, buffer type, and timestamp) of transmit messages is stored in the transmit history buffer after transmission is completed. This bit is enabled when the CFM[1:0] value is B'01 (transmit mode). 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.
28 to 0	CFID[28:0]	H’0000_0000	R/W	Transmit/Receive FIFO Buffer ID Data • When CFM[1:0] value is B'01 (transmit mode): Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11. • When CFM[1:0] value is B'00 (receive mode): Standard ID or extended ID in the received message can be read. For standard ID, read bits 10 to 0. Bits 28 to 11 are read as 0.

This register is writable only when the CFM[1:0] bits in the RSCFDnCFDCFCCk register are B'01 (transmit mode). This register is readable only when the CFM[1:0] bits are B'00 (receive mode). This register should not be read or written when the CFM[1:0] bits are B'10 (gateway mode).

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	CFDLC[3:0]	B’0000	R/W	Transmit/Receive FIFO Buffer DLC Data These bits indicate the data length of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is B'00. When the CFM[1:0] value is B'01, these bits are used to set the data length of the message to be transmitted from the transmit/receive FIFO buffer. When the CFFDF bit in the RSCFDnCFDCFFDCSTSk register is 0 (CAN frame) and a value equal to or larger than B'1001 is set to the CFDLC[3:0] bits, 8-byte data is actually transmitted. When the CFFDF bit is 1 (CAN FD frame), the range of values to be set differs depending on the TMME bit in the RSCFDnCFDCmFDCFG register and the CFPLS[2:0] bits in the RSCFDnCFDCFCCk register. • When the TMME bit is 0 (the transmit buffer merge mode is disabled): All values from B'0000 to B'1111 can be set. If the data length exceeds the size for storing the payload which has been set by the CFPLS[2:0] bits, the exceeded payload will be padded by CCH. • When the TMME bit is 1 (the transmit buffer merge mode is enabled): The data length must not exceed the size for storing the payload which has been set by the CFPLS[2:0] bits.

	Classical CAN frame	CAN FD frame
B’0000:	0 data bytes	
B’0001:	1 data byte	
B’0010:	2 data bytes	
B’0011:	3 data bytes	
B’0100:	4 data bytes	
B’0101:	5 data bytes	
B’0110:	6 data bytes	
B’0111:	7 data bytes	
B’1000:	8 data bytes	
B’1001:	8 data bytes	12 data bytes
B’1010:		16 data bytes
B’1011:		20 data bytes
B’1100:		24 data bytes
B’1101:		32 data bytes
B’1110:		48 data bytes
B’1111:		64 data bytes

27 to 16	CFPTR[11:0]	H'000	R/W	Transmit/Receive FIFO Buffer Label Data • When the CFM[1:0] bits are B'01 (transmit mode): When a message is transmitted, the CFPTR[7:0] bit values are stored in the transmit history. Only the CFPTR[7:0] bits are valid. • When the CFM[1:0] bits are B'00 (receive mode): The label information, which has been attached to the receive message in the transmit/receive FIFO buffer, is indicated.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	CFTS[15:0]	H'0000	R/W	Transmit/Receive FIFO Buffer Timestamp Data These bits indicate the timestamp value of the message stored in the transmit/receive FIFO buffer. These bits are valid when the CFM[1:0] bits are B'00.

This register is writable only when the CFM[1:0] bits in the RSCFDnCFDCFCCk register are B'01 (transmit mode). This register is readable only when the CFM[1:0] bits are B'00 (receive mode). This register should not be read or written when the CFM[1:0] bits are B'10 (gateway mode).

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	CFFDF	CFBRS	CFESI
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	Reserved	All 0	R	These bits are read as the value after reset.
2	CFFDF	B'0	R/W	CFFDF When the CFM[1:0] bits are B'00, this bit indicates the FD format (classical CAN frame or CAN FD frame) of the message stored in the transmit/receive FIFO buffer. When the CFM[1:0] bits are B'01, this bit is used to set the FD format of the message to be transmitted from the transmit/receive FIFO buffer. 0: Classical CAN frame 1: CAN FD frame
1	CFBRS	B'0	R/W	CFBRS When the CFM[1:0] bits are B'00, this bit indicates the BRS bit value of the receive message stored in the transmit/receive FIFO buffer if the CFFDF bit is 1. This bit is always read as 0 if the CFFDF bit is 0. When the CFM[1:0] bits are B'01, this bit is used to set the BRS bit value of the message transmitted from the transmit/receive FIFO buffer if the CFFDF bit is 1. Write 0 to this bit if the CFFDF bit is 0. 0: The bit rate in the data area is not changed. 1: The bit rate in the data area is changed.

Bit	Bit Name	Initial Value	R/W	Description
0	CFESI	B’0	R/W	CFESI When the CFM[1:0] bits are B'00, this bit indicates the ESI bit value of the receive message stored in the transmit/receive FIFO buffer if the CFFDF bit is 1. This bit is always read as 0 if the CFFDF bit is 0. When the CFM[1:0] bits are B'01, this bit is used to set the ESI bit value of the message transmitted from the transmit/receive FIFO buffer if the CFFDF bit is 1. The set value is transmitted when the ESIC bit in the RSCFDnCFDCmFDCFG register is 1 and the channel is in error-active state. When the channel is in error-passive state, the ESI bit value indicating the error-passive node is transmitted regardless of this bit. Write 0 to this bit if the CFFDF bit is 0. 0: Error-active node 1: Error-passive node

This register is writable only when the CFM[1:0] bits in the RSCFDnCFDCFCCk register are B'01 (transmit mode). This register is readable only when the CFM[1:0] bits are B'00 (receive mode). This register should not be read or written when the CFM[1:0] bits are B'10 (gateway mode).

48.9.7.7 RSCFDnCFDCFDFd_k — Transmit/receive FIFO Buffer Access Data Field d Register (d = 0 to 15, k = 0 to 5)

RSCFDnCFDCFDFd_kL, RSCFDnCFDCFDFd_kH registers can be read/written in 16-bit units

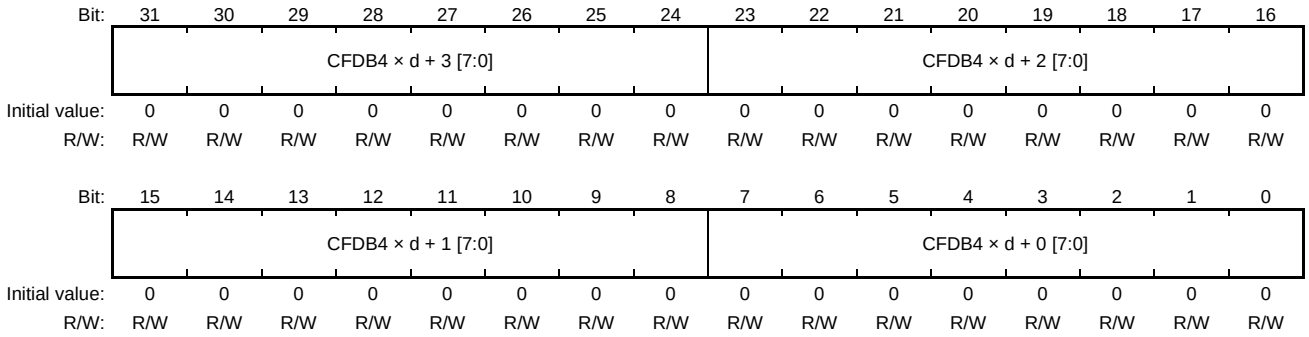
RSCFDnCFDCFDFd_kLL, RSCFDnCFDCFDFd_kLH, RSCFDnCFDCFDFd_kHL, RSCFDnCFDCFDFd_kHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCFDFd_k: <RSCFDn_base> + H'340C + (H'04 × d) + (H'80 × k)

RSCFDnCFDCFDFd_kL: <RSCFDn_base> + H'340C + (H'04 × d) + (H'80 × k),
RSCFDnCFDCFDFd_kH: <RSCFDn_base> + H'340E + (H'04 × d) + (H'80 × k)

RSCFDnCFDCFDFd_kLL: <RSCFDn_base> + H'340C + (H'04 × d) + (H'80 × k),
RSCFDnCFDCFDFd_kLH: <RSCFDn_base> + H'340D + (H'04 × d) + (H'80 × k),
RSCFDnCFDCFDFd_kHL: <RSCFDn_base> + H'340E + (H'04 × d) + (H'80 × k),
RSCFDnCFDCFDFd_kHH: <RSCFDn_base> + H'340F + (H'04 × d) + (H'80 × k)

Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	CFDB4 × d + 3 [7:0]	H'00	R/W	Transmit/Receive FIFO Buffer Data Byte 4 × d + 3 Transmit/Receive FIFO Buffer Data Byte 4 × d + 2 Transmit/Receive FIFO Buffer Data Byte 4 × d + 1 Transmit/Receive FIFO Buffer Data Byte 4 × d + 0 • When CFM[1:0] value is B'01 (transmit mode): Set the transmit/receive FIFO buffer data. • When CFM[1:0] value is B'00 (receive mode): The message data stored in the transmit/receive FIFO buffer can be read.
23 to 16	CFDB4 × d + 2 [7:0]	H'00	R/W	
15 to 8	CFDB4 × d + 1 [7:0]	H'00	R/W	
7 to 0	CFDB4 × d + 0 [7:0]	H'00	R/W	

This register is writable only when the CFM[1:0] bits in the RSCFDnCFDCFCCk register are B'01.

This register is readable only when the CFM[1:0] bits are B'00. When the CFDLC[3:0] bit values in the RSCFDnCFDCFPTRk register are smaller than the size for storing the payload in the transmit/receive FIFO buffer, data bytes for which no data is set are read as H'00.

The size for storing the payload in the transmit/receive FIFO buffer is specified with the CFPLS[2:0] bits in the RSCFDnCFDCFCCk register. The RSCFDnCFDCFDFd_k register, which corresponds to the larger area than the specified size, should not be read or written.

This register should not be read or written when the CFM[1:0] bits are B'10 (gateway mode).

1	RFDMAE1	B’0	R/W	
0	RFDMAE0	B’0	R/W	

Modify the RSCFDnCFDCDTCT register only in global operating mode or global test mode.

CFDMAEm Bits

The DMA transfer for transmit/receive FIFO buffer 3 × m (the first transmit/receive FIFO buffer assigned to channel m) is enabled. The DMA transfer is only enabled for the transmit/receive FIFO buffer in which the CFM[1:0] bits in the RSCFDnCFDCFCCk register have been set to B'00 (receive mode). Set these bits to 0 when the CFM[1:0] bits are B'01 (transmit mode) or B'10 (gateway mode).

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
13	CFDMASTS5	B'0	R	Transmit/Receive FIFO Buffer 15 DMA Status 0: The DMA for transmit/receive FIFO buffer 15 is not being transferred. 1: The DMA for transmit/receive FIFO buffer 15 is being transferred.
12	CFDMASTS4	B'0	R	Transmit/Receive FIFO Buffer 12 DMA Status 0: The DMA for transmit/receive FIFO buffer 12 is not being transferred. 1: The DMA for transmit/receive FIFO buffer 12 is being transferred.
11	CFDMASTS3	B'0	R	Transmit/Receive FIFO Buffer 9 DMA Status 0: The DMA for transmit/receive FIFO buffer 9 is not being transferred. 1: The DMA for transmit/receive FIFO buffer 9 is being transferred.
10	CFDMASTS2	B'0	R	Transmit/Receive FIFO Buffer 6 DMA Status 0: The DMA for transmit/receive FIFO buffer 6 is not being transferred. 1: The DMA for transmit/receive FIFO buffer 6 is being transferred.

Bit	Bit Name	Initial Value	R/W	Description
9	CFDMASTS1	B'0	R	Transmit/Receive FIFO Buffer 3 DMA Status 0: The DMA for transmit/receive FIFO buffer 3 is not being transferred. 1: The DMA for transmit/receive FIFO buffer 3 is being transferred.
8	CFDMASTS0	B'0	R	Transmit/Receive FIFO Buffer 0 DMA Status 0: The DMA for transmit/receive FIFO buffer 0 is not being transferred. 1: The DMA for transmit/receive FIFO buffer 0 is being transferred.
7	RFDMASTS7	B'0	R	Receive FIFO Buffer x DMA Status When the DMA transfer for receive FIFO buffer x is enabled (the RFDMAEx bit corresponding to the RSCFDnCFDCDTCT register is 1) and there is a message in the receive FIFO buffer, the RFDMAEx bit becomes 1 and indicates that the DMA is being transferred. When all messages in receive FIFO buffer x are transferred or the DMA transfer is disabled (the RFDMAEx bit is 0), the RFDMASTSx bit becomes 0 and indicates that the DMA transfer completed. When the RFDMAEx bit is cleared to 0 during DMA transfer, the RFDMASTSx bit becomes 0 after the DMA transfer in execution has completed (the message has been transferred to the last byte in the payload storage area). 0: The DMA for receive FIFO buffer x is not being transferred. 1: The DMA for receive FIFO buffer x is being transferred. (x = 0 to 7)

2	RFDMASTS2	B'0	R	
1	RFDMASTS1	B'0	R	
0	RFDMASTS0	B'0	R	

CFDMASTSm Bits

When the DMA transfer for transmit/receive FIFO buffer 3 × m (the first transmit/receive FIFO buffer assigned to channel m) is enabled (the CFDMAEm bit in the RSCFDnCFDCDTCT register is 1) and there is a message in the transmit/receive FIFO buffer, the CFDMASTSm bit becomes 1 and indicates that the DMA is being transferred.

When all messages in the transmit/receive FIFO buffer are transferred or the DMA transfer is disabled (the CFDMAEm bit is 0), the CFDMASTSm bit becomes 0 and indicates that the DMA transfer completed. When the CFDMAEm bit is cleared to 0 during DMA transfer, the CFDMASTSm bit becomes 0 after the DMA transfer in execution has completed (the message has been transferred to the last byte in the payload storage area).

48.9.10 Details of Transmit Buffer Related Registers

48.9.10.1 RSCFDnCFDTMCp — Transmit Buffer Control Register (p = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDTMCp register can be read/written in 8-bit units

Address: RSCFDnCFDTMCp: <RSCFDn_base> + H'0250 + (H'01 × p)

Value after reset: H'00

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	TMOM	TMTAR	TMTR
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W*	R/W*

Note: * The only effective value for writing to this bit is 1, which sets the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
2	TMOM	B'0	R/W	One-Shot Transmission Enable Setting this bit to 1 enables one-shot transmission. When transmission fails, retransmission defined in the CAN protocol is not performed. Modify the TMOM bit when the TMTRM flag in the RSCFDnCFDTMSTSp register is set to 0. Set the TMOM bit to 1 together with the TMTR bit. 0: One-shot transmission is disabled. 1: One-shot transmission is enabled.
1	TMTAR	B'0	R/W	Transmit Abort Request Setting this bit to 1 generates a transmit abort request for the message stored in the transmit buffer. However, a message that is being transmitted or one that will be transmitted next cannot be aborted. The TMTAR bit can be set to 1 when TMTR bit is 1. The TMTAR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit. • Transmission has been completed. • Transmit abort has been completed. • An error or arbitration loss has been detected. If this bit becomes 0 at the same time as the program writes 1 to this bit, this bit becomes 0. 0: Transmit abort is not requested. 1: Transmit abort is requested.

Bit	Bit Name	Initial Value	R/W	Description
0	TMTR	B'0	R/W	Transmit Request Setting this bit to 1 transmits the message stored in the transmit buffer. The TMTR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit. • Transmission has been completed. • Transmit abort has been completed after the TMTAR bit was set to 1. • An error or arbitration-lost has been detected with the TMOM bit set to 1. Set the TMTR bit to 1 when the value of TMTRF[1:0] in the RSCFDnCFDTMSTSp register is B'00. 0: Transmission is not requested. 1: Transmission is requested.

When the RSCFDnCFDTMCp register meets any of the following conditions, set it to H'00.

- The RSCFDnCFDTMCp register corresponds to the transmit buffer number selected by the CFTML[3:0] bits in the RSCFDnCFDCFCCk register (p = m × 16 + the value of CFTML[3:0] bits).
- The RSCFDnCFDTMCp register corresponds to the transmit buffer allocated to the transmit queue by the TXQDC[3:0] bits in the RSCFDnCFDTXQCCm (m = 0 or 1) register (p = (m × 16 + 15) to (m × 16 + 15 - the value of TXQDC[3:0] bits)).
- The TMME bit in the RSCFDnCFDCmFDCFG register is 1 (transmit buffer merge mode) and the RSCFDnCFDTMCp register corresponds to the transmit buffer allocated to the payload storage area (p = (m × 16) + 1, (m × 16) + 2, (m × 16) + 4, (m × 16) + 5).

Bits in the RSCFDnCFDTMCp register are all cleared to 0 in channel reset mode. Modify the RSCFDnCFDTMCp register in channel communication mode or channel halt mode.

48.9.10.2 RSCFDnCFDTMSTSp — Transmit Buffer Status Register (p = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDTMSTSp register can be read/written in 8-bit units

Address: RSCFDnCFDTMSTSp: <RSCFDn_base> + H'02D0 + (H'01 × p)

Value after reset: H'00

Bit:	7	6	5	4	3	2	1	0
	—	—	—	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
4	TMTARM	B’0	R	Transmit Buffer Transmit Abort Request Status Flag The TMTARM flag is set to 1 when the TMTAR bit in the RSCFDnCFDTMCp register is set to 1. The TMTARM flag is set to 0 when the TMTAR bit in the RSCFDnCFDTMCp register is set to 0. 0: No transmit abort request is present. 1: A transmit abort request is present.
3	TMTRM	B’0	R	Transmit Buffer Transmit Request Status Flag The TMTRM flag is set to 1 when the TMTR bit in the RSCFDnCFDTMCp register is set to 1. The TMTRM flag is set to 0 when the TMTR bit in the RSCFDnCFDTMCp register is set to 0. 0: No transmit request is present. 1: A transmit request is present.
2, 1	TMTRF[1:0]	B’00	R/W	Transmit Buffer Transmit Result Status Flag This flag indicates the result of transmission from the transmit buffer. B’00: Transmission is in progress or no transmit request is present. B’01: Transmission from the transmit buffer was aborted. B’10: Transmission has been completed with the TMTAR bit in the RSCFDnCFDTMCp register set to 0 (transmit abort is not requested). B’11: Transmission has been completed with the TMTAR bit in the RSCFDnCFDTMCp register set to 1 (transmit abort is requested). Write B'00 to the TMTRF[1:0] flag in channel communication mode or channel halt mode. Do not write any value other than B'00 to this flag.

Bit	Bit Name	Initial Value	R/W	Description
0	TMTSTS	B'0	R	Transmit Buffer Transmit Status Flag This flag is set to 1 when transmission from the transmit buffer starts, and is cleared to 0 when transmission from the transmit buffer has been completed or terminated due to a bus error or arbitration lost. 0: Transmission is not in progress. 1: Transmission is in progress.

The RSCFDnCFDTMSTSp register is cleared to all 0 in channel reset mode.

48.9.10.3 RSCFDnCFDTMIDp — Transmit Buffer ID Register (p = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDTMIDp register can be read/written in 32-bit units

RSCFDnCFDTMIDpL, RSCFDnCFDTMIDpH registers can be read/written in 16-bit units

RSCFDnCFDTMIDpLL, RSCFDnCFDTMIDpLH, RSCFDnCFDTMIDpHL, RSCFDnCFDTMIDpHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTMIDp: <RSCFDn_base> + H'4000 + (H'20 × p)

RSCFDnCFDTMIDpL: <RSCFDn_base> + H'4000 + (H'20 × p),
RSCFDnCFDTMIDpH: <RSCFDn_base> + H'4002 + (H'20 × p)

RSCFDnCFDTMIDpLL: <RSCFDn_base> + H'4000 + (H'20 × p),
RSCFDnCFDTMIDpLH: <RSCFDn_base> + H'4001 + (H'20 × p),
RSCFDnCFDTMIDpHL: <RSCFDn_base> + H'4002 + (H'20 × p),
RSCFDnCFDTMIDpHH: <RSCFDn_base> + H'4003 + (H'20 × p)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TMIDE	TMRTR	THLEN	TMID[28:16]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TMID[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	TMIDE	B'0	R/W	Transmit Buffer IDE This bit is used to set the ID format of the message to be transmitted from the transmit buffer. 0: Standard ID 1: Extended ID
30	TMRTR	B'0	R/W	Transmit Buffer RTR/RRS This bit is used to set the data format of the message to be transmitted from the transmit buffer. When the TMFDF bit in the RSCFDnCFDTMFDCTRp register is 1 (CAN FD frame), this bit must be cleared to 0. • When the transmit message is in the classical CAN frame: 0: Data frame 1: Remote frame • When the transmit message is in the CAN FD frame: Write 0 to this bit.
29	THLEN	B'0	R/W	Transmit History Data Store Enable With this bit set to 1, the transmit history data of the message transmitted (label information, buffer number, buffer type, and timestamp) is stored in the transmit history buffer after transmission is completed. 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.

Bit	Bit Name	Initial Value	R/W	Description
28 to 0	TMID[28:0]	H'0000_0000	R/W	Transmit Buffer ID Data These bits are used to set the ID of the message to be transmitted from the transmit buffer. Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11.

Modify this register when the TMTRM bit in the corresponding RSCFDnCFDTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write data to this register. If this register is allocated to the transmit queue, only write data to a transmit buffer p (p = m × 16 + 15) for the corresponding channel.

48.9.10.4 RSCFDnCFDTMPTRp — Transmit Buffer Pointer Register (p= 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDTMPTRp register can be read/written in 32-bit units

RSCFDnCFDTMPTRpL, RSCFDnCFDTMPTRpH registers can be read/written in 16-bit units

RSCFDnCFDTMPTRpLL, RSCFDnCFDTMPTRpLH, RSCFDnCFDTMPTRpHL, RSCFDnCFDTMPTRpHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTMPTRp: <RSCFDn_base> + H'4004 + (H'20 × p)

RSCFDnCFDTMPTRpL: <RSCFDn_base> + H'4004 + (H'20 × p),

<table>
<tr><th>Bit</th><th>Bit Name</th><th>Initial Value</th><th>R/W</th><th>Description</th></tr>
<tr><td>31 to 28</td><td>TMDLC[3:0]</td><td>H’0</td><td>R/W</td><td>Transmit Buffer DLC Data
These bits are used to set the data length of the message to be transmitted from the transmit buffer when the TMRTR bit in the RSCFDnCFDTMIDp register is set to 0 (data frame). When the TMFDF bit in the RSCFDnCFDTMFDCTRp register is 0 (classical CAN frame) and the value equal to or larger than B'1001 is set to the TMDLC[3:0] bits, 8-byte data is transmitted. When the TMFDF bit is 1 (CAN FD frame), the range of values to be set differs depending on the TMME bit in the RSCFDnCFDCmFDCFG register.
• When the TMME bit is 0 (the transmit buffer merge mode is disabled):
All values from B'0000 to B'1111 can be set. If B'1100 or larger value is set, the payload which exceeds 20 bytes will be padded by CCH.
• When the TMME bit is 1 (the transmit buffer merge mode is enabled):
When the number of the corresponding transmit buffer is p = (m × 16) + 0 or (m × 16) + 3, all values from B'0000 to B'1111 can be set. For other cases, set values up to B'1011 (20 data bytes).
When the TMRTR bit is set to 1 (remote frame), set the data length of messages to be requested.
<table>
<tr><th></th><th>Classical CAN frame</th><th>CAN FD frame</th></tr>

</table>

Modify this register when the TMTRM bit in the corresponding RSCFDnCFDTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write to this register. If this register is allocated to the transmit queue, only write to a transmit buffer p (p = m × 16 + 15) for the corresponding channel.

48.9.10.5 RSCFDnCFDTMFDCTRp — Transmit Buffer CAN FD Configuration Register (p = 0 to 31)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDTMFDCTRp register can be read/written in 32-bit units

RSCFDnCFDTMFDCTRpL, RSCFDnCFDTMFDCTRpH registers can be read/written in 16-bit units

RSCFDnCFDTMFDCTRpLL, RSCFDnCFDTMFDCTRpLH, RSCFDnCFDTMFDCTRpHL, RSCFDnCFDTMFDCTRpHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTMFDCTRp: <RSCFDn_base> + H'4008 + (H'20 × p)

RSCFDnCFDTMFDCTRpL: <RSCFDn_base> + H'4008 + (H'20 × p),
RSCFDnCFDTMFDCTRpH: <RSCFDn_base> + H'400A + (H'20 × p)

RSCFDnCFDTMFDCTRpLL: <RSCFDn_base> + H'4008 + (H'20 × p),
RSCFDnCFDTMFDCTRpLH: <RSCFDn_base> + H'4009 + (H'20 × p),
RSCFDnCFDTMFDCTRpHL: <RSCFDn_base> + H'400A + (H'20 × p),
RSCFDnCFDTMFDCTRpHH: <RSCFDn_base> + H'400B + (H'20 × p)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TMFDF	TMBRS	TMESI
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	Reserved	All 0	R	These bits are read as the value after reset. The write value should be the value after reset.
2	TMFDF	B'0	R/W	FDF This bit is used to set the FD format of the message to be transmitted from the transmit buffer. 0: Classical CAN frame 1: CAN FD frame
1	TMBRS	B'0	R/W	BRS When the TMFDF bit is 1 and this bit is set to 1, the data area for transmit messages is transmitted with data bit rate. Write 0 to this bit if the TMFDF bit is 0. 0: The bit rate in the data area is not changed. 1: The bit rate in the data area is changed.
0	TMESI	B'0	R/W	ESI When the TMFDF bit is 1, this bit is used to set the ESI bit value of the message transmitted from the transmit buffer. The set value is transmitted when the ESIC bit in the RSCFDnCFDCmFDCFG register is 1 and the channel is in error-active state. When the channel is in error-passive state, the ESI bit value indicating the error-passive node is transmitted regardless of this bit. Write 0 to this bit if the TMFDF bit is 0. 0: Error-active node 1: Error-passive node

Modify this register when the TMTRM bit in the corresponding RSCFDnCFDTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write to this register. If this register is allocated to the transmit queue, only write to a transmit buffer p (p = m × 16 + 15) for the corresponding channel.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TMIEp	H'0000_0000	R/W	Transmit Buffer Interrupt Enable p (p = y × 32 + 31 to y × 32 + 0) 0: Transmit buffer interrupt is disabled. 1: Transmit buffer interrupt is enabled.

TMIEp Bits (p = 0 to 31)

When any of these bits is set to 1 and the corresponding transmission has been completed, a transmit buffer interrupt request is generated.

Modify these bits when the TMTRM flag in the corresponding RSCFDnCFDTMSTSp register is 0 (no transmit request is present).

Write 0 to bits corresponding to transmit buffers linked to transmit/receive FIFO buffers or transmit buffers allocated to the transmit queue. When the TMME bit in the RSCFDnCFDCmFDCFG register is 1 (the transmit buffer merge mode is enabled), write 0 to bits corresponding to transmit buffers allocated to the payload storage area.

Table 48.23 shows the bit assignment.

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	TXQIM	TXQIE	TXQDC[3:0]				—	—	—	—	—	—	—	TXQE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
13	TXQIM	B'0	R/W	Transmit Queue Interrupt Source Select This bit is used to select a transmit queue interrupt source. Modify this bit in channel reset mode. 0: When the transmit queue becomes empty upon completion of message transmission, a transmit queue interrupt request is generated. 1: A transmit queue interrupt request is generated each time a message has been transmitted.
12	TXQIE	B'0	R/W	Transmit Queue Interrupt Enable When the TXQIE bit is set to 1 and the source selected by the TXQIM bit occurs, an interrupt request is generated. Set the TXQE bit to 0 before modifying the TXQIE bit. 0: Transmit queue interrupt is disabled. 1: Transmit queue interrupt is enabled.

Bit	Bit Name	Initial Value	R/W	Description
11 to 8	TXQDC[3:0]	B'0000	R/W	Transmit Queue Depth Configuration Setting these bits to g (g = 2 to 15) makes the (g + 1)-buffer transmit queue available. Setting these bits to 0 disables the transmit queue. Setting these bits to 1 is prohibited. For transmit buffer merge mode, set g = 2 to 9. These bits are used to specify the number of transmit buffers to be allocated to the transmit queues. Transmit buffers are allocated to transmit queues in descending order of buffer number, that is, from (m × 16 + 15) to (m × 16 + 0). For examples of how buffer allocation is done, see Figure 48.9. When the TMME bit in the RSCFDnCFDCmFDCFG register is 1 (transmit buffer merge mode), transmit buffers from (m × 16 + 5) to (m × 16 + 0) are merged and cannot be allocated to the transmit queues. Do not specify 10 to 15 to the TXQDC[3:0] bits. Modify these bits only in channel reset mode.
7 to 1	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	TXQE	B'0	R/W	Transmit Queue Enable Setting this bit to 1 makes the transmit queue available. Modify this bit in channel communication mode or channel halt mode. This bit is cleared to 0 in channel reset mode. Before setting the TXQE bit to 1, set the TXQDC[3:0] bits to B'0010 or more. 0: The transmit queue is not used. 1: The transmit queue is used.

48.9.12.2 RSCFDnCFDTXQSTSm — Transmit Queue Status Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQIF	TXQFLL	TXQEMP
Initial value:	0	0	0	—	—	—	—	—	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*	R	R

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
12 to 8	Reserved	Undefined	R	When read, an undefined value is returned. When writing to these bits, write the value after reset.
7 to 3	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	TXQIF	B'0	R/W	Transmit Queue Interrupt Request Flag The TXQIF flag is set to 1 when the event specified by the TXQIM bit in the RSCFDnCFDTXQCCm register has occurred. The TXQIF flag is cleared to 0 in channel reset mode or by writing 0 to this flag. This flag is not cleared to 0 by setting the TXQE bit in the RSCFDnCFDTXQCCm register to 0 (the transmit queue is not used). 0: No transmit queue interrupt request is present. 1: A transmit queue interrupt request is present.

Bit	Bit Name	Initial Value	R/W	Description
1	TXQFLL	B'0	R	Transmit Queue Full Status Flag The TXQFLL flag is set to 1 when the number of messages set for the transmit queue matches the transmit queue depth set by the TXQDC[3:0] bits in the RSCFDnCFDTXQCCm register. This flag is cleared to 0 in any of the following cases. • The number of messages set for the transmit queue is smaller than the transmit queue depth set by the TXQDC[3:0] bits. • In channel reset mode 0: The transmit queue is not full. 1: The transmit queue is full.
0	TXQEMP	B'1	R	Transmit Queue Empty Status Flag The TXQEMP flag is cleared to 0 when even a single message is set for the transmit queue. This flag is set to 1 in any of the following cases. • The TXQE bit is set to 0 (the transmit queue is not used). • The transmit queue becomes empty. • In channel reset mode 0: The transmit queue contains messages. 1: The transmit queue contains no message (transmit queue empty).

48.9.12.3 RSCFDnCFDTXQPCTRm — Transmit Queue Pointer Control Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDTXQPCTRm register can only be written in 32-bit units

RSCFDnCFDTXQPCTRmL, RSCFDnCFDTXQPCTRmH registers can only be written in 16-bit units

RSCFDnCFDTXQPCTRmLL, RSCFDnCFDTXQPCTRmLH, RSCFDnCFDTXQPCTRmHL, RSCFDnCFDTXQPCTRmHH registers can only be written in 8-bit units

Address: RSCFDnCFDTXQPCTRm: <RSCFDn_base> + H'03E0 + (H'04 × m)

RSCFDnCFDTXQPCTRmL: <RSCFDn_base> + H'03E0 + (H'04 × m),
RSCFDnCFDTXQPCTRmH: <RSCFDn_base> + H'03E2 + (H'04 × m)

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	TXQPC[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	Reserved	All 0	R	The write value should be the value after reset.
7 to 0	TXQPC[7:0]	H'00	W	Transmit Queue Pointer Control Writing H'FF to the TXQPC[7:0] bits moves the write pointer to the next transmit queue buffer and generates a transmit request of the message. Write transmit messages to the RSCFDnCFDTMIDp, RSCFDnCFDTMPTRp, RSCFDnCFDTMFDCTRp, and RSCFDnCFDTMDFb_p registers (p = 15, 31) before writing H'FF to the TXQPC[7:0] bits. When writing H'FF to these bits, make sure that the TXQE bit in the RSCFDnCFDTXQCCm register is set to 1 (the transmit queue is used) and the TXQFLL flag in the RSCFDnCFDTXQSTSm register is 0 (the transmit queue is not full).

48.9.13 Details of Transmit History Related Registers

48.9.13.1 RSCFDnCFDTHLCCm — Transmit History Configuration and Control Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDTHLCCm register can be read/written in 32-bit units

RSCFDnCFDTHLCCmL, RSCFDnCFDTHLCCmH registers can be read/written in 16-bit units

RSCFDnCFDTHLCCmLL, RSCFDnCFDTHLCCmLH, RSCFDnCFDTHLCCmHL, RSCFDnCFDTHLCCmHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTHLCCm: <RSCFDn_base> + H'0400 + (H'04 × m)

RSCFDnCFDTHLCCmL: <RSCFDn_base> + H'0400 + (H'04 × m),
RSCFDnCFDTHLCCmH: <RSCFDn_base> + H'0402 + (H'04 × m)

RSCFDnCFDTHLCCmLL: <RSCFDn_base> + H'0400 + (H'04 × m),
RSCFDnCFDTHLCCmLH: <RSCFDn_base> + H'0401 + (H'04 × m),
RSCFDnCFDTHLCCmHL: <RSCFDn_base> + H'0402 + (H'04 × m),
RSCFDnCFDTHLCCmHH: <RSCFDn_base> + H'0403 + (H'04 × m)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	THLDTE	THLIM	THLIE	—	—	—	—	—	—	—	THLE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
10	THLDTE	B'0	R/W	Transmit History Target Buffer Select When this bit is set to 0, the transmit history data of messages transmitted from transmit/receive FIFO buffers and the transmit queue is stored in the transmit history buffer. When this bit is set to 1, the transmit history data of messages transmitted from transmit buffers, transmit/receive FIFO buffers, and the transmit queue is stored in the transmit history buffer. Modify this bit only in channel reset mode. 0: Entry from transmit/receive FIFO buffers and transmit queue 1: Entry from transmit buffers, transmit/receive FIFO buffers, and transmit queue
9	THLIM	B'0	R/W	Transmit History Interrupt Source Select This bit is used to select a transmit history interrupt source. Modify this bit only in channel reset mode. 0: When 12 sets of data have been stored in the transmit history buffer 1: When a single set of transmit history data has been stored

Bit	Bit Name	Initial Value	R/W	Description
8	THLIE	B'0	R/W	Transmit History Interrupt Enable When the THLIE bit is set to 1 and the source selected by the THLIM bit has occurred, a transmit history interrupt request is generated. Modify the THLIE bit only when the THLE bit set to 0. 0: Transmit history interrupt is disabled. 1: Transmit history interrupt is enabled.
7 to 1	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	THLE	B'0	R/W	Transmit History Buffer Enable Setting this bit to 1 makes the transmit history buffer available. When data transmission from the buffer selected by the THLDTE bit has been completed, the transmit history data of transmit messages is stored in the transmit history buffer. Modify this bit in channel communication mode or channel halt mode. 0: Transmit history buffer is not used. 1: Transmit history buffer is used.

48.9.13.2 RSCFDnCFDTHLSTSm — Transmit History Status Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDTHLSTSm register can be read/written in 32-bit units

RSCFDnCFDTHLSTSmL, RSCFDnCFDTHLSTSmH registers can be read/written in 16-bit units

RSCFDnCFDTHLSTSmLL, RSCFDnCFDTHLSTSmLH, RSCFDnCFDTHLSTSmHL, RSCFDnCFDTHLSTSmHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTHLSTSm: <RSCFDn_base> + H'0420 + (H'04 × m)

RSCFDnCFDTHLSTSmL: <RSCFDn_base> + H'0420 + (H'04 × m),
RSCFDnCFDTHLSTSmH: <RSCFDn_base> + H'0422 + (H'04 × m)

RSCFDnCFDTHLSTSmLL: <RSCFDn_base> + H'0420 + (H'04 × m),
RSCFDnCFDTHLSTSmLH: <RSCFDn_base> + H'0421 + (H'04 × m),
RSCFDnCFDTHLSTSmHL: <RSCFDn_base> + H'0422 + (H'04 × m),
RSCFDnCFDTHLSTSmHH: <RSCFDn_base> + H'0423 + (H'04 × m)

Value after reset: H'0000_0001

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	THLMC[4:0]					—	—	—	—	THLIF	THLELT	THLFLL	THLEMP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R	R

Note: * The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
12 to 8	THLMC[4:0]	B'0_0000	R	Transmit History Buffer Unread Data Counter These bits indicate the number of unread data sets stored in the transmit history buffer.
7 to 4	Reserved	All 0	R	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	THLIF	B'0	R/W	Transmit History Interrupt Request Flag The THLIF flag is set to 1 when the interrupt source specified with the THLIM bit in the RSCFDnCFDTHLCCm register occurs. This flag is cleared to 0 in channel reset mode or by the program writing 0 to this flag. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: No transmit history interrupt request is present. 1: A transmit history interrupt request is present.

Bit	Bit Name	Initial Value	R/W	Description
2	THLELT	B'0	R/W	Transmit History Buffer Overflow Flag The THLELT flag is set to 1 when an attempt is made to store new transmit history data while the transmit history buffer is full. In this case, the new data is discarded. This flag becomes 0 in channel reset mode or by the program writing 0 to this flag. To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1". 0: Transmit history buffer overflow has not occurred. 1: Transmit history buffer overflow has occurred.
1	THLFLL	B'0	R	Transmit History Buffer Full Status Flag The THLFLL flag is set to 1 when 16 data sets have been stored in the transmit history buffer, and is cleared to 0 when the number of data sets stored in the transmit history buffer has decreased to less than 16. This bit is also cleared to 0 in channel reset mode or when the THLE bit in the RSCFDnCFDTHLCCm register is set to 0 (transmit history buffer is not used). 0: Transmit history buffer is not full. 1: Transmit history buffer is full.
0	THLEMP	B'1	R	Transmit History Buffer Empty Status Flag The THLEMP flag is cleared to 0 when even a single set of transmit history data has been stored in the transmit history buffer. This flag is set to 1 when all the data in the transmit history buffer has been read. This flag is also set to 1 in channel reset mode or when the THLE bit in the RSCFDnCFDTHLCCm register is set to 0 (transmit history buffer is not used). 0: Transmit history buffer contains unread data. 1: Transmit history buffer contains no unread data (buffer empty).

Note: To clear THLIF or THLELT flag to 0, the program must write 0. When writing, use a store instruction to write "0" to the given flag and "1" to other flags.

48.9.13.3 RSCFDnCFDTHLPCTRm — Transmit History Pointer Control Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDTHLPCTRm register can only be written in 32-bit units

RSCFDnCFDTHLPCTRmL, RSCFDnCFDTHLPCTRmH registers can only be written in 16-bit units

RSCFDnCFDTHLPCTRmLL, RSCFDnCFDTHLPCTRmLH, RSCFDnCFDTHLPCTRmHL, RSCFDnCFDTHLPCTRmHH registers can only be written in 8-bit units

Address: RSCFDnCFDTHLPCTRm: <RSCFDn_base> + H'0440 + (H'04 × m)

RSCFDnCFDTHLPCTRmL: <RSCFDn_base> + H'0440 + (H'04 × m),
RSCFDnCFDTHLPCTRmH: <RSCFDn_base> + H'0442 + (H'04 × m)

RSCFDnCFDTHLPCTRmLL: <RSCFDn_base> + H'0440 + (H'04 × m),
RSCFDnCFDTHLPCTRmLH: <RSCFDn_base> + H'0441 + (H'04 × m),
RSCFDnCFDTHLPCTRmHL: <RSCFDn_base> + H'0442 + (H'04 × m),
RSCFDnCFDTHLPCTRmHH: <RSCFDn_base> + H'0443 + (H'04 × m)

Value after reset: H'0000_0000

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	THLPC[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	Reserved	All 0	R	When writing to these bits, write the value after reset.
7 to 0	THLPC[7:0]	H'00	W	Transmit History List Pointer Control When the THLPC[7:0] bits are set to H'FF, the read pointer moves to the next data in the transmit history buffer. At this time, the THLMC[4:0] (transmit history buffer unread data counter) value in the RSCFDnCFDTHLSTSm register is decremented. Write H'FF to the THLPC[7:0] bits after reading from the RSCFDnCFDTHLACCm register. When writing H'FF to these bits, make sure that the THLE bit in the RSCFDnCFDTHLCCm register is set to 1 (transmit history buffer is used) and the THLEMP flag in the RSCFDnCFDTHLSTSm register is 0.

48.9.13.4 RSCFDnCFDTHLACCm — Transmit History Access Register (m = 0 or 1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDTHLACCm register can be read only in 32-bit units

RSCFDnCFDTHLACCmL, RSCFDnCFDTHLACCmH registers can be read only in 16-bit units

RSCFDnCFDTHLACCmLL, RSCFDnCFDTHLACCmLH, RSCFDnCFDTHLACCmHL, RSCFDnCFDTHLACCmHH registers can be read only in 8-bit units

Address: RSCFDnCFDTHLACCm: <RSCFDn_base> + H'6000 + (H'04 × m)

RSCFDnCFDTHLACCmL: <RSCFDn_base> + H'6000 + (H'04 × m),
RSCFDnCFDTHLACCmH: <RSCFDn_base> + H'6002 + (H'04 × m)

RSCFDnCFDTHLACCmLL: <RSCFDn_base> + H'6000 + (H'04 × m),
RSCFDnCFDTHLACCmLH: <RSCFDn_base> + H'6001 + (H'04 × m),

R/W:	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*	W*

Note: * Writing to these bits is effective only when the RS-CANFD module is in global test mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Reserved	All 0	R	When writing to these bits, write the value after reset.
15 to 0	LOCK[15:0]	H'0000	W	Lock Key Writing the protection release data to the LOCK[15:0] bits in succession enables writing 1 to the RTME bit in the RSCFDnCFDGTSTCTR register. After the protection has been released, writing to the I/O register area (<RSCFDn_base> + H'0000 to <RSCFDn_base> + H'0FFF) of the CAN (except the RAM) enables the protection again. Reading from the I/O register area of the CAN or reading from/writing to other areas does not enable the protection.

The RSCFDnCFDGLOCKK register releases protection of special test bits and is write only.

For the protection release data, see section 48.16.4.2, Procedure for Releasing the Protection.

48.9.14.4 RSCFDnCFDRPGACCr — RAM Test Page Access Register (r = 0 to 63)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Access: RSCFDnCFDRPGACCr register can be read/written in 32-bit units

RSCFDnCFDRPGACCrL, RSCFDnCFDRPGACCrH registers can be read/written in 16-bit units

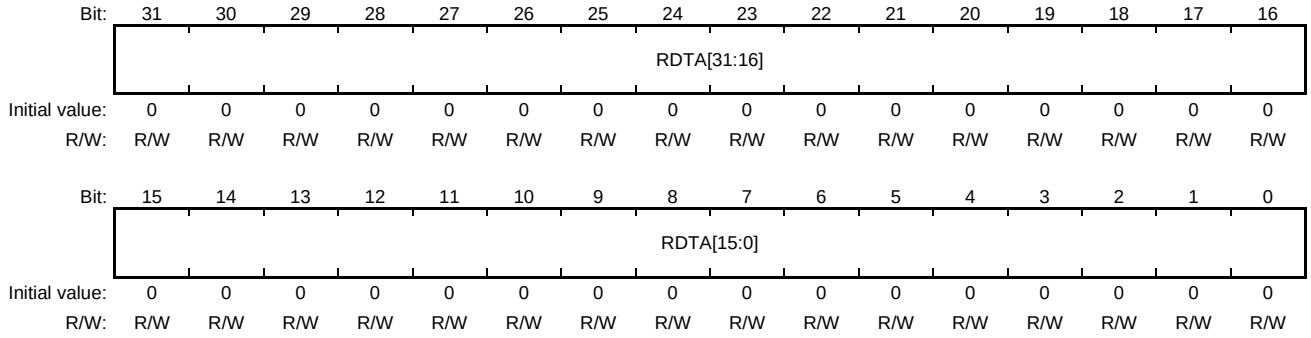
RSCFDnCFDRPGACCrLL., RSCFDnCFDRPGACCrLH, RSCFDnCFDRPGACCrHL, RSCFDnCFDRPGACCrHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRPGACCr: <RSCFDn_base> + H'6400 + (H'04 × r)

RSCFDnCFDRPGACCrL: <RSCFDn_base> + H'6400 + (H'04 × r),
RSCFDnCFDRPGACCrH: <RSCFDn_base> + H'6402 + (H'04 × r)

RSCFDnCFDRPGACCrLL: <RSCFDn_base> + H'6400 + (H'04 × r),
RSCFDnCFDRPGACCrLH: <RSCFDn_base> + H'6401 + (H'04 × r),
RSCFDnCFDRPGACCrHL: <RSCFDn_base> + H'6402 + (H'04 × r),
RSCFDnCFDRPGACCrHH: <RSCFDn_base> + H'6403 + (H'04 × r)

Value after reset: H'0000_0000



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDTA[31:0]	H'0000_0000	R/W	RAM Data Test Access Data can be read and written in RSCAN RAM.

Modify the RSCFDnCFDRPGACCr register in global test mode with the RTME bit in the RSCFDnCFDGTSTCTR register set to 1 (RAM test is enabled).

The RSCFDnCFDRPGACCr register is readable and writable when the RTME bit is set to 1.

48.10 Interrupt Sources and DMA Triggers

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

48.10.1 Interrupt Sources

Interrupt sources are classified into global and channel interrupts.

- Global interrupts (2 sources):
  - Receive FIFO interrupt
  - Global error interrupt
- Channel interrupts (3 sources/channel):
  CANm transmit interrupt (m = 0 or 1)
  - CANm transmit complete interrupt
  - CANm transmit abort interrupt
  - CANm transmit/receive FIFO transmit complete interrupt (in transmit mode, gateway mode)
  - CANm transmit history interrupt
  - CANm transmit queue interrupt

  CANm transmit/receive FIFO receive complete interrupt (in receive mode, gateway mode)
  CANm error interrupt

When an interrupt request is generated, the corresponding interrupt request flag is set to 1 (interrupt request present). In that case, when the interrupt enable bit is set to 1 (enabling interrupts), an interrupt request is output from the RS-CANFD module. (Generation of interrupts also depends on the interrupt control register settings of the interrupt controller.)

Setting the interrupt request flag to 0 (no interrupt request present) or setting the interrupt enable bit to 0 (disabling interrupts) clears the current interrupt request. The current interrupt request is still output until the interrupt request flag is cleared.

Table 48.28 lists the CAN interrupt sources. Figure 48.2 shows the CAN global interrupt block diagram. Figure 48.3 shows the CAN channel interrupt block diagram.

Table 48.28 List of CAN Interrupt Sources

	Interrupt Source		Corresponding Interrupt Request Flag	Corresponding Interrupt Enable Bit
Global interrupts	Receive FIFO	Receive FIFO 0	RFIF in the RSCFDn(CFD)RFSTS0 register	RFIE in the RSCFDn(CFD)RFCC0 register
		Receive FIFO 1	RFIF in the RSCFDn(CFD)RFSTS1 register	RFIE in the RSCFDn(CFD)RFCC1 register
		Receive FIFO 2	RFIF in the RSCFDn(CFD)RFSTS2 register	RFIE in the RSCFDn(CFD)RFCC2 register
		Receive FIFO 3	RFIF in the RSCFDn(CFD)RFSTS3 register	RFIE in the RSCFDn(CFD)RFCC3 register
		Receive FIFO 4	RFIF in the RSCFDn(CFD)RFSTS4 register	RFIE in the RSCFDn(CFD)RFCC4 register
		Receive FIFO 5	RFIF in the RSCFDn(CFD)RFSTS5 register	RFIE in the RSCFDn(CFD)RFCC5 register
		Receive FIFO 6	RFIF in the RSCFDn(CFD)RFSTS6 register	RFIE in the RSCFDn(CFD)RFCC6 register
		Receive FIFO 7	RFIF in the RSCFDn(CFD)RFSTS7 register	RFIE in the RSCFDn(CFD)RFCC7 register
	Global error		• DEF in the RSCFDn(CFD)GERFL register • MES in the RSCFDn(CFD)GERFL register • THLES in the RSCFDn(CFD)GERFL register • CMPOF in the RSCFDnCFDGERFL register	• DEIE in the RSCFDn(CFD)GCTR register • MEIE in the RSCFDn(CFD)GCTR register • THLEIE in the RSCFDn(CFD)GCTR register • CMPOFIE in the RSCFDnCFDGCTR register
Channel interrupts (m = 0 or 1)	CANm transmit	CANm transmit complete	TMTRF[1:0] in the RSCFDn(CFD)TMSTSp register	TMIEp in the RSCFDn(CFD)TMIECy register
		CANm transmit abort	TMTRF[1:0] in the RSCFDn(CFD)TMSTSp register	TAIE in the RSCFDn(CFD)CmCTR register
		CANm transmit/receive FIFO transmit complete	CFTXIF in the RSCFDn(CFD)CFSTSk register	CFTXIE in the RSCFDn(CFD)CFCCk register
		CANm transmit queue	TXQIF in the RSCFDn(CFD)TXQSTSm register	TXQIE in the RSCFDn(CFD)TXQCCm register
		CANm transmit history	THLIF in the RSCFDn(CFD)THLSTSm register	THLIE in the RSCFDn(CFD)THLCCm register
	CANm transmit/receive FIFO receive complete		CFRXIF in the RSCFDn(CFD)CFSTSk register	CFRXIE in the RSCFDn(CFD)CFCCk register

	Interrupt Source	Corresponding Interrupt Request Flag	Corresponding Interrupt Enable Bit
Channel interrupts (m = 0 or 1)	CANm error	• BEF in the RSCFDn(CFD)CmERFL register • ALF in the RSCFDn(CFD)CmERFL register • BLF in the RSCFDn(CFD)CmERFL register • OVLF in the RSCFDn(CFD)CmERFL register • BORF in the RSCFDn(CFD)CmERFL register • BOEF in the RSCFDn(CFD)CmERFL register • EPF in the RSCFDn(CFD)CmERFL register • EWF in the RSCFDn(CFD)CmERFL register • SOCO in the RSCFDn(CFD)CmERFL register • EOCO in the RSCFDn(CFD)CmERFL register • TDCVF in the RSCFDn(CFD)CmERFL register	• BEIE in the RSCFDn(CFD)CmCTR register • ALIE in the RSCFDn(CFD)CmCTR register • BLIE in the RSCFDn(CFD)CmCTR register • OLIE in the RSCFDn(CFD)CmCTR register • BORIE in the RSCFDn(CFD)CmCTR register • BOEIE in the RSCFDn(CFD)CmCTR register • EPIE in the RSCFDn(CFD)CmCTR register • EWIE in the RSCFDn(CFD)CmCTR register • SOCOIE in the RSCFDnCFDCmCTR register • EOCOIE in the RSCFDnCFDCmCTR register • TDCVFIE in the RSCFDnCFDCmCTR register

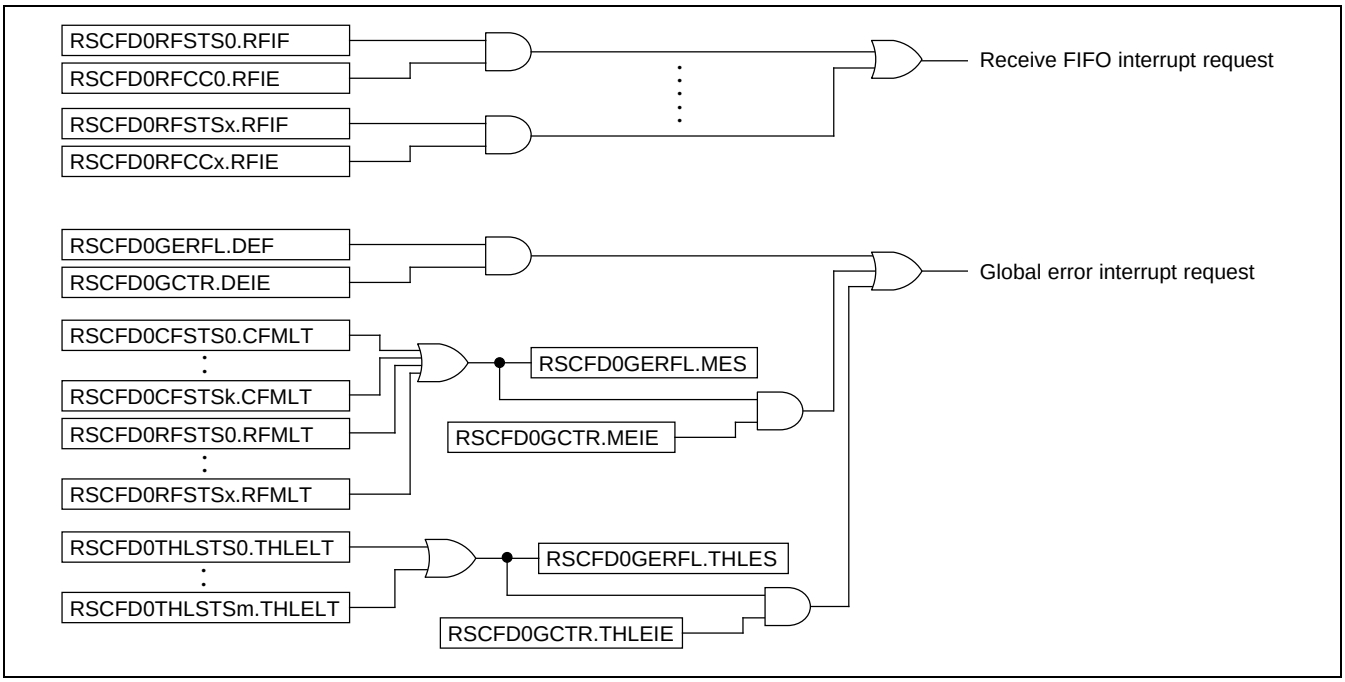


Figure 48.2 CAN Global Interrupt Block Diagram

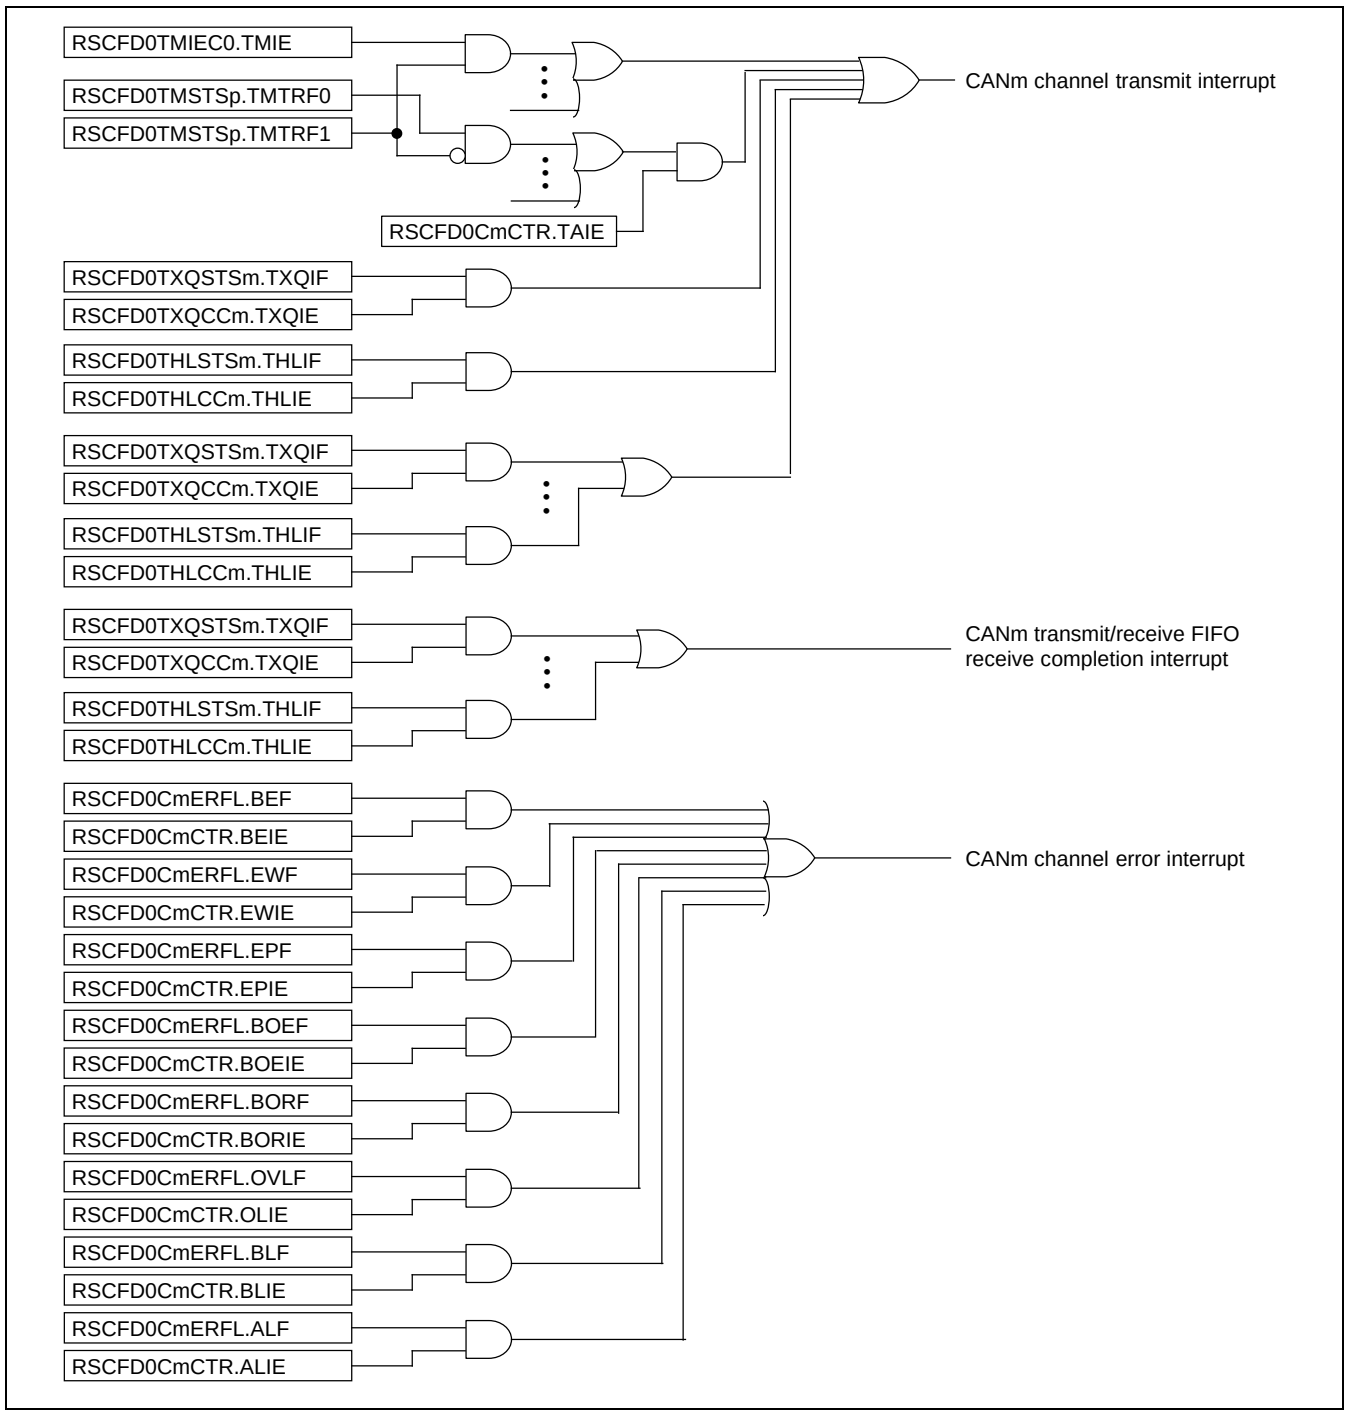

Figure 48.3 CAN Channel Interrupt Block Diagram

48.10.2 DMA Triggers (CAN FD Mode Only)

In CAN FD mode, the FIFO buffer for reception can be related to DMA channels. The following 10 FIFO buffers are available.

- All receive FIFO buffers x (x = 0 to 7)
- The first transmit/receive FIFO buffer k (k = 3 × m, m = 0 or 1) assigned to channel m

When the DMA enable bit (the RFDMAEx or CFDMAEm bit in the RSCFDnCFDCDTCT register) is set to 1 and there are unread messages in the related FIFO, a DMA transfer request trigger is generated.

48.11 CAN Modes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

The RS-CANFD module has four global modes to control the entire RS-CANFD module status and four channel modes to control individual channel status. Details of global modes are described in section 48.11.1, Global Modes, and details of channel modes are described in section 48.11.2, Channel Modes.

- Global stop mode: Stops the clocks of the entire module to achieve low power consumption.
- Global reset mode: Performs initial settings for the entire module.
- Global test mode: Performs test settings and performs the RAM test.
- Global operating mode: Makes the entire module operable.
- Channel stop mode: Stops the channel clock.
- Channel reset mode: Performs initial settings for the channels.
- Channel halt mode: Stops CAN communication and allows channel testing.
- Channel communication mode: Performs CAN communication.

48.11.1 Global Modes

Figure 48.4 shows the transitions of global modes.

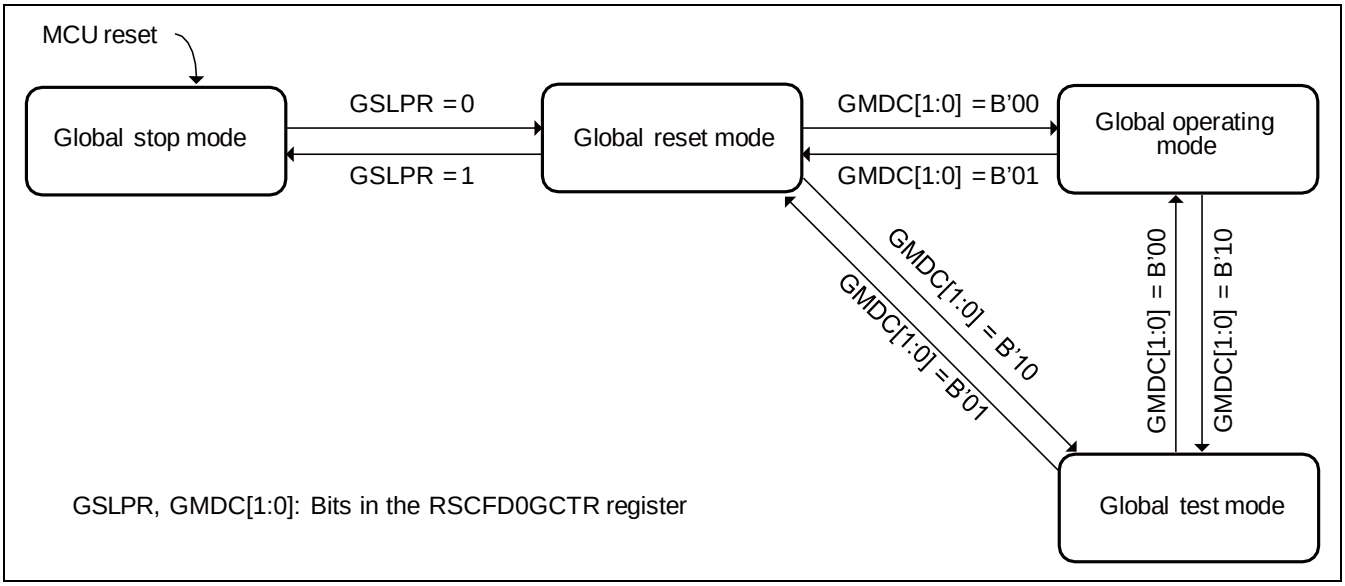

Figure 48.4 Transitions of Global Modes

In some cases, global mode transitions also force channel mode transitions. Table 48.29 shows the channel mode transitions depending on the global mode setting dictated by the GMDC[1:0] bits and the GSLPR bit.

Table 48.29 Transitions of Channel Modes Depending on Global Mode Setting (GMDC[1:0] and GSLPR Bits)

	Channel Mode after Setting			
Channel Mode before Setting	**GMDC[1:0] = B'00 GSLPR = 0 (Global Operation)**	**GMDC[1:0] = B'10 GSLPR = 0 (Global Test)**	**GMDC[1:0] = B'01 GSLPR = 0 (Global Reset)**	**GMDC[1:0] = B'01 GSLPR = 1 (Global Stop)**
Channel communication	Channel communication	Channel halt	Channel reset	Transition prohibited
Channel halt	Channel halt	Channel halt	Channel reset	Transition prohibited
Channel reset	Channel reset	Channel reset	Channel reset	Channel stop
Channel stop	Channel stop	Channel stop	Channel stop	Channel stop

Note: GMDC[1:0], GSLPR: Bits in the RSCFDn(CFD)GCTR register

Table 48.30 shows the global mode transition time.

Table 48.30 Global Mode Transition Time

Mode before Transition	Mode after Transition	Maximum Transition Time
Global stop	Global reset	Three pclk cycles
Global reset	Global stop	Three pclk cycles
Global reset	Global test	Ten pclk cycles
Global reset	Global operating	Ten pclk cycles
Global test	Global reset	Two CAN bit times*1*2
Global test	Global operating	Three pclk cycles
Global operating	Global reset	Two CAN bit times*1*2
Global operating	Global test	Two CAN frames*1

Notes: 1. It is the CAN bit time and CAN frame time with the lowest communication speed of the channels in use.
2. In CAN FD mode, it is the CAN bit time with normal bit rate.

48.11.1.1 Global Stop Mode

In global stop mode, clocks of the CAN do not run and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained. Only the clock used by the CPU for writing to the GSLPR bit runs in this mode.

After the MCU is reset, the RS-CANFD module transitions to global stop mode. Setting the GSLPR bit in the RSCFDn(CFD)GCTR register to 1 (in global stop mode) in global reset mode sets the CSLPR bit in each of the RSCFDn(CFD)CmCTR register to 1 (channel stop mode). Afterwards, if all channels are forced to transition to channel stop mode, the RS-CANFD module transitions to global stop mode. The GSLPR bit should not be modified in global operating mode or global test mode.

48.11.1.2 Global Reset Mode

In global reset mode, RS-CANFD module settings are performed. When the RS-CANFD module transitions to global reset mode, some registers are initialized. Table 48.33 and Table 48.34 list the registers to be initialized.

Setting the GMDC[1:0] bits in the RSCFDn(CFD)GCTR register to B'01 sets the CHMDC[1:0] bits in each of the RSCFDn(CFD)CmCTR registers (m = 0 or 1) to B'01 (channel reset mode). If all channels are forced to transition to channel reset mode, the RS-CANFD module transitions to global reset mode. Channels that are already in channel reset mode or channel stop mode do not transition (because the CHMDC[1:0] bits have already been set to B'01).

48.11.1.3 Global Test Mode

In global test mode, settings for test-related registers are performed. When the CAN module transitions to global test mode, all CAN communications are disabled.

Setting the GMDC[1:0] bits in the RSCFDn(CFD)GCTR register to B'10 sets the CHMDC[1:0] bits in each of the RSCFDn(CFD)CmCTR register to B'10 (channel halt mode). If all channels are forced to transition to channel halt mode, the CAN module transitions to global test mode. Channels that are in channel stop mode, channel reset mode, or channel halt mode do not transition.

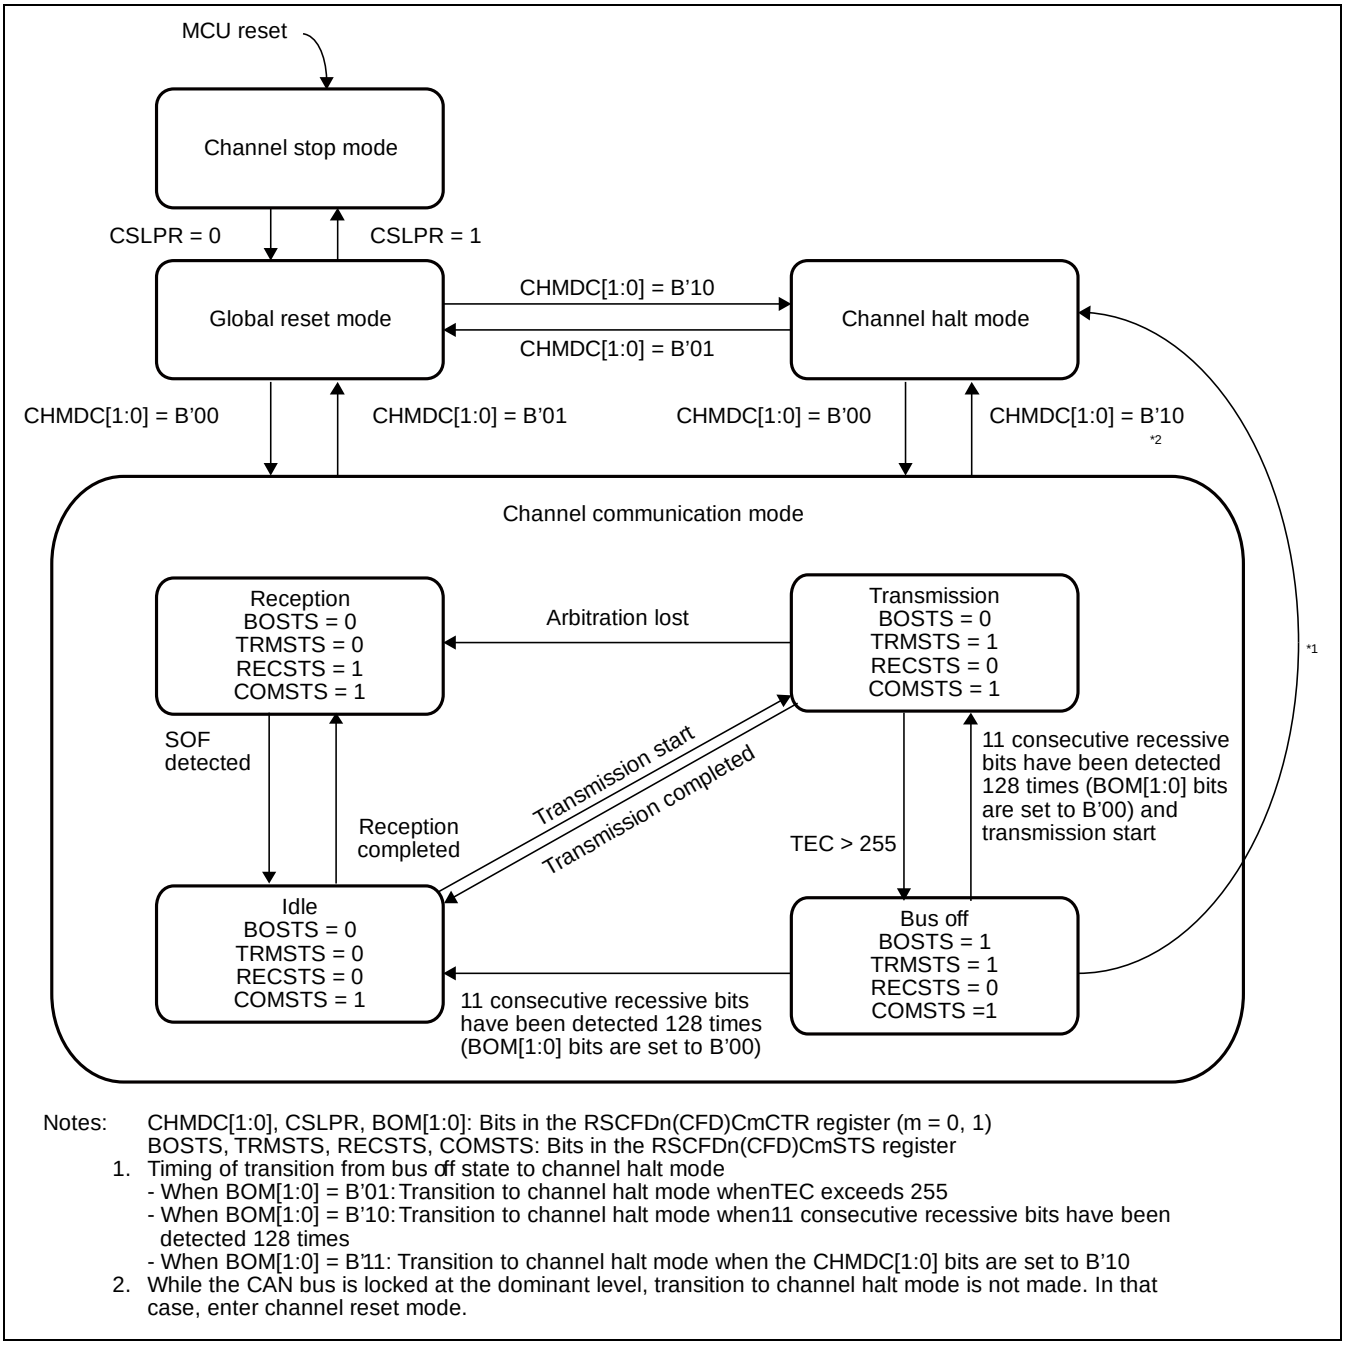
48.11.1.4 Global Operating Mode

The RS-CANFD module operates in global operating mode.

When the GMDC[1:0] bits in the RSCFDn(CFD)GCTR register are set to B'00, the RS-CAN module transitions to global operating mode.

48.11.2 Channel Modes

Figure 48.5 shows a channel mode state transition chart. Table 48.31 shows the channel mode transition time.



Notes: CHMDC[1:0], CSLPR, BOM[1:0]: Bits in the RSCFDn(CFD)CmCTR register (m = 0, 1)
BOSTS, TRMSTS, RECSTS, COMSTS: Bits in the RSCFDn(CFD)CmSTS register

1. Timing of transition from bus off state to channel halt mode
   - When BOM[1:0] = B'01: Transition to channel halt mode when TEC exceeds 255
   - When BOM[1:0] = B'10: Transition to channel halt mode when 11 consecutive recessive bits have been detected 128 times
   - When BOM[1:0] = B'11: Transition to channel halt mode when the CHMDC[1:0] bits are set to B'10
2. While the CAN bus is locked at the dominant level, transition to channel halt mode is not made. In that case, enter channel reset mode.

Figure 48.5 Channel Mode State Transition Chart

Table 48.31 Channel Mode Transition Time

Mode before Transition	Mode after Transition	Maximum Transition Time
Channel stop	Channel reset	Three pclk cycles
Channel reset	Channel stop	Three pclk cycles
Channel reset	Channel halt	Three CANm bit times*
Channel reset	Channel communication	Three CANm bit times*

Mode before Transition	Mode after Transition	Maximum Transition Time
Channel halt	Channel reset	Two CANm bit times*
Channel halt	Channel communication	Four CANm bit times*
Channel communication	Channel reset	Two CANm bit times*
Channel communication	Channel halt	Two CANm frames

Note: * In CAN FD mode, it is the CANm bit time with normal bit rate.

48.11.2.1 Channel Stop Mode

In channel stop mode, clocks are not supplied to channels and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained.

Each channel enters channel stop mode after the MCU is reset. Channels also transition to channel stop mode when the CSLPR bit in the RSCFDn(CFD)CmCTR register (m = 0 or 1) is set to 1 (channel stop mode) in channel reset mode. The CSLPR bit should not be modified in channel communication mode and channel halt mode.

48.11.2.2 Channel Reset Mode

In channel reset mode, channel settings are performed. When a channel transitions to channel reset mode, some channel-related registers are initialized. Table 48.33 lists the registers to be initialized.

When the CHMDC[1:0] bits in the RSCFDn(CFD)CmCTR register are set to B'01 (channel reset mode) during CAN communication, communication is terminated before it is completed and the channel transitions to channel reset mode. Table 48.32 shows the operation when the CHMDC[1:0] bits are set to B'01 (channel reset mode) during CAN communication.

48.11.2.3 Channel Halt Mode

In channel halt mode, settings for test-related registers of channels are performed. When a channel transitions to channel halt mode, CAN communication of the channel stops.

Table 48.32 shows operation when the CHMDC[1:0] bits are set to B'10 (channel halt mode) during CAN communication.

Table 48.32 Operation a Channel Transitions to Channel Reset Mode/Channel Halt Mode

Mode	During Reception	During Transmission	Bus Off State
Channel reset (CHMDC[1:0] = B'01)	Transitions to channel reset mode before reception is completed.*1	Transitions to channel reset mode before transmission is completed.*1	Transitions to channel reset mode before bus off recovery.
Channel halt*3 (CHMDC[1:0] = B'10)	Transitions to channel halt mode after reception is completed.*2	Transitions to channel halt mode after transmission is completed.	[When BOM[1:0] = B'00] Transitions to channel halt mode (CHMDC[1:0] = B'10) only after bus off recovery. [When BOM[1:0] = B'01] Transitions to channel halt mode automatically when the condition for transition to bus off state is met. [When BOM[1:0] = B'10] Transitions to channel halt mode automatically after bus off recovery. [When BOM[1:0] = B'11] Transitions to channel halt mode immediately after the CHMDC[1:0] bits are set to B'10 before bus off recovery.

Notes: 1. To allow transition to channel reset mode after communication is completed, set the CHMDC[1:0] bits to B'10 and confirm that communication has been completed and transition to channel halt mode has been made, and then set the CHMDC[1:0] bits to B'01.
2. While the CAN bus is locked at the dominant level, transition to channel halt mode is not made. In that case, enter channel reset mode. The CAN bus status can be confirmed with the BLF flag of the RSCFDn(CFD)CmERFL register that becomes 1 when dominant lock is detected.
3. When the transition from channel reset mode to channel halt mode is to be made, in classical CAN mode, set the RSCFDnCmCFG register in channel reset mode and then shift to channel halt mode. In CAN FD mode, make transition to channel halt mode after setting the RSCFDnCFDCmNCFG and RSCFDnCFDCmDCFG registers.

48.11.2.4 Channel Communication Mode

In channel communication mode, CAN communication is performed. Each channel has the following communication states during CAN communication.

- Idle: Neither reception nor transmission is in progress.
- Reception: Receiving a message sent from another node.
- Transmission: Transmitting a message.
- Bus off: Isolated from CAN communication.

When the CHMDC[1:0] bits in the RSCFDn(CFD)CmCTR register are set to B'00, the channel transitions to channel communication mode. After that, once 11 consecutive recessive bits have been detected, the COMSTS flag in the RSCFDn(CFD)CmSTS register (m = 0 or 1) is set to 1 (communication is ready) and transmission and reception are enabled on the CAN network as an active node. At this time, transmission and reception of messages can be started.

48.11.2.5 Bus Off State

A channel transitions to the bus off state according to the transmit/receive error counter increment/decrement rules of the CAN specifications.

The conditions for returning from the bus off state are determined by the BOM[1:0] bits in the RSCFDn(CFD)CmCTR register.

- When BOM[1:0] = B'00:

  Bus off recovery is compliant with the CAN specifications. After 11 consecutive recessive bits have been detected 128 times, a channel returns from the bus off state to the CAN communication ready state (error active state). At that time, the TEC[7:0] and REC[7:0] bits in the RSCFDn(CFD)CmERFL register are initialized to H'00, the BORF flag in the RSCFDn(CFD)CmERFL register is set to 1 (bus off recovery is detected), and a bus off recovery interrupt request is generated. When the CHMDC[1:0] bits in the RSCFDn(CFD)CmCTR register are set to B'10 (channel halt mode) in the bus off state, the channel transitions to channel halt mode after bus off recovery has been completed (11 consecutive recessive bits have been detected 128 times).
- When BOM[1:0] = B'01:

  When a channel transitions to the bus off state, the CHMDC[1:0] bits are set to B'10 and the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to H'00. The BORF flag is not set to 1, and bus off recovery interrupt request is not generated.
- When BOM[1:0] = B'10:

  When a channel has transitioned to the bus off state, the CHMDC[1:0] bits are set to B'10. After bus off recovery has been completed (11 consecutive recessive bits have been detected 128 times), the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to H'00, the BORF flag is set to 1, and a bus off recovery interrupt request is generated.
- When BOM[1:0] = B'11:

  When the CHMDC[1:0] bits are set to B'10 in the bus off state, the channel transitions to channel halt mode before bus off recovery is completed. At that time, the TEC[7:0] and REC[7:0] bits are initialized to H'00, but the BORF flag is not set to 1. Also, a bus off recovery interrupt is not generated.

  However, the BORF flag becomes 1 and a bus off recovery interrupt request is generated if a CAN module transitions to error active state (by detecting 128 times of 11 consecutive recessive bits) before CHMDC[1:0] bits are set to B'10.

If the RS-CANFD module causes the channel to transition to channel halt mode simultaneously with a program write to the CHMDC[1:0] bits, the program write takes precedence. An automatic transition to channel halt mode when the BOM[1:0] bits are set to B'01 or B'10 is made only when the CHMDC[1:0] bits are B'00 (channel communication mode).

Furthermore, setting the RTBO bit in the RSCFDn(CFD)CmCTR register to 1 allows a forced return from the bus off state. As soon as the RTBO bit is set to 1, the state changes to the error active state. After 11 consecutive recessive bits have been detected, the CAN module becomes ready for communication. In this case, the BORF flag is not set to 1 and the TEC[7:0] and REC[7:0] bits are initialized to H'00. Write 1 to the RTBO bit only when the BOM[1:0] value is B'00. Writing the RTBO bit to 1 in a state other than the bus off state is ignored, and the RTBO bit is immediately set to 0.

48.11.3 Registers Initialized by Transition to CAN Mode

Table 48.33 shows bits and flags initialized by transition to channel reset mode. These bits and flags are also initialized by transition to global reset mode. Table 48.34 shows bits and flags that are only initialized by transition to global reset mode.

Table 48.33 Registers Initialized in Global Reset Mode or Channel Reset Mode

Register	Bit / Flag
RSCFDn(CFD)CmCTR register	(ROM), CRCT, CTMS[1:0], CTME, CHMDC[1:0]
RSCFDn(CFD)CmSTS register	CHLTSTS, EPSTS, BOSTS, TRMSTS, RECSTS, COMSTS, (ESIF), REC[7:0], TEC[7:0]

RSCFDnCFDCDTSTS register	CFDMASTSm, RFDMASTSx
RSCFDn(CFD)GTSTCFG register	RTMPS[6:0], C0ICBCE, C1ICBCE, C2ICBCE, C3ICBCE, C4ICBCE, C5ICBCE
RSCFDn(CFD)GTSTCTR register	RTME, ICBCTME

Note: Bits and flags enclosed by () only exist in registers for CAN FD mode.

48.12 Reception Function

RZ/G2H | RZ/G2M V1.3 | RZ/G2M V3.0 | RZ/G2N | RZ/G2E

There are two reception types.

Reception by receive buffers:

- 0 to 31 receive buffers can be shared by all channels. Since messages stored in receive buffers are overwritten at each reception, the latest receive data can always be read.
- Reception by receive FIFO buffers and transmit/receive FIFO buffers (receive mode):
  Eight receive FIFO buffers can be shared by all channels and three dedicated transmit/receive FIFO buffers are provided for each channel. Messages of up to the number of buffer stages specified with the RFDC[2:0] and CFDC[2:0] bits can be stored in FIFO buffers and can be read sequentially from the oldest.

48.12.1 Data Processing Using the Receive Rule Table

Data processing using the receive rule table allows dispatching of selected messages to the specified buffer. Data processing includes acceptance filter processing, DLC filter processing, routing processing, label addition processing, and mirror function processing.

Up to 128 receive rules can be registered per channel and up to (64 × number of channels) total receive rules can be registered in the entire module. (Up to 128 receive rules can be registered in this module that has two channels.) Set receive rules for each channel. Receive rules cannot be shared with other channels. If receive rules are not set, no messages can be received. Figure 48.6 illustrates how receive rules are registered.

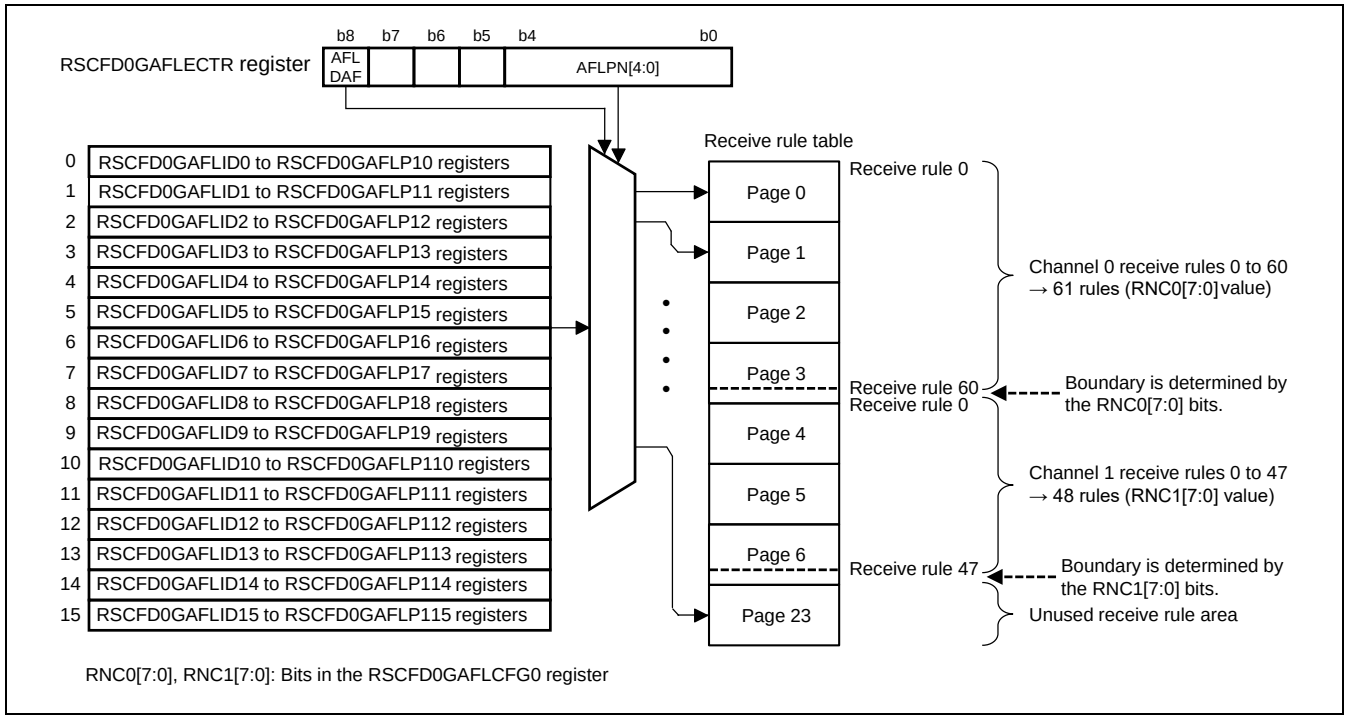

Figure 48.6 Entry of Receive Rules (for Setting Channels 0 and 1)

Note: Receive rules for each channel must be set in contiguous blocks. Channel 1 rules and channel 0 rules must be set separately.

Each receive rule consists of 16 bytes in the RSCFDn(CFD)GAFLIDj, RSCFDn(CFD)GAFLMj, RSCFDn(CFD)GAFLP0_j, and RSCFDn(CFD)GAFLP1_j registers (j = 0 to 15). The RSCFDn(CFD)GAFLIDj register is used to set GAFLID, GAFLIDE bit, GAFLRTR bit, and the mirror function, the RSCFDn(CFD)GAFLMj register is used to set mask, the RSCFDn(CFD)GAFLP0_j register is used to set label information to be added, DLC value, and storage receive buffer, and the RSCFDn(CFD)GAFLP1_j register is used to set storage FIFO buffer. Up to 16 receive rules can be set per page.

48.12.1.1 Acceptance Filter Processing

In the acceptance filter processing, the ID data, IDE bit, and RTR bit in a received message are compared with the ID data, IDE bit, and RTR bit set in the receive rule of the corresponding channel. When all these bits match, the message passes through the acceptance filter processing. The ID data, IDE bit, and RTR bit in the received message which correspond to the bits set to 0 (bits are not compared) in the RSCFDn(CFD)GAFLMj register are not compared and are regarded as matched.

Check begins with the receive rule of the minimum number for the corresponding channel. When all the bits to be compared in a received message match the bits set in the receive rule or when all the receive rules are compared without any match, filter processing stops. If there is no matching receive rule, the received message is not stored in the receive buffer or FIFO buffer.

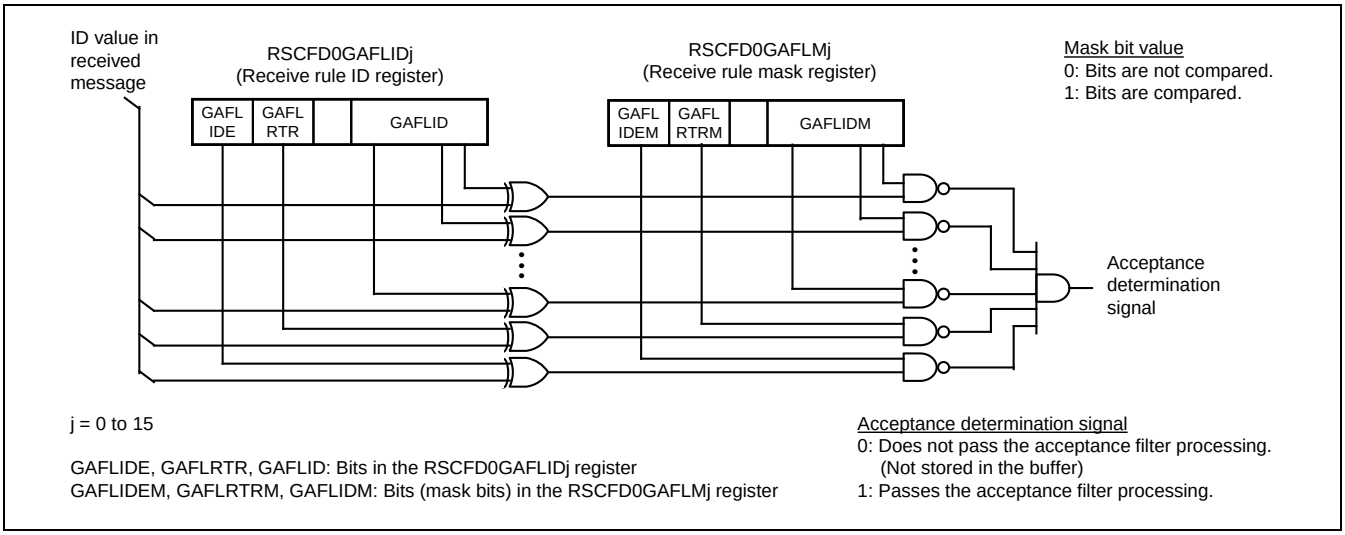

Figure 48.7 Acceptance Filter Function

48.12.1.2 DLC Filter Processing

When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), DLC filter processing is added to messages that passed through the acceptance filter processing. When the DLC value in a message is equal to or larger than the DLC value set in the receive rule, the message passes through the DLC filter processing.

When a message has passed through the DLC filter processing with the DRE bit in the RSCFDn(CFD)GCFG register set to 0 (DLC replacement is disabled), the DLC value in the received message is stored in the buffer. In this case, all the data bytes in the received message are stored in the buffer.

When a message has passed through the DLC filter processing with the DRE bit in the RSCFDn(CFD)GCFG register set to 1 (DLC replacement is enabled), the DLC value in the receive rule is stored in the buffer instead of the DLC value in the received message. In this case, a value of H'00 is stored in each data byte beyond the number of bytes which is indicated by the DLC value in the receive rule.

When the DLC value in the received message is smaller than that in the receive rule, the message does not pass through the DLC filter processing. In this case, the message is not stored in the receive buffer or the FIFO buffer and the DEF flag in the RSCFDn(CFD)GERFL register is set to 1 (a DLC error is present).

48.12.1.3 Routing Processing

Messages that passed through the acceptance filter processing and the DLC filter processing are stored in receive buffers, receive FIFO buffers, or transmit/receive FIFO buffers (set to receive mode or gateway mode). Message storage destination is set by the GAFLRMV and GAFLRMDP[6:0] bits in the RSCFDn(CFD)GAFLP0_j register (j = 0 to 15) and by the RSCFDn(CFD)GAFLP1_j register. Messages that passed through the acceptance filter processing and the DLC filter processing can be stored in up to eight buffers.

In CAN FD mode, when the payload length of the received message exceeds the size for storing the payload in the storage buffer, the CMPOF flag in the RSCFDnCFDGERFL register is set to 1 (payload overflow) and handled according to the CMPOC bit in the RSCFDnCFDGCFG register. When the CMPOC bit is 0, a message which exceeds the size for storing the payload is not stored in the buffer. When the CMPOC bit is 1, the payload which exceeds the storage size is truncated and a message is stored in the buffer.

48.12.1.4 Label Addition Processing

It is possible to add 12-bit label information to messages that passed through the filter processing and store them in buffers. This label information is set in the GAFLPTR[11:0] bits in the RSCFDn(CFD)GAFLP0_j register.

48.12.1.5 Mirror Function Processing

The mirror function allows the CAN node to receive its own transmitted messages. The mirror function is made available by setting the MME bit in the RSCFDn(CFD)GCFG register to 1 (mirror function is enabled).

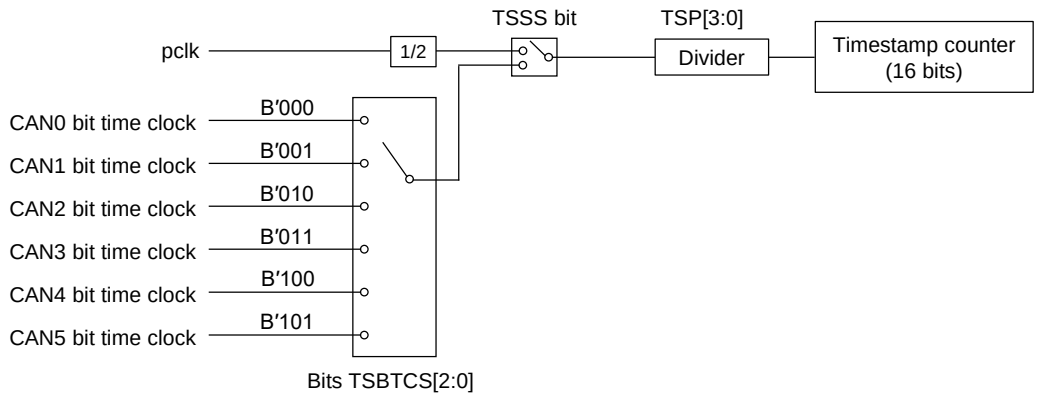
When the mirror function is in use, receive rules for which the GAFLLB bit in the RSCFDn(CFD)GAFLIDj register is set to 0 are used for data processing when receiving messages transmitted from other CAN nodes. When the CAN node is receiving its own transmitted messages, receive rules for which the GAFLLB bit is set to 1 are used for data processing.

48.12.1.6 Timestamp

The timestamp counter is a 16-bit free-running counter used for recording the time for receiving and transmitting messages. The timestamp counter value is fetched at the start-of-frame (SOF) timing of a message and stored in a receive buffer or a FIFO buffer with a message ID and data at reception. The clock source of the timestamp counter is selected by the TSBTCS[2:0] and TSSS bits in the RSCAN0GCFG register; it is selected by pclk/2 or the CANm bit time clock (m = 0 or 1) in classical CAN mode and pclk/2 or the CANm normal bit time clock in CAN FD mode. However, do not select the CANm normal bit time clock of a channel which handles the CAN FD frame. The count source of the timestamp counter is obtained by a clock which divides the selected clock source by the TSP[3:0] bits in the RSCAN0GCFG register.

When the CANm bit time clock or CANm normal bit time clock is used as a clock source, the timestamp counter stops when the corresponding channel transitions to channel reset mode or channel halt mode. When the pclk/2 is used as a clock source, the timestamp function is not affected by channel mode.

The timestamp counter value is reset to H'0000 by setting the TSRST bit in the RSCFDn(CFD)GCTR register to 1.



TSBTCS[2:0], TSSS, TSP[3:0]: Bits in the RSCFD0GCFG register

Note: When specifying pclk/2 as the timestamp counter count source, set bits TSBTCS[2:0] to B′000.

Figure 48.8 Timestamp Function Block Diagram

48.13 Transmission Function

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

There are three types of transmission. In classical CAN mode, the 8-byte payload length can be transmitted in each type of transmission. In CAN FD mode, the payload length to be transmitted differs depending on the type of transmission.

- Transmission using transmit buffers:

  Each channel has 16 buffers. In CAN FD mode, the 20-byte payload length can be transmitted. However, when transmit buffer merge mode is used, four of 16 buffers are allocated as storage areas for the payload and two buffers can be used to transmit the payload which exceeds 20 bytes.
- Transmission using transmit/receive FIFO buffers (transmit mode):

  Each channel has three FIFO buffers. Up to 128 messages can be contained in a single FIFO buffer. In CAN FD mode, the 64-byte payload length can be transmitted. Each FIFO buffer is used with a link to a transmit buffer. Only the message to be transmitted next in a FIFO buffer becomes the target of transmit priority determination. Messages are transmitted sequentially on a first-in, first-out basis.
- Transmission using transmit queues:

  Up to 16 transmit buffers per channel can be allocated to the transmit queues. In CAN FD mode, the 20-byte payload length can be transmitted. Transmit buffer ((16 × m) + 15) is used as an access window of a corresponding channel. Transmit buffers are allocated to transmit queues in descending order of buffer number. All messages in transmit queues, which are targets of priority determination, are transmitted in the order of ID number.

Figure 48.9 shows the allocation of transmit queues and transmit/receive FIFO buffer link.

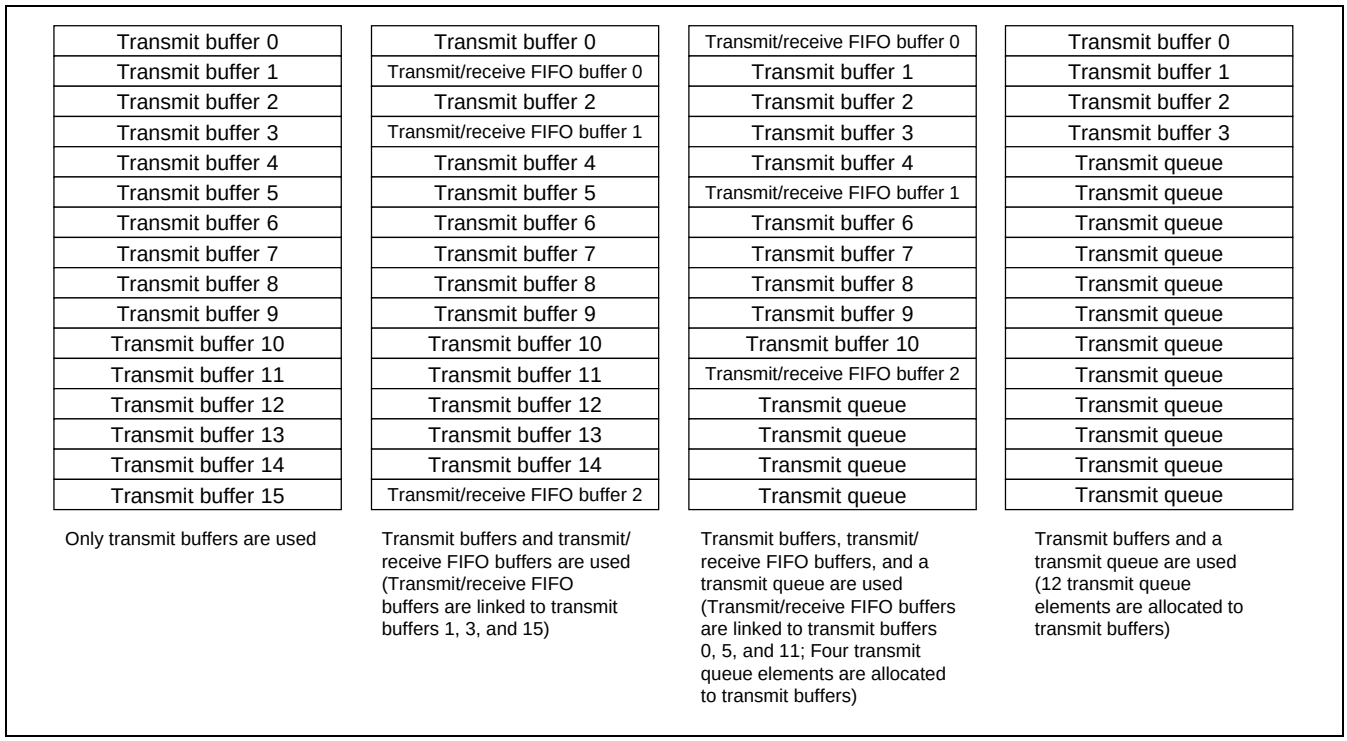


Figure 48.9 Allocation of Transmit Queues and Transmit/Receive FIFO Buffer Links

48.13.1 Transmit Priority Determination

If transmit requests are issued from multiple buffers or from the queue on the same channel, transmit priority is determined using one of the following methods.

The priority is determined by using one of the following methods.

- ID priority (TPRI bit = 0)
- Transmit buffer number priority (TPRI bit = 1)

All CAN channels use the setting of the TPRI bit in the RSCFDn(CFD)GCFG register.

When the TPRI bit is set to 0, messages are transmitted according to the priority of stored message IDs. ID priority conforms to the CAN bus arbitration specification defined in the CAN specifications. All IDs of pending transmit messages are targets of priority determination, regardless of whether they are stored in transmit buffers, transmit/receive FIFO buffers (set to transmit mode or gateway mode), or the transmit queue. If even a single transmit queue is used, select ID priority. When transmit/receive FIFO buffers are used, the oldest message in a FIFO buffer becomes the target of priority determination.

When a message is being transmitted from a transmit/receive FIFO buffer, the next message in the FIFO buffer becomes the target of priority determination. When a transmit queue is used, all messages in the transmit queue are targets of priority determination. If the same ID is set for two or more buffers, the buffer with the smaller buffer number takes precedence. When the TPRI bit is set to 1, the message in the transmit buffer with the minimum buffer number among all buffers with a transmit request is transmitted first. When transmit/receive FIFO buffers are linked to transmit buffers, transmit priority is determined according to linked transmit buffer numbers.

When messages are retransmitted due to an arbitration-lost or an error, transmit priority determination is made again regardless of the TPRI bit. If the ECC2 bit error is detected in priority determination, transmission will not be performed (only when the EEFE bit in the RSCFDnGCFG register is 1 in classical CAN mode).

48.13.2 Transmission Using Transmit Buffers

Setting the transmit request bit (TMTR bit in the RSCFDn(CFD)TMCp register) in a transmit buffer to 1 (transmission is requested) allows transmission of data frames or remote frames.

The transmit result is shown by the TMTRF[1:0] flag in the corresponding RSCFDn(CFD)TMSTSp register (p = 0 to 31). When transmit completes successfully, the TMTRF[1:0] flag is set to B'10 (transmission has been completed (without transmit abort request)) or B'11 (transmission has been completed (with transmit abort request)).

48.13.2.1 Transmit Abort Function

With respect to transmit buffers for which the TMTRM bit in the RSCFDn(CFD)TMSTSp register is set to 1 (a transmit request is present), when the TMTAR bit in the RSCFDn(CFD)TMCp register is set to 1 (transmit abort is requested), the transmit request is canceled. When transmit abort is completed, the TMTRF[1:0] flag in the RSCFDn(CFD)TMSTSp register is set to B'01 (transmit abort has been completed) and the transmit request is canceled (clearing the TMTRM bit to 0).

A message that is being transmitted or a message to be transmitted next according to the transmit priority determination cannot be aborted. However, when an arbitration-lost or an error occurs during transmission of a message for which the TMTAR bit is set to 1, retransmission is not performed.

48.13.2.2 One-Shot Transmission Function (Retransmission Disabling Function)

When the TMOM bit in the RSCFDn(CFD)TMCp register is set to 1 (one-shot transmission is enabled), transmission is performed only once. Even if an arbitration-lost or an error occurs, retransmission is not performed.

The one-shot transmit result is shown by the TMTRF[1:0] flag in the corresponding RSCFDn(CFD)TMSTSp register. When one-shot transmission completes successfully, the TMTRF[1:0] flag is set to B'10 or B'11. When an arbitration-lost or an error occurs, the TMTRF[1:0] flag is set to B'01 (transmit abort has been completed).

48.13.2.3 Transmit Buffer Merge Mode (CAN FD Mode Only)

Although the 20-byte payload length can be transmitted from the transmit buffer, it is possible to transmit messages having a maximum of 64-byte payload length after merging three transmit buffers in transmit buffer merge mode.

When the TMME bit in the RSCFDnCFDCmFDCFG register is set to 1, transmit buffer merge mode is enabled. In this mode, six buffers are used as merge areas in each channel and two transmit buffers ((16 × m) + 0 to (16 × m) + 2 and (16 × m) + 3 to (16 × m) + 5) are merged. Transmission is requested in the first transmit buffer and the following two buffers are used as the payload storage area. For other transmit buffers than the first buffer, do not set 1 to the transmission request bit (the TMTR bit in the RSCFDnCFDTMCp register) and the transmission abort request bit (the TMTAR bit in the RSCFDnCFDTMCp register).

While transmit buffer merge mode is being enabled, do not link the transmit/receive FIFO buffer to six merged buffers or allocate the buffer to the transmit queue.

48.13.3 Transmission Using FIFO Buffers

Multiple messages can be stored in a single transmit/receive FIFO buffers, up to the number specified by the FIFO buffer depth, which is set by the CFDC[2:0] bits in the RSCFDn(CFD)CFCCk register (k = 0 to 5). Messages are transmitted sequentially on a first-in, first-out basis.

Each transmit/receive FIFO buffer is linked to a transmit buffer selected by the CFTML[3:0] bits in the RSCFDn(CFD)CFCCk register. When the CFE bit in the RSCFDn(CFD)CFCCk register is set to 1 (transmit/receive FIFO buffers are used), transmit/receive FIFO buffers become targets of transmit priority determination. Priority of only the next transmit message is determined in the FIFO buffer.

When the CFE bit is set to 0 (no transmit/receive FIFO buffer is used), the CFEMP flag is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)) at the timing below.

- The transmit/receive FIFO buffer becomes empty immediately if the message in it is not being transmitted or is not to be transmitted next.
- The transmit/receive FIFO buffer becomes empty after transmission completion, CAN bus error detection, or arbitration-lost in the case that a message in it is being transmitted or to be transmitted next.

When the CFE bit is cleared to 0, all messages in transmit/receive FIFO buffers are lost and messages cannot be stored in FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

48.13.3.1 Interval Transmission Function

A message transmission interval time can be set to space the transmission of messages from the same FIFO buffer when using a transmit/receive FIFO buffer set to transmit mode or gateway mode.

Immediately after the first message has been transmitted successfully from the FIFO buffer with the CFE bit in the RSCFDn(CFD)CFCCk register set to 1, the interval timer starts counting (after EOF7 of the CAN protocol). After that, when the interval time has passed, the next message is transmitted. The interval timer stops in channel reset mode or by clearing the CFE bit to 0.

The interval time is set by the CFITT[7:0] bits in the RSCFDn(CFD)CFCCk register. When the interval timer is not used, set the CFITT[7:0] bits to H'00.

Select an interval timer count source using the CFITR and CFITSS bits in the RSCFDn(CFD)CFCCk register. When the CFITR and CFITSS bits are set to B'00, the count source is obtained by dividing pclk/2 by the value of the ITRCP[15:0] bits. When the CFITR and CFITSS bits are set to B'10, the count source is obtained by dividing pclk/2 by (the value of

the ITRCP[15:0] bits in the RSCFDn(CFD)GCFG register × 10). When the CFITR and CFITSS bits are set to B'x1, the CANm bit time clock and the CANm normal bit time clock are used as a count source in classical CAN mode and CAN FD mode, respectively.

The interval time is calculated by the following equations where M is the value of ITRCP[15:0] and N is the value of CFITT[7:0].

- When CFITR and CFITSS = B’00:

$$\frac{1}{\text{Frequency of pclk}} \times 2 \times M \times N$$

- When CFITR and CFITSS = B’10:

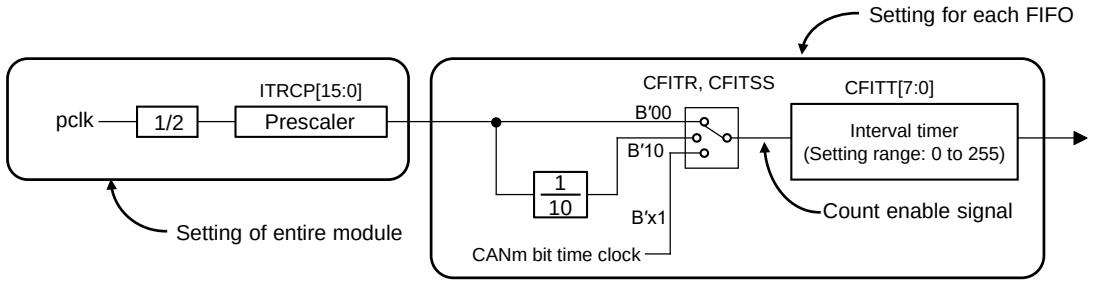
$$\frac{1}{\text{Frequency of pclk}} \times 2 \times M \times 10 \times N$$

- When CFITR and CFITSS = B’x1:

Classical CAN mode : $\frac{1}{\text{Frequency of CANm bit time clock}} \times N$

CAN FD mode : $\frac{1}{\text{Frequency of CANm normal bit time clock}} \times N$

Figure 48.10 shows the interval timer block diagram.

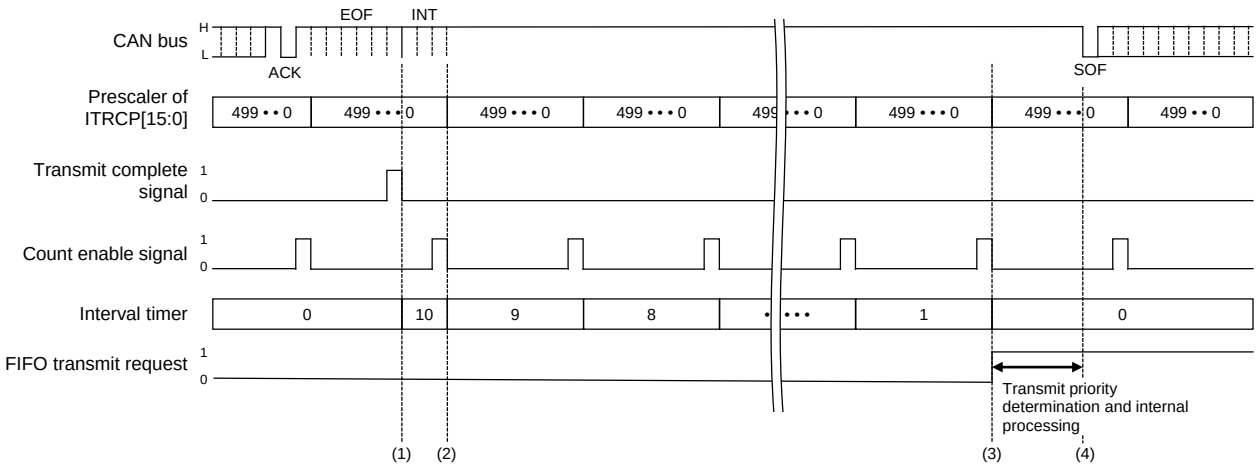


ITRCP[15:0]: Bits in the RSCFD0GCFG register
CFITR, CFITSS, CFITT[7:0] : Bits in the RSCFD0CFCCk register

Note: m = 0, 1, k = 0 to 17

Figure 48.10 Interval Timer Block Diagram

Figure 48.11 shows the interval timer timing diagram.



Interval time (logical value) = 2/fPBA × (set ITRCP[15:0] value) × set CFITT[7:0] value

fPBA: Frequency of pclk
ITRCP[15:0]: Bits in the RSCFD0GCFG register (The set value is 500 in this figure.)
CFITT[7:0]: Bits in the RSCFD0CFCCk register (The set value is 10 in this figure.)

Figure 48.11 Interval Timer Timing Chart

(1) The interval timer starts counting upon completion of transmission. Since the prescaler is not initialized at the time of transmission completion, the first interval time contains an error of up to one count of the interval timer.

(2) The interval timer is decremented by the next count enable signal.

(3) When the interval timer has decreased to 0, the transmit/receive FIFO buffer issues a transmit request.

(4) The transmit/receive FIFO buffer is determined for the next transmission by the priority determination, it starts transmitting data. Transmission starts usually with a delay of three CANm bit time clock cycles or less from the issue of transmit request. If multiple internal processes (such as receive filter processing, message routing, and transmit priority determination) take place in all channels, a delay of up to 1164 cycles of the pclk may be generated.

48.13.4 Transmission Using Transmit Queues

Three to sixteen buffers (up to ten buffers in transmit buffer merge mode) are allocated to a transmit queue for each channel, and a transmit buffer ((16 × m) + 15) is used as an access window of a corresponding channel. All messages in a transmit queue are targets of transmit priority determination and are transmitted in the ID priority order regardless of storage sequence. If two messages having the same ID are stored in a transmit queue, these messages are not always transmitted in the order of their storage in the transmit queue. Setting the TXQE bit in the RSCFDn(CFD)TXQCCm register to 0 disables transmit queues. When the TXQE bit is set to 0, the TXQEMP flag in the RSCFDn(CFD)TXQSTSm register is set to 1 (the transmit queue contains no messages (transmit queue empty)) at the timing below.

- The transmit queue becomes empty immediately when no message in it is being transmitted or will be transmitted next.
- The transmit queue becomes empty after transmission completion, CAN bus error detection, or arbitration-lost when a message in it is being transmitted or will be transmitted next.

When the TXQE bit is cleared to 0, all messages in transmit queues are lost and messages cannot be stored in transmit queues. Confirm that the TXQEMP flag is set to 1 before setting the TXQE bit to 1 again.

48.13.5 Padding Transmit Data (CAN FD Mode Only)

If the payload length indicated by the DLC value of the specified transmission message exceeds the size of the payload storage area of the transmit buffer, the exceeded payload will be padded by H'CC.

The processing is performed at the following cases when transmit merge mode is not enabled (the TMME bit in the RSCFDnCFDCmFDCFG register is 0).

- Transmit/receive FIFO which has been set for transmit or gateway mode:
  The payload length of the transmission DLC exceeds the size of the payload storage area of the transmit/receive FIFO buffer which has been set for the CFPLS[2:0] bits in the RSCFDnCFDCFCCk register.
- Transmit buffer (including transmit queues):
  The payload length of the transmit DLC exceeds 20 bytes.

When transmit buffer merge mode is enabled, the transmit data is not padded even if transmission is performed by using transmit buffers, transmit/receive buffers, or transmit queues. In this case, do not set the payload length, which exceeds the size of the payload storage area of the transmit buffer, to the DLC value of the transmission message.

48.13.6 Transmit History Function

Information on the transmitted messages can be stored in the transmit history buffer. Each channel has a single transmit history buffer that can contain 16 sets of transmit history data.

Types of message transmit source buffers can be selected by the THLDTE bit in the RSCFDn(CFD)THLCCm register. The THLEN bit in the RSCFDn(CFD)CFIDk register (k = 0 to 5) determines whether or not the transmit history data is stored for each message.

In classical CAN mode, the TMTSCE bit in the RSCFDnGCFG register determines whether or not a timestamp value is included in the transmit history data. In CAN FD mode, a timestamp value is always included.

The following information on a transmitted message will be stored in the transmission history buffer after transmission has successfully completed.

Storage of the transmission history data after successful completion of transmission may take up to 152 clock cycles of pclk.

- Buffer type B'001: Transmit buffer
  B'010: Transmit/receive FIFO buffer
  B'100: Transmit queue
- Buffer number Number of a transmit buffer, a transmit queue, or a transmit/receive FIFO buffer in the transmit source. This number depends on the buffer types. See Table 48.35.
- Label data Label information of the transmit message
- Timestamp Timestamp value of the transmit message
  (In classical CAN mode, the TMTSCE bit is 1.)

Table 48.35 Transmit History Data Buffer Numbers

	Buffer type		
Buffer No.	**B'001**	**B'010**	**B'100**
B'0000	Transmit buffer 16 × m + 0	Buffer numbers of the transmit buffer linked to the transmit/receive FIFO buffer by the CFTML[3:0] bits in the RSCFDn(CFD)CFCCk register (k = 0 to 5)	Buffer numbers of the transmit buffer allocated to the transmit queue that performed transmission
B'0001	Transmit buffer 16 × m + 1		
B'0010	Transmit buffer 16 × m + 2		
B'0011	Transmit buffer 16 × m + 3		
B'0100	Transmit buffer 16 × m + 4		
B'0101	Transmit buffer 16 × m + 5		
B'0110	Transmit buffer 16 × m + 6		
B'0111	Transmit buffer 16 × m + 7		
B'1000	Transmit buffer 16 × m + 8		
B'1001	Transmit buffer 16 × m + 9		
B'1010	Transmit buffer 16 × m + 10		
B'1011	Transmit buffer 16 × m + 11		
B'1100	Transmit buffer 16 × m + 12		
B'1101	Transmit buffer 16 × m + 13		
B'1110	Transmit buffer 16 × m + 14		
B'1111	Transmit buffer 16 × m + 15		

Label data is used to identify each message. Unique label data can be added to each message transmitted from a transmit buffer, a transmit queue, or a transmit/receive FIFO buffer.

A timestamp value is obtained from the timestamp counter at the timing of the start-of-frame (SOF) of a message. For details on the timestamp counter, refer to section 48.12.1.6, Timestamp.

Transmit history data can be read from the RSCFDn(CFD)THLACCm register. If an attempt is made to store new transmit history data while the buffer is full, the buffer overflows and the new data is discarded.

48.14 Gateway Function

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

When a transmit/receive FIFO buffer is set to gateway mode, receive messages can be transmitted from an arbitrary channel without CPU intervention.

When the CFM [1:0] bits in the RSCFDn(CFD)CFCCk register are set to B'10 (gateway mode) for the transmit/receive FIFO buffer selected by the RSCFDn(CFD)GAFLP1_j register of a channel being used for transmission, messages that pass through filter processing according to the reception rule are stored in the specified transmit/receive FIFO buffer and are automatically transmitted from the buffer.

Messages stored in a transmit/receive FIFO buffer are transmitted sequentially on a first-in, first-out basis. Only the message to be transmitted next becomes the target of transmit priority determination.

Transmit/receive FIFO buffers in the gateway mode are disabled by setting the CFE bit in the RSCFDn(CFD)CFCCk register to 0 and the CFEMP flag becomes 1 according to the timing below.

- The transmit/receive FIFO buffer becomes empty immediately when the message in it is not being transmitted and will not to be transmitted next.
- The transmit/receive FIFO buffer becomes empty after transmission completion, CAN bus error detection, or arbitration-lost when the message in it is being transmitted or will be transmitted next.

When the CFE bit is cleared to 0, all messages in transmit/receive FIFO buffers are lost and messages can no longer be stored in transmit/receive FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

48.14.1 CAN-CAN FD Gateway (CAN FD Mode Only)

When the gateway function is used in CAN FD mode, the transmit frame can be replaced with the classical CAN frame or CAN FD frame.

When the GWEN bit in the RSCFDnCFDCmFDCFG register is set to 1, the CAN-CAN FD gateway is enabled. The GWFDF and GWBRS bits in the RSCFDnCFDCmFDCFG register can be used to select the FDF and BRS bits of the transmit frame. When the DLC value of the received classical CAN frame is equal to or larger than B'1001 and the GWFDF bit is 1 (CAN FD frame), the DLC value is replaced with B'1000.

When the CAN-CAN FD gateway is enabled, do not route the following frames.

- CAN FD frame of which payload length is longer than 8 bytes
- Remote frame

48.15 Test Function

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

Test functions are classified into communication tests and global tests.

- Communication tests: Performed for each channel.
  - Standard test mode
  - Listen-only mode
  - Self-test mode 0 (external loopback mode)
  - Self-test mode 1 (internal loopback mode)
  - Limited operation mode (CAN FD mode only)
- Global tests: Performed for the entire module
  - RAM test (read/write test)
  - Inter-channel communication test [CRC error test is enabled.]

48.15.1 Standard Test Mode

Standard test mode allows CRC test. The CRC value, which has been calculated by the RS-CANFD module according to the transmit or receive message, is stored in the register; the CRCREG[14:0] bits in the RSCFDn(CFD)CmERFL register when the message is in the classical CAN frame (15-bit CRC length) and the CRCREG[20:0] bits in the RSCFDnCFDCmFDCRC register when the message is in the CAN FD frame (17-bit or 21-bit CRC length). Use the inter-channel communication test function for the CRC error test. For details, refer to section 48.15.6.1, CRC Error Test.

48.15.2 Listen-Only Mode

Listen-only mode allows reception of data frames and remote frames. Only recessive bits are transmitted on the CAN bus, and the ACK bit, overload flag, and active error flag are not transmitted. Listen-only mode is available for detecting the communication speed. Do not make a transmit request from any buffer or queue in listen-only mode.

Figure 48.12 shows the connection when listen-only mode is selected.

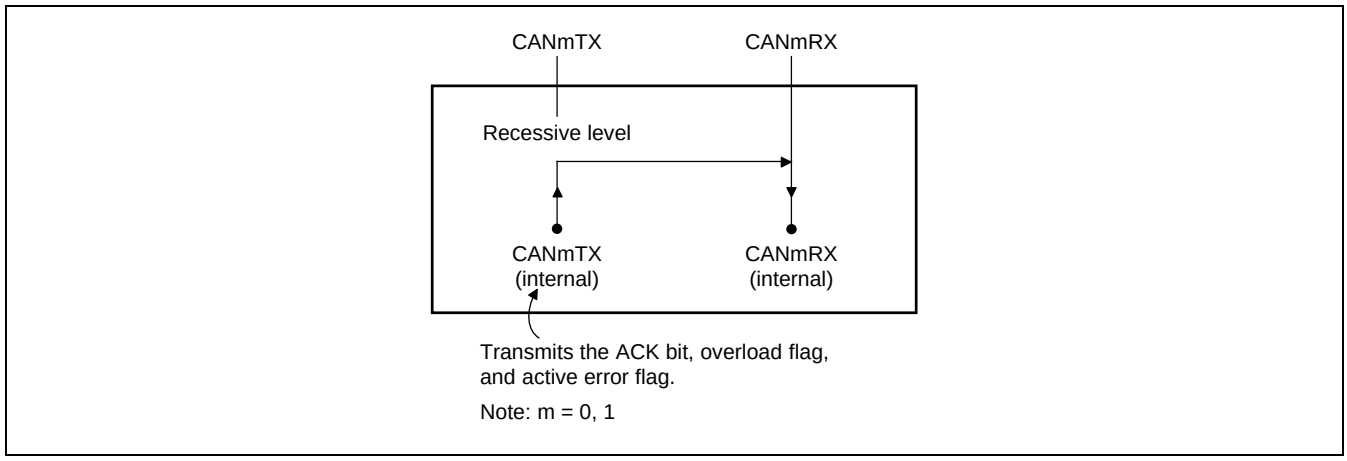


Figure 48.12 Connection when Listen-Only Mode is Selected

48.15.3 Self-Test Mode (Loopback Mode)

In self-test mode, transmitted messages are compared with the receive rule of the own channel and the messages are stored in a buffer if they have passed through the filter processing. Messages transmitted from other CAN nodes are compared only with the receive rule for which the GAFLLB bit in the RSCFDn(CFD)GAFLIDj register (j = 0 to 15) is set to 0 (when a message transmitted from another CAN node is received).

If the mirror function and self-test mode are both enabled, the self-test mode setting takes precedence.

48.15.3.1 Self-Test Mode 0 (External Loopback Mode)

Self-test mode 0 is used to perform a loopback test within a channel including the CAN transceiver.

In self-test mode 0, transmitted messages are handled as messages received through the CAN transceiver and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.

Figure 48.13 shows the connection when self-test mode 0 is selected.

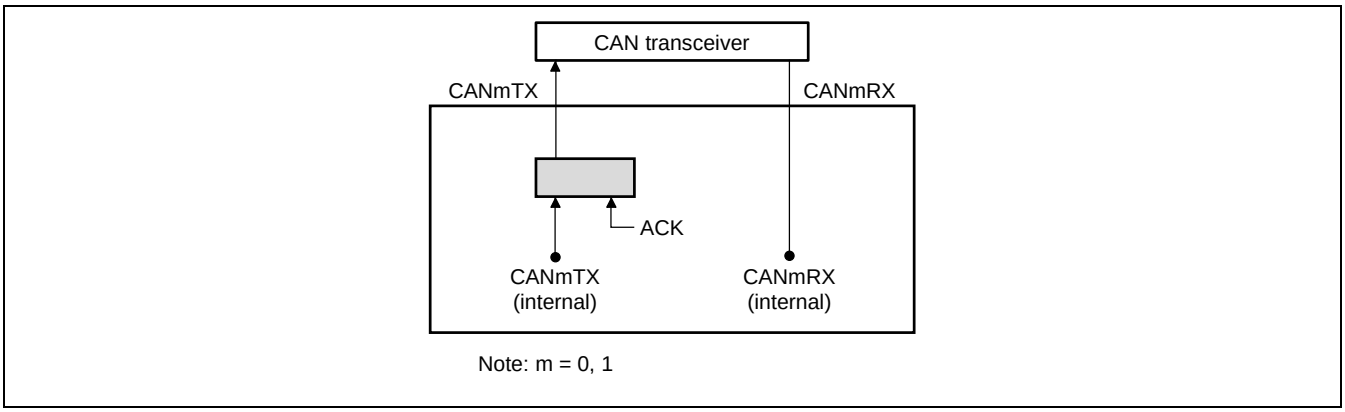

Figure 48.13 Connection when Self-Test Mode 0 is Selected

48.15.3.2 Self-Test Mode 1 (Internal Loopback Mode)

In self-test mode 1, transmitted messages are handled as received messages and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.

In self-test mode 1, internal feedback from the internal CANmTX pin (m = 0 or 1) to the internal CANmRX pin is performed. The external CANmRX pin input is isolated. The external CANmTX pin outputs only recessive bits.

Figure 48.14 shows the connection when self-test mode 1 is selected.

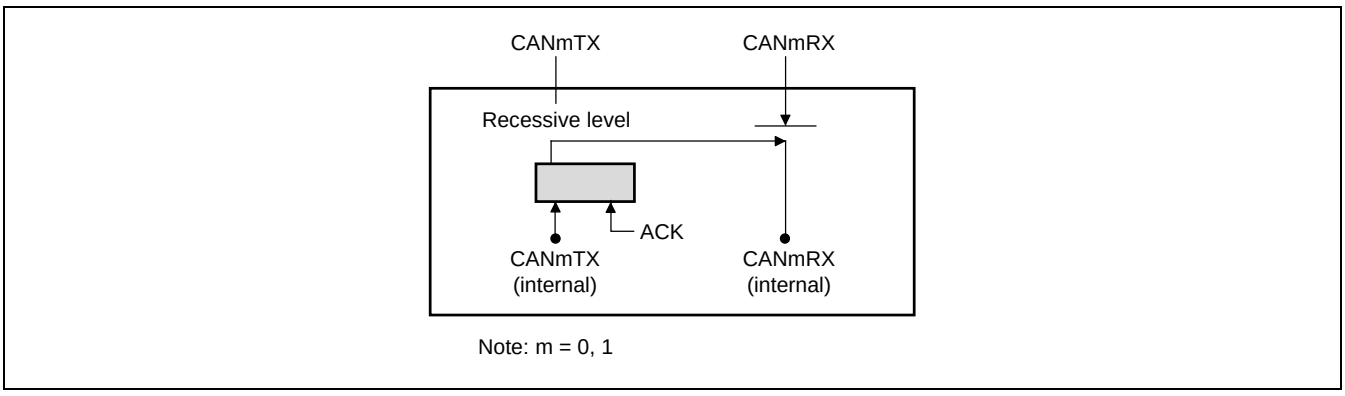

Figure 48.14 Connection when Self-Test Mode 1 is Selected

48.15.4 Limited Operation Mode (CAN FD Mode Only)

When the enabled data and remote frames are received in limited operation mode, an ACK bit is generated. However, these frames are not transmitted even if the error frame or overload frame transmit condition is detected. When the condition is detected, CANFD waits for the bus idling state to resynchronize CAN communications. The receive error counter (REC) and the transmit error counter (TEC) are not changed if an error occurs.

For transmission, any transmit request can be issued with no limitations.

48.15.5 RAM Test

The RAM test function allows accesses to all CAN RAM addresses.

When the RAM test function is used, the RAM is divided into pages of 256 bytes each. RAM test page is set by the RTMPS[6:0] bits in the RSCFDn(CFD)GTSTCFG register. Data in the set page can be read from and written to the RSCFDn(CFD)RPGACCr register (r = 0 to 63). The available total RAM size is 15360 bytes (H'3C00) in classical CAN mode and 21312 bytes (H'53D0) in CAN FD mode.

48.15.6 Inter-Channel Communication Test

The inter-channel communication test function allows communication test by internally connecting CAN channels to each other. During this test, channels are isolated from the external CAN bus.

Before starting data transmission/reception in channel communication mode, make transmission/reception settings for each channel.

Figure 48.15 shows the connection for inter-channel communication test.

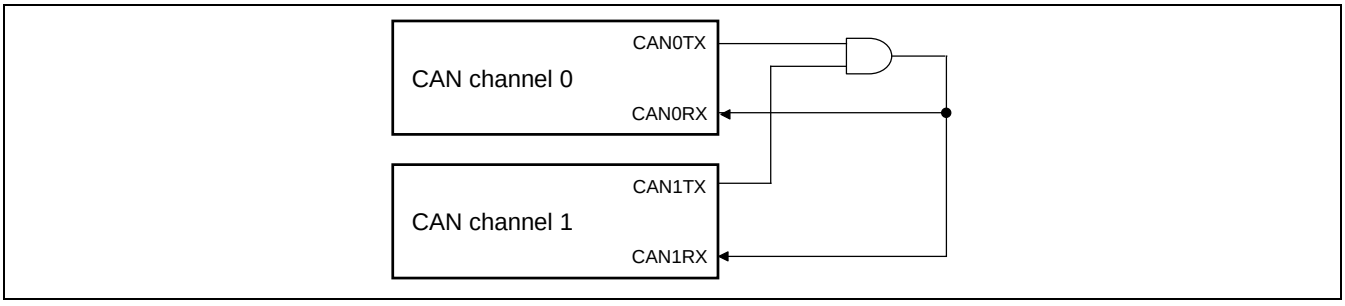

Figure 48.15 Connection for Inter-Channel Communication Test

48.15.6.1 CRC Error Test

During inter-channel communication test, a CRC error test can be performed. The following shows an example of procedure when a CRC error test on channel 0 is performed during communication test between channels 0 and 1.

Conditions:

- Inter-channel communication test is enabled.
- Channels 0 and 1 are in standard test mode.

Procedure:

1. Make a setting that a message is transmitted from transmit buffer p in channel 1.
2. Set 1 to the CRCT bit in the RSCFDn(CFD)C0CTR register (inversion of the start bit in the receive ID field is enabled).
3. Set 1 to the TMTR bit in the RSCFDn(CFD)TMCp register (a transmission request is issued to transmit buffer p in channel 1).
4. Wait for generation of the CAN0 error interrupt due to a channel bus error.
5. Read the CRCREG[15:0] bits in the RSCFDn(CFD)CmERFL register or the CRCREG[20:0] bits in the RSCFDnCFDCmFDCRC register on both channels and check that the CRC values are different in the transmit and receive sides.
6. Check that the CERR bit in the RSCFDm(CFD)C0ERFL register is 1 (a CRC error is detected).

Using the CRC error test function generates an illegal CRC value by inverting the start bit in the receive ID field. Therefore, if the higher-order five bits of the ID are B'1_0000 or the higher-order six bits are B'01_1111 in the received message, note that a stuff error (consecutive 6-bit data with the same level) will be detected.

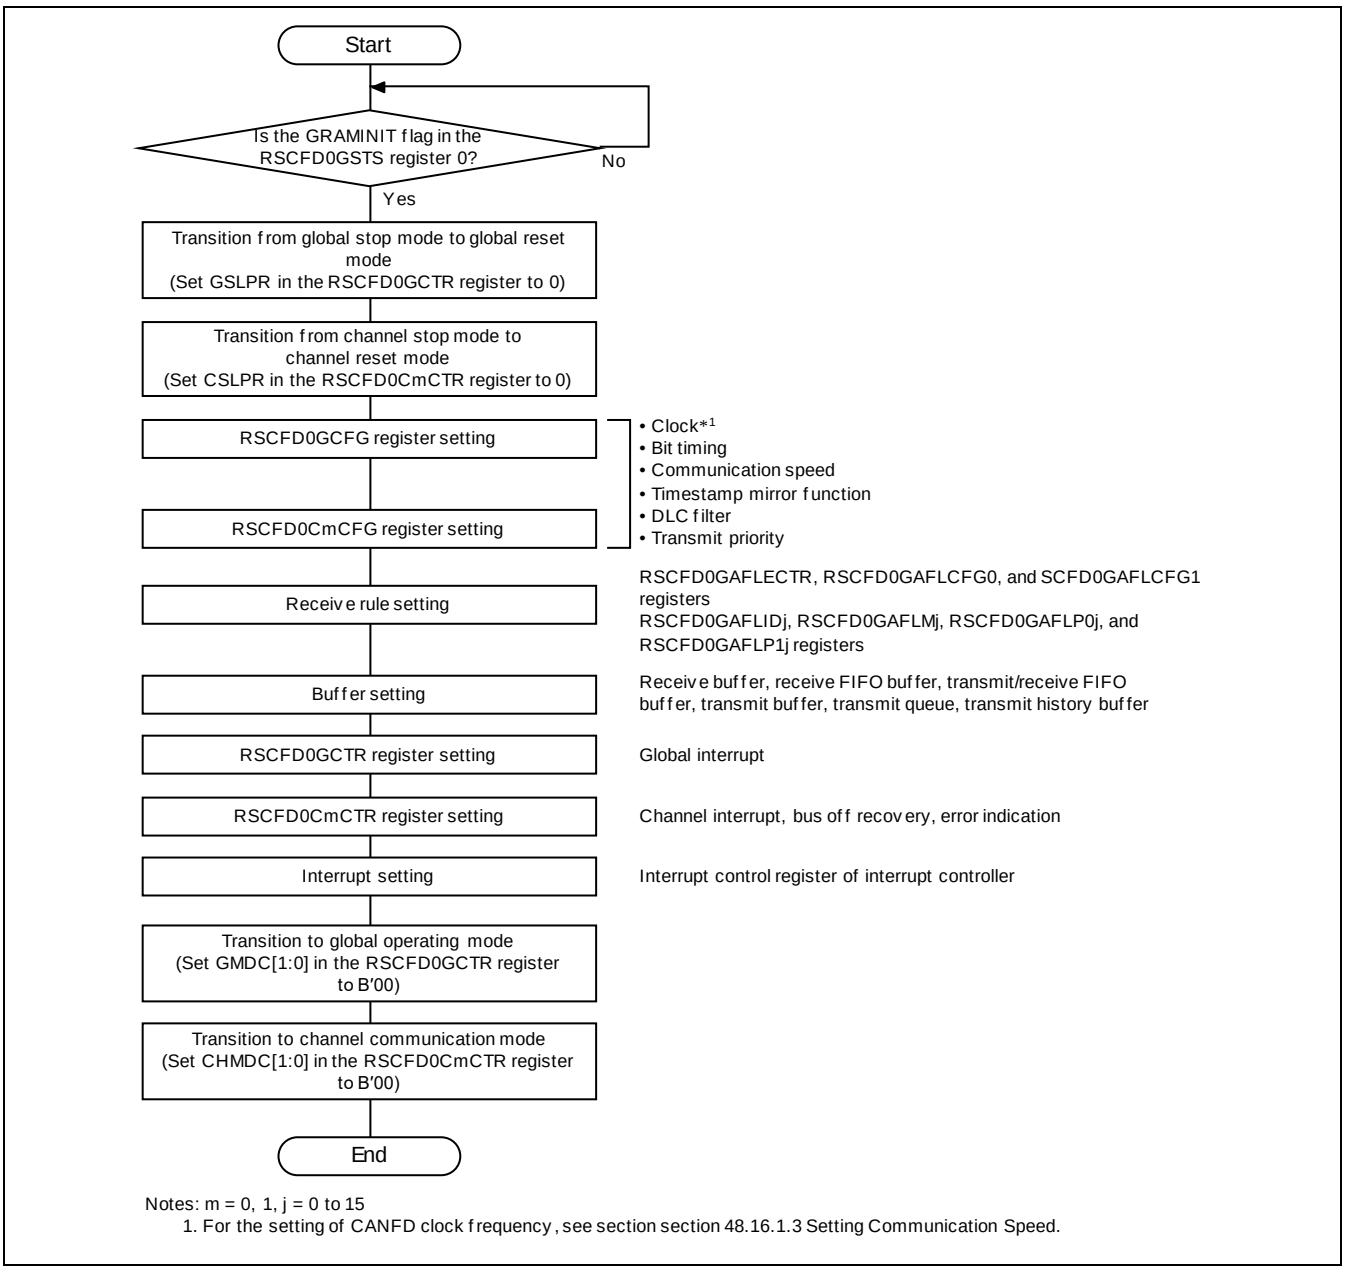
Since the CRC generation circuit in the RS-CANFD module is incorporated in each protocol controller of channels and the same circuit is shared in transmission and reception, a CRC calculation test needs not be performed at transmission.

48.16 RS-CANFD Setting Procedure

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

48.16.1 Initial Settings

The RS-CAN module initializes the CAN RAM after the MCU is reset. The RAM initialization time is 7586 cycles of the pclk. The GRAMINIT flag in the RSCFDn(CFD)GSTS register is set to 1 (CAN RAM initialization is ongoing) during the RAM initialization and is cleared to 0 (CAN RAM initialization is finished) when the initialization is completed. Make CAN settings after the GRAMINIT flag is cleared to 0. Figure 48.16 shows the CAN setting procedure after the MCU is reset.



Notes: m = 0, 1, j = 0 to 15
1. For the setting of CANFD clock frequency, see section section 48.16.1.3 Setting Communication Speed.

Figure 48.16 CAN Setting Procedure after the MCU is Reset

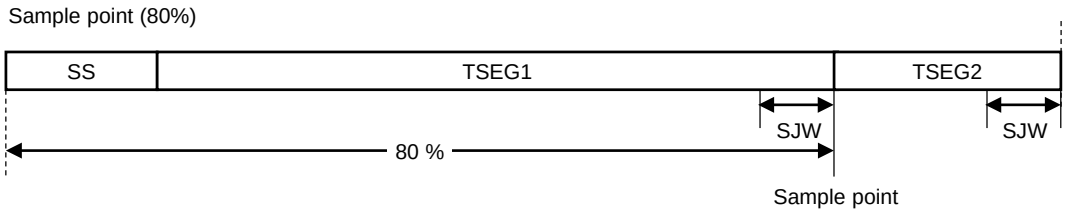
48.16.1.1 Setting a Clock

Set the CAN clock (fCAN) as a clock source of the RS-CANFD module. Select the clk_xincan or clkc using the DCS bit in the RSCFDn(CFD)GCFG register.

48.16.1.2 Setting Bit Timing

In the CAN protocol, one bit of a communication frame consists of three segments SS, TSEG1, and TSEG2, of which two segments TSEG1 and TSEG2 can be set by the register for each channel. These segments are set by the RSCFDnCmCFG register in classical CAN mode. In CAN FD mode, these segments have two types of bit rates (normal and data bit rates) and each bit rate is set by the RSCFDnCFDCmNCFG and RSCFDnCFDCmDCFG registers. Sample point timing can be determined by setting these two segments. This timing can be adjusted in units of 1 Time Quantum (hereafter referred to as Tq). 1 Tq is equal to one CANmTq clock cycle. A 1Tq is a clock cycle which divides the clock selected with the DCS bit in the RSCFDnGCFG register. The division ratio is set by the BRP[9:0] bits in the RSCFDnCmCFG register (CANmTq clock cycle) in classical CAN mode and set by the NBRP[9:0] bits in the RSCFDnCFDCmNCFG register and the DBRP[7:0] bits in the RSCFDnCFDCmDCFG register (CANmTq(N) and CANmTq(D) clock cycles) in CAN FD mode. ISO 11898-1 allows the normal and data bit rates individually have each division ratio. However, if different values are set to each division ratio, resynchronization between CAN nodes may be lost at the timing when the normal bit rate is switched to the data bit rate. Therefore, it is recommended that the NBRP[9:0] and DBRP[7:0] bits are set to the same value and two bit rates are set to the different values depending on the segment value.

Figure 48.17 shows the bit timing chart. Table 48.36 shows an example of bit timing setting.



SS = 1 Tq fixed
Set TSEG1 to a range of 4 Tq to 16 Tq
Set TSEG2 to a range of 2 Tq to 8 Tq
Set SJW to a range of 1 Tq to 4 Tq
Set SS + TSEG1 + TSEG2 to a range of 8 Tq to 25 Tq
TSEG1 > TSEG2 > SJW

SS (synchronization segment):
- The SS is a segment that performs synchronization by monitoring the edge from recessive to dominant bits in the Interframe Space.
  Interframe Space consists of Intermission, Suspend Transmission, and Bus Idle. All nodes can start transmission during Bus Idle.
- TSEG1 (Time segment 1):
  TSEG1 is a segment that absorbs physical delay on the CAN network. The physical delay on the CAN network is twice the total of the delay on the CAN bus, the delay in the input comparator, and the delay in the output driver.
- TSEG2 (Time segment 2):
  TSEG2 is a segment that compensates phase error due to an error in frequency.
- SJW (Resynchronization jump width)
  The SJW is a length to extend or reduce the time segment to compensate for an error in phase due to phase error.

Figure 48.17 Bit Timing Chart

Table 48.36 Example of Bit Timing Setting

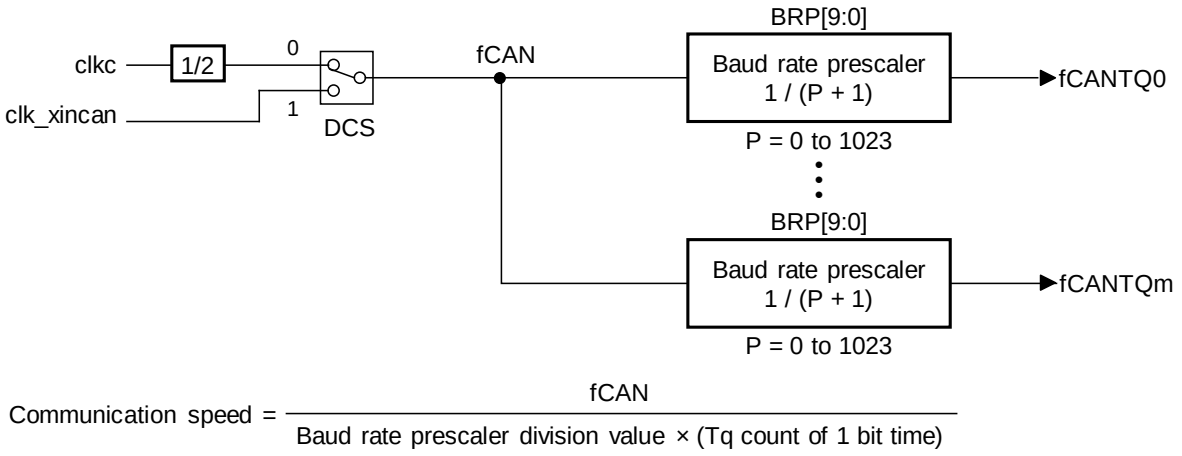
	Set Value (Tq)				Sample Point (%)
1 Bit	SS	TSEG1	TSEG2	SJW	Note: See Figure 48.17.
5 Tq*	1	2	2	1	60.00
8 Tq	1	4	3	1	62.50
	1	5	2	1	75.00
10 Tq	1	6	3	1	70.00
	1	7	2	1	80.00
16 Tq	1	10	5	1	68.75
	1	11	4	1	75.00
20 Tq	1	12	7	1	65.00
	1	13	6	1	70.00
50 Tq*	1	39	10	4	80.00

Note: * CAN FD mode only.

48.16.1.3 Setting Communication Speed

Set the CAN communication speed for each channel using the fCAN, baud rate prescaler division value, and Tq count per bit time. In CAN FD mode, set communication speed for each channel in arbitration and data phases.

Figure 48.18 shows the CAN clock control block diagram, and Table 48.37 shows an example of the communication speed setting.



$$\text{Communication speed} = \frac{\text{fCAN}}{\text{Baud rate prescaler division value} \times (\text{Tq count of 1 bit time})}$$

Note: m = 0, 1
DCS: Bit in the RSCFDn(CFD)GCFG register
BRP[9:0]: Bits in the RSCFDnCmCFG register
NBRP[9:0]: Bits in the RSCFDnCFDCmNCFG register
DBRP[7:0]: Bits in the RSCFDnCFDCmDCFG register
fCAN: CAN clock
fCANTQm: CANmTq clock
fCANTQ(N)m: CANmTq(N) clock
fCANTQ(D)m: CANmTq(D) clock

The clkc is CANFDϕ in section 8. Clock Pulse Generator (CPG).
For the CANFDϕ clock frequency settings, see section 8.

CANFDϕ maximum frequency : 80 (MHz)

Figure 48.18 CAN Clock Control Block Diagram

Table 48.37 Example of Communication Speed Setting (Classical CAN Mode)

Communication speed	fCAN					
	40 MHz	32 MHz	24 MHz	20 MHz	16 MHz	8 MHz
1 Mbps	8 Tq (5) 20 Tq (2)	8 Tq (4) 16 Tq (2)	8 Tq (3) 12 Tq (2) 24 Tq (1)	10 Tq (2) 20 Tq (1)	8 Tq (2) 16 Tq (1)	8 Tq (1)

125 Kbps	8 Tq (40) 20 Tq (16)	8 Tq (32) 16 Tq (16)	8 Tq (24) 12 Tq (16) 24 Tq (8)	10 Tq (16) 20 Tq (8)	8 Tq (16) 16 Tq (8)	8 Tq (8) 16 Tq (4)

Table 48.38 Example of Communication Speed Setting (CAN FD Mode, Normal Bit Rate and Data Bit Rate)

Communication speed	fCAN	
	40 MHz	20 MHz
Normal: 1-Mbps data 5 Mbps	Normal: 40 Tq (1) Data: 8 Tq (1)	None
Normal: 500-Kbps data 2 Mbps	Normal: 80 Tq (1) Data: 20 Tq (1)	Normal: 40 Tq (1) Data: 10 Tq (1)

Note: Values in ( ) are baud rate prescaler division values.
The clkc is CANFDϕ in section 11. Clock Pulse Generator (CPG).
For the CANFDϕ clock frequency settings, see section 11.
CANFDϕ maximum frequency are as follows.
RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N, RZ/G2E: 80 (MHz)

48.16.1.4 Setting Receive Rules

Receive rules can be set using registers related to receive rules.

Up to 16 receive rules can be registered per page. Specify pages 0 to 23 (when a unit incorporates six channels) by the AFLPN[4:0] bits in the RSCFDn(CFD)GAFLECTR register. Use the AFLDAE bit to set enabling or disabling writing to the receive rule table.

Figure 48.19 shows the receive rule setting procedure.

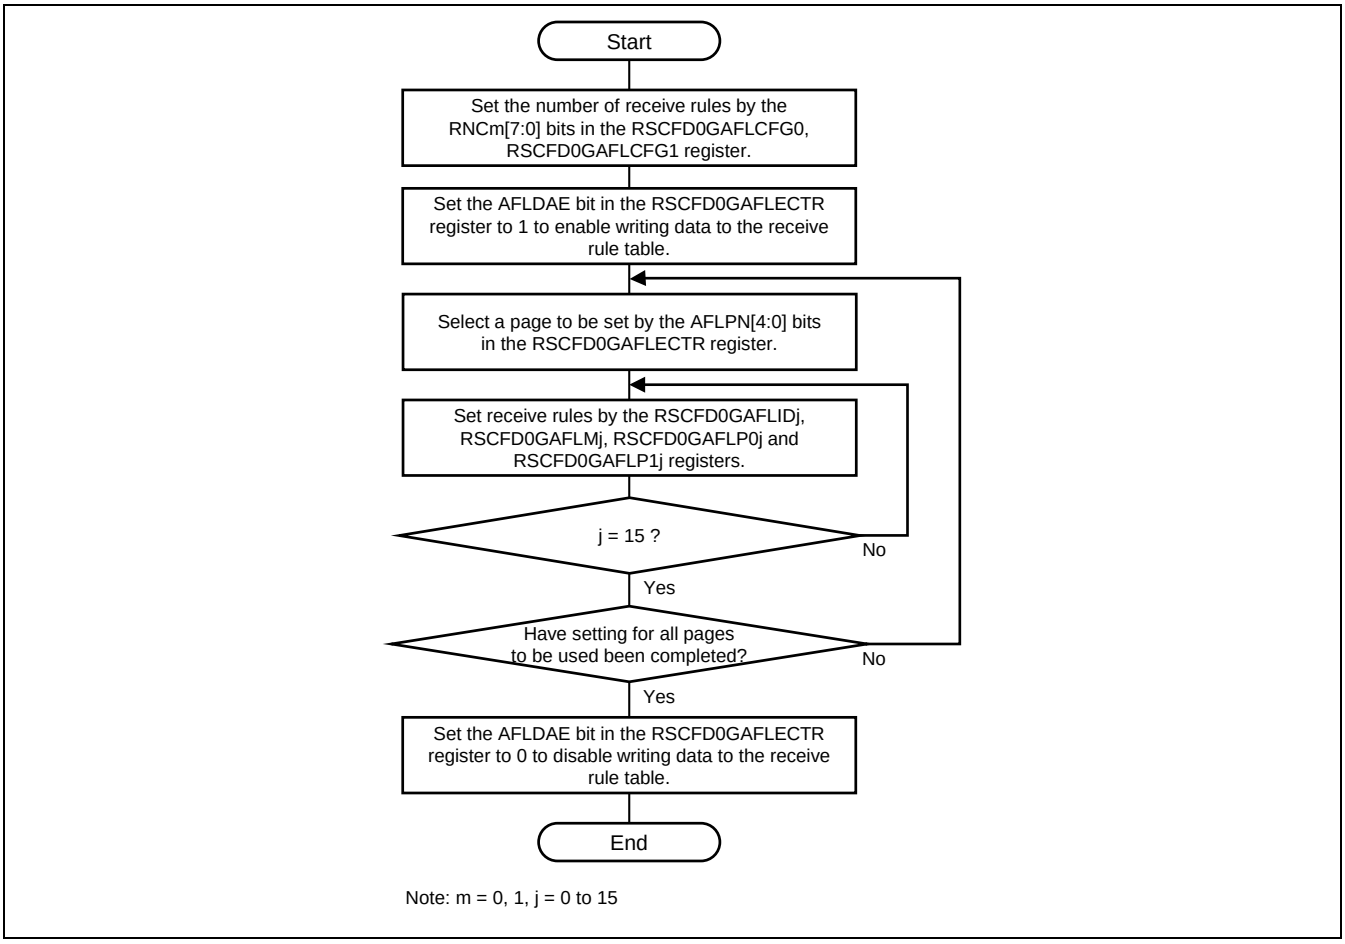

Figure 48.19 Receive Rule Setting Procedure

48.16.1.5 Setting Buffers

Set the number of buffers (messages to be stored) to be used and interrupt sources of buffers. In CAN FD mode, the size for storing the payload is also set. For transmit/receive FIFO buffers that are set to transmit mode, set transmit buffers to be linked.

In classical CAN mode, receive and FIFO buffers can use a maximum of 2048-byte RAM. Up to 128 buffers can be used and 16 bytes are used per buffer. The following conditions must be satisfied.

The number of receive buffers
+ The total of depth of receive FIFO buffer x
+ The total of depth of transmit/receive FIFO buffer k ≤ 128 buffers

In CAN FD mode, receive and FIFO buffers can use a maximum of 10752-byte RAM. The following conditions must be satisfied.

The number of receive buffers × (12 + the size for storing the payload)
+ The total of (depth × (12 + the size for storing the payload) of receive FIFO buffer x
+ The total of (depth × (12 + the size for storing the payload) of transmit/receive FIFO buffer k
≤ 3584 bytes

Figure 48.20 shows the buffer configuration. Figure 48.21 shows the buffer setting procedure.

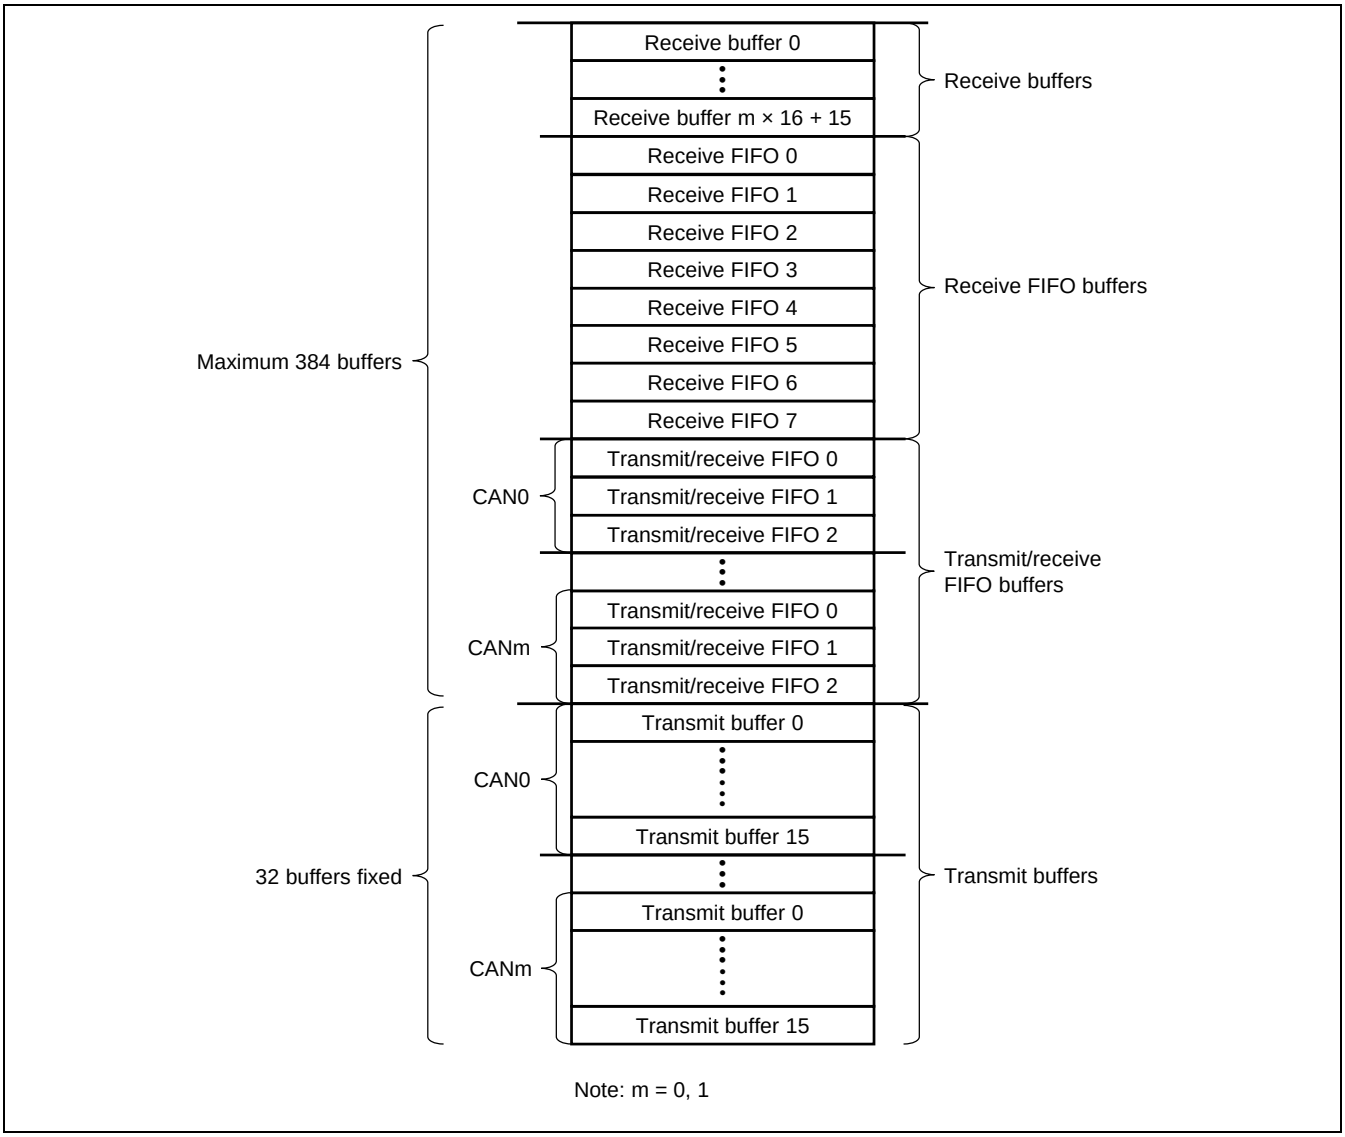

Figure 48.20 Buffer Configuration

Note: Receive buffers, receive FIFO buffers, transmit/receive FIFO buffers, and transmit buffers are located in succession.

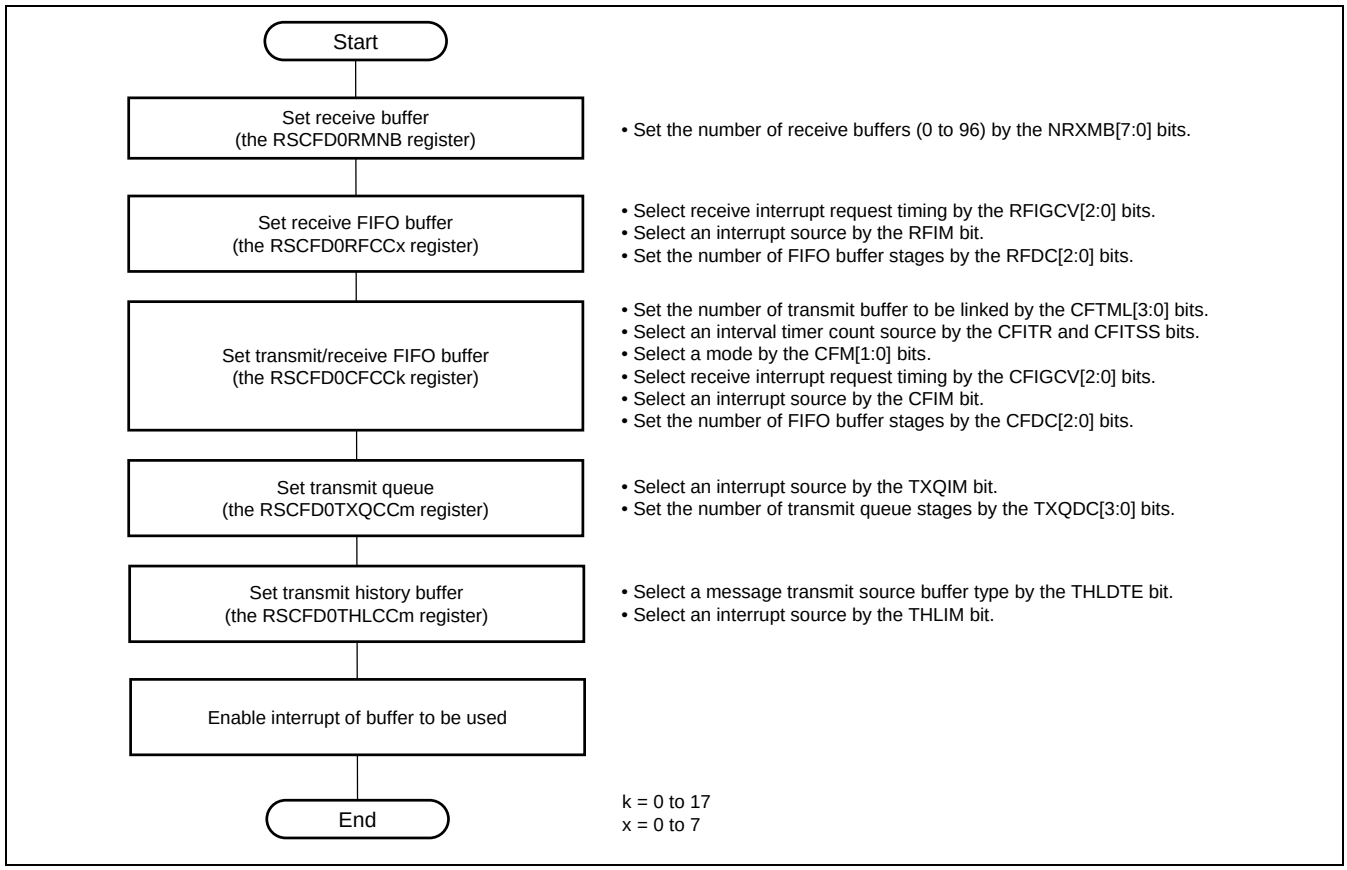

Figure 48.21 Buffer Setting Procedure

48.16.1.6 Transmit Delay Correction (CAN FD Mode Only)

A high baud rage is used for the data phase in CAN FD mode. At this time, the transmit delay correction function is used to enable transmit delay.

When this function is used, set the TDCE bit in the RSCFDnCFDCmFDCFG register to 1. The timing of the secondary sample point (SSP) used for a data phase must be set by the TDCOC and TDCO[6:0] bits in the RSCFDnCFDCmFDCFG register.

When the TDCOC bit is 0, the SSP timing is equal to the sum of the values of the delay measured by the RS-CANFD module and the TDCO[6:0] bits (it is rounded down to Tq which is the approximate integer). The value of the TDCO[6:0] bits must always be the sum of the sample point timing SS and TSEG1.

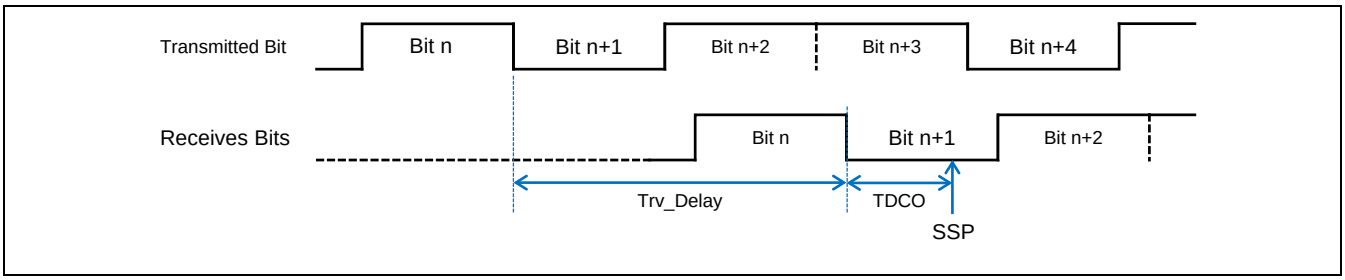

Figure 48.22 SSP Timing

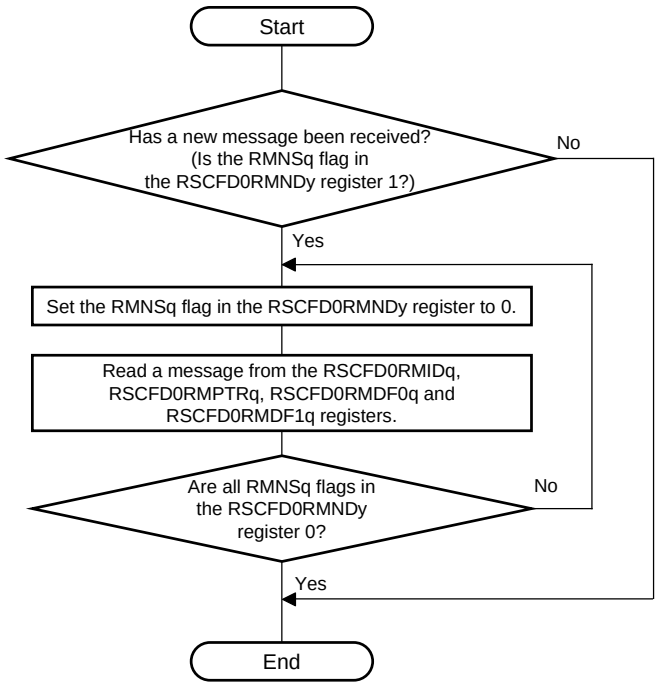
When the TDCOC bit is 1, the SSP timing is only determined by the value of the TDCO[6:0] bits (if the DBRP[7:0] bits in the RSCFDnCFDCmDCFG register are larger than 0, the value of the TDCO[6:0] bits are also rounded down to Tq which is the approximate integer).

The RS-CANFD module corrects the delay of a maximum of 3CANm bit time - 2Tq (the CANm bit time and Tq are the values of data bit rate).

48.16.2 Reception Procedure

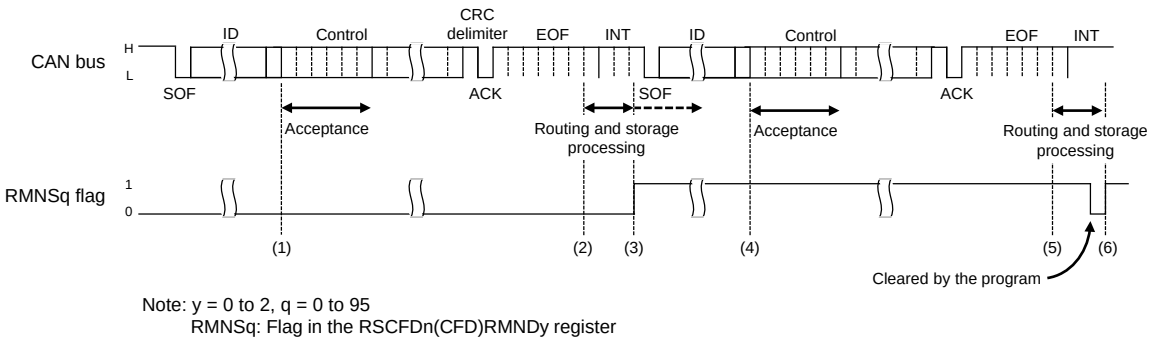
48.16.2.1 Receive Buffer Reading Procedure

When the processing to store received messages in a receive buffer starts, the RMNSq flag in the RSCFDn(CFD)RMNDy register (y = 0 to 2, q = 0 to 31) is set to 1 (receive buffer q contains a new message). Messages can be read from the RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDnCFDRMFDSTSq (CAN FD mode only), and RSCFDn(CFD)RMDFb_q (b = 0 or 1 in classical CAN mode, and b = 0 to 4 in CAN FD mode) registers. If the next message has been received before the current message is read from the receive buffer, the message is overwritten. Figure 48.23 shows the receive buffer reading procedure. Using this procedure maintains consistency of the message read from the RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDnCFDRMFDSTSq, and RSCFDn(CFD)RMDFb_q registers.



Note: y = 0 to 2, q = 0 to 95, b = 0, 1 (classical CAN mode), 0 to 4 (CAN FD mode)

Figure 48.23 Receive Buffer Reading Procedure



Note: y = 0 to 2, q = 0 to 95
RMNSq: Flag in the RSCFDn(CFD)RMNDy register

Figure 48.24 Receive Buffer Reception Timing Chart

(1) When the ID field in a message has been received, the acceptance filter processing starts.
(2) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.
(3) When the message has passed through the DLC filter processing, the processing to store the message in the specified receive buffer starts. When the message storage processing starts, the RMNSq flag in the corresponding RSCFDn(CFD)RMNDy register is set to 1 (the receive buffer contains a new message). If other channels are performing filter processing or transmit priority determination processing, the routing processing and the storage processing may be delayed.
(4) When the ID field of the next message has been received, the acceptance filter processing starts.
(5) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.
(6) When the corresponding RMNSq flag is cleared to 0 (the receive buffer contains no new message), this flag is set to 1 again when the message storage processing starts. Even if the RMNSq flag remains 1, a new message is overwritten to the receive buffer. The RMNSq flag should not be cleared to 0 during storage of messages.

48.16.2.2 FIFO Buffer Reading Procedure

When received messages have been stored in one or more receive FIFO buffers or a transmit/receive FIFO buffer that is set to receive mode or gateway mode, the corresponding message count display counter (RFMC[7:0] bits in the RSCFDn(CFD)RFSTSx register (x = 0 to 7) or CFMC[7:0] bits in the RSCFDn(CFD)CFSTSk register (k = 0 to 5)) is incremented. At this time, when the RFIE bit (receive FIFO interrupt is enabled) in the RSCFDn(CFD)RFCCx register or the CFRXIE bit (transmit/receive FIFO receive interrupt is enabled) in the RSCFDn(CFD)CFCCk register is set to 1, an interrupt request is generated. Received messages can be read from the RSCFDn(CFD)RFIDx, RSCFDn(CFD)RFPTRx, RSCFDnCFDRFFDSTSx (CAN FD mode only), and RSCFDn(CFD)RFDFd_x (d = 0 or 1 in classical CAN mode, and d = 0 to 15 in CAN FD mode) registers for receive FIFO buffers, or from the RSCFDn(CFD)CFIDk, RSCFDn(CFD)CFPTRk, RSCFDnCFDCFFDCSTSk (CAN FD mode only), and RSCFDn(CFD)CFDFd_k registers for transmit/receive FIFO buffers. Messages in FIFO buffers can be read sequentially on a first-in, first-out basis.

When the message count display counter value matches the FIFO buffer depth (a value set by the RFDC[2:0] bits in the RSCFDn(CFD)RFCCx register or the CFDC[2:0] bits in the RSCFDn(CFD)CFCCk register), the RFFLL or CFFLL flag is set to 1 (the receive FIFO buffer is full).

When all messages have been read out of the FIFO buffer, the RFEMP flag in the RSCFDn(CFD)RFSTSx register or the CFEMP flag in the RSCFDn(CFD)CFSTSk register is set to 1 (the receive FIFO buffer contains no unread message (buffer empty)).

If the RFE bit or the CFE bit is cleared to 0 (no receive FIFO buffer is used) with the interrupt request flag (RFIF flag in the RSCFDn(CFD)RFSTSx register or CFRXIF flag in the RSCFDn(CFD)CFSTSk register) set to 1 (a receive FIFO interrupt request is present), the interrupt request flag is not automatically cleared to 0. The program must clear the interrupt request flag to 0.

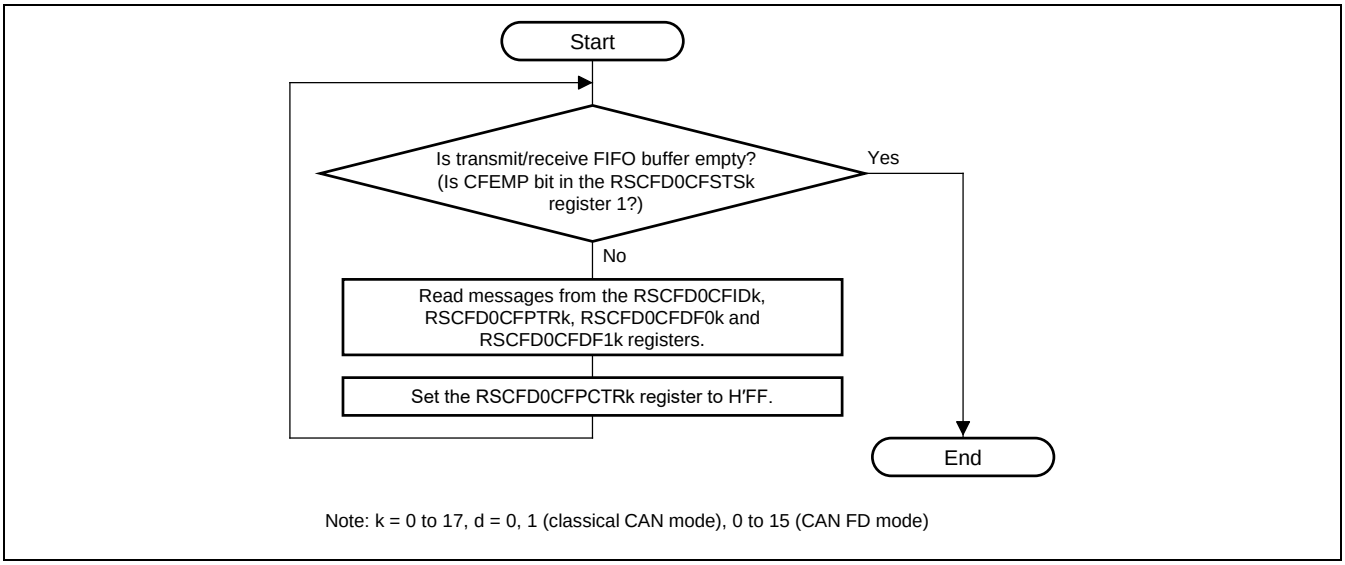


Figure 48.25 Transmit/Receive FIFO Buffer Reading Procedure

When a message is read in CAN FD mode, do not read the RSCFDnCFDRFDFd_x or RSCFDnCFDCFDFd_k register corresponding to the area which exceeds the payload storage size set by the RFPLS[2:0] bits in the RSCFDnCFDRFCCx register or the CFPLS[2:0] bits in the RSCFDnCFDCFCCk register.

Table 48.39 Payload Storage Area in the Receive FIFO Buffer

Value Set by the RFPLS[2:0] Bits	Payload Storage Size	Corresponding Data Field Register
B'000	8 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF1_x
B'001	12 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF2_x
B'010	16 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF3_x
B'011	20 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF4_x
B'100	24 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF5_x
B'101	32 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF7_x
B'110	48 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF11_x
B'111	64 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF15_x

Table 48.40 Payload Storage Area in the Transmit/Receive FIFO Buffer

Value Set by the CFPLS[2:0] Bits	Payload Storage Size	Corresponding Data Field Register
B'000	8 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF1_k
B'001	12 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF2_k
B'010	16 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF3_k
B'011	20 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF4_k
B'100	24 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF5_k
B'101	32 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF7_k
B'110	48 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF11_k
B'111	64 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF15_k

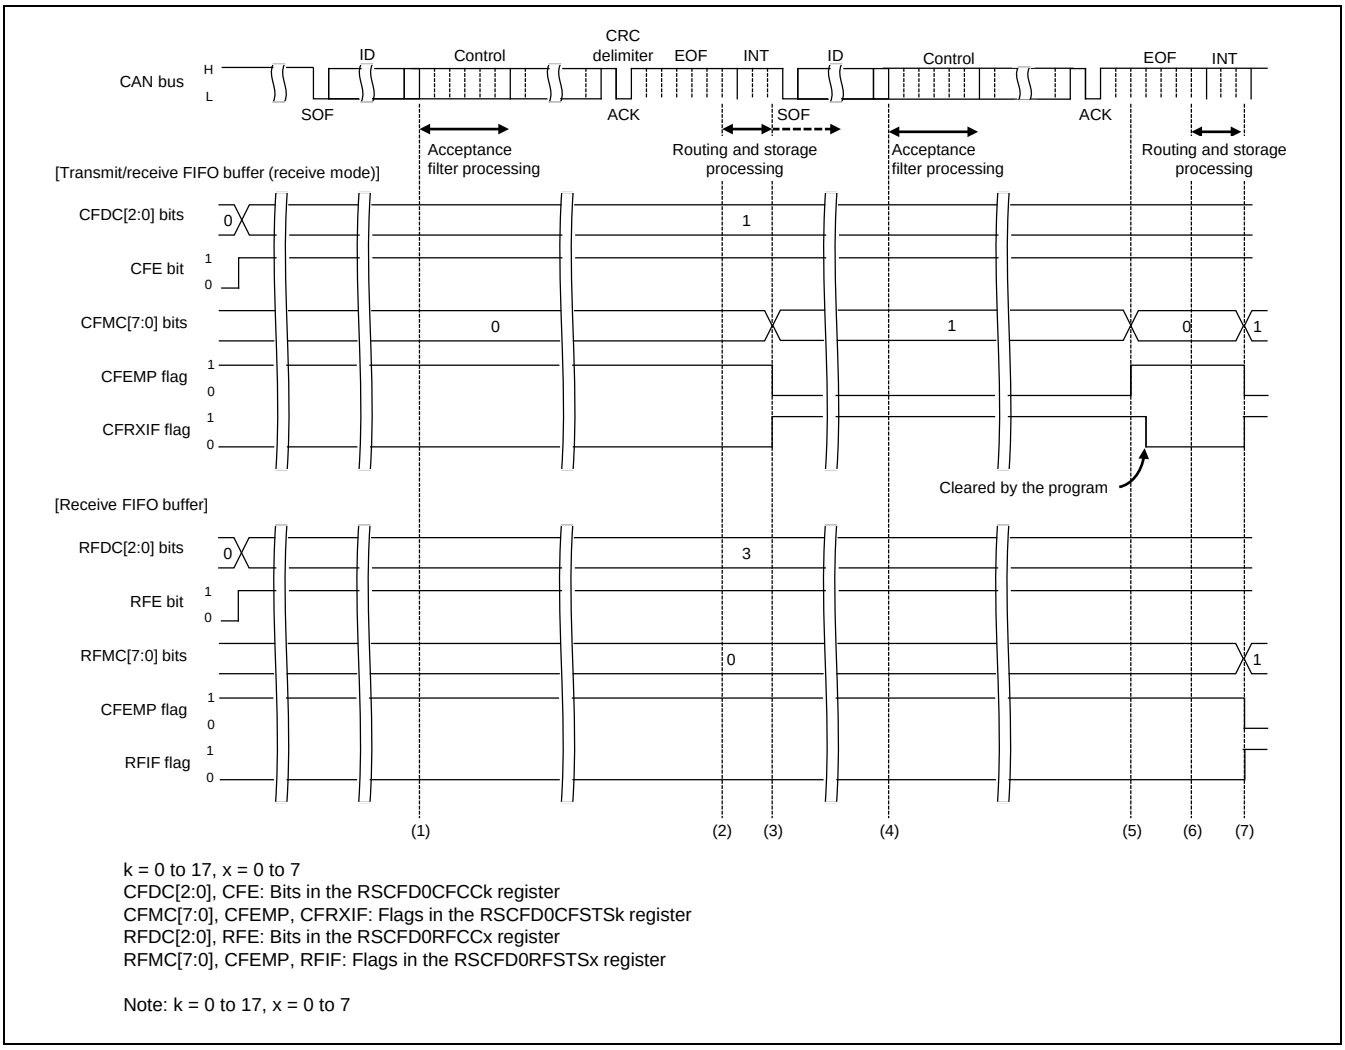

Figure 48.26 FIFO Buffer Reception Timing Chart

(1) When the ID field in a message has been received, the acceptance filter processing starts.

(2) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(3) When the message has passed through the DLC filter processing and the CFE bit in the RSCFDn(CFD)CFCCk register is 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] value in the RSCFDn(CFD)CFCCk register is B'001 or more, the message is stored in the transmit/receive FIFO buffer that is set to receive mode. The CFMC[7:0] value in the RSCFDn(CFD)CFSTSk register is incremented and becomes H'01. When the CFIM bit in the RSCFDn(CFD)CFCCk register is set to 1 (a FIFO receive interrupt request is generated each time a message has been received), the CFRXIF flag in the RSCFDn(CFD)CFSTSk register is set to 1 (a transmit/receive FIFO receive interrupt request is present). The CFRXIF flag can be reset to 0 by the program.

(4) When the ID field of the next message has been received, the acceptance filter processing starts.

(5) Read received messages from the RSCFDn(CFD)CFIDk, RSCFDn(CFD)CFPTRk, and RSCFDn(CFD)CFDFd_k registers and write H'FF to the RSCFDn(CFD)CFPCTRk register. This causes the CFMC[7:0] bits in the RSCFDn(CFD)CFSTSk register to be decremented. When CFMC[7:0] becomes H'00, the CFEMP flag in the RSCFDn(CFD)CFSTSk register becomes 1 (the transmit/receive FIFO buffer contains no message (buffer empty)).

(6) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(7) The message is stored in the transmit/receive FIFO buffer set in receive mode when the message has passed through the DLC filter process if the CFE bit is set to 1 (transmit/receive FIFO buffers are used), and the CFDC[2:0] bits are set to B'001 or more. The CFMC[7:0] bit value is incremented by 1 to be H'01. When the CFIM bit is set to 1 (an interrupt occurs each time a message has been received), the CFRXIF flag is set to 1 (a transmit/receive FIFO receive interrupt request is present). The message is stored in the receive FIFO buffer if the RFE bit in the RSCFDn(CFD)RFCCx register is set to 1 (receive FIFO buffers are used), and the RFDC[2:0] bits in the RSCFDn(CFD)RFCCx register are set to B'001 or more. The RFMC[7:0] bits in the RSCFDn(CFD)RFSTSx register are set to H'01 by being incremented by 1. When the RFIM bit in the RSCFDn(CFD)RFCCx register is set to 1 (an interrupt occurs each time a message has been received), the RFIF flag in the RSCFDn(CFD)RFSTSx register is set to 1 (a receive FIFO interrupt request is present).

48.16.2.3 Procedure for Reading FIFO Buffers by the DMA Transfer

In CAN FD mode, the following FIFO buffers can be read by the DMA transfer.

- All receive FIFO buffers x (x = 0 to 7)
- The first transmit/receive FIFO buffer k (k = 3 × m, m = 0 or 1) assigned to channel m

The DMA enable bit (the RFDMAEx or CFDMAEm bit in the RSCFDnCFDCDTC register) can be set at any timing. However, before this bit is set to 1 (the DMA transfer request is enabled), clear the receive interrupt enable bit of the related FIFO (the RFIE bit in the RSCFDnCFDRFCCx register or the CFRXIE bit in the RSCFDnCFDCFCCk register) to 0 (interrupts are disabled). When the DMA transfer request is enabled, do not write the FIFO control register (the RSCFDnCFDRFCCx or RSCFDnCFDCFCCk register).

If there are unread messages in the FIFO buffer that the DMA transfer is enabled, a DMA transfer request trigger will be generated. Specify the address for the FIFO access register to the transfer source address and adjust the transfer size so that the end of the payload storage area is read with a trigger. The end of the payload depends on the payload storage size set by the RFPLS[2:0] bits in the RSCFDnCFDRFCCx register or the CFPLS[2:0] bits in the RSCFDnCFDCFCCk register.

When the end of the payload stored in the FIFO buffer is read, the RFMC[7:0] bits in the RSCFDnCFDRFSTSx register or the CFMC[7:0] bits in the RSCFDnCFDCFSTSk register are automatically decremented by 1. If there is an unread message in the FIFO buffer after the end of the payload is read, a trigger will be generated again.

If the RFDMAEx or CFDMAEm bit is cleared to 0 (the DMA transfer request is disabled) during DMA transfer, wait for the DMA transfer state (the RFDMASTSx or CFDMASTSm bit in the RSCFDnCFDCDTSTS register) is cleared to 0 (DMA is not being transferred) and perform the next processing (the DMA transfer is enabled again, etc.). When the DMA transfer is disabled, consider handling of messages that have remained in the FIFO buffer and are newly received. When the FIFO buffer is enabled, reception by the FIFO buffer will proceed.

The calculation of payload size shuld add the ID and PTR, STS. The ID and PTR, STS is the total 12byte.

If the payload size and transfer size of SYS-DMA is mismatch, use the PIO transfer.

The choices of SYS-DMA are following.
- 1byte
- 2byte
- 4byte
- 8byte
- 16byte
- 32byte
- 64byte

48.16.3 Transmission Procedure

48.16.3.1 Procedure for Transmission from Transmit Buffers

Figure 48.27 shows the procedure for transmission from transmit buffers.

Figure 48.28 shows a timing chart where messages are transmitted from two transmit buffers in the same channel and transmission has been successfully completed. Figure 48.29 shows a timing chart where messages are transmitted from two transmit buffers in the same channel and transmit abort has been completed.

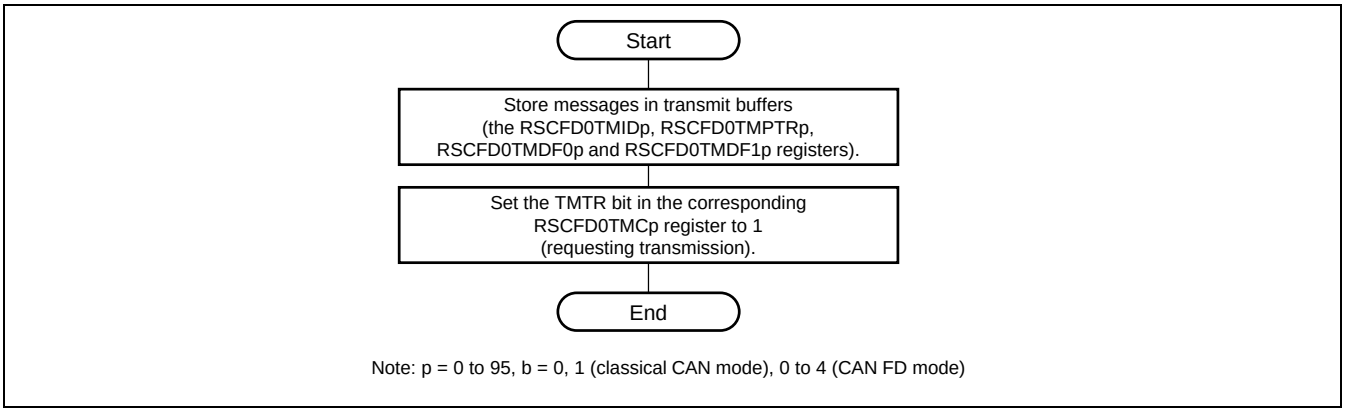

Figure 48.27 Procedure for Transmission from Transmit Buffers

In CAN FD mode and transmit buffer merge mode, transmit buffers ("(16 × m) + 0" and "(16 × m) + 3") can transmit a message which has a payload of 20 bytes or more. In this case, transmit buffers ("(16 × m) + 1 to (16 × m) + 2" and "(16 × m) + 4 to (16 × m) + 5") are assigned to the payload storage areas. The RSCFDnCFDTMIDp, RSCFDnCFDTMPTRp, and RSCFDnCFDTMFDCTRp registers corresponding to those buffers, similarly to the RSCFDnCFDTMDFb_p register, can be used as data field registers which store the 4-byte data byte (payload). Table 48.41 shows message storage registers when a message which has a payload of 20 bytes or more is transmitted in transmit buffer 0.

Table 48.41 Message Storage Registers in Transmit Buffer Merge Mode (Transmit Buffer 0)

Transmit Buffer	Offset from Base Address	Abbreviation	Register Function for Transmit Buffer Merge Mode
Transmit buffer 0	H'4000	RSCFDnCFDTMID0	ID data, transmit history data storage enable, RTR and IDE bits in transmit buffer 0
	H'4004	RSCFDnCFDTMPTR0	Label data and DLC data in transmit buffer 0
	H'4008	RSCFDnCFDTMFDCTR0	ESI, BRS, and FDF bits in transmit buffer 0
	H'400C to H'401C	RSCFDnCFDTMDF0_0 to RSCFDnCFDTMDF4_0	Data bytes 0, 1, 2, and 3 in transmit buffer 0 to data bytes 16, 17, 18, and 19 in transmit buffer 0
Transmit buffer 1	H'4020	RSCFDnCFDTMID1	Data bytes 20, 21, 22, and 23 in transmit buffer 0
	H'4024	RSCFDnCFDTMPTR1	Data bytes 24, 25, 26, and 27 in transmit buffer 0
	H'4028	RSCFDnCFDTMFDCTR1	Data bytes 28, 29, 30, and 31 in transmit buffer 0
	H'402C to H'403C	RSCFDnCFDTMDF0_1 to RSCFDnCFDTMDF4_1	Data bytes 32, 33, 34, and 35 in transmit buffer 0 to data bytes 48, 49, 50, and 51 in transmit buffer 0
Transmit buffer 2	H'4040	RSCFDnCFDTMID2	Data bytes 52, 53, 54, and 55 in transmit buffer 0
	H'4044	RSCFDnCFDTMPTR2	Data bytes 56, 57, 58, and 59 in transmit buffer 0
	H'4048	RSCFDnCFDTMFDCTR2	Data bytes 60, 61, 62, and 63 in transmit buffer 0
	H'404C to H'405C	RSCFDnCFDTMDF0_2 to RSCFDnCFDTMDF4_2	Not used

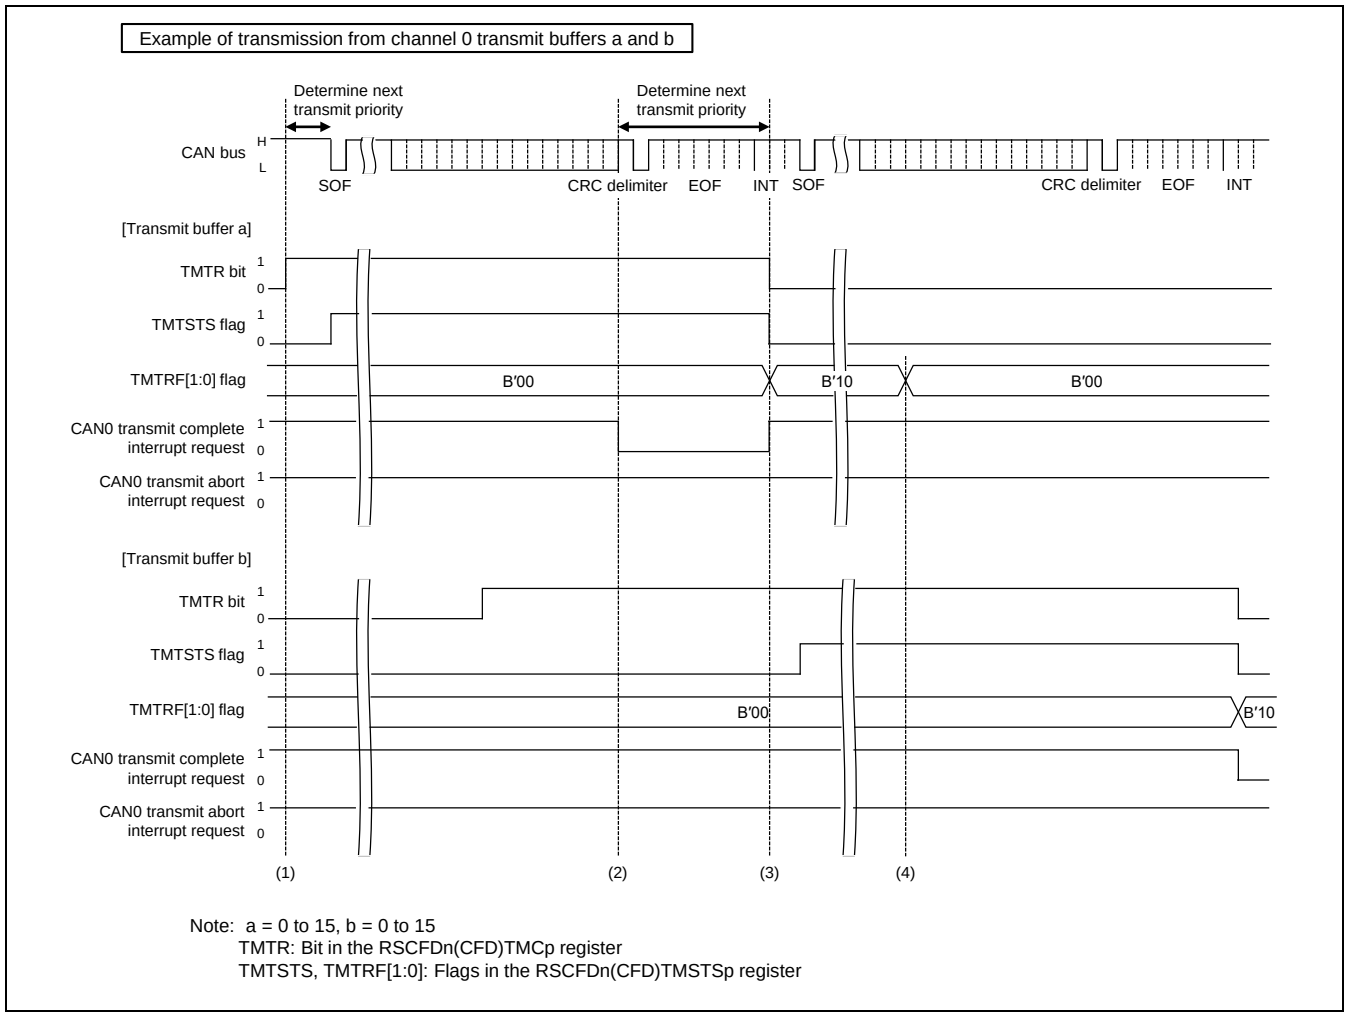

Figure 48.28 Transmit Buffer Transmission Timing Chart (Transmission Completed Successfully)

(1) When the TMTR bit in the RSCFDn(CFD)TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmit buffer. If transmit buffer a is determined to be the highest-priority transmit buffer, the TMTSTS flag in the corresponding RSCFDn(CFD)TMSTSa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.

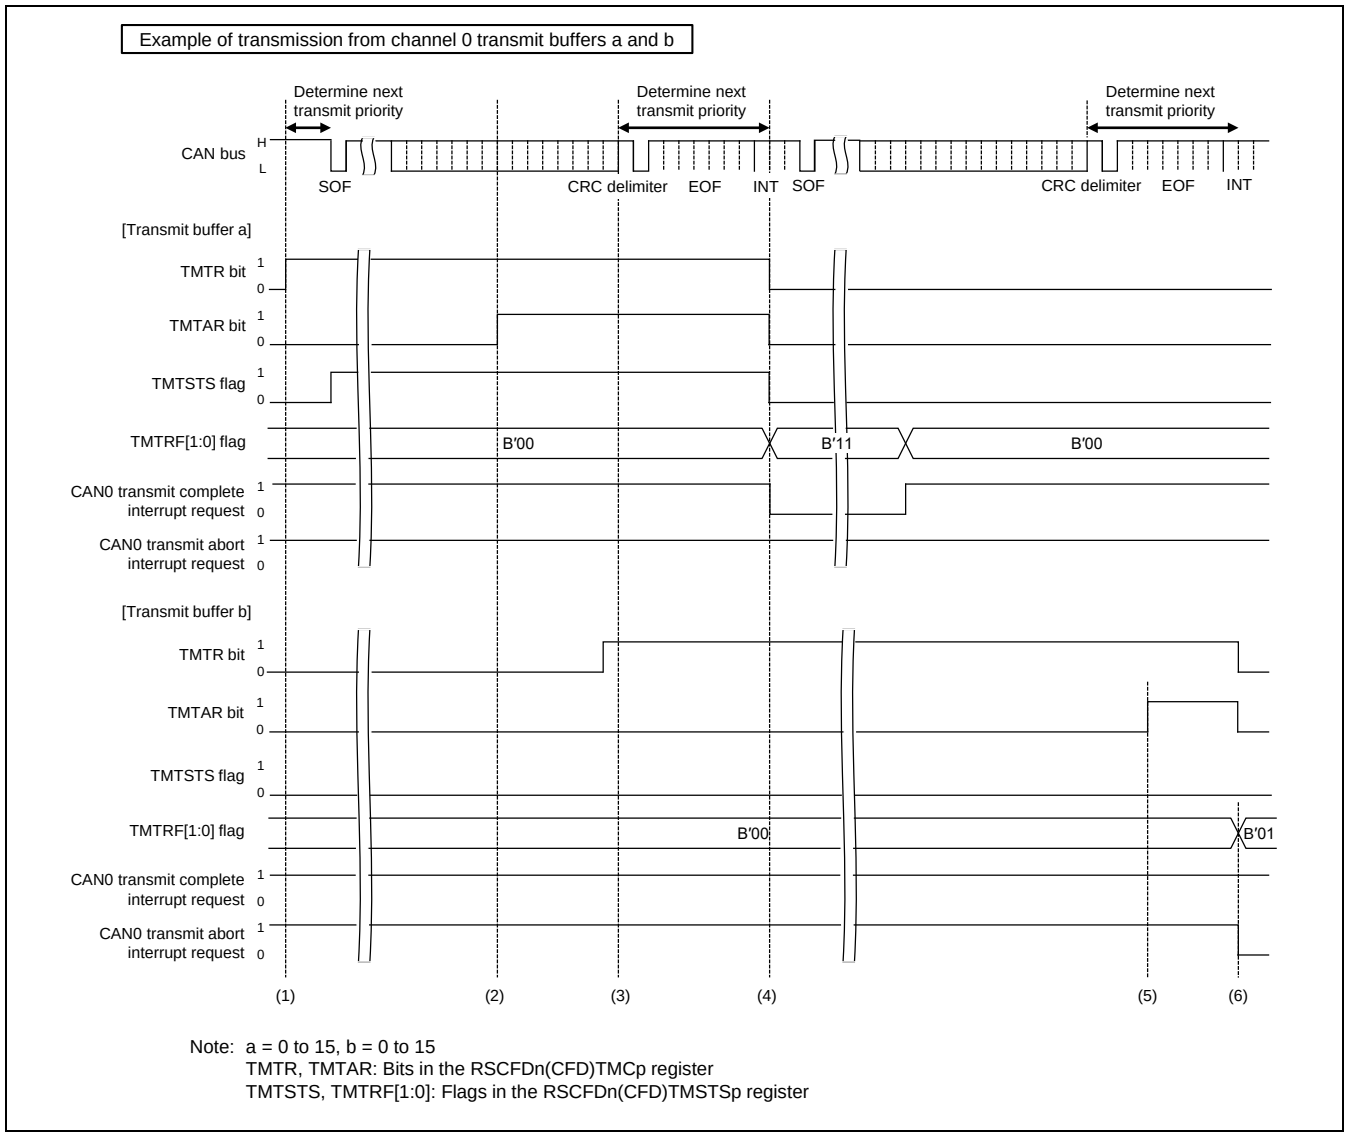
(2) When a transmit request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.

(3) When transmission completes successfully, the TMTRF[1:0] flag in the RSCFDn(CFD)TMSTSa register is set to B'10 (transmission has been completed (without transmit abort request)) and the TMTSTS flag and the TMTR bit in the RSCFDn(CFD)TMIEC0 register are cleared to 0. When the TMIEa bit in the RSCFDn(CFD)TMIEC0 register is 1 (transmit buffer interrupt is enabled), a CAN0 transmit complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to B'00 (transmission is in progress or no transmit request is present).

(4) Before starting the next transmission, set the TMTRF[1:0] flag to B'00. Write the next message to the transmit buffer, and then set the TMTR bit to 1 (transmission is requested). The TMTR bit can be set to 1 only when the TMTRF[1:0] flag value is B'00.

If an arbitration lost has occurred after transmission is started, the TMTSTS flag is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC delimiter to search the highest-priority transmit buffer. If an error has occurred during transmission or after arbitration lost, the priority determination processing is reexecuted during transmission of an error frame.

If an ECC2 bit error is detected in the priority determination processing, transmission will not be performed (for classical CAN mode, the EEFE bit in the RSCFDnGCFG register is 1).



Note: a = 0 to 15, b = 0 to 15
TMTR, TMTAR: Bits in the RSCFDn(CFD)TMCp register
TMTSTS, TMTRF[1:0]: Flags in the RSCFDn(CFD)TMSTSp register

Figure 48.29 Transmit Buffer Transmission Timing Chart (Transmit Abort Completed)

(1) When the TMTR bit in the RSCFDn(CFD)TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmit buffer. If transmit buffer a is determined to be the highest-priority transmit buffer, the TMTSTS flag in the corresponding RSCFDn(CFD)TMSTSa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.

(2) When it is determined that the transmit buffer is used for the next transmission or transmission is in progress, message transmission is not aborted unless an error or arbitration loss occurs even if the TMTAR bit is set to 1 (transmit abort is requested).

(3) The priority determination starts with the CRC delimiter for the next transmission. In this timing chart, buffer b is not selected as the next transmit buffer. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.

(4) When transmission completes successfully, the TMTRF[1:0] flag in the RSCFDn(CFD)TMSTSa register is set to B'11 (transmission has been completed (with transmit abort request)) and the TMTSTS flag and the TMTR bit in the RSCFDn(CFD)TMCa register are cleared to 0. When the TMIEa value in the RSCFDn(CFD)TMIEC0 register is 1

(transmit buffer interrupt is enabled), a CAN0 transmit complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to B'00 (transmission is in progress or no transmit request is present).

(5) While another CAN node is transmitting data on the CAN bus (TMTSTS flag = 0), if the TMTAR bit is set to 1 while the corresponding channel is determining transmit priority, the TMTR bit cannot be cleared to 0.

(6) After the internal processing time has passed, the transmission is terminated and the TMTRF[1:0] flag is set to B'01. When the transmit buffer is not transmitting data and is not selected as the next transmit buffer and priority determination is not being made, an abort request is immediately accepted and the TMTRF[1:0] flag is set to B'01. At this time, the TMTR and TMTAR bits are cleared to 0. When transmit abort is completed with the TAIE bit in the RSCFDn(CFD)CmCTR register set to 1 (transmit abort interrupt is enabled), an interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to B'00.

If an arbitration lost has occurred after the CAN channel started transmission, the TMTSTS bit is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC delimiter to find the highest-priority transmit buffer. If an error has occurred during transmission or after arbitration lost, the priority determination processing is reexecuted during transmission of an error frame.

If an ECC2 bit error is detected in the priority determination processing, transmission will not be performed (for classical CAN mode, the EEFE bit in the RSCFDnGCFG register is 1).

48.16.3.2 Procedure for Transmission from Transmit/Receive FIFO Buffers

Figure 48.30 shows the procedure for transmission from transmit/receive FIFO buffers.

Figure 48.31 shows a timing chart where messages are transmitted from two transmit/receive FIFO buffers in the same channel and transmission has been successfully completed. Figure 48.32 shows a timing chart where messages are transmitted from two transmit/receive FIFO buffers in the same channel and transmit abort has been completed.

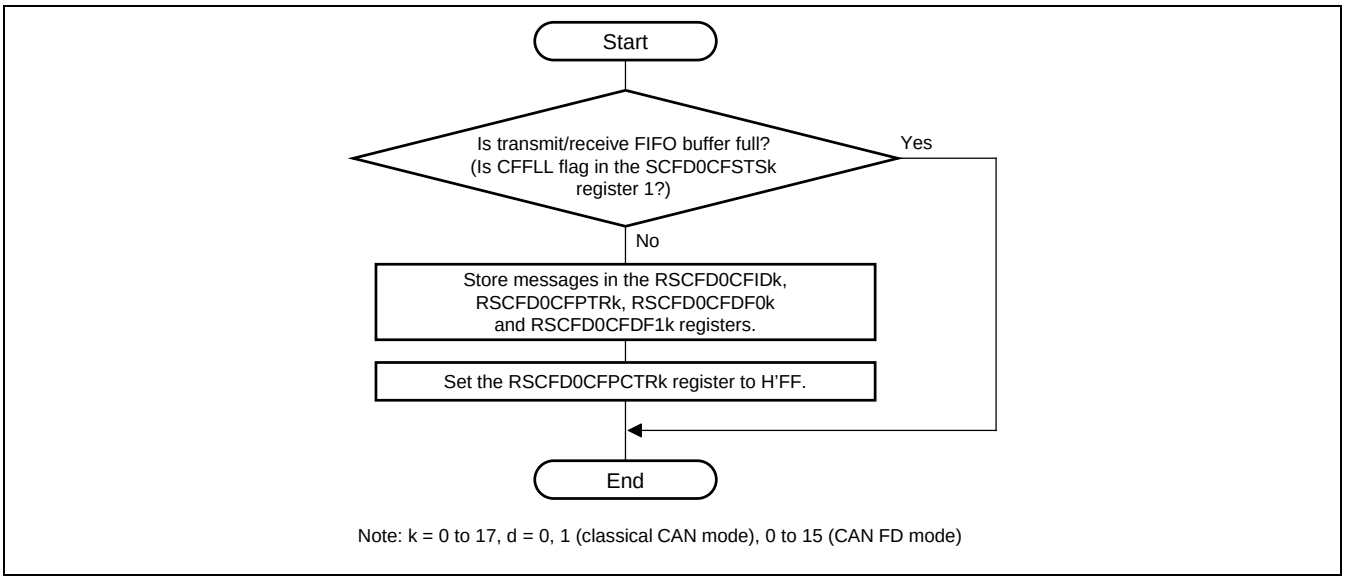


Figure 48.30 Procedure for Transmission from Transmit/Receive FIFO Buffers

When a message is stored, do not write the RSCFDnCFDCFDFd_k register corresponding to the area which exceeds the payload storage size set by the CFPLS[2:0] bits in the RSCFDnCFDCFCCk register.

Table 48.42 Payload Storage Area in the Transmit/Receive FIFO Buffer

Value Set by the CFPLS[2:0] Bits	Payload Storage Size	Corresponding Data Field Register
B'000	8 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF1_k
B'001	12 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF2_k
B'010	16 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF3_k
B'011	20 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF4_k
B'100	24 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF5_k
B'101	32 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF7_k
B'110	48 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF11_k
B'111	64 bytes	RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF15_k

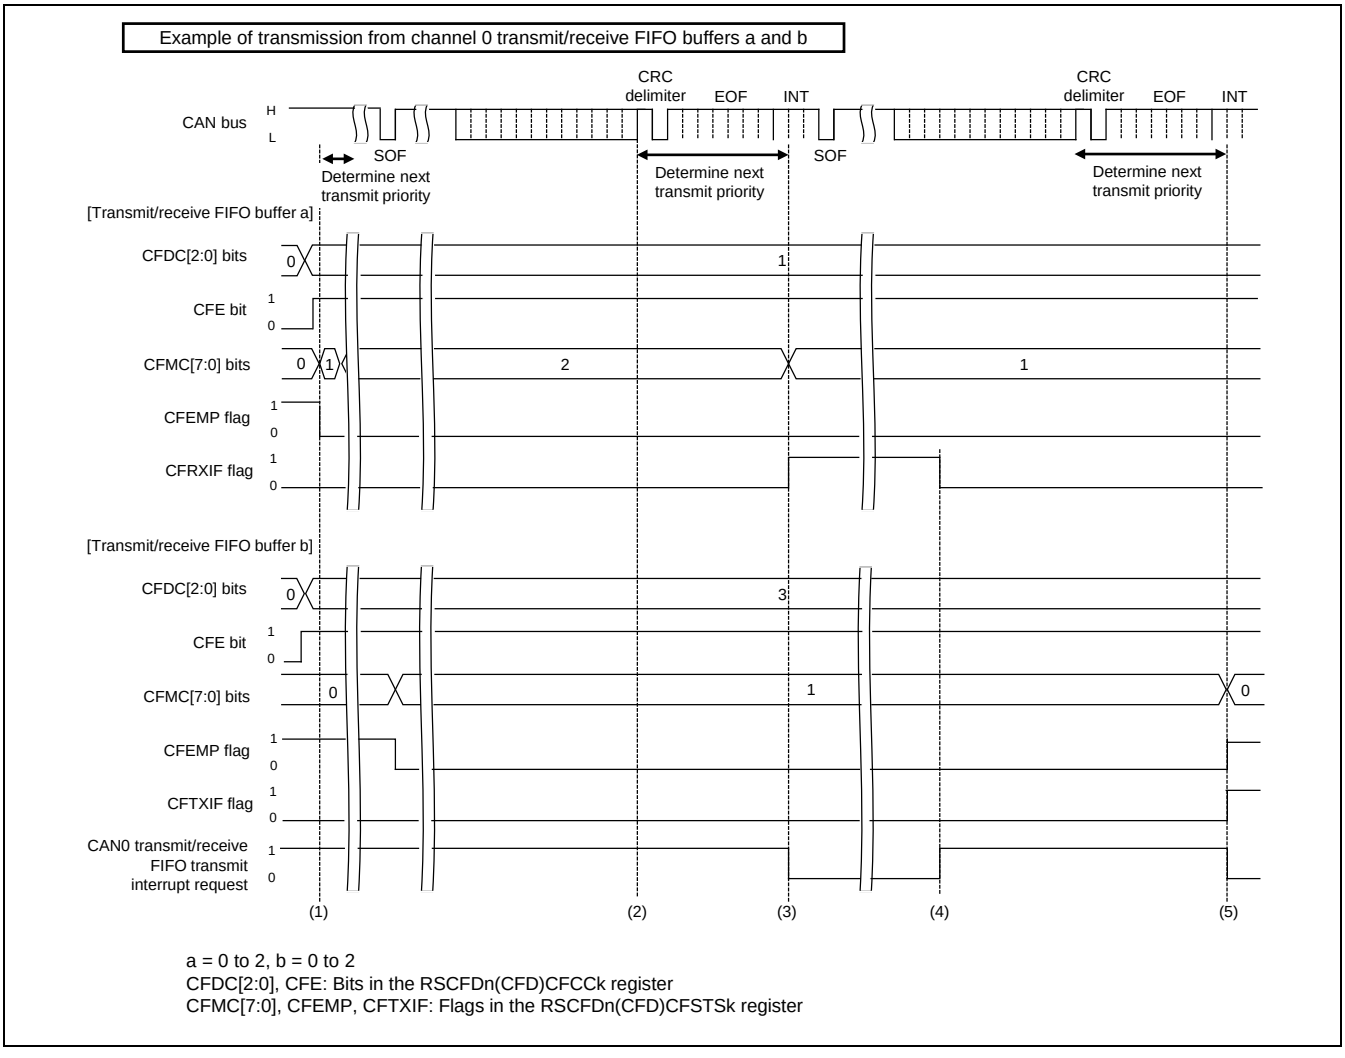

Figure 48.31 Transmit/Receive FIFO Buffer Transmission Timing Chart (Transmission Completed Successfully)

(1) While the CAN bus is idle, when the CFE bit in the RSCFDn(CFD)CFCCa register is 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] value in the RSCFDn(CFD)CFCCa register is B'001 (4 messages) or more and the CFMC[7:0] value in the RSCFDn(CFD)CFSTSa register is H'01 or more, the priority determination processing starts to determine the highest-priority transmit message. When the highest-priority transmit message has been determined, transmission of the message starts. In this figure, the message is transmitted from transmit/receive FIFO buffer a of channel 0.

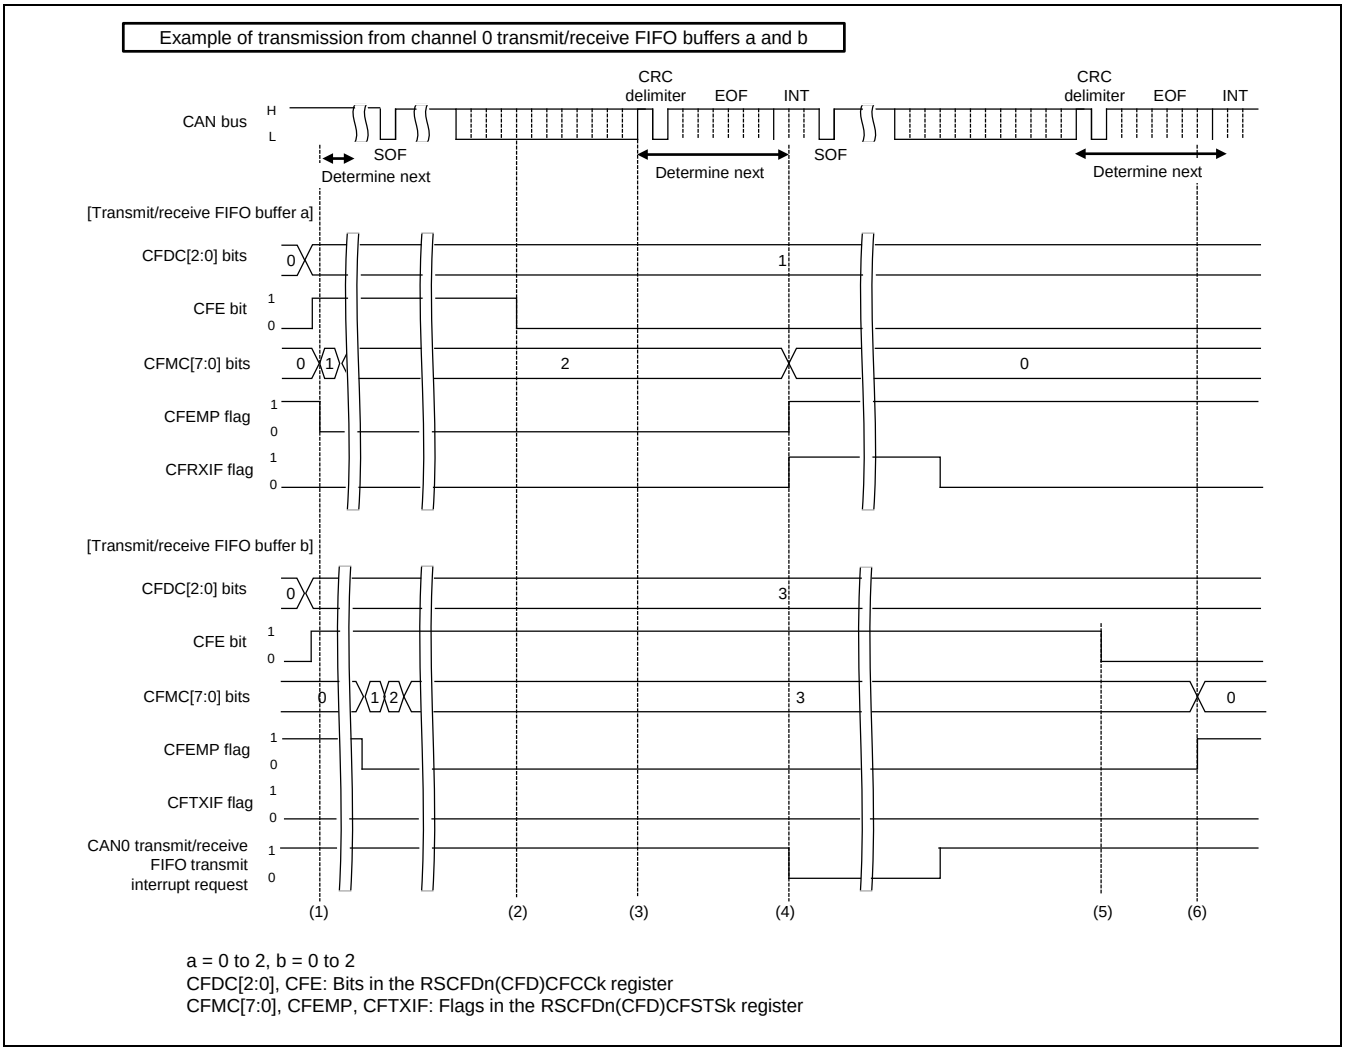
(2) When a transmit request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.

(3) When transmission completes successfully, the CFMC[7:0] value in the RSCFDn(CFD)CFSTSa register is decremented. Setting the CFIM bit in the RSCFDn(CFD)CFCCa register to 1 (a FIFO transmit interrupt request is generated each time a message has been transmitted) sets the CFTXIF flag in the RSCFDn(CFD)CFSTSk register to 1 (a transmit/receive FIFO transmit interrupt request is present).

(4) The program can clear the CFTXIF flag.

(5) Message transmission from transmit/receive FIFO buffer b of channel 0 has been completed and the CFMC[7:0] value in the RSCFDn(CFD)CFSTSb register is decremented. The CFMC[7:0] bits are cleared to H'00 and therefore the CFEMP flag in the RSCFDn(CFD)CFSTSk register is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)).

Transmission is continued until the CFEMP flag is set to 1. It is possible to continuously store transmit messages in FIFO buffers until the CFFLL flag in the RSCFDn(CFD)CFSTSa and RSCFDn(CFD)CFSTSb register is set to 1 (the transmit/receive FIFO buffer is full).



a = 0 to 2, b = 0 to 2
CFDC[2:0], CFE: Bits in the RSCFDn(CFD)CFCCk register
CFMC[7:0], CFEMP, CFTXIF: Flags in the RSCFDn(CFD)CFSTSk register

Figure 48.32 Transmit/Receive FIFO Buffer Transmission Timing Chart (Transmission Abort Completed)

(1) While the CAN bus is idle, when the CFE bit in the RSCFDn(CFD)CFCCa register is 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] value in the RSCFDn(CFD)CFCCa register is B'001 (4 messages) or more and the CFMC[7:0] value in the RSCFDn(CFD)CFSTSa register is H'01 or more, the priority determination processing starts to determine the highest-priority transmit message. When the highest-priority transmit message has been determined, transmission of the message starts. In this figure, the message is transmitted from transmit/receive FIFO buffer a of channel 0.

(2) When transmission is in progress or it is determined that the transmit/receive FIFO buffer is used for the next transmission, message transmission is not aborted unless an error or arbitration loss occurs even if the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).

(3) When a transmit request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission. In this figure, transmit/receive FIFO buffer b is not selected as a buffer for the next transmission. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.

(4) When transmit completes successfully, the CFMC[7:0] value is cleared to H'00. Setting the CFIM bit to 1 (a FIFO transmit interrupt request is generated each time a message has been transmitted) sets the CFTXIF flag in the RSCFDn(CFD)CFSTSa register to 1 (a transmit/receive FIFO transmit interrupt request is present). The program can clear the CFTXIF flag.

(5) If another CAN node on the CAN bus is transmitting data (not from transmit/receive FIFO buffer b), transmit/receive FIFO buffers cannot be disabled immediately even if the CFE bit in the RSCFDn(CFD)CFCCb register is cleared to 0 (no transmit/receive FIFO buffer is used) during transmit priority determination. (The CFEMP flag in the RSCFDn(CFD)CFSTSb register is not set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)) immediately.)

(6) After the internal processing time has passed, transmit/receive FIFO buffers are disabled and the CFMC[7:0] bits in the RSCFDn(CFD)CFSTSb register are cleared to H'00 and the CFEMP flag is set to 1. When the transmit/receive FIFO buffer is not transmitting data and is not selected as the next transmit buffer and priority determination is not in progress, the transmit/receive FIFO buffer is immediately disabled. (The CFMC[7:0] bits are cleared to H'00 and the CFEMP flag is set to 1.)

48.16.3.3 Procedure for Transmission from the Transmit Queue

Figure 48.33 shows the procedure for transmission from the transmit queue.

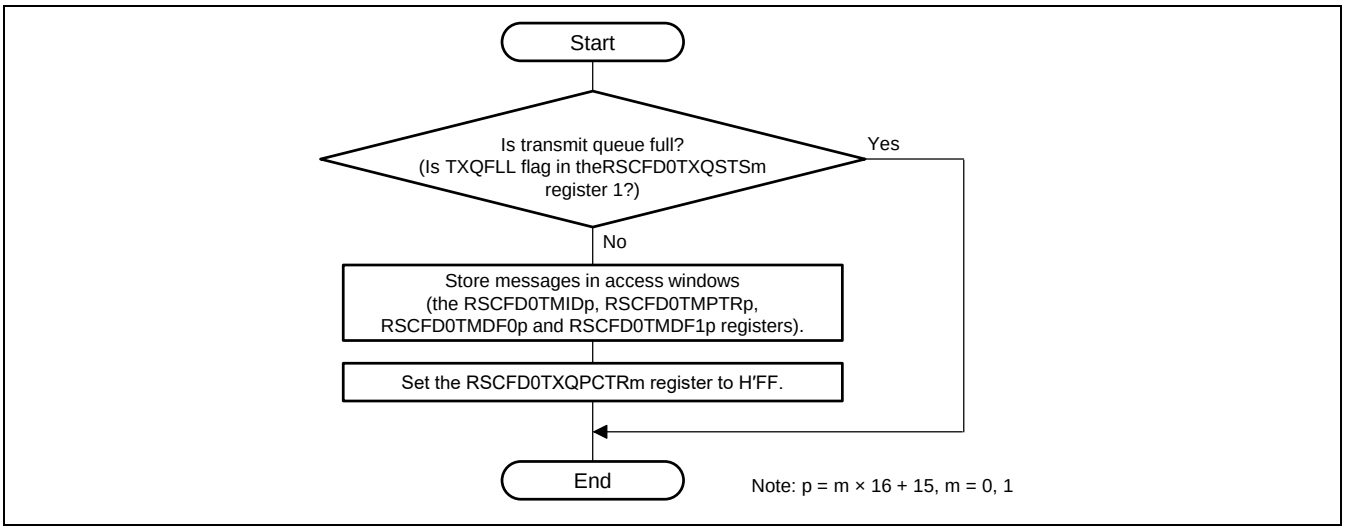


Figure 48.33 Procedure for Transmission from the Transmit Queue

48.16.3.4 Transmit History Buffer Reading Procedure

Transmit history data can be read from the RSCFDn(CFD)THLACCm register. The next data can be accessed by writing H'FF to the corresponding RSCFDn(CFD)THLPCTRm register (m = 0 or 1) after reading a set of data. Figure 48.34 shows the transmit history buffer reading procedure.

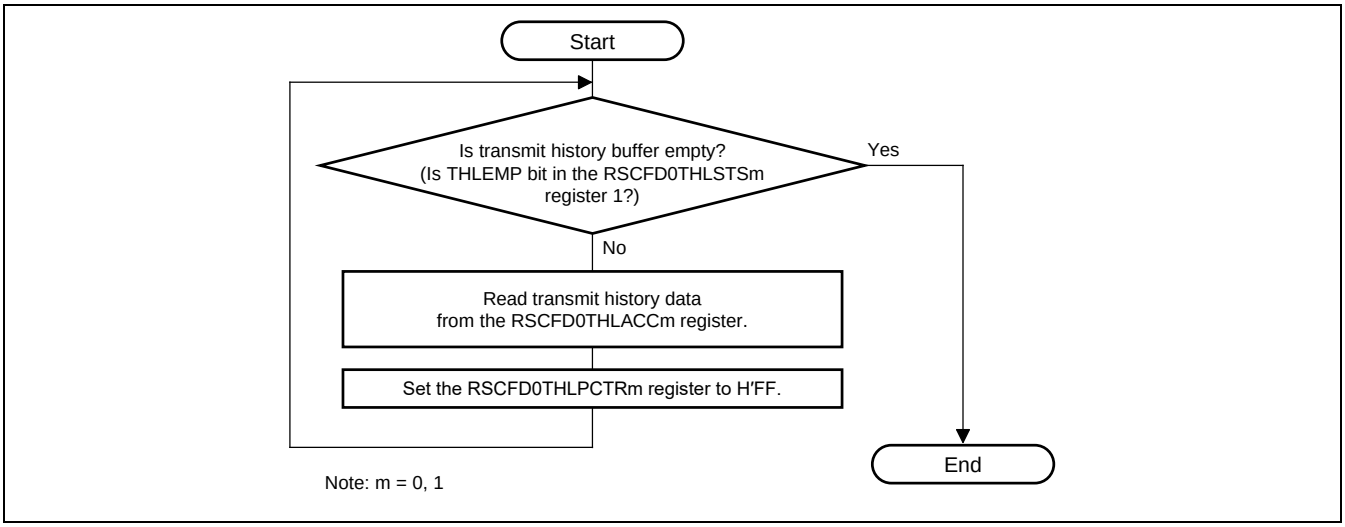

Figure 48.34 Transmit History Buffer Reading Procedure

48.16.4 Test Settings

48.16.4.1 Self-Test Mode Setting Procedure

Self-test mode allows communication test on a channel basis by enabling a CAN node to receive its own transmitted messages.

Figure 48.35 shows the self-test mode setting procedure.

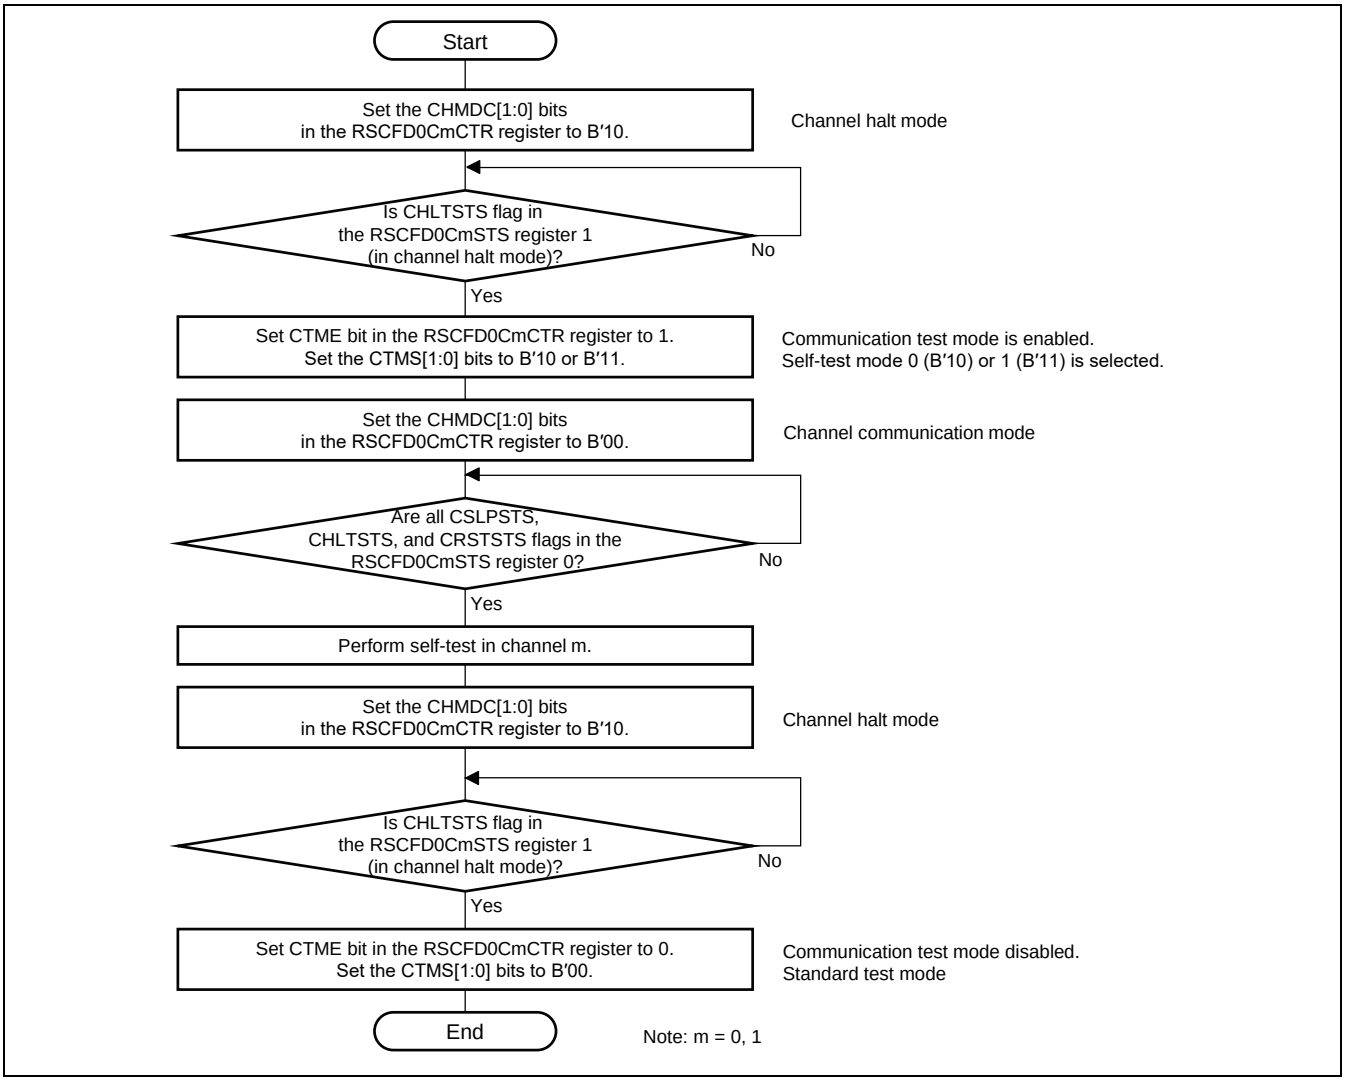

Figure 48.35 Self-Test Mode Setting Procedure

48.16.4.2 Procedure for Releasing the Protection

Since the global test function in Table 48.43 is protected, write the protection release data 1 and release data 2 in succession to the LOCK[15:0] bits in the RSCFDn(CFD)GLOCKK register, then set the target test bit to 1.

Table 48.43 Protection Release Data for Test Function

Test Function	Protection Release Data 1	Protection Release Data 2	Target Bit
RAM test	H'7575	H'8A8A	RTME bit in the RSCFDn(CFD)GTSTCTR register

If an incorrect value is written to the LOCK[15:0] bits, restart from writing the protection release data 1. Figure 48.36 shows the procedure for releasing the protection.

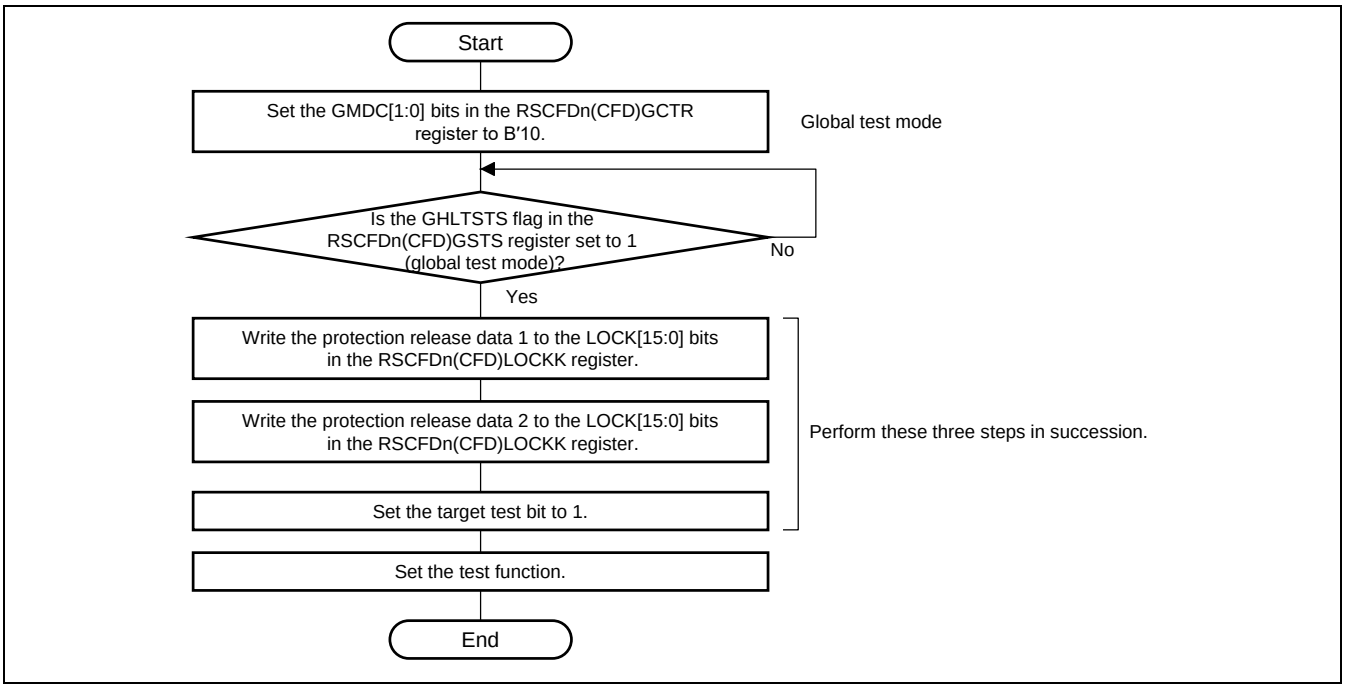

Figure 48.36 Protection Release Procedure

48.16.4.3 RAM Test Setting Procedure

RAM tests include CAN RAM read/write test. The read/write test verifies that data written to the RAM is read correctly. Before closing the RAM test, write H'0000_0000 to all pages of the CAN RAM.

Figure 48.37 shows the RAM test setting procedure.

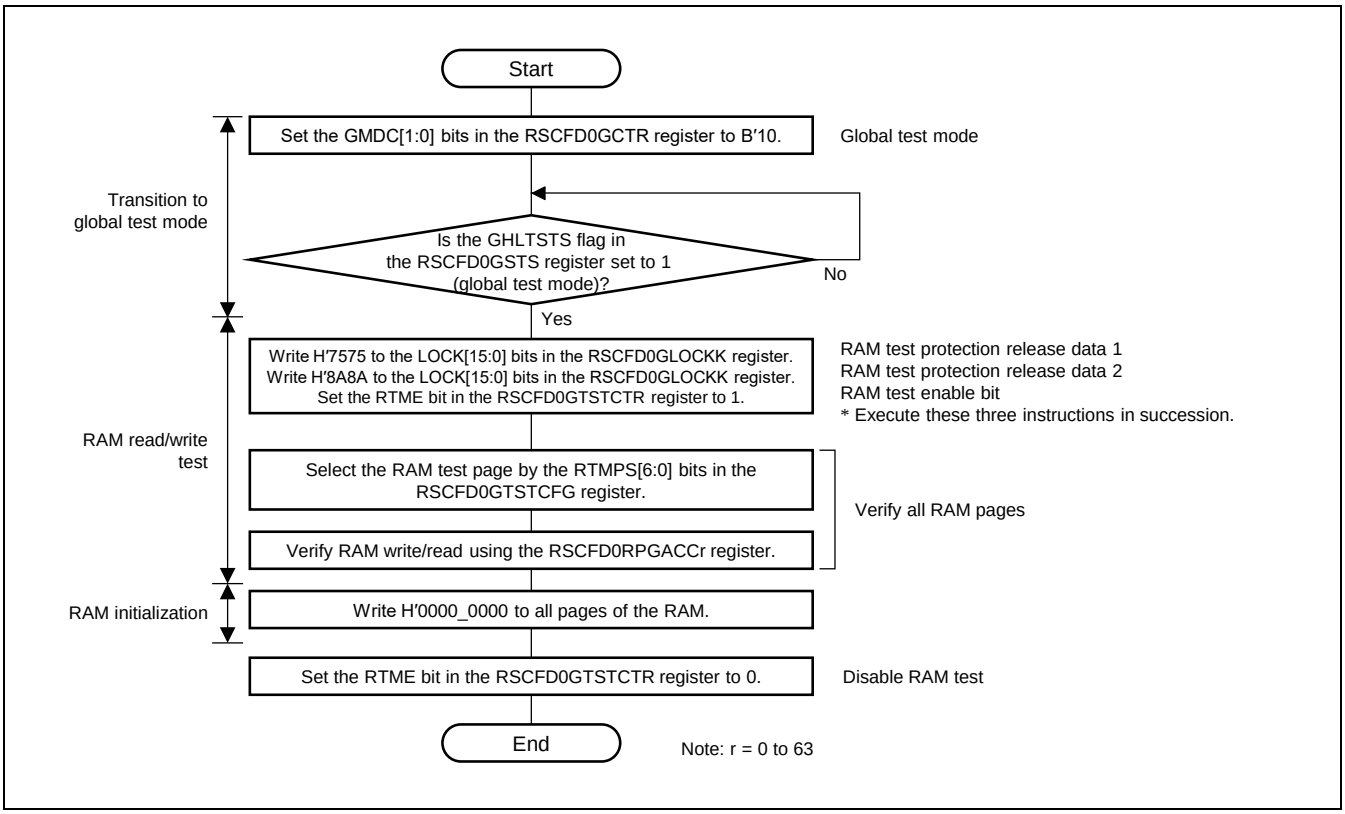

Figure 48.37 RAM Test Setting Procedure

48.16.4.4 Inter-Channel Communication Test Setting Procedure

Communication testing can be performed by transmitting and receiving data between different channels.

Figure 48.38 shows the inter-channel communication test setting procedure.

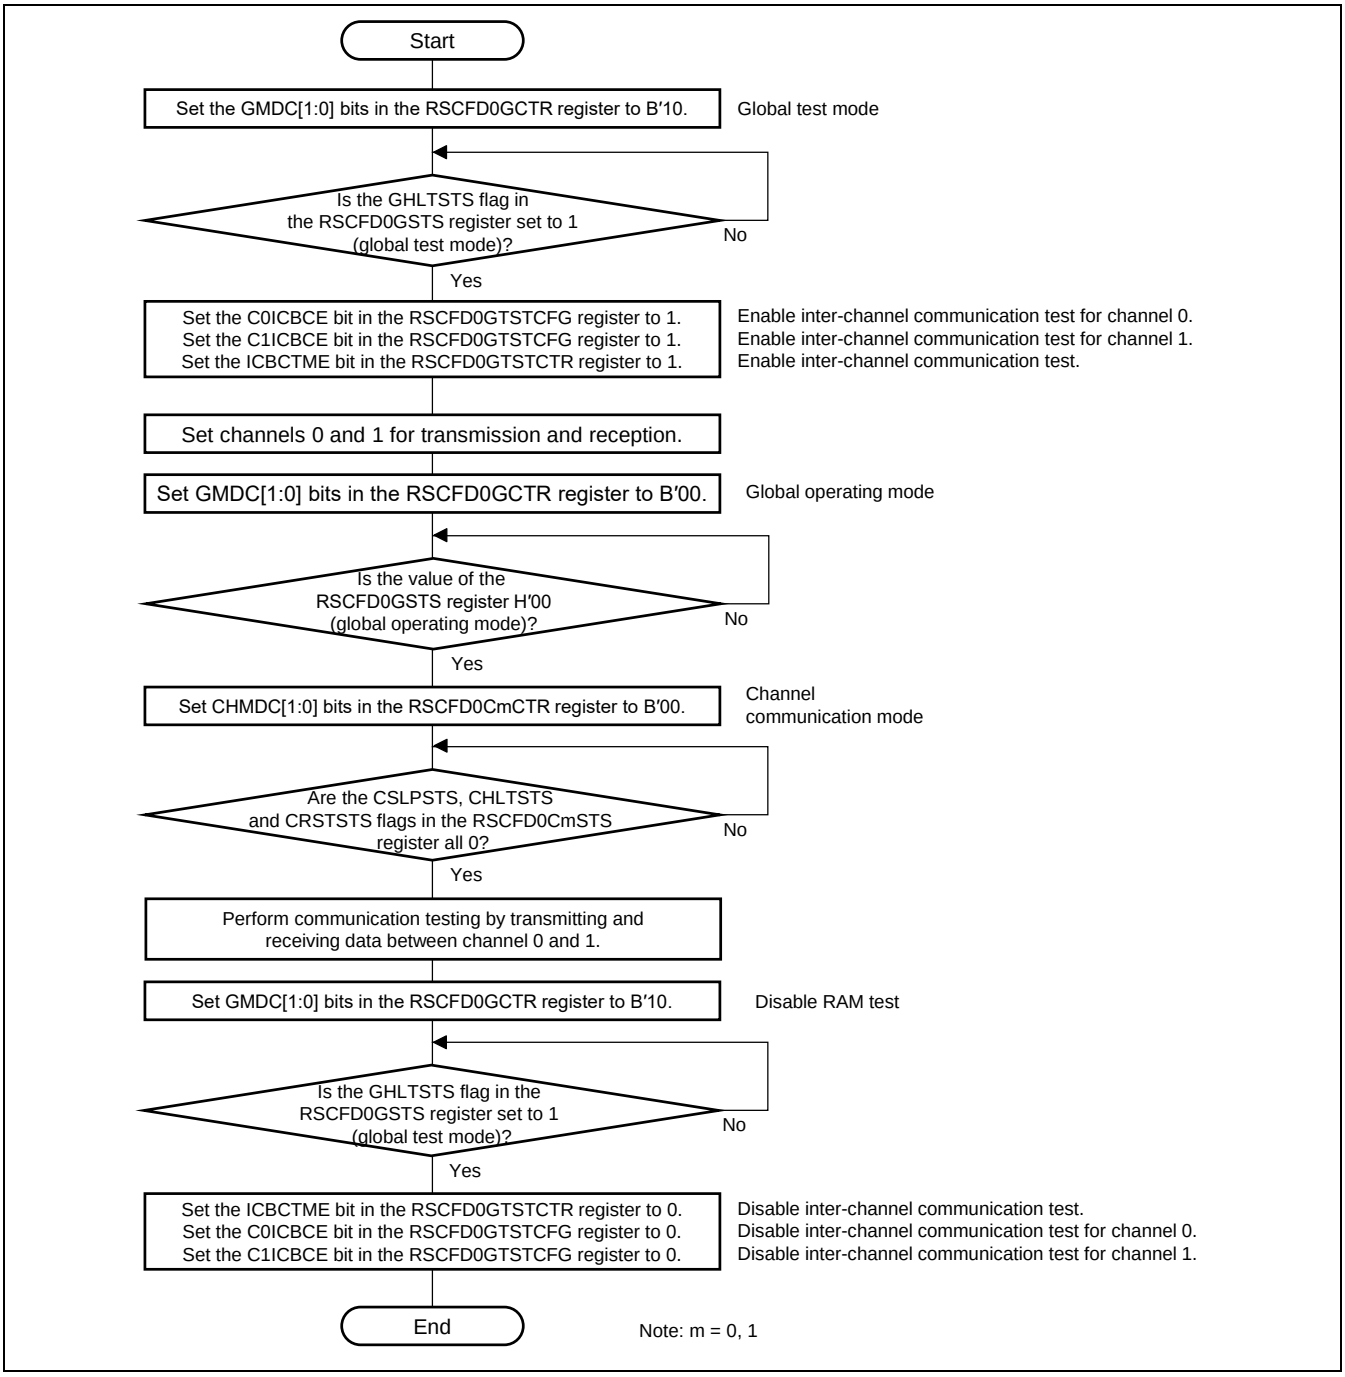

Figure 48.38 Inter-Channel Communication Test Setting Procedure (Example of Communication Test between Channel 0 and Channel 1)

48.17 Usage Notes

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

- When the interface mode is changed without resetting RS-CANFD, write values after a reset to all registers and bits that are not assigned to the switched register map and rewrite the RSCFDnCFDGRMCFG register.
- When changing a global mode, check the GSLPSTS, GHLTSTS, and GRSTSTS flags in the RSCFDn(CFD)GSTS register for transitions. When changing a channel mode, check the CSLPSTS, CHLTSTS, and CRSTSTS flags in the RSCFDn(CFD)CmSTS register (m = 0 or 1) for transitions.
- If a classical CAN frame is only used in CAN FD mode, specify the same value to the RSCFDnCFDCmDCFG register as that specified for the RSCFDnCFDCmNCFG register.
- The acceptance filter processing checks receive rules sequentially in ascending order from the minimum rule number. If the same ID, IDE bit, or RTR bit value is set for multiple receive rules, the minimum number of receive rule is used for the acceptance filter processing. If the message does not pass through the subsequent DLC filter processing, the data processing is terminated without returning to the acceptance filter processing and the message is not stored in the buffer.
- When linking transmit buffers to transmit/receive FIFO buffers or allocating transmit buffers to transmit queues, set the control register (RSCFDn(CFD)TMCp) of the corresponding transmit buffer to H'00. The status register (RSCFDn(CFD)TMSTSp) of the corresponding transmit buffer should not be used. Flags in other status registers (registers RSCFDn(CFD)TMTRSTS0 to RSCFDn(CFD)TMTRSTS2, RSCFDn(CFD)TMTARSTS0 to RSCFDn(CFD)TMTARSTS2, RSCFDn(CFD)TMTCSTS0 to RSCFDn(CFD)TMTCSTS2, and RSCFDn(CFD)TMTASTS0 to RSCFDn(CFD)TMTASTS2), which correspond to transmit buffers linked to transmit/receive FIFO buffers or allocated to transmit queues remain unchanged. Set the enable bit in the corresponding interrupt enable register (registers RSCFDn(CFD)TMIEC0 to RSCFDn(CFD)TMIEC2) to 0 (transmit buffer interrupt is disabled).
- When the transmit buffer merge mode (for CAN FD mode) is used, set H'00 to the control register (the RSCFDn(CFD)TMCp register) of the transmit buffer corresponding to the transmit buffer that has been assigned to the payload storage area. The enable bit of the corresponding interrupt enable registers (RSCFDn(CFD)TMIEC0 to RSCFDn(CFD)TMIEC2 registers) must be cleared to 0 (interrupts are disabled).
- Transmit buffers that are linked to transmit/receive FIFO buffers must not be assigned to transmit queues. Additionally, transmit buffers that are assigned to the payload storage area in buffer merge mode (CAN FD mode) must not be assigned to transmit queues.
- Only a single transmit/receive FIFO buffer can be linked to a transmit buffer. Do not link two or more transmit/receive FIFO buffers to transmit buffers of the same number.
- When the CANm bit time clock is selected as a timestamp counter clock source in classical CAN mode, the timestamp counter stops when the corresponding channel has transitioned to channel reset mode or channel halt mode.
- In case of an attempt to store a new received message when the receive FIFO buffer and the transmit/receive FIFO buffer are full, the new message is discarded. If you wish to store a new transmit message in the transmit/receive FIFO buffer or the transmit queue, check that the transmit/receive FIFO buffer or the transmit queue is not full.
- When registers access RAM, values after a reset described in chapter 48.3, Registers (classical CAN mode), and chapter 48.4, Registers (CAN FD mode), indicate values that have been cleared by initialization of RAM for CAN. Values that have not been cleared are undefined. The registers are shown below.
  - Receive rule (RSCFDn(CFD)GAFLIDj, RSCFDn(CFD)GAFLMj, RSCFDn(CFD)GAFLP0_j, and RSCFDn(CFD)GAFLP1_j registers)
  - Receive buffer (RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDnCFDRMFDSTSq, and RSCFDn(CFD)RMDFb_q registers)
  - Receive FIFO buffer access (RSCFDn(CFD)RFIDx, RSCFDn(CFD)RFPTRx, RSCFDnCFDRFFDSTSx, and RSCFDn(CFD)RFDFd_x registers)

  - Transmit/receive FIFO buffer access (RSCFDn(CFD)CFIDk, RSCFDn(CFD)CFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDn(CFD)CFDFd_k registers)
  - Transmit buffer (RSCFDn(CFD)TMIDp, RSCFDn(CFD)TMPTRp, RSCFDnCFDTMFDCTRp, and RSCFDn(CFD)TMDFb_p registers)
  - Transmit history access (RSCFDn(CFD)THLACCm register)
  - RAM test page access (RSCFDn(CFD)RPGACCr register)
- The values of unused receive buffers (RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDnCFDRMFDSTSq, and RSCFDn(CFD)RMDFb_q registers), receive FIFO buffer access registers (RSCFDn(CFD)RFIDx, RSCFDn(CFD)RFPTRx, RSCFDnCFDRFFDSTSx, and RSCFDn(CFD)RFDFd_x registers), and transmit/receive FIFO buffer access registers (RSCFDn(CFD)CFIDk, RSCFDn(CFD)CFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDn(CFD)CFDFd_k registers) are undefined when the RS-CAN module transitions to global operation mode or global test mode after exiting from global reset mode.

49. PCIE Controller

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

49.1 Overview

This module performs PCIE controls, and transfers data between this LSI internal bus (AXI bus) and the PCI devices connected to the PCIE Controller. This module facilitates the design of systems using the PCI Express while at the same time permitting high-speed data transfers in a compact system.

This module functions as a bus bridge connecting the PCI Express to this LSI internal bus (AXI bus), and provides transfer channels between PCI Express devices and devices connected to the LSI internal bus (AXI bus).

This LSI incorporates a PCI Express physical module that supports one lane (×1).

This module has two modes: a Root Port and an Endpoint and can operate as a Root Port or Endpoint that is defined in the PCI Express specification.

49.1.1 Features

This module has the following features.

- The AXI bus clock and APB bus clock that are used in PCIEC are as below.
  - S3D1ϕ and S3D2ϕ (RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N)
  - S3D1ϕ (RZ/G2E)
- Functions as a bridge that connects the PCI Express to the LSI internal bus (AXI bus)
  - Generates a PCIe packet from the AXI bus transaction to the PCI area
  - Generates a AXI bus transaction from a PCI Express packet
- Supports high-speed data transfer between PCI Express devices and internal bus (AXI bus) via the internal DMAC
- Supports the subset of PCI Express Base Specification Revision 2.0 (Dec. 20, 2006)
- Operates as a PCI Express Endpoint or a PCI Express Root Port
- Supports the requester and completer functions for the PCIe transaction
- Incorporates configuration registers and the following capability structures
  - Power management capability structure
  - MSI capability structure (supports masking function and pending bits.)
  - PCI Express capability structure
  - Virtual channel capability structure
- Supports interrupts by INTx and MSI
- Supports one lane (×1)
- Supports multiple speeds (2.5 GT/s and 5.0 GT/s).
- Automatically performs link training and link configurations
- Supports the D+/D-line automatic swap function (lane polarity inversion)
- Achieves QoS through transaction ordering.
- Automatically performs flow control by managing six types of credits
- Automatic handling function by hardware
- Buffer for holding error packet headers and error indication status provided
- Supports the link power control function (L0, L0s, and L1 states)
- Supports device power control function (D0, D3 hot, and D3 cold states).

- Supports 128-byte max payload size.
- Supports completion timeout disable.

Note: This module does not support the following PCI Express functions.

- Expansion ROM for system boot
- Card bus
- Phantom function
- Power-management event (PME) handling by hardware
- Slot function (including Hot Plug)
- AER function
- BIST function
- Surprise Down error function
- ARI forwarding function
- Port arbitration function
- Peer-to-peer transfer
- Separate Refclk Architecture

49.1.2 Block Diagram

Figure 49.1 shows a block diagram of the PCIE Controller.

The PCIE Controller comprises a bridge, PCIE Controller, and PCIE Controller physical unit.

The bridge provides the bridge function of connecting the internal bus (AXI bus) to the PCI Express controller.

The PCIE Controller is a block that controls the PCI Express packet transmission and reception, and it implements the functions of transaction and data link layers that are defined by the PCI Express standards. The configuration registers defined by the PCI Express standards are installed in this block.

The PCIE Controller physical unit is a block that controls PCI Express transmission paths, and implements the physical layer function that is defined by the PCI Express standards.

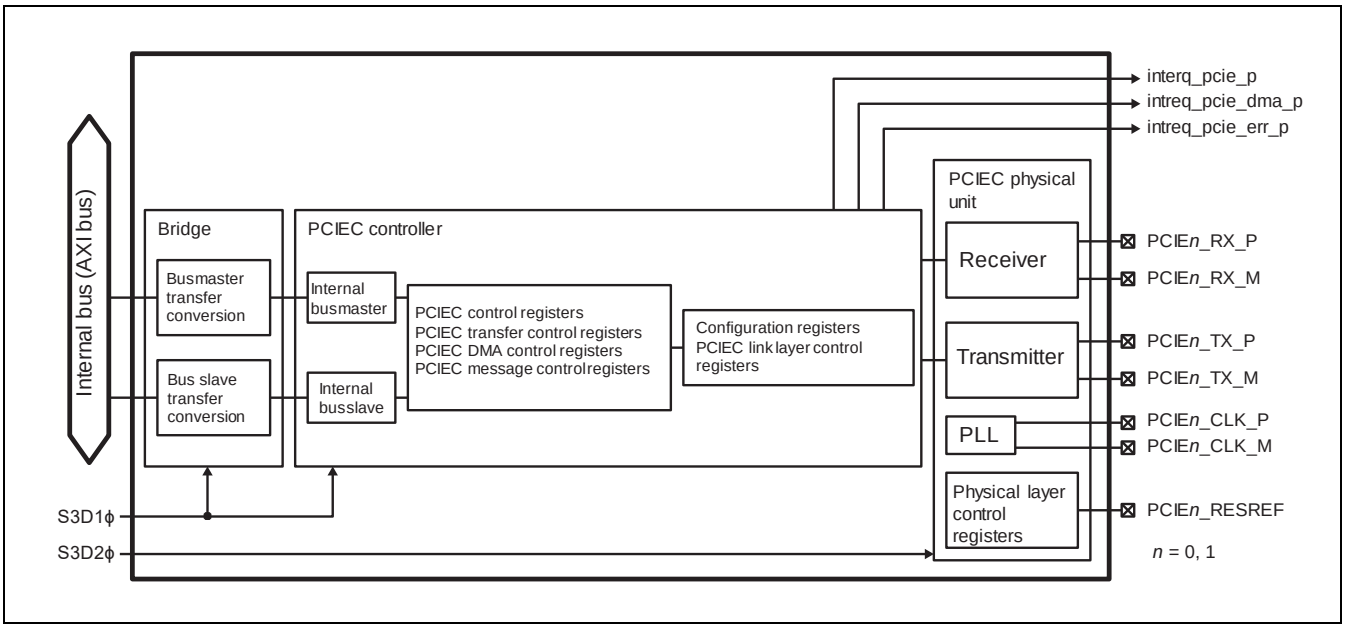

Figure 49.1 Block Diagram

49.1.3 External Pins

Table 49.1 shows the pin configuration.

Table 49.1 Pin Configuration

Signal Name	Signal Conforming to PCI Standard	I/O	Description	Second Generation RZ/G Series Products: RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
PCIE*n*_CLK_P* PCIE*n*_CLK_M* (*n* = 0, 1)	REFCLK+ REFCLK-	Input	Reference clock inputs to the PLL incorporated in the PCIE Controller module (differential inputs). 100-MHz clock should be applied.	√	√	√	√
PCIE*n*_TX_P* PCIE*n*_TX_M* (*n* = 0, 1)	PETp0 PETn0	Output	Transmit data pins used by a physical module, where 2.5- or 5.0-GHz signals are propagated. (Differential output)	√	√	√	√
PCIE*n*_RX_P* PCIE*n*_RX_M* (*n* = 0, 1)	PERp0 PERn0	Input	Receive data pins used by a physical module, where 2.5- or 5.0-GHz signals are propagated. (Differential input)	√	√	√	√

Note: RZ/G2E supports only one channel (n = 0).

49.1.4 Register Configuration

Table 49.4 shows the PCIE Controller registers and Table 49.5 shows the PCIE Controller phy registers. In these table, the Address Offset columns show an offset for each register from the PCIE Controller base address or the PCIE Controller phy base address. The actual access address is obtained by adding each offset to the PCIE Controller base address or the PCIE Controller phy base address. Table 49.2 shows the PCIE Controller base address and Table 49.3 shows the PCIE Controller phy base address. These registers should be accessed through the AXI bus. Only the little endian mode can be used for this module.

Table 49.2 PCIE Controller Base Address

	PCI Express
PCIE0 Base Address	H'FE00_0000
PCIE1 BaseAddress	H’EE80_0000

Notes: 1. AX: AXI bus (internal bus)
PCI: PCI local bus
'—' in R/W column: Access prohibited.
For details of R/W attribute for each bit, see section 49.2, Register Description.
2. Depends on the setting of the local address mask register 0.
3. R/W changes by the state. RootPort:R/W.EndPoint:R.

4. Depends on the setting of the local address mask register 1.
5. Depends on the setting of the local address mask register 2.
6. Depends on the setting of the local address mask register 3.
7. Depends on the setting of the local address mask register 4.
8. Depends on the setting of the local address mask register 5.

Do not write to any addresses other than listed above. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed above are undefined.

	Software Reset	Execute software reset
	INTC-AP	Control to interrupt

49.2 Register Description

[Legend for the Register Description]

A bit assignment figure is shown for each register. The initial value and R/W attribute are indicated for each bit.

Bit:	Bit number or bit range
Bit Name:	Bit name or field name
Initial value:	Register value after a reset
—:	Undefined value
R/W:	Readable/writable. The written value can be read.
RW1C:	Readable/writable. The bit is initialized when 1 is written. Writing 0 is ignored.
R:	Read-only. The write value should always be 0. (If there is a direction on a read or write value in the Description column, set the bit as directed.)
RWS*:	Sticky-read write bit. Readable/writable. The bit is not initialized by a hot reset.
RW1CS*:	Sticky-read-only status bit. The bit is initialized when 1 is written. Writing 0 is ignored. The bit is not initialized by a hot reset.

Note: * RWS and RW1CS are only used for the configuration registers. For details, see section 49.4.1, Write/Read Attributes of Configuration Registers.

49.2.1 Configuration Transmission Address Register (PCIECAR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BN								DN					FN		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	EREGNO				REGNO						—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	BN	H'00	R/W	Bus Number Specifies the number of the bus to be accessed when a configuration request is issued.
23 to 19	DN	B'0_0000	R/W	Device Number Specifies the number of the device to be accessed when a configuration request is issued. Note: A type 0 configuration request can be issued only to device #0; do not send a type 0 configuration request to the device with the other number.
18 to 16	FN	B'000	R/W	Function Number Specifies the number of the function to be accessed when a configuration request is issued.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	EREGNO	H'0	R/W	Extended Register No. Specifies the number of the extended register to be accessed when a configuration request is issued.
7 to 2	REGNO	H'00	R/W	Register No. Specifies the number of the register to be accessed when a configuration request is issued.
1, 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.2 Configuration Transmission Control Register (PCIECCTLR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CCIE	—	—	—	—	—	—	—	—	—	WUR	WCRS	—	—	RUR	RCRS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	RW1C	RW1C	R	R	RW1C	RW1C

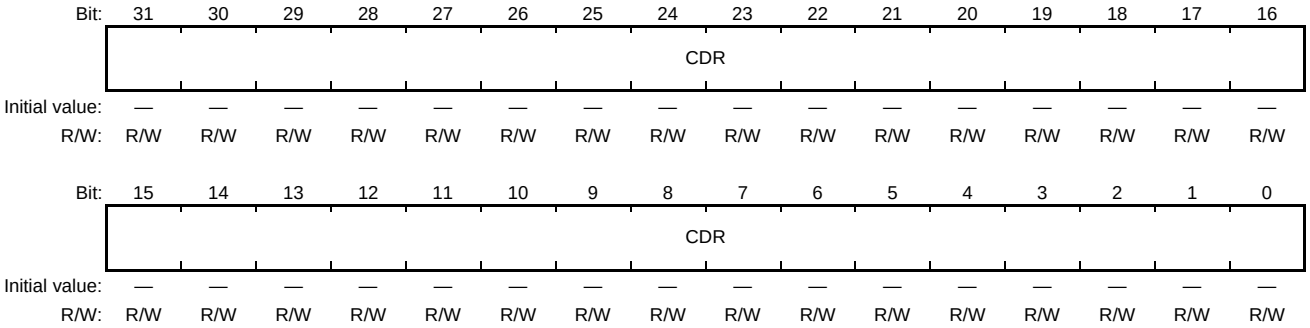
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TYPE	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	CCIE	B’0	R/W	Configuration Send Enable Enables issuance of a configuration request. Set to 1 when the configuration transmission address register and configuration transmission data register are used to issue the configuration cycle.
30 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	WUR	B’0	RW1C	Write Unsupported Request Indicates that an unsupported request has been received. This bit is set to 1 when a completion with the unsupported request status is received in response to the configuration write request transmitted.
20	WCRS	B’0	RW1C	Write CRS Indicates that CRS (configuration retry status) has been received. This bit is set to 1 when a completion with the CRS status is received in response to the configuration write request transmitted.
19, 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17	RUR	B’0	RW1C	Read Unsupported Request Indicates that an unsupported request has been received. This bit is set to 1 when a completion with the unsupported request status is received in response to the configuration read request transmitted.
16	RCRS	B’0	RW1C	Read CRS Indicates that CRS (configuration retry status) has been received. This bit is set to 1 when a Completion with the CRS status is received in response to the configuration read request transmitted.
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
8	TYPE	B'0	R/W	TYPE Specifies the type of a configuration request issued by accessing the PCIECDR register. 0: Type 0 configuration request 1: Type 1 configuration request Note: A type 0 configuration request can be issued only to device #0; do not send a type 0 configuration request to the device with the other number.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.3 Configuration Transmission Data Register (PCIECDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CDR	Undefind	R/W	Configuration Data Register Allows a configuration request to be issued. A write access to this field allows issuance of a configuration write request containing the information written to this field as data. A read access to this field allows issuance of a configuration read request and reading of the data contained in the response. When the peer device returns an unsupported request response, the read value is H'FFFF_FFFF. When EXPCAP7[4].CRSVISE = 0: When the peer device returns a CRS response, the read value is H'FFFF_FFFF (error response). When EXPCAP7[4].CRSVISE = 1: Until the peer device returns a response other than a CRS response, the first access to the peer device should be a read access to register address 0. When the peer device returns a CRS response, the read value is H'FFFF_0001. In Endpoint mode, this field must not be accessed. Except when PCIECCTLR.CCIE = 1 and PCIETCTLR.CFINIT = 1, the read value is H'FFFF_FFFF.

49.2.4 Mode Setting Register (PCIEMSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PEM
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	PEM	B'1	R/W	PCI Express Mode Sets operating mode of the PCI Express. 0: Operates as a PCI Express Endpoint. 1: Operates as a PCI Express Root Port.

49.2.5 Unlock Transmission Control Register (PCIEUNLOCKCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ASTUNLOCK
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ASTUNLOCK	B’0	R/W	Assert Unlock Specifies issuance of an unlock message. Writing 1 to this bit allows issuance of an unlock message (message code = B'0000_0000; routing = B'011). Transmission of an unlock message through a write access to this bit can be used only in Root Port mode. Transmission of an unlock message from an Endpoint is prohibited by the standard. While a link is not established, do not write 1 to this bit. This bit is always read as 0.

49.2.6 INTx Register (PCIEINTXR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ASTINTX
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	INTDE	INTCE	INTBE	INTAE	—	—	—	—	INTD	INTC	INTB	INTA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	ASTINTX	B'0	R/W	Assert INTx Specifies generation of an INTx interrupt. Writing 1 to this bit asserts the INTx interrupt specified by the PCICONF15[15:8].Interrupt Pin bits and writing 0 deasserts the INTx interrupt. When generating an INTx interrupt using this bit, the PCICONF1[10].INTDIS bit must be 0. This bit is cleared if the PCICONF1[10].Interrupt Disable bit is set to 1 while this bit is 1. When MSI is used, an INTx interrupt cannot be used. Therefore, when the MSICAP0[16].MSI Enable bit is 1, 1 cannot be written to this bit. This bit is cleared if the MSICAP0[16].MSI Enable bit is set to 1 while this bit is 1. This bit is valid only in Endpoint mode. When a link goes down, this bit is cleared. A write access is ignored while a link is down.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	INTDE	B'0	R/W	INTD Enable Enables generation of an interrupt by INTD assertion. This bit is valid only in Root Port mode.
10	INTCE	B'0	R/W	INTC Enable Enables generation of an interrupt by INTC assertion. This bit is valid only in Root Port mode.
9	INTBE	B'0	R/W	INTB Enable Enables generation of an interrupt by INTB assertion. This bit is valid only in Root Port mode.
8	INTAE	B'0	R/W	INTA Enable Enables generation of an interrupt by INTA assertion. This bit is valid only in Root Port mode.
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3	INTD	B'0	R	Indicates that INTD has been asserted by a PCI Express interrupt. This bit is asserted upon reception of an Assert_INTD message and deasserted upon reception of a Deassert_INTD message. When this bit is asserted while PCICONF15[7:0].Interrupt Line is not H'FF and PCIEINTXR[11].INTDE is 1, the interrupt is generated. This bit is valid only in Root Port mode.
2	INTC	B'0	R	Indicates that INTC has been asserted by a PCI Express interrupt. This bit is asserted upon reception of an Assert_INTC message and deasserted upon reception of a Deassert_INTC message. When this bit is asserted while PCICONF15[7:0].Interrupt Line is not H'FF and PCIEINTXR[10].INTCE is 1, the interrupt is generated. This bit is valid only in Root Port mode.
1	INTB	B'0	R	Indicates that INTB has been asserted by a PCI Express interrupt. This bit is asserted upon reception of an Assert_INTB message and deasserted upon reception of a Deassert_INTB message. When this bit is asserted while PCICONF15[7:0].Interrupt Line is not H'FF and PCIEINTXR[9].INTBE is 1, the interrupt is generated. This bit is valid only in Root Port mode.
0	INTA	B'0	R	Indicates that INTA has been asserted by a PCI Express interrupt. This bit is asserted upon reception of an Assert_INTA message and deasserted upon reception of a Deassert_INTA message. When this bit is asserted while PCICONF15[7:0].Interrupt Line is not H'FF and PCIEINTXR[8].INTAE is 1, the interrupt is generated. This bit is valid only in Root Port mode.

49.2.7 Message Reception Status Register (PCIERMSGR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	PM_PME	B’0	R/W	Specifies issuance of a PM_PME message. Writing 1 to this bit allows issuance of a PM_PME Message (message code = B'0001 1000; routing = B'000). This bit is always read as 0. Transmission of a PM_PME message through a write access to this bit can be used only in Endpoint mode. Transmission of a PM_PME message from a Root Port is prohibited by the standard. While a link is not established, do not write 1 to this bit.
8 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.10 Physical Layer Status Register (PCIEPHYSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	PHYRDYCE	B'0	R/W	PHYRDY Change Enable Enables generation of an INT_PCISC interrupt upon change of PHYRDY.
23 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	PHYRDYC	B'0	RW1C	PHYRDY Change Indicates that PHYRDY has changed.
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	PHYRDY	B'0	R	0: Indicates that the clock supplied by the physical layer has not been stabilized and that it is not ready to be used. 1: Indicates that the clock supplied by the physical layer has been stabilized and that it is ready to be used.

49.2.11 MSI Transmission Register (PCIEMSITXR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MSIE	—	—	—	—	—	—	—	—	—	—	MMENUM				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSIPCLR	—	—	—	—	—	—	—	—	—	—	MSIAST				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	MSIE	B’0	R	MSI Enable Indicates the MSICAP0[16]. MSIE value.
30 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20 to 16	MMENUM	B’0_0000	R	Multiple Message Enable Number Indicates the number of sources specified with MSICAP0[22:20].MMESE. B’0_0000: 1 source (only source number 0 is available) B’0_0001: 2 sources (source numbers 0 and 1 are available) B’0_0011: 4 sources (source numbers 0 to 3 are available) B’0_0111: 8 sources (source numbers 0 to 7 are available) B’0_1111: 16 sources (source numbers 0 to 15 are available) B’1_1111: 32 sources (source numbers 0 to 31 are available)
15	MSIPCLR	B’0	R/W	MSI Pending Clear Forcibly clears the MSI interrupt sources to be transmitted. If the MSI source is canceled because of the user side reason (internal source), set the information of the MSI interrupt to be cleared to the MSI Assert field, and simultaneously write 1 to this bit. In the other cases, hold this bit to 0. This bit is always read as 0.
14 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4 to 0	MSIAST	B'0_0000	R/W	MSI Assert Specifies generation of an MSI interrupt. This field is valid only when the MSI is enabled in Endpoint mode. A write access to this field allows setting of the relevant bits to 1 in MSICAP5.Message Pending. After that, among the MSI interrupts whose corresponding bits are 0 in MSICAP4.Message Mask, the MSI interrupts are allowed to be generated one by one in ascending order of the assigned number. The maximum source number that may be written to this field is indicated by the Multiple Message Enable Number field. These bits are always read as 0. While communication with the connection destination device is not established, do not write to this field.

49.2.12 Transfer Control Register (PCIETCTLR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	DL_DOWN	—	—	CFINIT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	DL_DOWN	B'1	R	DL_DOWN Indicates whether connection in the data link layer is lost. This bit is set to 1 after cancellation of a reset. This bit is cleared to 0 when a connection with the target device is established, and set to 1 when a connection in the data link layer is lost due to communication failure.
2, 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CFINIT	B'0	R/W	Configuration Initialization Specifies initialization of registers to establish a PCI Express link. Set this bit to 1 after setting the appropriate values in the following registers. PCIELAR0 to PCIELAR 5 PCIELAMR0 to PCIELAMR5 The above registers must not be written to while this bit is 1. Setting this bit starts PCI Express link establishment process. Only writing 1 to this bit is valid; writing 0 is invalid. Write 1 at initialization only once and do not write any value to this bit after that. 0: Initialization has not yet been done. 1: Initialization has been completed. In Endpoint mode: Triggered by this bit, hardware sets the BARn registers based on PCIELAMRn.

49.2.13 Transfer Status Register (PCIETSTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	RW1C	*	*	*	R

Note: * R/W changes by the state. Root Port: R, EndPoint: RW1C

Bit	Bit Name	Initial Value	R/W	Description
31	INT_PCITE	B'0	RW1C	Interrupt PCI Express Transfer Error Indicates that the interrupt by a PCI Express transfer error has been generated. The error can be either of the following. • When PCIECCTLR[31].CCIE = 0, PCIECDR is accessed. • When PCIEPCTLRn[31].PARE = 0, the corresponding PIO space is accessed. • Transfer is executed with TC being set that is not mapped to VC0. • When PCICONF1[2].BME = 0 in Endpoint mode, PIO transfer is executed (MRd, MWr). • Transfer is executed with the attribute being set that is not enabled with the configuration register. • Transfer other than PME message (PM_PME) transfer is executed in the non-D0 state. • When PMCAP1[8].PMEE = 0 in Endpoint mode, PM_PME message transfer is executed.
30	INT_PM_PME_RCV	B'0	R	Interrupt PM_PME Receive Generates an interrupt when PM_PME is received. This bit is valid only in Root Port mode. To clear the interrupt, write 1 to EXPCAP8[16].PMEST.
29	INT_TXALLEMP	B'1	R	Interrupt TX All Empty Generates an interrupt when all the transmission buffers are empty for PCI Express.
28	INT_PCIBW	B'0	R	Interrupt PCI Express Bandwidth Indicates that the interrupt by change of the link bandwidth (link width × link speed) has been generated. This bit is valid only in Root Port mode. To clear the interrupt, write 1 to EXPCAP4[31].LKAUTOBWSTS or EXPCAP4[30].LKBWMNGSTS.
27 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
13	INT_MAC	B'0	R	Interrupt MAC Indicates that the MAC interrupt has been generated. To clear the interrupt, write 1 to the corresponding field in MACSR.
12	INT_PM	B'0	R	Interrupt PM Indicates that the PM interrupt has been generated. To clear the interrupt, write 1 to the corresponding field in PMSR.
11 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	INT_PCIMES	B'0	R	Interrupt PCI Message Indicates that the interrupt has been generated upon reception of a PCI Express message. However, if the interrupt corresponding to individual message is not enabled, this interrupt is not generated; process the message through software when a message is received.
4	INT_PCIPOWER	B'0	RW1C	Interrupt PCI Express Power Indicates that a configuration write request has been received in Endpoint mode thus generating a request for a power down sequence to the L1 state.
3	INT_PCICERR	B'0	R	Interrupt PCI Correctable Error Root Port: Indicates that the interrupt has been generated by detection of the correctable error or reception of the ERR_COR message. This bit is a read-only bit; to clear this bit, use the configuration register.
			RW1C	Interrupt PCI Correctable Error Endpoint: Indicates that an error classified as ERR_COR has been generated. This bit is a read-write-1-to-clear bit; writing 1 clears this bit only.
2	INT_PCINFERR	B'0	R	Interrupt PCI Non-Fatal Error Root Port: Indicates that the interrupt has been generated by detection of the non-fatal error or reception of the ERR_NONFATAL message. This bit is a read-only bit; to clear this bit, use the configuration register.
			RW1C	Interrupt PCI Non-Fatal Error Endpoint: Indicates that an error classified as ERR_NONFATAL has been generated. This bit is a read-write-1-to-clear bit; writing 1 clears this bit only.

Bit	Bit Name	Initial Value	R/W	Description
1	INT_PCIFERR	B'0	R	Interrupt PCI Fatal Error Root Port: Indicates that the interrupt has been generated by detection of the fatal error or reception of the ERR_FATAL message. This bit is a read-only bit; to clear this bit, use the configuration register.
			RW1C	Interrupt PCI Fatal Error Endpoint: Indicates that an error classified as ERR_FATAL has been generated. This bit is a read-write-1-to-clear bit; writing 1 clears this bit only.
0	INT_PCISERR	B'0	R	Interrupt PCI System Error Indicates that a system error has occurred. When a system error occurs, check the related registers through software and execute error recovery processing. A system error is: A PCIEERRFR error has occurred (when enabled).

49.2.15 Interrupt Enable Register (PCIEINTER)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	IBERR	B'0	RW1C	IBERR Indicates that a transfer error has occurred on the internal bus.
27	MTLP	B'0	RW1C	MTLP Indicates that a malformed TLP has been received.
26	UR	B'0	RW1C	UR Indicates that an unsupported request has been received.
25	PTLP	B'0	RW1C	PTLP Indicates that a poisoned TLP has been received.
24 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	POVF	B'0	RW1C	POVF Indicates that the posted request packet reception buffer has overflowed.
20	NPOVF	B'0	RW1C	NPOVF Indicates that the non-posted request packet reception buffer has overflowed.
19 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	RCVCPLLK	B'0	RW1C	Receive Completion Lock Indicates that a completion lock (without data) has been received. This completion is returned when memory locking of the device supporting memory lock has failed.
12	UNEXPCPL	B'0	RW1C	Unexpected Completion Indicates that an unexpected completion has been received.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	RCVSZECPL	B'0	RW1C	Receive Size Error Completion Indicates that the size of the completion received is different from the requested size.
8	CPLTOUT	B'0	RW1C	CPL Timeout Indicates that a completion timeout has occurred.
7	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	RCVCRSCPL	B'0	RW1C	Receive Configuration Retry Status Completion Indicates that a completion with the configuration retry status has been received.
5	RCVCACPL	B'0	RW1C	Receive Completion Abort Status Completion Indicates that a completion with the completion abort status has been received.
4	RCVURCPL	B'0	RW1C	Receive Unsupported Request Status Completion Indicates that a completion with the unsupported request status has been received.
3, 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	SENDCACPL	B'0	RW1C	Send Completion Abort Status Completion Indicates that a completion with the completion abort status has been transmitted.
0	SENDURCPL	B'0	RW1C	Send Unsupported Request Status Completion Indicates that a completion with the unsupported request status has been transmitted.

49.2.17 Error Interrupt Enable Register (PCIEERRFER)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register determines whether to reflect the occurrence of errors to PCIEINTR.INT_PCISERR.

R/W:	R	R	R/W	R/W	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	IBERRE	B'0	R/W	IBERRE Enables generation of the INT_PCISERR interrupt upon occurrence of a transfer error on the internal bus.
27 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	POVFE	B'0	R/W	POVFE Enables generation of the INT_PCISERR interrupt upon overflow of a posted request packet reception buffer.
20	NPOVFE	B'0	R/W	NPOVFE Enables generation of the INT_PCISERR interrupt upon overflow of a non-posted request packet reception buffer.
19 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	RCVCPLLKE	B'0	R/W	Receive Completion Lock Enables generation of the INT_PCISERR interrupt upon reception of the completion lock (without data).
12	UNEXPCPLE	B'0	R/W	Unexpected Completion Enabled Enables generation of the INT_PCISERR interrupt upon reception of the unexpected completion.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	RCVSZECPLE	B'0	R/W	Receive Size Error Completion Enabled Enables generation of the INT_PCISERR interrupt upon reception of the completion whose size is different from the requested size.

Bit	Bit Name	Initial Value	R/W	Description
8	CPLTOUTE	B'0	R/W	Completion Timeout Interrupt Enable Enables generation of the INT_PCISERR interrupt upon detection of a completion timeout.
7	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	RCVCRSCPLE	B'0	R/W	Configuration Retry Status Completion Receive Interrupt Enable Enables generation of the INT_PCISERR interrupt upon reception of a completion with the configuration retry status.
5	RCVCACPLE	B'0	R/W	Completion Abort Status Completion Receive Interrupt Enable Enables generation of the INT_PCISERR interrupt upon reception of a completion with the completion abort status.
4	RCVURCPLE	B'0	R/W	Unsupported Request Status Completion Receive Interrupt Enable Enables generation of the INT_PCISERR interrupt upon reception of a completion with the unsupported request status.
3, 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	SENDCACPLE	B'0	R/W	Send Completion Abort Status Completion Interrupt Enable Enables generation of the INT_PCISERR interrupt upon transmission of a completion with the completion abort status.
0	SENDURCPLE	B'0	R/W	Send Unsupported Request Status Completion Interrupt Enable Enables generation of the INT_PCISERR interrupt upon transmission of a completion with the unsupported request status.

49.2.18 Error Factor Register 2 (PCIEERRFR2)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	—	—	—	—	—	—	—	PST	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	PSTC	B'0	RW1C	Power State Change Indicates that PST has changed. This bit is valid only in Endpoint mode.
23 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	PST	B'0	R	Power State Indicates the power state. 0: D0 1: Non-D0 Do not issue a request in the non-D0 state. This bit is valid only in Endpoint mode.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.21 Power Management State Interrupt Enable Register (PCIEPMSCIER)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

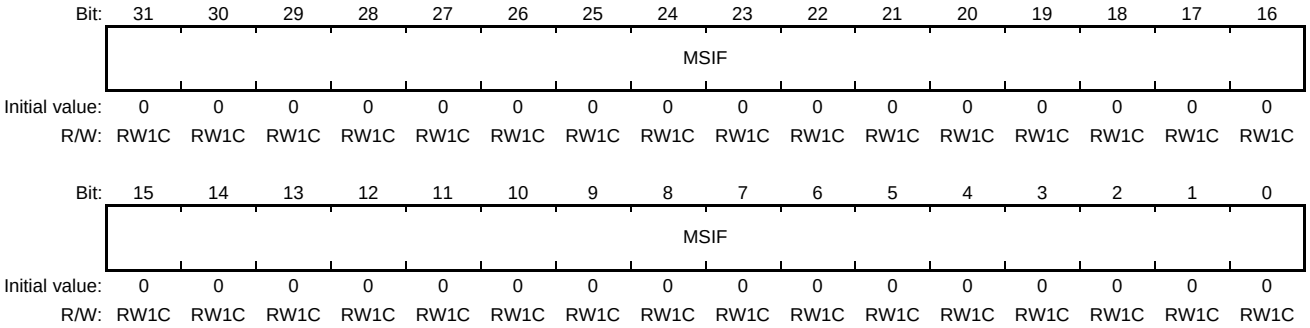
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	PSTCE	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	PSTCE	B'0	R/W	Power State Change Enable Enables generation of the INT_PCISC interrupt upon change of PST. This bit is valid only in Endpoint mode.
23 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.22 MSIF Register (PCIEMSIFR)

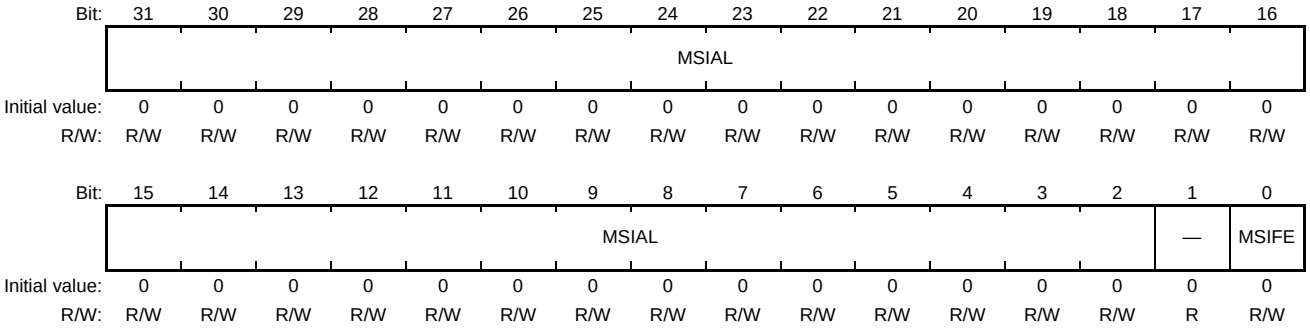
RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MSIF	All 0	RW1C	MSIF Indicates that an MSI interrupt has occurred. This field is valid only when PCIEMSIALR.MSIFE = 1 in Root Port mode. A write from the internal bus is interpreted as interrupt cancellation thus clearing the bit to 0 to which 1 has been written. A read from the internal bus is processed as a normal read. A 1DW write to the address specified with PCIEMSIAUR and PCIEMSIALR from the PCI Express side is interpreted as an MSI interrupt. This IP sets 1 to the bit determined by the sum of the values in bits [4:0] and [12:8] in the write data in order to convert the MSI message data into a flag. Set the function appropriately so that the interrupt should not be reflected to the same bit. A read from the address specified with PCIEMSIAUR and PCIEMSIALR from the PCI Express side is processed as a normal read.

49.2.23 MSI Address Lower Register (PCIEMSIALR)

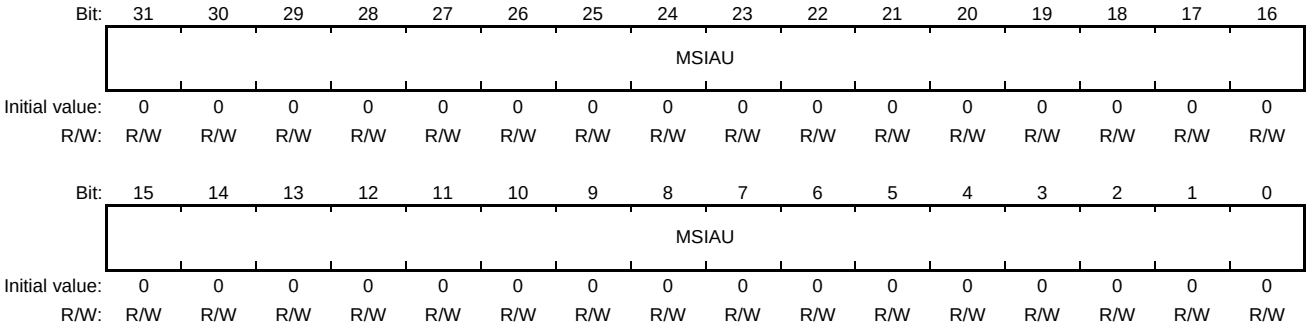
RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 2	MSIAL	All 0	R/W	MSI Address Lower Specifies the lower address bits [31:2] of the memory write by MSI in the PCI space in Root Port mode. (Refer to section 49.3.3 (6), MSI Reception.) This field is invalid when PCIEMSIALR.MSIFE = 0.
1	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	MSIFE	B’0	R/W	MSIF Enable Enables address decoding of the MSI interrupt. Be sure to set this bit to 0 in Endpoint mode.

49.2.24 MSI Address Upper Register (PCIEMSIAUR)

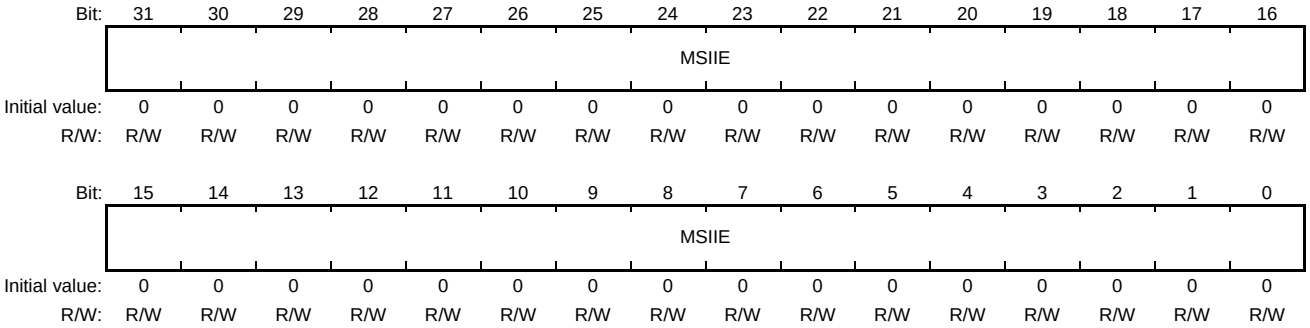
RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MSIAU	All 0	R/W	MSI Address Upper Specifies the upper address bits [63:32] of the memory write by MSI in the PCI space in Root Port mode. (Refer to section 49.3.3 (6), MSI Reception.) This field is invalid when PCIEMSIALR.MSIFE = 0.

49.2.25 MSI Interrupt Enable Register (PCIEMSIIER)

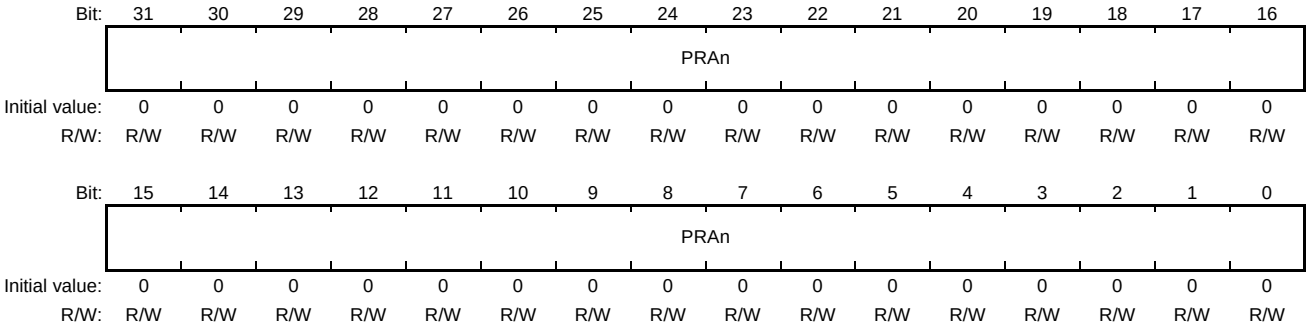
RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MSIIE	All 0	R/W	MSI Interrupt Enable Individually enables the interrupts by MSI in Root Port mode. This field is invalid when PCIEMSIALR.MSIFE = 0.

49.2.26 PCI Express Root Port Address Register 0 to 5 (PCIEPRAR0 to PCIEPRAR5)

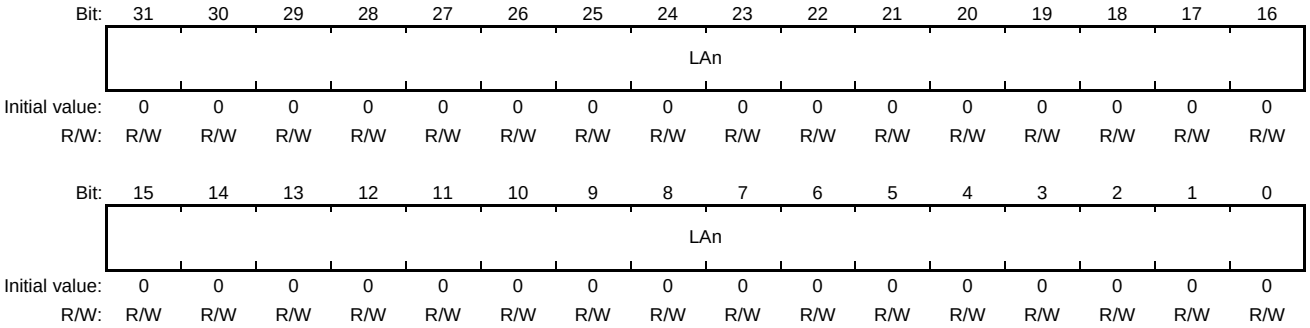
RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PRAn	All 0	R/W	PCI Express Root Port Address n Specifies the PCI Express address for transferring a transaction from the PCI Express to the internal bus in Root Port mode. This field is invalid in Endpoint mode. Set the appropriate value corresponding to the local address registers and local address mask registers. Modify this field only when no access should occur to the corresponding PCI Express, for example, while a link is down and the master enable of the peer is off.

49.2.27 Local Address Register 0 to 5 (PCIELAR0 to PCIELAR5)

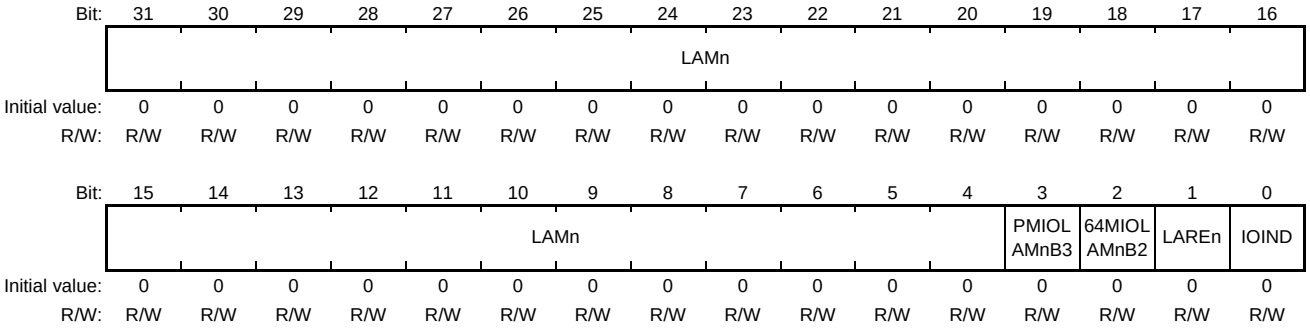
RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	LAn	All 0	R/W	Local Address n Indicates the local (internal bus) address for transferring a transaction from the PCI Express to the internal bus. When the addresses in the space allocated by the BARn of the PCI Express are translated into the internal bus space addresses, this field is used as the upper address bits. The lower address bits of the PCI Express packets are used as the lower address bits. The boundary between upper and lower bits is determined by PCIELAMR0 to PCIELAMR5. Writing to this field is prohibited while PCIETCTLR.CFINIT is 1. When a 64-bit access is enabled with PCIELAMR0 to PCIELAMR5, write 0 to all the bits in PCIELARn + 1. The write value for bits 1 and 0 should always be 0.

49.2.28 Local Address Mask Register 0 to 5 (PCIELAMR0 to PCIELAMR5)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 4	LAMn	All 0	R/W	Local Address Mask n Masks the local (internal bus) addresses when transactions are transferred from PCI Express to the internal bus. When the addresses in the space allocated by the BARn of the PCI Express are translated into the internal bus space addresses, the PCIELARn.LAn value is used as the upper bits while the address in the PCI Express packet header is used as the lower bits. This field determines the boundary between upper and lower bits. Therefore, this field also determines the size of the space to be allocated to the PCI Express space. B'0000_0000_0000_0000_0000_0000_0000: 4, 8, or 16 bytes B'0000_0000_0000_0000_0000_0000_0001: 32 bytes B'0000_0000_0000_0000_0000_0000_0011: 64 bytes B'0000_0000_0000_0000_0000_0000_0111: 128 bytes B'0000_0000_0000_0000_0000_0000_1111: 256 bytes (Omitted) B'0000_1111_1111_1111_1111_1111_1111: 256 Mbytes B'0001_1111_1111_1111_1111_1111_1111: 512 Mbytes B'0011_1111_1111_1111_1111_1111_1111: 1 Gbyte B'0111_1111_1111_1111_1111_1111_1111: 2 Gbytes B'1111_1111_1111_1111_1111_1111_1111: 4 Gbytes This field must not be set to any value other than those given above. Writing to this field is prohibited when PCIETCTLR.CFINIT is 1. When using the space as a memory space, set a size of 128 bytes or more with BAR. When setting a 4-Gbyte space, set 64M_IOLAMB2 to 1. When 64-bit addresses are used with PCIELAMRn, PCIELAMRn + 1 is used as the upper address of PCIELAMRn, and so PCIELAMRn cannot be used as an independent space. In this case, set this field as follows. B'0000_0000_0000_0000_0000_0000_0000_0000: 4 Gbytes or less

Bit	Bit Name	Initial Value	R/W	Description
3	PMIOLAMnB3	B'0	R/W	Prefetchable Memory or IO Local Address Mask n Bit 3 • When IO indicator is 0: Specifies memory space prefetch. 0: A non-prefetchable memory space is allocated. 1: A prefetchable memory space is allocated. • When IO indicator is 1: Masks bit 3 as an extension of local address mask n. 0: A space of 4 or 8 bytes is allocated. 1: A space of 16 bytes or more is allocated. Writing to this field is prohibited when PCIETCTLR.CFINIT is 1. When 64-bit addresses are used with PCIELAMRn, PCIELAMRn + 1 is used as the upper address of PCIELAMRn, and so PCIELAMRn cannot be used as an independent space. Set all the bits to 0.
2	64MIOLAMnB2	B'0	R/W	64-bit Access Space Memory or IO Local Address Mask n Bit 2 • When IO indicator is 0: Specifies the width of the addresses to define BAR in the memory space. 0: Indicates that 32-bit addresses are used with PCIELAMRn. 1: Indicates that 64-bit addresses are used with PCIELAMRn. • When IO indicator is 1: Masks bit 2 as an extension of local address mask n. 0: A space of 4 bytes is allocated. 1: A space of 8 bytes or more is allocated. Writing to this field is prohibited when PCIETCTLR.CFINIT is 1. When 64-bit addresses are used with PCIELAMRn, PCIELAMRn + 1 is used as the upper address of PCIELAMRn, and so PCIELAMRn cannot be used as an independent space. Set all the bits to 0.
1	LAREn	B'0	R/W	Local Address Enable Enables local address. Setting this field to 1 enables transaction transfer in the area specified by PCIELARn and PCIELAMRn. Set this field to 1 to enable address translation by LAn and LAMn. Writing to this field is prohibited when PCIETCTLR.CFINIT is 1. When 64-bit addresses are used with PCIELAMRn, PCIELAMRn + 1 is used as the upper address of PCIELAMRn, and so PCIELAMRn cannot be used as an independent space. Set all the bits to 0.
0	IOIND	B'0	R/W	IO Indicator Specifies the type of space on the PCI Express side allocated for transaction transfer from the PCI Express to the internal bus. 0: Memory space 1: IO space Writing to this field is prohibited when PCIETCTLR.CFINIT is 1. When 64-bit addresses are used with PCIELAMRn, PCIELAMRn + 1 is used as the upper address of PCIELAMRn, and so PCIELAMRn cannot be used as an independent space. Set all the bits to 0.

Note: Setting the memory space type of 1 Mbyte or less (defined in the PCI Express standard 2.2 and the earlier versions) is not supported.

49.2.29 PCIEC Address Lower Register 0 to 3 (PCIEPALR0 to PCIEPALR3)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
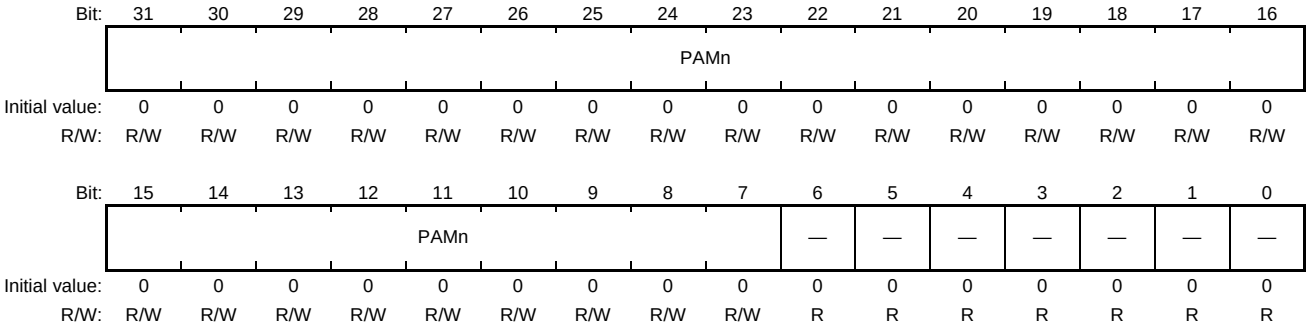
31 to 0	PAUn	All 0	R/W	PCI Express Address Upper Sets the PCI Express address (upper) for PIO transfer from the internal bus to the PCI Express.

49.2.31 PCIEC Address Mask Register 0 to 3 (PCIEPAMR0 to PCIEPAMR3)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 7	PAMn	All 0	R/W	PCI Express Address Mask Masks the PCI Express addresses. When the packet accessing the internal bus space n is converted to the PCI Express packet, PAUn and PALn are used as the upper bits while the address on the internal bus packet is used as the lower bits. Here, PAMn determines the boundary between them. That is, the packet address addr[31:0] on the PCI Express is generated as follows. Addr[31:7] = PALn[31:7] when the corresponding bit in PAMn[31:7] is 0, and Addr[31:7] = internal bus - addr[31:7] when the corresponding bit in PAMn[31:7] is 1. Addr[6:0] = internal bus - addr[6:0] According to the setting of this field, the size of the space to which the PCI Express side transactions is transferred is determined as follows. B'0000_0000_0000_0000_0000_0000_0: 128 bytes B'0000_0000_0000_0000_0000_0000_1: 256 bytes B'0000_0000_0000_0000_0000_0001_1: 512 bytes B'0000_0000_0000_0000_0000_0011_1: 1 Kbyte B'0000_0000_0000_0000_0000_0111_1: 2 Kbytes (Omitted) B'0000_0111_1111_1111_1111_1111_1: 128 Mbytes B'0000_1111_1111_1111_1111_1111_1: 256 Mbytes B'0001_1111_1111_1111_1111_1111_1: 512 Mbytes B'0011_1111_1111_1111_1111_1111_1: 1 Gbyte B'0111_1111_1111_1111_1111_1111_1: 2 Gbytes The area size exceeding the size defined in the address map must not be set. Any value other than those given above must not be set.
6 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.32 PCIEC Conversion Control Register 0 to 3 (PCIEPTCTLR0 to PCIEPTCTLR3)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

	—	—	—	LOCKn	—	—	—	SPCn	—	—	—	ZLR	—	—	ATTRn	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	PARE	B'0	R	PAR Enable Indicates that the PCI Express address upper and lower registers are enabled.
30 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 20	TCn	All 0	R/W	Traffic Class Specifies the traffic class (TC) of the PCI Express packet to be transferred.
19 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	LOCKn	B'0	R/W	LOCK Sets the lock of PCI Express packets to be transmitted. When this bit is set, locked transactions are transmitted. In Endpoint mode, this bit must not be set. Before making access requiring exclusive processing, confirm that the locked transaction has not caused an error.
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	SPCn	B'0	R/W	SPC Specifies a transfer destination space. 0: Memory 1: IO (A request cannot be issued to the IO space in Endpoint mode.) When issuing a request to the IO space, be sure to separate the accesses at 1DW boundaries.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	ZLR	B'0	R/W	ZLR Sets the zero-length read. 0: A read access to this space is output as a read access as is. 1: A 1DW read access to this space is output after converted to a zero-length read. Do not make any read access other than 1DW read access when this bit is set. The read value depends on the dummy data used by PCI Express for zero-length read. According to the standard, the value is undefined. Setting this bit has no effect for write access.
3, 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	ATTRn	All 0	R/W	ATTR Specifies the attribute of the PCI Express packet to be transferred. ATTR[0]: No snoop ATTR[1]: Relaxed ordering Setting ATTR[0] (no snoop bit) to 1 disables snooping in the transfer destination. Setting ATTR[1] (relaxed ordering bit) to 1 relaxes ordering in the transfer destination.

49.2.33 PCIEC DMAC DMA Operation Register (PCIEDMAOR)

Bit	Bit Name	Initial Value	R/W	Description
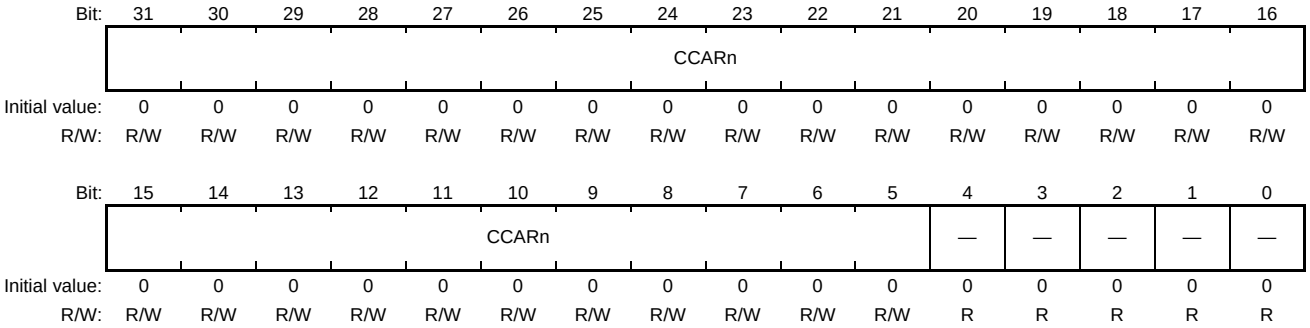
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 3	BCNT	All 0	R/W	Byte Count Specifies the transfer byte count. Only a multiple of 8 can be specified. In this field, set one-eighth of the number to be specified (omit the lower three bits from the number). When 0 is set, 2^{29} bytes are transferred. Note: If the transfer direction is changed after a transfer, the byte count read value will be undefined until the next transfer byte count is set (written). Be sure to write the byte count after initialization or completion of the previous transfer and before the start of the next transfer. The value before modification cannot be referenced or used.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.38 PCIEC DMAC Command Chain Address Register 0 to 7 (PCIEDMCCAR0 to PCIEDMCCAR7)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 5	CCARn	All 0	R/W	Command Chain Address Specifies a command chain address for DMA transfer. Only a 32-byte boundary address can be set.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.39 PCIEC DMAC Channel Control Register 0 to 7 (PCIEDMCHCR0 to PCIEDMCHCR7)

√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CHEn	DIRn	CCEn	CHTn	—	—	—	—	—	—	ATTRn		—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—		TC		—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	CHEn	B'0	R/W	Channel Enable Enables a DMA channel. Setting this bit to 1 starts DMA transfer on the corresponding channel. Note that, DMA transfer is not performed while the bit that indicates a transfer end (PCIEDMCHSRn.TE), a transfer error (PCIEDMCHSRn.PEE/IBE), or completion of DMA transfer suspension processing (PCIEDMCHSRn.CHTC) is 1. This bit must not be cleared during DMA transfer. This bit is not cleared to 0 by a transfer end or suspension. 0: Disables data transfer. 1: Enables data transfer.
30	DIRn	B'0	R/W	Direction Specifies the data transfer direction. 0: PCI Express → internal bus 1: Internal bus → PCI Express
29	CCEn	B'0	R/W	Command Chain Enable Enables a command chain. If data transfer is requested with this bit set to 1, the data is transferred by reading a command from an address set in PCIEDMCCARn. 0: Disables a command chain. 1: Enables a command chain.
28	CHTn	B'0	R/W	Channel Terminate Forcibly suspends DMA transfer in normal transfer. Setting this bit to 1 during DMA transfer suspends DMA transfer forcibly. Completion of DMA transfer suspension processing can be checked with PCIEDMCHSRn.CHTC. After transfer suspension, initialize the registers for the channel suspended. When setting this bit to 1, set other bits to the same value. This bit can be set to 1 only when a command chain is disabled (PCIEDMCHCRn.CCE = 0). When PCIEDMCHCRn.CCE is 1, this bit must be cleared to 0. This bit is always read as 0.

Bit	Bit Name	Initial Value	R/W	Description
27 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	ATTRn	All 0	R/W	ATTR Specifies the attribute of the PCI Express packet to be transferred. ATTR[0]: No snoop ATTR[1]: Relaxed ordering
19 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 9	TC	All 0	R/W	TC Specifies the traffic class (TC) of the PCI Express packet to be transferred.
8 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.40 PCIEC DMAC Channel Status Register 0 to 7 (PCIEDMCHSR0 to PCIEDMCHSR7)

R/W:	R	R	R	RW1C	RW1C	R	RW1C	R	R	R	R	R	R/W	R	R	RW1C

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	CHTCEn	B'0	R/W	Channel Terminate Complete Interrupt Enable Enables an interrupt caused by completion of forced suspension. 0: Disables generation of an interrupt. 1: Enables generation of an interrupt.
27	PEEEn	B'0	R/W	PCIE Error Interrupt Enable Enables an interrupt caused by a transfer error on the PCI Express side. 0: Disables generation of an interrupt. 1: Enables generation of an interrupt.
26	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
25	IBEEn	B'0	R/W	Internal Bus Error Interrupt Enable Enables an interrupt caused by a transfer error on the internal bus side. 0: Disables generation of an interrupt. 1: Enables generation of an interrupt.
24 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	CHTCn	B'0	RW1C	Channel Terminate Complete Indicates that the forced suspension processing started by setting PCIEDMCHCRn.CHT or PCIEDMCHC2Rn.CHT has been completed. With this bit set, DMA transfer is not performed by setting PCIEDMCHCRn.CHE to 1.

Bit	Bit Name	Initial Value	R/W	Description
11	PEEn	B'0	RW1C	PCIE Error Indicates that a transfer error has occurred on the PCI Express side. This error is caused in the following cases: • PCIEDMCHCRn.CHE is set to 1 while PCIEDMAOR.DMAE is 0. • DMA transfer is started while a link is not established, or DL_Down is caused during DMA transfer. • DMA transfer is started in the Non-D0 state. • DMA transfer is started with TC being set that is not mapped to VC0. • DMA transfer is started with PCICONF1[2].BME = 0 in Endpoint mode, or the bit is deasserted during DMA transfer. • DMA transfer is started with an attribute being set that is not enabled in the configuration registers. • A completion other than SC is received when PCI Express → internal bus. • A completion timeout occurs when PCI Express → internal bus. • A malformed completion is received when PCI Express → internal bus. • A poisoned completion is received when PCI Express → internal bus. • With this bit set, DMA transfer is not performed by setting PCIEDMCHCRn.CHE to 1.
10	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
9	IBEn	B'0	RW1C	Internal Bus Error Indicates that a transfer error has occurred on the internal bus side. With this bit set, DMA transfer is not performed by setting PCIEDMCHCRn.CHE to 1.
8 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	IEn	B'0	R/W	Interrupt Enable Enables an interrupt request. When this bit is 1, setting TE bit requests an interrupt. 0: Disables an interrupt request. 1: Enables an interrupt request.
2, 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	TEn	B'0	RW1C	Transfer End Indicates a transfer end. This bit is set to 1 when data transfer ends with the value in PCIEDMBCNTR0- PCIEDMBCNTR7 cleared to 0. This bit is not set to 1 when a transfer end is caused by a transfer error or data transfer is forcibly terminated by setting the PCIEDMCHCRn.CHT bit. With this bit set, DMA transfer is not performed by setting PCIEDMCHCRn.CHE to 1. 0: Indicates that data transfer is being performed or has been suspended. 1: Indicates that data transfer has ended (with PCIEDMBCNTRn cleared to 0).

49.2.41 PCIEC DMAC Channel Control 2 Register 0 to 7 (PCIEDMCHC2R0 to PCIEDMCHC2R7)

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31	DPE	B'0	RW1C	RW1C	Detected Parity Error Indicates that a parity error has been detected on the primary bus side. • Root Port: This bit is set to 1 when a poisoned TLP is transmitted. • Endpoint: This bit is set to 1 when a poisoned TLP is received.
30	SSE	B'0	RW1C	RW1C	Signaled System Error Indicates that a system error has been detected. • Root Port: This bit is set to 1 if a fatal/non-fatal error is detected while PCICONF1[8].SERRE = 1 or if a ERR_FATAL/ERR_NONFATAL message is received while PCICONF1[8].SERRE = 1 and PCICONF15[17].SERRE = 1. • Endpoint: This bit is set to 1 if a ERR_FATAL/ERR_NONFATAL message is transmitted while PCICONF1[8].SERRE = 1.
29	RMA	B'0	RW1C	RW1C	Received Master Abort Indicates that a master abort has been detected on the primary bus side. • Root Port: This bit is set to 1 when a completion with the unsupported request completion status is transmitted. • Endpoint: This bit is set to 1 when a completion with the unsupported request completion status is received.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
28	RTA	B'0	RW1C	RW1C	Received Target Abort Indicates that a target abort has been detected on the primary bus side. • Root Port: This bit is set to 1 when a completion with the completer abort completion status is transmitted. • Endpoint: This bit is set to 1 when a completion with the completer abort completion status is received.
27	STA	B'0	RW1C	RW1C	Signaled Target Abort Indicates that a target abort has been transmitted to the primary bus side. • Root Port: This bit is set to 1 when a completion with the completer abort completion status is received. • Endpoint: This bit is set to 1 when a completion with the completer abort completion status is transmitted.
26, 25	DEVSEL Timing	All 0	R	R	DEVSEL Timing Fixed to 0. These bits are not used for PCI Express.
24	MDPE	B'0	RW1C	RW1C	Master Data Parity Error Indicates that a master data parity error has occurred on the primary bus side. This bit is set to 1 when any of the following conditions are satisfied while PCICONF1[6].PERS is 1. • Root Port: 1. A poisoned completion is transmitted. 2. A poisoned request is received. • Endpoint: 1. A poisoned completion is received. 2. A poisoned request is transmitted.
23	FBBTCAP	B'0	R	R	Fast Back to Back Transaction Capable Fixed to 0. This bit is not used for PCI Express.
22	—	B'0	R	R	Reserved This bit is always read as 0. The write value should always be 0.
21	66MCAP	B'0	R	R	66 MHz Capable This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
20	CAPL	B'1	R	R/W	Capabilities List Indicates that the extended capabilities list exists in the PCI compatible configuration space. This IP supports the extended capabilities list. This bit must not be set to a value other than 1.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
19	INTST	B'0	R	R	Interrupt Status This bit is set to 1 when an interrupt is generated by INTx message transmission. It is cleared to 0 when a requested interrupt processing ends. When MSI is used by the device, this field is not set to 1. Fixed to 0 in Root Port mode.
18 to 16	—	All 0	R	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 11	—	All 0	R	R	Reserved These bits are always read as 0. The write value should always be 0.
10	INTDIS	B'0	R/W	R/W	Interrupt Disable Disables an INTx message transmission. Setting this bit to 1 disables an INTx message transmission.
9	FBBTE	B'0	R	R	Fast Back to Back Transaction Enable This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
8	SERRE	B'0	R/W	R/W	System Error Enable Enables an error message transmission when a non-fatal/fatal error is detected. Setting this bit to 1 enables an error message transmission.
7	IDSS/WCC	B'0	R	R	IDSel Stepping/Wait Cycle Control This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
6	PERS	B'0	R/W	R/W	Parity Error Response Enables setting the PCICONF1[24].MDPE bit.
5	VGAPS	B'0	R	R	VGA Plate Snoop This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
4	MWIE	B'0	R	R	Memory Write and Invalidate Enable This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
3	SC	B'0	R	R	Special Cycle This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
2	BME	B'0	R/W	R/W	Bus Master Enable • Root Port: Enables software to transfer the memory/IO request received from the endpoint device to the upper layer. When this bit is 0, the memory/IO request received is handled as an unsupported request. • Endpoint: When this bit is cleared to 0, transmission of a memory/IO request is disabled.
1	MSE	B'0	R/W	R/W	Memory Space Enable Enables an access to memory space. When this bit is 0, the memory request to this device is handled as an unsupported request.
0	IOSE	B'0	R/W	R/W	IO Space Enable Enables an access to I/O space. When this bit is 0, the IO request to this device is handled as an unsupported request.

√	√	√	√

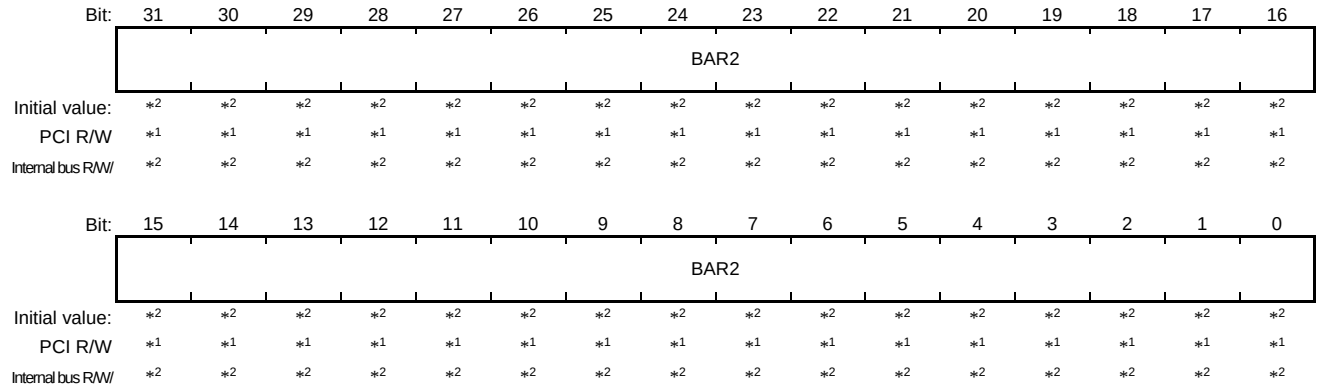
Header TYPE00



Notes: 1. R/W changes by the state. RootPort:R/W.EndPoint:R
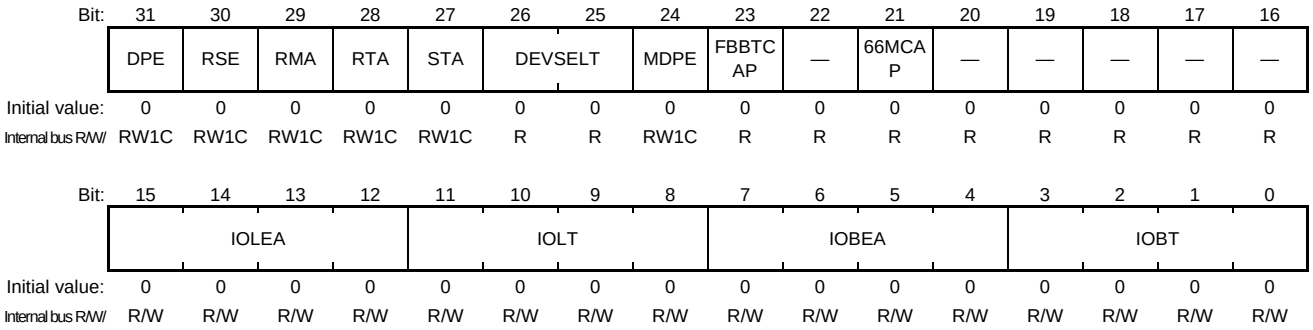
2. Depends on the value of local address mask register 3.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31 to 0	BAR3	*3	R/W	*3	BAR3 Indicates the value of base address register 3. • Root Port: This field has no effect in Root Port mode.
			R	*3	BAR3 Indicates the value of base address register 3. • Endpoint: This field is set by local address mask register 3 in Endpoint mode.

Notes: 3 It is the same as *2.

Header TYPE01

- Secondary status register



Bit	Bit Name	Initial Value	Internal Bus R/W	Description
31	DPE	B'0	RW1C	Detected Parity Error Indicates that a parity error has been detected on the secondary bus side. This bit is set to 1 upon reception of a poisoned TLP.
30	RSE	B'0	RW1C	Received System Error Indicates that a system error has been detected. This bit is set to 1 upon reception of an ERR_FATAL/NON_FATAL message.
29	RMA	B'0	RW1C	Received Master Abort Indicates that a master abort has been detected on the secondary bus side. This bit is set to 1 upon reception of a completion with the unsupported request completion status.
28	RTA	B'0	RW1C	Received Target Abort Indicates that a target abort has been detected on the secondary bus side. This bit is set to 1 upon reception of a completion with the completer abort completion status.
27	STA	B'0	RW1C	Signaled Target Abort Indicates that a target abort has been transmitted to the secondary bus side. This bit is set to 1 upon transmission of a completion with the completer abort completion status.
26, 25	DEVSELT	All 0	R	DEVSEL Timing Fixed to 0. These bits are not used for PCI Express.
24	MDPE	B'0	RW1C	MDPE Indicates that a master data parity error has occurred on the secondary bus side. This bit is set when either of the following conditions is satisfied while PCICONF15[16].PERS is 1. 1. A poisoned completion has been received. 2. A poisoned request has been transmitted.
23	FBBTCA	B'0	R	Fast Back to Back Transaction Capable Fixed to 0. This bit is not used for PCI Express.
22	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	Internal Bus R/W	Description
21	66MCAP	B'0	R	66 MHz Capable This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
20 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 12	IOLEA	All 0	R/W	IO Limit End Address According to the PCI standard, sets the address[15:12] of the upper limit address of the IO transaction to be transferred to the primary bus. In this IP, this field has no effect on the hardware.
11 to 8	IOLT	All 0	R/W	IO Limit Type According to the PCI standard, indicates the upper limit address decoding format of the IO transactions to be transferred to the primary bus. H'0: 16-bit I/O address H'1: 32-bit I/O address In this IP, this field has no effect on the hardware.
7 to 4	IOBEA	All 0	R/W	IO Base End Address According to the PCI standard, sets the address[15:12] of the base address of the IO transaction to be transferred to the primary bus. In this IP, this field has no effect on the hardware.
3 to 0	IOBT	All 0	R/W	IO Base Type According to the PCI standard, indicates the base address decoding format of the IO transactions to be transferred to the primary bus. H'0: 16-bit I/O address H'1: 32-bit I/O address In this IP, this field has no effect on the hardware.

Notes: 1. R/W changes by the state. RootPort:R/W.EndPoint:R
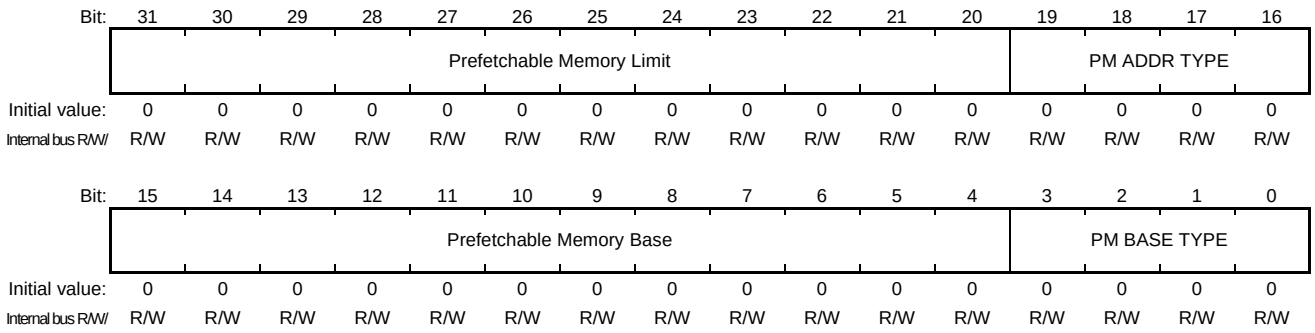
2. Depends on the value of local address mask register 5.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31 to 0	BAR5	*3	R/W	*3	BAR5 Indicates the value of base address register 5. • Root Port: This field has no effect in Root Port mode.
			R	*3	BAR5 Indicates the value of base address register 5. • Endpoint: This field is set by local address mask register 5 in Endpoint mode.

Notes: 3. It is the same as *2.

Header TYPE01



Bit	Bit Name	Initial Value	Internal Bus R/W	Description
31 to 20	Prefetchable Memory Limit	H'000	R/W	Prefetchable Memory Limit According to the PCI standard, sets the upper limit address of the prefetchable memory performing transfer between the primary IF and the secondary IF. This field corresponds to address[31:20]. In this IP, this field has no effect on the hardware.
19 to 16	PM ADDR TYPE	H'0	R/W	Prefetchable Memory Address Decode TYPE According to the PCI standard, indicates the upper limit address decoding format of the prefetchable memory performing transfer between the primary IF and the secondary IF. H'0: 32-bit address H'1: 64-bit address In this IP, this field has no effect on the hardware.
15 to 4	Prefetchable Memory Base	H'000	R/W	Prefetchable Memory Base According to the PCI standard, sets the base address of the prefetchable memory performing transfer between the primary IF and the secondary IF. This field corresponds to address[31:20]. In this IP, this field has no effect on the hardware.
3 to 0	PM BASE TYPE	H'0	R/W	Prefetchable Memory Base Type According to the PCI standard, indicates the base address decoding format of the prefetchable memory performing transfer between the primary IF and the secondary IF. H'0: 32-bit address H'1: 64-bit address In this IP, this field has no effect on the hardware.

Bit	Bit Name	Initial Value	Internal Bus R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27	DTSEE	B'0	R	Discard Timer SERR Enable This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
26	DTSTS	B'0	R	Discard Timer Status This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
25	SECDT	B'0	R	Secondary Discard Timer This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
24	PRDT	B'0	R	Primary Discard Timer This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
23	FBBTCAP	B'0	R	Fast Back to Back Transaction Capable This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
22	SECBRST	B'0	R/W	Secondary Bus Reset Resets the secondary IF. Setting this bit to 1 causes the LTSSM to make a transition to the hot reset state. Clearing this bit cancels the hot reset state of LTSSM.
21	MABMD	B'0	R	Master Abort Mode This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.
20	VGA16DEC	B'0	R/W	VGA 16-bit Decode According to the PCI standard, enables VGA IO decoding. In this IP, this field has no effect on the hardware.

Bit	Bit Name	Initial Value	Internal Bus R/W	Description
19	VGAE	B'0	R/W	VGA Enable According to the PCI standard, enables VGA address translation. In this IP, this field has no effect on the hardware.
18	ISAE	B'0	R/W	ISA Enable According to the PCI standard, enables ISA IO address translation. In this IP, this field has no effect on the hardware.
17	SERRE	B'0	R/W	SERR Enable Enables ERR_FATAL/ERR_NONFATAL/ERR_COR message transfer (notification) from the secondary IF to the primary IF. 1: Enables error message transfer (notification). 0: Disables error message transfer (notification).
16	PERS	B'0	R/W	Parity Error Response Enables setting of the PCICONF7[24].MDPE bit.
15 to 8	Interrupt Pin	All 0	R/W	Interrupt Pin Specifies a legacy interrupt message to be used by the device. When no legacy interrupts are used, set 0.
7 to 0	Interrupt Line	H'FF	R/W	Interrupt Line According to the PCI standard, indicates information on legacy interrupt routing. According to this IP, the set values are defined as follows. H'00 - H'FE: INTx interrupt is reported to INTC. H'FF: INTx interrupt is not reported to INTC.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31	PMESPD3COLD	B'1	R	R/W	PME Support D3COLD Indicates whether PME generation is supported or not in the D3Cold state. 0: Does not support PME generation in the D3Cold state. 1: Supports PME generation in the D3Cold state. • Root Port: Set this bit to 1 at initialization. • Endpoint: Set the device function at initialization.
30	PMESPD3HOT	B'1	R	R/W	PME Support D3HOT Indicates whether PME generation is supported or not in the D3Hot state. 0: Does not support PME generation in the D3Hot state. 1: Supports PME generation in the D3Hot state. • Root Port: Set this bit to 1 at initialization. • Endpoint: Set the device function at initialization.
29	PMESPD2	B'0	R	R/W	PME Support D2 Indicates whether PME generation is supported or not in the D2 state. 0: Does not support PME generation in the D2 state. 1: Supports PME generation in the D2 state. Set the device function at initialization.
28	PMESPD1	B'0	R	R/W	PME Support D1 Indicates whether PME generation is supported or not in the D1 state. 0: Does not support PME generation in the D1 state. 1: Supports PME generation in the D1 state. Set the device function at initialization.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
27	PMESPD0	B'1	R	R/W	PME Support D0 Indicates whether PME generation is supported or not in the D0 state. 0: Does not support PME generation in the D0 state. 1: Supports PME generation in the D0 state. • Root Port: Set this bit to 1 at initialization. • Endpoint: Set the device function at initialization.
26	D2SP	B'0	R	R/W	D2 Support Indicates whether the D2 power management state is supported or not. 0: Does not support the D2 state. 1: Supports the D2 state. Set the device function at initialization.
25	D1SP	B'0	R	R/W	D1 Support Indicates whether the D1 power management state is supported or not. 0: Does not support the D1 state. 1: Supports the D1 state. Set the device function at initialization.
24 to 22	AUX Current	H'0	R	R/W	AUX Current Indicates the current of 3.3V auxiliary power supply. Set this field at initialization. H'0: 0 mA (without auxiliary power supply) H'1: 55 mA H'2: 100 mA H'3: 160 mA H'4: 220 mA H'5: 270 mA H'6: 320 mA H'7: 375 mA When PMCAP0[31].PMESPD3COLD = 0, use the device with this field set to the initial value (= 0).
21	DSI	B'0	R	R/W	Device Specific Initialization Indicates that the device-specific initialization sequence is required after D0 initialization. 0: The device-specific initialization sequence is not necessary. 1: The device-specific initialization sequence is required. Set this field at initialization.
20	—	B'0	R	R	Reserved This bit is always read as 0. The write value should always be 0.
19	PMECLK	B'0	R	R	PME Clock This bit is always read as 0. The write value should always be 0. This bit is not used for PCI Express.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
18 to 16	PCI PM Version	H'3	R	R/W	PCI PM Version Indicate the corresponding PCI PM Interface Specification version. This device corresponds to the PCI PM Interface Specification version 1.2.
15 to 8	Next Capability Pointer	H'50	R	R/W	Next Capability Pointer Pointer to the extended capability list This field points to MSI capability pointer H'50.
7 to 0	Capability ID	H'01	R	R/W	Capability ID Capability List ID Indicates the power management capability (H'01).

Internal bus R/W/	RW1C	R	R	R	R	R	R	R/W	R	R	R	R	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31 to 24	DATA	All 0	R	R	DATA According to the PCI standard, indicates the value selected with PMCAP1[12:0].Data Select. This IP does not support this field.
23	BPCCE	B'0	R	R/W	Bus Power Clock Control Enable Enables the PCI bus power/clock control function. 0: Disables the PCI bus power/clock control function. 1: Enables the PCI bus power/clock control function. Set this field to 0 at initialization.
22	B2B3SP	B'0	R	R/W	B2 B3 Support Indicates the bus state in the D3Hot state. This field is valid when PMCAP1[23].BPCCE = 1. 0: Clock supply to the secondary IF does not stop in the D3Hot state. (B3) 1: Clock supply to the secondary IF stops in the D3Hot state. (B2) Set this field to 0 at initialization.
21 to 16	—	All 0	R	R	Reserved These bits are always read as 0. The write value should always be 0.
15	PMEST	B'0	RW1C or RW1CS	RW1C	PME Status This field is valid when the PME is supported. Indicates the PME generation status. 0: A PME message is not being transmitted. 1: A PME message is being transmitted. This bit is set to 1 when a PME message is transmitted. Note: When PME generation is enabled in the D3Cold state, this field is RW1CS.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
14, 13	Data Scale	All 0	R	R	Data Scale According to the PCI standard, indicates the scale used to indicate the value selected with PMCAP1[12:9].Data Select in PMCAP1[31:24].DATA. This IP does not support this field.
12 to 9	Data Select	All 0	R	R	Data Select According to the PCI standard, sets the value and unit to be indicated in PMCAP1[31:24].DATA and PMCAP1[14:13].Data Scale. This IP does not support this field.
8	PMEE	B'0	R/W or RWS	R/W	PME Enable Enables PME message transmission. 0: Disables PME message transmission. 1: Enables PME message transmission. When the device does not support the PME message transmission function, this bit should always be 0. Note: When PME generation is enabled in the D3Cold state, this field is RWS.
7 to 4	—	All 0	R	R	Reserved These bits are always read as 0. The write value should always be 0.
3	NOSRST	B'0	R	R/W	No Soft Reset Indicates whether internal reset is performed or not when the device makes a transition from the D3Hot state to the D0 state. 0: Internal reset is performed when the device makes a transition from D3Hot state to D0 state. 1: Internal reset is not performed when the device makes a transition from D3Hot state to D0 state. Set the device function at initialization.
2	—	B'0	R	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	Power State	B'00	R/W	R/W	Power State Specifies the power state. B'00: D0 B'01: D1 B'10: D2 B'11: D3Hot Note: The setting is ignored when 1 is set with D1 unsupported or 2 is set with D2 unsupported.

Internal bus R/W/	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31 to 0	Message Pending	All 0	R	R	Message Pending Indicates that MSI transmission is pending. If a transmission request of the interrupt vector corresponding to bit [N] is generated while it is masked by MSICAP4.Message Mask[N] = 1, MSICAP5.Message Pending[N] is set to 1 to indicate that transmission is pending. When MSICAP4.Message Mask[N] is updated to 0 upon reception of a configuration write request, MSICAP5.Message Pending[N] is updated to 0 to transmit the MSI message. This field is set to 1 when an interrupt transmission request is detected while MSICAP4.Message Mask[N] = 1. When MSICAP4.Message Mask[N] is cleared to 0 while MSICAP5.Message Pending[N] = 1, MSICAP5.Message Pending[N] is cleared to 0, and at the same time an MSI message is transmitted.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31 to 22	—	All 0	R	R	Reserved These bits are always read as 0. The write value should always be 0.
21	TRPD	B'0	R	R	Transaction Pending Indicates that there is a non-posted request not yet completed. 0: Non-posted request processing is not pending. 1: Non-posted request processing is pending. Non-posted requests issued are managed and the applicable value is reflected here.
20	AUXPDTCD	B'0	R	R	AUX Power Detected This field is fixed to 0 with this IP.
19	URDTCD	B'0	RW1C	RW1C	Unsupported Request Detected Indicates the unsupported request detection status. 0: An unsupported request has not been detected. 1: An unsupported request has been detected. This field is set to 1 when an unsupported request is detected.
18	FEDTCD	B'0	RW1C	RW1C	Fatal Error Detected Indicates the fatal error detection status. 0: A fatal error has not been detected. 1: A fatal error has been detected. This field is set to 1 when a fatal error is detected.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
17	NFEDTCD	B'0	RW1C	RW1C	Non-fatal Error Detected Indicates the non-fatal error detection status. 0: A non-fatal error has not been detected. 1: A non-fatal error has been detected. This field is set to 1 when a non-fatal error is detected.
16	CEDTCD	B'0	RW1C	RW1C	Correctable Error Detected Indicates the correctable error detection status. 0: A correctable error has not been detected. 1: A correctable error has been detected. This field is set to 1 when a correctable error is detected.
15	Reserved	B'0	R	R	This bit is always read as 0. The write value should always be 0.
14 to 12	Max Read Request Size	B'010	R/W	R/W	Max Read Request Size Indicates the maximum size of the read request that can be issued as the requester. B'000: 128 bytes max. B'001: 256 bytes max. B'010: 512 bytes max. B'011: 1024 bytes max. B'100: 2048 bytes max. B'101: 4096 bytes max. B'110: Reserved B'111: Reserved
11	ENSNP	B'1	R/W	R/W	Enable No Snoop Enables the device to issue the no-snoop transaction. 0: The no-snoop transaction cannot be issued. 1: The no-snoop transaction can be issued.
10	AUXPPME	B'0	RWS	R/W	AUX Power PM Enable Enables AUX power power management. 0: AUX power power management is disabled. 1: AUX power power management is enabled. Note: When the AUX power function is not implemented (when PMCAP0[24:22].AUX Current = 0), this bit is fixed to 0.
9	PFE	B'0	R	R	Phantom Function Enable Enables the phantom function. 0: The phantom function is disabled. 1: The phantom function is enabled. This IP does not support the phantom function. Fixed to 0.
8	ETAGE	B'0	R/W	R/W	Extended Tag Enable Enables the extension 8-bit tag ID function. 0: The extension 8-bit tag ID function is disabled. 1: The extension 8-bit tag ID function is enabled. This ID supports the extension 8-bit tag ID function.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
7 to 5	Max Payload Size	B'000	R/W	R/W	Max Payload Size Indicates the maximum payload size for the device. B'000: 128 bytes max. B'001: 256 bytes max. B'010: 512 bytes max. B'011: 1024 bytes max. B'100: 2048 bytes max. B'101: 4096 bytes max. B'110: Reserved B'111: Reserved
4	ERLOD	B'1	R/W	R/W	Enabled Relax Ordering Enables the device to issue the relaxed ordering transaction. 0: The relaxed ordering transaction cannot be issued. 1: The relaxed ordering transaction can be issued.
3	URRPE	B'0	R/W	R/W	Unsupported Request Reporting Enable Enables the error message report on detection of an unsupported request. 0: The FATAL_ERR or NONFATAL_ERR message is not transmitted on detection of an unsupported request. 1: The FATAL_ERR or NONFATAL_ERR message is transmitted on detection of an unsupported request.
2	FERPE	B'0	R/W	R/W	Fatal Error Reporting Enable Enables the error message report on detection of a FATAL_ERR. 0: The ERR_FATAL message is not transmitted on detection of a FATAL_ERR. 1: The ERR_FATAL message is transmitted on detection of a FATAL_ERR.
1	NFERPE	B'0	R/W	R/W	Non-fatal Error Reporting Enable Enables the error message report on detection of a NON_FATAL_ERR. 0: The ERR_NONFATAL message is not transmitted on detection of a NON FATAL_ERR. 1: The ERR_NONFATAL message is transmitted on detection of a NON FATAL_ERR.
0	CERPE	B'0	R/W	R/W	Correctable Error Reporting Enable Enables the error message report on detection of a correctable error. 0: The ERR_COR message is not transmitted on detection of a correctable error. 1: The ERR_COR message is transmitted on detection of a correctable error.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31 to 24	Port Number	All 0	R	R/W	Port Number Indicates the port number of this PCI Express port. Specify the port number at initialization.
23, 22	—	All 0	R	R	Reserved These bits are always read as 0. The write value should always be 0.
21	LKBWNOTFCAP	B'0	R	R/W	Link Bandwidth Notification Capability Indicates whether or not the link bandwidth change report function is supported by EXPCAP4[30].LKBWMNGSTS or EXPCAP4[31].LKAUTOBWSTS. 0: The link bandwidth change report function is not supported. 1: The link bandwidth change report function is supported. • Root Port: To support this function, set 1 at initialization. • Endpoint: Use the initial value. Not need to be changed.
20	DLLACTRPCAP	B'0	R	R/W	Data Link Layer Active Reporting Capable Indicates whether or not the Data Link Layer Active State can be indicated by EXPCAP4[29].DLLACT. 0: The Data Link Layer Active State cannot be indicated. 1: The Data Link Layer Active State can be indicated. • Root Port: To support this function, set 1 at initialization. • Endpoint: Use the initial value. Not need to be changed.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
19	SDNERPCAP	B'0	R	R	Surprise Down Error Reporting Capable Indicates that the Surprise Down error detection function is supported. 0: The Surprise Down error detection function is not supported. 1: The Surprise Down error detection function is supported. This device does not support the Surprise Down error detection function. Fixed to 0.
18	CLKPM	B'0	R	R/W	Clock Power Management Indicates that the clock can be stopped when the link is in the L1, L2Ready, or L3Ready state. 0: Clock cannot be stopped. 1: Clock can be stopped. Set the device function at initialization. Note: This field can be set with the device that conforms to the form factor supporting Clock Request Capability.
17 to 15	L1ELAT	B'111	R	R/W	L1 Exit Latency Indicates the L1 to L0 transition latency of the device. B'000: L0 recovery is completed in less than 1 µs. B'001: L0 recovery is completed in 1 µs or more, but less than 2 µs. B'010: L0 recovery is completed in 2 µs or more, but less than 4 µs. B'011: L0 recovery is completed in 4 µs or more, but less than 8 µs. B'100: L0 recovery is completed in 8 µs or more, but less than 16 µs. B'101: L0 recovery is completed in 16 µs or more, but less than 32 µs. B'110: L0 recovery is completed in 32 µs or more, but 64 µs or less. B'111: L0 recovery is completed in more than 64 µs. Set the device condition at initialization.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
14 to 12	L0s Exit Latency	B'111	R	R/W	L0s Exit Latency Indicates the L0s to L0 transition latency of the device. B'000: L0 recovery is completed in less than 64 ns. B'001: L0 recovery is completed in 64 ns or more, but less than 128 ns. B'010: L0 recovery is completed in 128 ns or more, but less than 256 ns. B'011: L0 recovery is completed in 256 ns or more, but less than 512 ns. B'100: L0 recovery is completed in 512 ns or more, but less than 1 µs. B'101: L0 recovery is completed in 1 µs or more, but less than 2 µs. B'110: L0 recovery is completed in 2 µs or more, but 4 µs or less. B'111: L0 recovery is completed in more than 4 µs. Set the device condition at initialization.
11, 10	ASPM Supported	B'01	R	R	ASPM Supported Indicates the ASPM support status. B'00: Reserved B'01: Supports L0s transition. B'10: Reserved B'11: Supports L0s and L1 transition (not supported with this IP). This IP only supports L0s transition.
9 to 4	Maximum Link Width	H'01	R	R/W	Maximum Link Width Indicates the maximum link width. H'00: Reserved H'01: x1 link H'02: x2 link (not supported) H'04: x4 link (not supported) H'08: x8 link (not supported) H'0C: x12 link (not supported) H'10: x16 link (not supported) H'20: x32 link (not supported)
3 to 0	Supported Link Speeds	H'2	R	R/W	Supported Link Speeds Indicates the maximum link speed. H'1: 2.5 GT/s H'2: 5.0 GT/s and 2.5 GT/s link speeds supported Other than above: Reserved

3. R/W changes by the state. Root Port:R/W, Endpoint:R

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31	LKAUTOBWSTS	B'0	—	RW1C	Link Autonomous Bandwidth Status • Root Port: When a change of link bandwidth due to intentional factor is detected, 1 is set. This bit is cleared to 0 when 1 is written. Note: This field is only valid when EXCAP3[21].LKBWNOTFCAP is set to 1. If set to 0, this bit is fixed to 0.
			R	R	Link Autonomous Bandwidth Status • Endpoint: Use the initial value. Not need to be changed.
30	LKBWMNGSTS	B'0	—	RW1C	Link Bandwidth Management Status • Root Port: When a change of link bandwidth due to reliability-related factor is detected, 1 is set. This bit is cleared to 0 when 1 is written. Note: This field is only valid when EXCAP3[21].LKBWNOTFCAP is set to 1. If set to 0, this bit is fixed to 0.
			R	R	Link Bandwidth Management Status • Endpoint: Use the initial value. Not need to be changed.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
29	DLLACT	B’0	R	R	Data Link Layer Active Indicates that DLCMSM is in the DL_ACTIVE state. 0: Not in the DL_ACTIVE state 1: In the DL_ACTIVE state Note: This bit is only valid when EXCAP3[20].DLLACTRPCAP is set to 1. If set to 0, this bit is fixed to 0.
28	SLCLKCFG	B’0	R	R/W	Slot Clock Configuration Indicates that the same reference clock as that supplied to the connector by the platform is used. 0: The same reference clock is not used. 1: The same reference clock is used.
27	LKTR	B’0	R	R	Link Training Indicates that link training by MAC LTSSM is in progress. • Root Port: Set to 1 when link training is in progress. • Endpoint: Fixed to 0.
26	—	B’0	R	R	Reserved This bit is always read as 0. The write value should always be 0.
25 to 20	Negotiated Link Width	H'04	R	R	Negotiated Link Width Indicates the link width determined by negotiation between links. H'01: x1 link width H'02: x2 link width H'04: x4 link width H'08: x8 link width H'0C: x12 link width H'10: x16 link width H'20: x32 link width This field value is undefined while a link is not established.
19 to 16	Current Link Speed	H'1	R	R	Current Link Speed Indicates the link speed determined by negotiation between links. H'1: 2.5 GT/s H'2: 5.0 GT/s
15 to 12	—	All 0	R	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
11	LKAUTOBWINTE	B'0	Root Port: —	Root Port: R/W	Link Autonomous Bandwidth Interrupt Enable Enables generation of the interrupt by EXPCAP4[31].LKAUTOBWSTS. • Root Port: An interrupt is generated when LKAUTOBWSTS is 1. Note: This bit is only valid when EXCAP3[21].LKBMNOTFCAP is set to 1. If set to 0, this bit is fixed to 0.
			Endpoint: R	Endpoint: R	• Endpoint: Use the initial value. Not need to be changed.
10	LKBWMNGINTE	B'0	Root Port: —	Root Port: R/W	Link Bandwidth Management Interrupt Enable Enables generation of the interrupt by EXPCAP4[30].LKBWMNGSTS. • Root Port: Writing 1 to this bit sets it to 1, and enables generation of the interrupt when LKBWMNGSTS is 1. Note: This bit is only valid when EXCAP3[21].LKBMNOTFCAP is set to 1. If set to 0, this bit is fixed to 0.
			Endpoint: R	Endpoint: R	• Endpoint: Use the initial value. Not need to be changed.
9	HWAUTOWDIS	B'0	R	R	Hardware Autonomous Width Disable Disables autonomous change of link width by hardware except for the cases of poor link reliability. 0: Autonomous change of link width by hardware is enabled. 1: Autonomous change of link width by hardware is disabled. According to the standard, fixing this bit to 0 is allowed if hardware does not provide the autonomous link width changing mechanism. Since this IP does not provide the autonomous link width changing mechanism, this bit is fixed to 0.
8	ECLKPM	B'0	R/W	R/W	Enable Clock Power Management Enables the clock power management function. Note: This bit is only valid when EXCAP3[18].CLKPM is set to 1. If set to 0, this bit is fixed to 0.
7	EXTSYNC	B'0	R/W	R/W	Extended SYNC Transmits the ordered set when the MAC LTSSM makes a transition from L0s or in the recovery state.
6	CCLKCFG	B'0	R/W	R/W	Common Clock Configuration Indicates that the same clock is used by both ends of the link.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
5	RTRNLK	B'0	R	R/W	Retrain Link Directs link retraining. Note: The read value is always 0. • Root Port: Write 1 to allow link retraining. • Endpoint: This bit is reserved. The write value should always be 0.
4	LKDIS	B'0	R	R/W	Link Disable Disables the link. • Root Port: Write 1 to disable the link. • Endpoint: This bit is reserved. The write value should always be 0.
3	RCB	B'0	R/W	Root Port: R/W Endpoint: R/W	Read Completion Boundary Indicates the read completion boundary. 0: 64-byte boundary 1: 128-byte boundary This field does not effect on the hardware. This IP divides a read completion only at 128-byte boundaries.
2	Reserved	B'0	R	R	This bit is always read as 0. The write value should always be 0.
1, 0	ASPM Control	B'00	R/W	R/W	ASPM Control Sets the ASPM support level. B'00: Disabled B'01: L0s transition enabled B'10: L1 transition enabled (setting prohibited) B'11: L0s/L1 transition enabled (setting prohibited)

Internal bus R/W/	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	Internal Bus R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	DLLSTCHG	B'0	R	Data Link Layer ST Changed According to the PCI standard, indicates that the EXPCAP4[29].DLLACT has changed. This field is invalid with this IP.

Bit	Bit Name	Initial Value	Internal Bus R/W	Description
23	EMLKSTS	B'0	R	Electro Mechanical Interlock Status According to the PCI standard, indicates the Electromechanical Interlock state. 0: Not locked by Electromechanical Interlock. 1: Locked by Electromechanical Interlock This field is invalid with this IP.
22	PRDETST	B'1	R	Presence Detect State According to the PCI standard, indicates that the adapter is inserted in the slot. 0: The slot is empty. 1: The adapter is inserted in the slot. This field is invalid with this IP.
21	MRLSENST	B'0	R	MRL Sensor State According to the PCI standard, indicates the MRL sensor state. 0: MRL is open. 1: MRL is closed. This field is invalid with this IP.
20	COMCPL	B'0	R	Command Completed According to the PCI standard, indicates that the Hot Plug command has been completed when EXPCAP5[18].NOCCSP = 0. 0: The Hot Plug command is being executed. 1: The Hot Plug command execution has been completed. This field is invalid with this IP.
19	PRDETCHG	B'0	R	Presence Detect Changed According to the PCI standard, indicates that the EXPCAP6[22].PRDETST has changed. This field is invalid with this IP.
18	MRLSENCHG	B'0	R	MRL Sensor Changed According to the PCI standard, indicates that the EXPCAP6[21].MRLSENST has changed. This field is invalid with this IP.
17	PWFALDET	B'0	R	Power Fault Detect According to the PCI standard, indicates that the power fault has been detected. This field is invalid with this IP.
16	ATBTNPRES	B'0	R	Attention Button Pressed According to the PCI standard, indicates that the attention button has been pressed. This field is invalid with this IP.
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	DLLSTCHGE	B'0	R	Data Link Layer State Change Enable According to the PCI standard, enables the setting of PCIEXP6[24].DLLSTCHG. This field is invalid with this IP.

Bit	Bit Name	Initial Value	Internal Bus R/W	Description
11	EMLKCON	B'0	R	Electro Mechanical Interlock Control According to the PCI standard, toggles the state of Electromechanical Interlock. This field is invalid with this IP.
10	PWCONCON	B'0	R	Power Controller Control According to the PCI standard, controls the power controller. 0: Power Off 1: Power On This field is invalid with this IP.
9, 8	PWINDCON	B'00	R	Power Indicator Control According to the PCI standard, controls the power indicator. B'00: Reserved B'01: On B'10: Blink B'11: Off This field is invalid with this IP.
7, 6	ATINDCON	B'00	R	Attention Indicator Control According to the PCI standard, controls the attention indicator. B'00: Reserved B'01: On B'10: Blink B'11: Off This field is invalid with this IP.
5	HOTPLGINTE	B'0	R	Hot Plug Interrupt Enable According to the PCI standard, enables MSI generation upon Hot Plug.
4	COMCPLINTE	B'0	R	Command Completed Interrupt Enable According to the PCI standard, enables MSI generation upon Command Complete. This field is invalid with this IP.
3	PRDETCHGE	B'0	R	Presence Detect Changed Enable According to the PCI standard, enables MSI generation by PRDETCHG. This field is invalid with this IP.
2	MRLSENCHGE	B'0	R	MRL Sensor Changed Enable According to the PCI standard, enables MSI generation by MRLSENCHG. This field is invalid with this IP.
1	PWFALDETE	B'0	R	Power Fault Detect Enable According to the PCI standard, enables MSI generation by PWFALDET. This field is invalid with this IP.
0	ATBTNPRESE	B'0	R	Attention Button Pressed Enable According to the PCI standard, enables MSI generation by ATBTNPRES. This field is invalid with this IP.

Internal bus R/W/	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

- Root control register

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	CRSVISE	PMEINTE	SERRFEE	SERRNFEE	SERRCEE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Internal bus R/W/	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	Internal Bus R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	Internal Bus R/W	Description
16	CRSVIS	B'0	R/W	CRS Software Visibility Indicates whether Root Port has the function of returning Configuration Retry Status to the upper software. Set the device function at initialization.
15 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CRSVISE	B'0	R/W	CRS Software Visibility Enable Enables Root Port to return Configuration Retry Status to the upper software. Before setting this bit to 1, the CRSVIS bit should be set. If these bits are set at the same time, CRSVISE is not set to 1. Setting this bit to 1 changes Configuration access behavior. For details, see section 49.3.2, Configuration Cycle.
3	PMEINTE	B'0	R/W	PME Interrupt Enable Enables Root Port to generate the interrupt to the upper software upon reception of a PME message. 0: If a PM_PME has been received when another PM_PME is received, EXPCAP8[15:0].PME_RequesterID is overwritten. 1: If a PM_PME has been received when another PM_PME is received, EXPCAP8[15:0].PM_RequesterID is not overwritten. PM_RequesterID of the PM_PME received later is placed in the pending state. At this time, all the receive operations are stopped. Thus, always clear EXPCAP8[16].PMEST.
2	SERRFEE	B'0	R/W	System Error on Fatal Error Enable Enables Root Port to generate the interrupt to the upper software upon reception of an ERR_FATAL message or occurrence of an error reported by Root Port itself.
1	SERRNFEE	B'0	R/W	System Error on Non-fatal Error Enable Enables Root Port to generate the interrupt to the upper software upon reception of an ERR_NONFATAL message or occurrence of an error reported by Root Port itself.
0	SERRCEE	B'0	R/W	System Error on Correctable Error Enable Enables Root Port to generate the interrupt to the upper software upon reception of an ERR_COR message or occurrence of an error reported by Root Port itself.

Internal bus R/W/	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	Internal Bus R/W	Description
31 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17	PMEPD	B'0	R	PME Pending Indicates that another PME is pending when this bit is 1. If the PME status is cleared by the upper software with PMEPD = 1 and PMEST = 1, PMEST is set to 1 again and the pending requester ID is set in the PME Requester ID bits.

Bit	Bit Name	Initial Value	Internal Bus R/W	Description
16	PMEST	B'0	RW1C	PME Status Indicates that PME has been received from the requester indicated by the PME Requester ID bits. This bit is set to 1 when the PME is received and cleared to 0 when the upper software writes 1 to this bit.
15 to 0	PME Requester ID	All 0	R	PME Requester ID Indicates the requester ID having issued the PME. This field sets the requester ID on reception of PME.

Internal bus R/W/	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31 to 17	—	All 0	R	R	Reserved These bits are always read as 0. The write value should always be 0.
16	CURDEEMLEV	B'1	R	R	Current De-emphasis Level Indicates the current de-emphasis level during 5-GT/s link operation. 0: -6 dB 1: -3.5 dB The value is undefined during 2.5-GT/s operation.
15 to 13	—	All 0	R	R	Reserved These bits are always read as 0. The write value should always be 0.
12	CMPDEEM	B'0	RWS	R/W	Compliance De-emphasis Specifies the de-emphasis level when setting EXPCAP12[4].ENTCMP bit to 1 causes LTSSM to be placed in Polling.Compliance mode. 0: -6 dB 1: -3.5 dB The value is undefined during 2.5-GT/s operation.
11	CMPSOS	B'0	RWS	R/W	Compliance SOS When this bit is 1, LTSSM periodically inserts the SKP ordered set between compliance patterns. 0: The SKP ordered set is not periodically inserted. 1: The SKP ordered set is periodically inserted.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
10	ETMDFCMP	B'0	RWS	R/W	Enter Modified Compliance When this bit is 1, LTSSM transmits modified compliance patterns on transition to the Polling.Compliance state. 0: Normal compliance patterns are used. 1: Modified compliance patterns are used.
9 to 7	Transmit Margin	B'000	RWS	R/W	Transmit Margin Sets the signal level without de-emphasis. B'000: Normal signal level B'001: 800 to 1200 mV for full swing, 400 to 700 mV for half swing B'010-(n-1): n is specified by PHY (3 ≤ n ≤ 7). n-111: Reserved Determine n according to the PHY specification. Do not set the value exceeding the PHY specification.
6	SELDEEM	B'0	R	R/W	Selectable De-emphasis Indicates the de-emphasis level during 5-GT/s upstream component operation. • Root Port: Set a value appropriate for the PHY at initialization. 0: -6 dB 1: -3.5 dB • Endpoint: Fixed to 0.
5	HWATSPDIS	B'0	R	R	Hardware Autonomous Speed Disable Disables autonomous change of link width by hardware except for the cases of poor reliability. 0: Autonomous change of link width by hardware is enabled. 1: Autonomous change of link width by hardware is disabled. According to the standard, fixing this bit to 0 is allowed if hardware does not provide the autonomous link width changing mechanism. Since this IP does not provide the autonomous link width changing mechanism, this bit is fixed to 0. The write value should always be 0.
4	ENTCMP	B'0	RWS	R/W	Enter Compliance Setting this bit of both ends of the link forcibly places a link into compliance mode at the specified speed. Used to set compliance mode.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
3 to 0	Target Link Speed	B'0010	RWS	R/W	Target Link Speed • Root Port: Specifies the upper limit speed that is conveyed to the communication peer during link training. Also, specifies the speed in compliance mode. B'0001: 2.5 GT/s B'0010: 5.0 GT/s • Endpoint: Specifies the speed in compliance mode. B'0001: 2.5 GT/s B'0010: 5.0 GT/s

Internal bus R/W/	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31 to 12	—	All 0	R	R	Reserved These bits are always read as 0. The write value should always be 0.
11, 10	PT ARBTBL SIZE	B'00	R	R	Port Arbitration Table entry Size Indicates the size of port arbitration table entry. This IP does not support port arbitration.
9, 8	REFCLK	B'00	R	R	Reference Clock Indicates the reference clock for Time Base WRR port arbitration. This IP does not support port arbitration.
7	—	B'0	R	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 4	LPEXTVC	B'000	R	R	Low Priority Extended VC Count Indicates the low priority VC count except the default VC0. With this IP, only VC0 is a low priority VC.
3	—	B'0	R	R	Reserved This bit is always read as 0. The write value should always be 0.
2 to 0	EXT VC	B'000	R	R/W	Extended VC Count Indicates the VC count except the default VC0. The write value should always be 0.

Internal bus R/W/	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
31 to 24	Port Arbitration Table Offset	All 0	R	R	Port Arbitration Table Offset Indicates that the offset address to the port arbitration table. VC0 does not have the port arbitration table.
23	—	B'0	R	R	Reserved This bit is always read as 0. The write value should always be 0.
22 to 16	Maximum Time Slot	All 0	R	R	Maximum Time Slot Indicates the maximum time slot in port arbitration according to Time Based WRR. VC0 does not provide the WRR port arbitration.
15	RJCTSNPTR	B'0	R	R/W	Reject Snoop Transactions Indicates that snoop transactions are rejected. • Root Port: Set the VC condition at initialization. • Endpoint: The write value should always be 0.
14 to 6	—	All 0	R	R	Reserved These bits are always read as 0. The write value should always be 0.
5	PTARBWRR256	B'0	R	R	Port Arbitration WRR256 Indicates that Weighted Round Robin 256 Phase is applied to port arbitration. This IP does not support port arbitration.
4	PTARBTBWRR128	B'0	R	R	Port Arbitration Time Base WRR128 Indicates that Time Base Weighted Round Robin 128 Phase is applied to port arbitration. This IP does not support port arbitration.

Bit	Bit Name	Initial Value	PCI R/W	Internal Bus R/W	Description
3	PTARBWRR128	B'0	R	R	Port Arbitration WRR128 Indicates that Weighted Round Robin 128 Phase is applied to port arbitration. This IP does not support port arbitration.
2	PTARBWRR64	B'0	R	R	Port Arbitration WRR64 Indicates that Weighted Round Robin 64 Phase is applied to port arbitration. This IP does not support port arbitration.
1	PTARBWRR32	B'0	R	R	Port Arbitration WRR32 Indicates that Weighted Round Robin 32 Phase is applied to port arbitration. This IP does not support port arbitration.
0	PTARBFIX	B'0	R	R	Port Arbitration Hardware Fixed Indicates that HardWareFix scheme is applied to port arbitration. This IP does not support port arbitration.

R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Bus Number	H'00	R/W	Bus Number The value of this field is used as the bus number at issuance of a request. The value of this field is used for checking the transaction ID bus number part within this IP on reception of Completion. Root Port: Set the device bus number. Endpoint: This field is always updated on reception of a Type0 Configuration Write request.
23 to 19	Device Number	H'00	R/W	Device Number The value of this field is used as the device number at issuance of a request. The value of this field is used for checking the transaction ID device number part within this IP on reception of Completion. Root Port: Set the device number. Endpoint: This field is always updated on reception of a Type0 Configuration Write request.
18 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 8	Default Completion Timeout Time	H'00	R/W	Default Completion Timeout Time Sets the Completion Timer timeout time for default setting (unit: ms). If a Completion cannot be received within the time set by this field, it is handled as a Completion timeout. Set a value from 10 to 50 ms.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.97 MAC Status Register (MACSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

R/W:	R	R	R	R	R	R	R	R	RW1C	RW1C	RW1C	RW1C	RW1C	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	—	—	R	Reserved The read value is undefined. The write value should always be 0.
30	LKTR	B'0	R	Link Training Indicates that MAC LTSSM is in the recovery or configuration state and that link training is in progress. 0: Link training is not in progress. 1: Link training is in progress. The value of this field is reflected to EXPCAP4[27].LKTR.
29	LPBAK1ST	B'0	R	Loop Back1 State Indicates that the MAC LTSSM is in Per Lane Loop BAK mode. Loopback test can be executed as a loopback master. Note: LTSSM has made a transition to the loopback state without executing Configuration. 0: Not in the Loop Back1 state 1: In the Loop Back1 state
28	LPBAK2ST	B'0	R	Loop Back2 State Indicates that the MAC LTSSM is in Configured Link Loop BAK mode. Loopback test can be executed as a loopback master. Note: LTSSM has made a transition to the loopback state after executing Configuration. 0: Not in the Loop Back2 state 1: In the Loop Back2 state
27	DISST	B'0	R	Disabled State Indicates that the MAC LTSSM is in the disabled state. Note: This bit is set only when this IP itself makes a request for link disable (sets 1 to EXPCAP4[4].LKDIS). Therefore, in Endpoint mode, 0 is always read. 0: Not in the disabled state 1: In the disabled state

Bit	Bit Name	Initial Value	R/W	Description
26	HOTRSTST	B'0	R	Hot Reset State Indicates that the MAC LTSSM is in the Hot Reset state. 0: Not in the Hot Reset state 1: In the Hot Reset state
25 to 20	Link Width	B'00_0100	R	Link Width Indicates the width of the link established by MAC configuration. This field is valid when PCIETSTR.DLLACT = 1. B'00_0001: x1 link width B'00_0010: x2 link width B'00_0100: x4 link width Indicates the same value as the value of EXPCAP4.Negotiated Link Width.
19 to 16	Link Speed	H'1	R	Link Speed Indicates the speed of the link established by the MAC configuration. This field is valid when PCIETSTR.DLLACT = 1. This IP supports the following link speeds: H'1: 2.5 GT/s H'2: 5.0 GT/s Indicates the same value as EXPCAP4.Current Link Speed. When read by firmware, the same value is read from the both fields.
15, 14	—	—	R	Reserved The read value is undefined. The write value should always be 0.
13	—	—	R	Reserved Ignore the value of this bit. The read value is undefined. The write value should always be 0.
12	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
11, 10	—	—	R	Reserved The read value is undefined. The write value should always be 0.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	SPCHGSUC	B'0	RW1C	Speed Change Success Indicates that speed negotiation started by this module has succeeded. Clear this bit by writing 1. Writing 0 is invalid.
6	SPCHGFAIL	B'0	RW1C	Speed Change Fail Indicates that speed negotiation started by this module has failed. Clear this bit by writing 1. Writing 0 is invalid.
5	SPCHG	B'0	RW1C	Speed Change Indicates that speed has been changed. When this bit is set to 1, write 1 to clear the bit. Writing 0 is invalid.

Bit	Bit Name	Initial Value	R/W	Description
4	SPCHGFIN	B'0	RW1C	Speed Change Finish Indicates that speed change processing requested by this IP has been completed. This bit is set to 1 at the same time that MACCTLR.SPCHG is cleared to 0. This bit is not updated if speed change processing is caused by the communication peer. For the usage, see section 49.3.9 (1), Changing Speed. When this bit is set to 1, write 1 to clear the bit. Writing 0 is invalid.
3	L0ENT	B'0	RW1C	L0 Enter This bit is set to 1 when a transition to L0 is made. This bit is cleared by hardware when the MACSR.SPCHGFIN interrupt is generated. For the usage, see section 49.3.9 (1), Changing Speed. When this bit is set to 1, write 1 to clear the bit. However, the bit cannot be cleared in the L0 state. Writing 0 is invalid.
2, 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	—	—	R	Reserved The read value is undefined. The write value should always be 0.

49.2.98 MAC Control Register (MACCTLR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	LTSMDIS	—	LPBAK	—	SCRDIS	FRCCMP	—	SPCHG	—	—	—	—	—	—	—	—
Initial value:	1	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	LTSMDIS	B'1	R/W	LTSSM Disable Disables MAC LTSSM operation. LTSSM does not operate while this bit is 1. 0: MAC LTSSM is not disabled and operation is performed. 1: MAC LTSSM is disabled. This bit is automatically cleared when PCIETCTLR[0].CFINIT is set.
30	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
29	LPBAK	B'0	R/W	Loop Back Requests MAC LTSSM to perform loopback transfer. When this bit is set, MAC LTSSM will be a loopback master after the Configuration or Recovery state, and makes a transition to the loopback state. Read MACSR.LPBAK1ST or LPBAK2ST to confirm that loopback state transition has been completed. 0: MAC LTSSM will not be a loopback master. 1: MAC LTSSM will be a loopback master.
28	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
27	SCRDIS	B'0	R/W	Scramble Disable Disables the MAC data scramble function. Note: Set this bit when MACCTLR.LTSMDIS is 1. If this bit is changed with MACCTLR.LTSMDIS being 0, operation is undefined. 0: The data scramble function is enabled. 1: The data scramble function is disabled.
26	FRCCMP	B'0	R/W	Force Compliance Directs a forcible transition to compliance mode. If set to 1 before a transition to the Polling.Active state is made, Polling.Compliance state transition is made after a timeout occurs in the Polling.Active state. If cleared to 0 during or after a transition, a transition to the Detect state is made.

Bit	Bit Name	Initial Value	R/W	Description
25	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
24	SPCHG	B'0	R/W	Speed Change Directs speed change. If set to 1 when LTSSM is in the L0, L0s, or L1 state, LTSSM makes a transition to the recovery state thus allowing speed negotiation. Only writing 1 is valid and writing 0 is invalid. This bit is read as 1 during a transition.
23 to 16	—	H'FF	R	Reserved Modifying these bits is prohibited. The write value should be H'FF.
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	—	B'1	R	Reserved The write value should always be 0. Note: Write 0 at initialization.

49.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

The following describes the operation of this module.

Note: The following operation flowcharts are each divided in two parts and described. One part covers the H/W, hardware operation of this module and the other covers the S/W, software operation to control this module. The arrows originating from the outside of the figure frame indicate that the event arises from the user program.

In the explanation of the operation flows, interrupt sources are described in the H/W part. The S/W should first verify a given interrupt flag and then clear it.

If generation of interrupt sources is expected, enable each of the interrupt sources referring to Figure 49.31 and 49.32.

49.3.1 Initialization

(1) Standby State Cancellation

- After canceling a reset, cancel the module standby state. For the module standby state, refer to section “12. Module Standby and Software Reset”. This module is in the module standby state after a power-on reset is canceled.

(2) Initial Setting of PCI Express

- Figure 49.2 shows the PCIEC operation in initial setting.
- After start-up processing for the physical layer is completed, the initial setting is executed to start operation as a PCI Express. Until the initial setting is completed, this module cannot work correctly as a PCI Express device. Therefore, a link is not established immediately after a reset is canceled. When the initial setting is completed, enable the PCIETCTLR.CFINIT to start operation.
- Set the bits in the configuration registers as directed in the related register description, if there is a direction on initialization.
- Set H'000 in the Next Capability Offset [31:20] bits in VCCAP0.
- Be sure to write the initial value (= H'80FF 0000) to MACCTLR before enabling PCIETCTLR.CFINIT.
- When a register is used with the default setting, setting the register is not required.

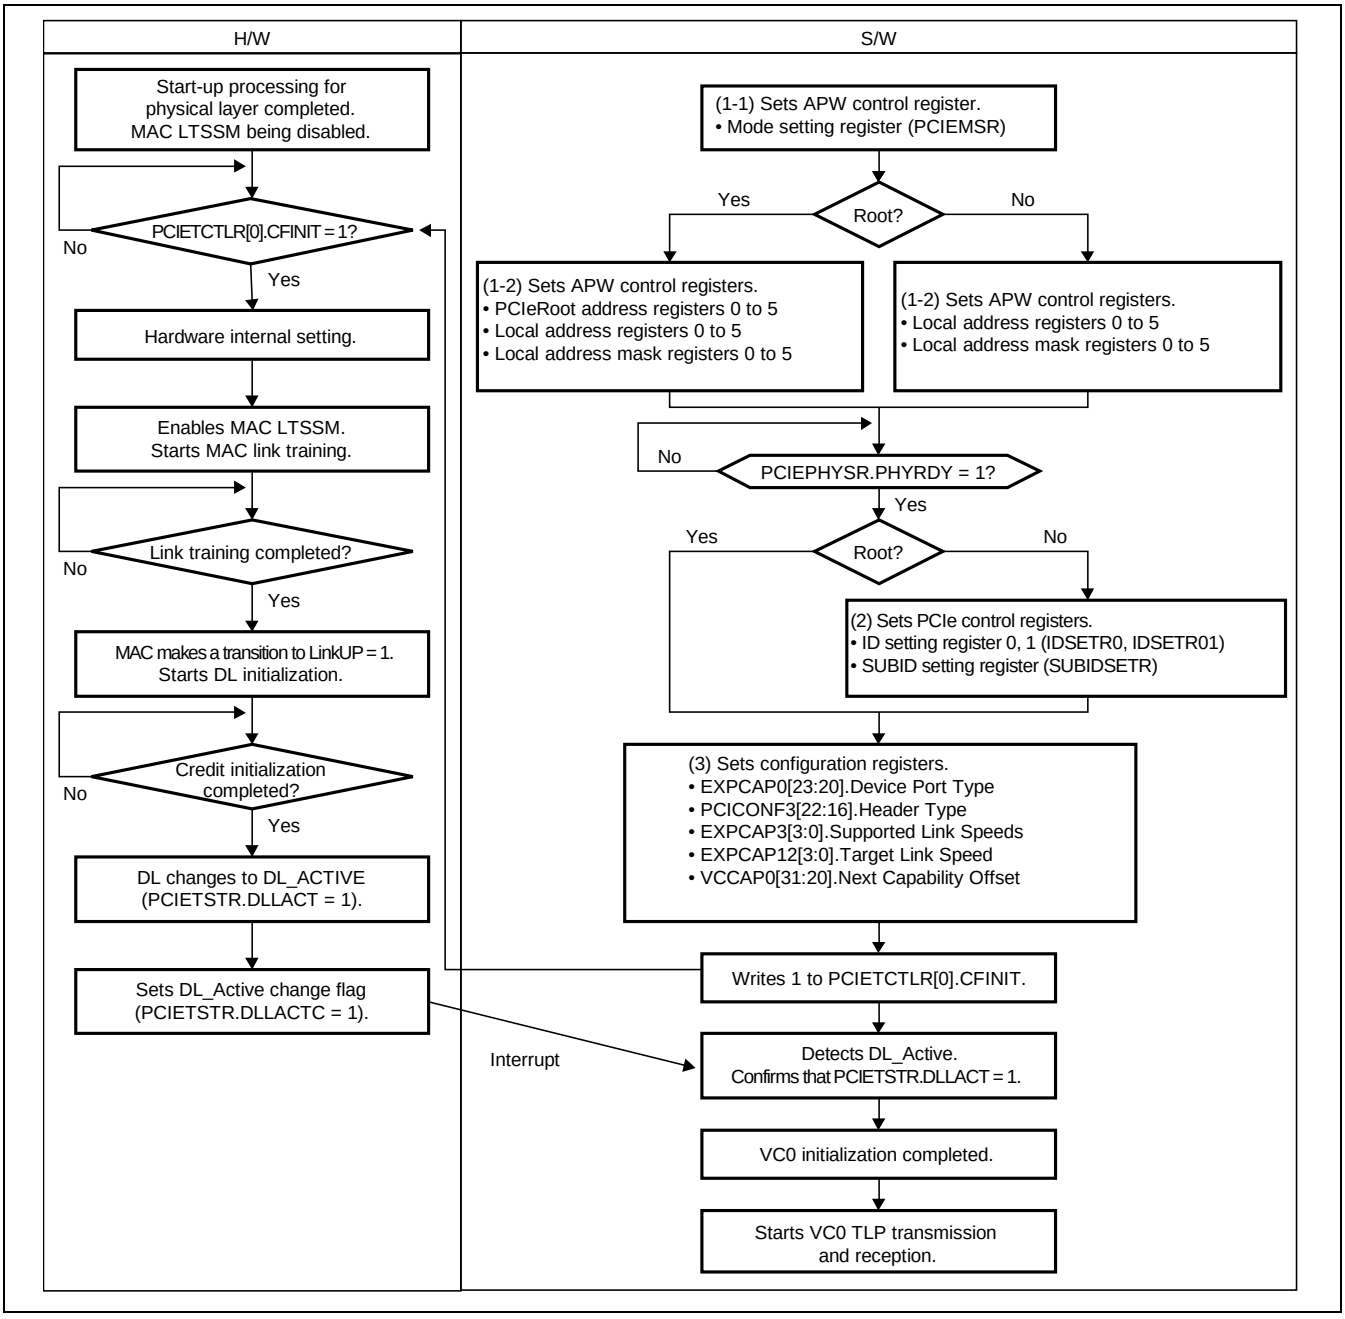

Figure 49.2 Initial Setting of PCIEC

(3) DL_Down Operation

Figure 49.3 shows the operation when a link goes down (LinkUP = 0) in the state where a link is established, thus causing DL_Down. When DL_Down is caused, PCIETCTLR.DLDOWN is set to 1. Since the current data is invalidated, all the resources of the data transmitter/receiver of this module are initialized.

- Upon DL_Down, a write to the transmission buffer is disabled thus stopping transmission.
- Upon DL_Down, the receive buffer is forcibly cleared.
- If a link goes down, transmission and reception are suspended; therefore, data before and after DL_Down becomes illegal. Since the specific process here differs depending on the application, the operation is simply indicated as “Processes errors.” in the flowchart shown in Figure 49.3.

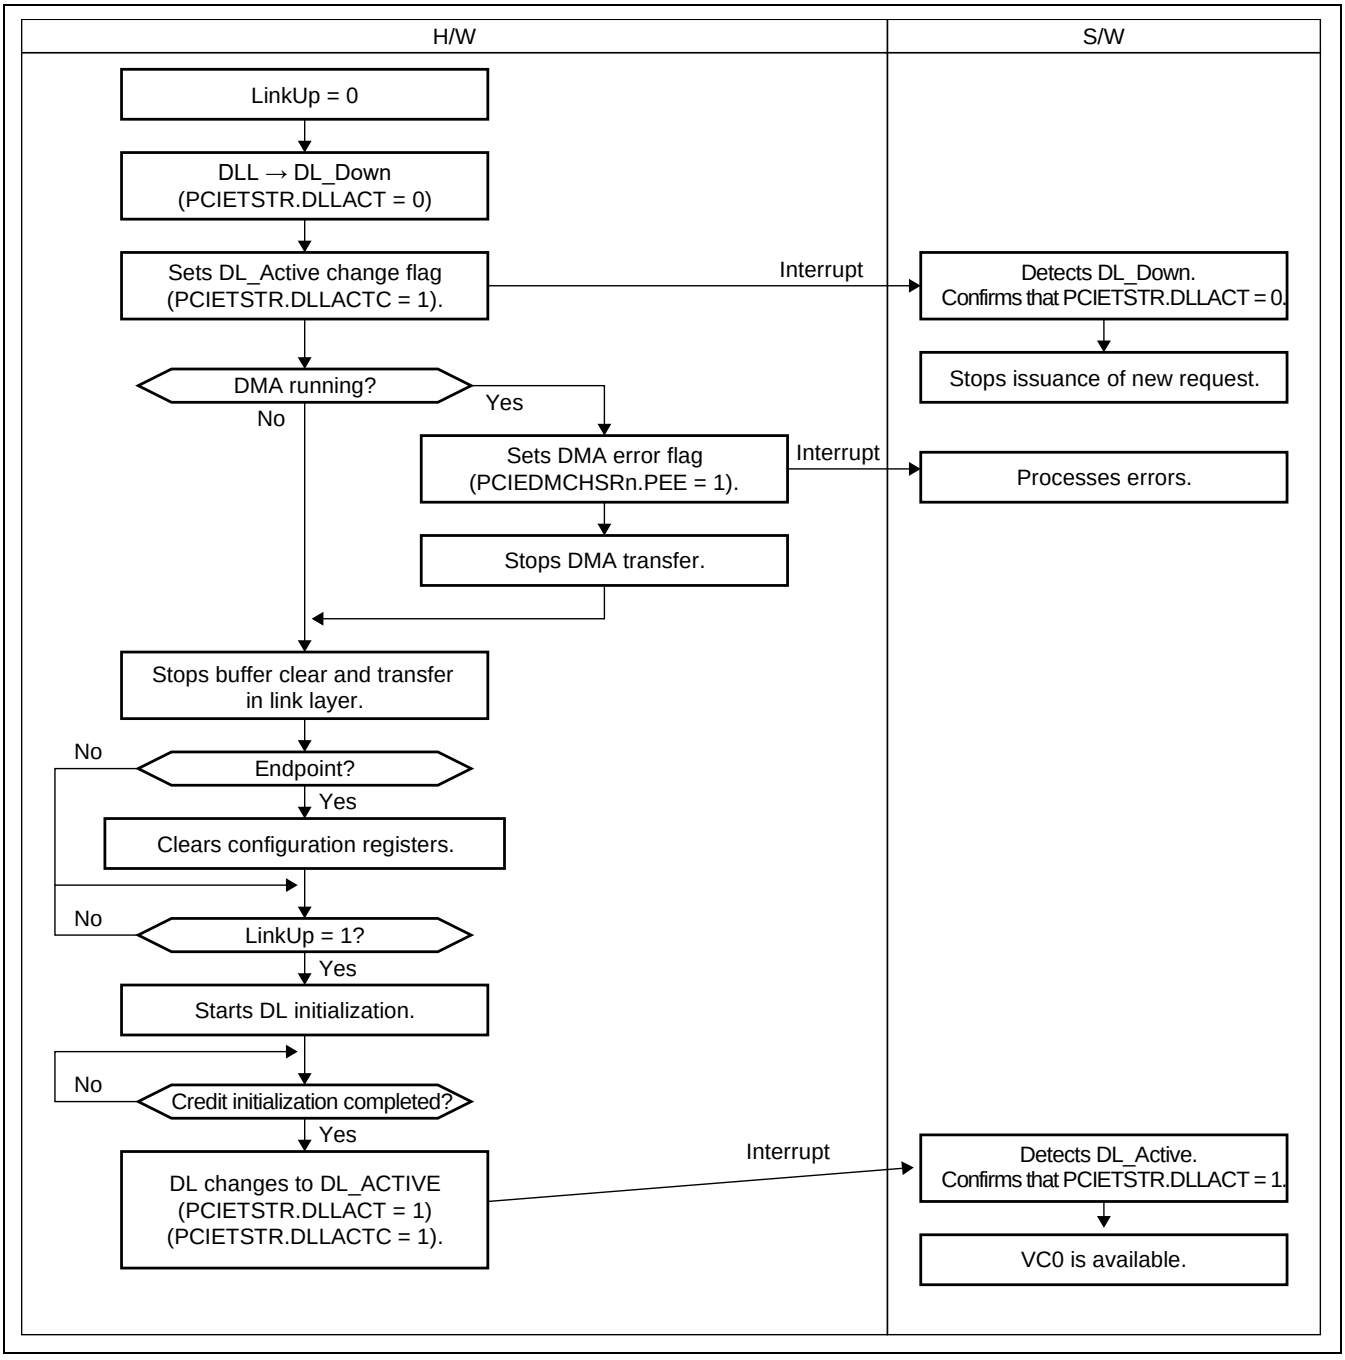

Figure 49.3 DL_Down Operation

(4) Hot Reset Operation

(a) Hot Reset Transmission

In Root Port mode, to send a hot reset to a downstream port, write 1 to the secondary bus reset bit in the configuration register. Before issuing a hot reset, confirm that this module has completed transfer.

(b) Hot Reset Reception

In Endpoint mode, when a hot reset is received from an upstream port, the LTSSM on the link layer makes a transition to the hot reset state. This causes LinkUp = 0 and then DL_Down = 1. After this, the same operation is performed as the operation upon the DL_Down.

49.3.2 Configuration Cycle

When using this module as a Root Port, a configuration cycle must be generated to configure the connection-target device. A configuration cycle refers to the process of checking the status of the configuration register of the connection-target Endpoint, switch, or bridge through the use of configuration access, and assigning values to the configuration registers of the Root Port itself and the Endpoint according to the result of the checking. When the Root Port accesses its own configuration register, such access is normally made through the internal bus.

This section describes the transmission (write) and reception (read) operations of the configuration access, and the items to be specified during a configuration cycle.

When this module is used as an Endpoint, it receives a configuration access from a Root Port, and accepts the initialization processing.

(1) Configuration Read Operation

Figure 49.4 shows a flow of configuration read operation.

With EXPCAP7[4].CRSVISE = 0, an error response is returned when the CRS status is received.

With EXPCAP7[4].CRSVISE = 1, response data is H'FFFF_0001 when the CRS status is received. Therefore, the first access to the peer device from which the CRS status may possibly be returned must be configuration read from register 0. Here, judgment is possible only by the VID that has read that no device is existent (including an unsupported request response) or that a CRS response is received, thus simplifying the procedure for setting the bus number of the PCI bus topology.

Automatic hardware response according to the CRS status is not supported.

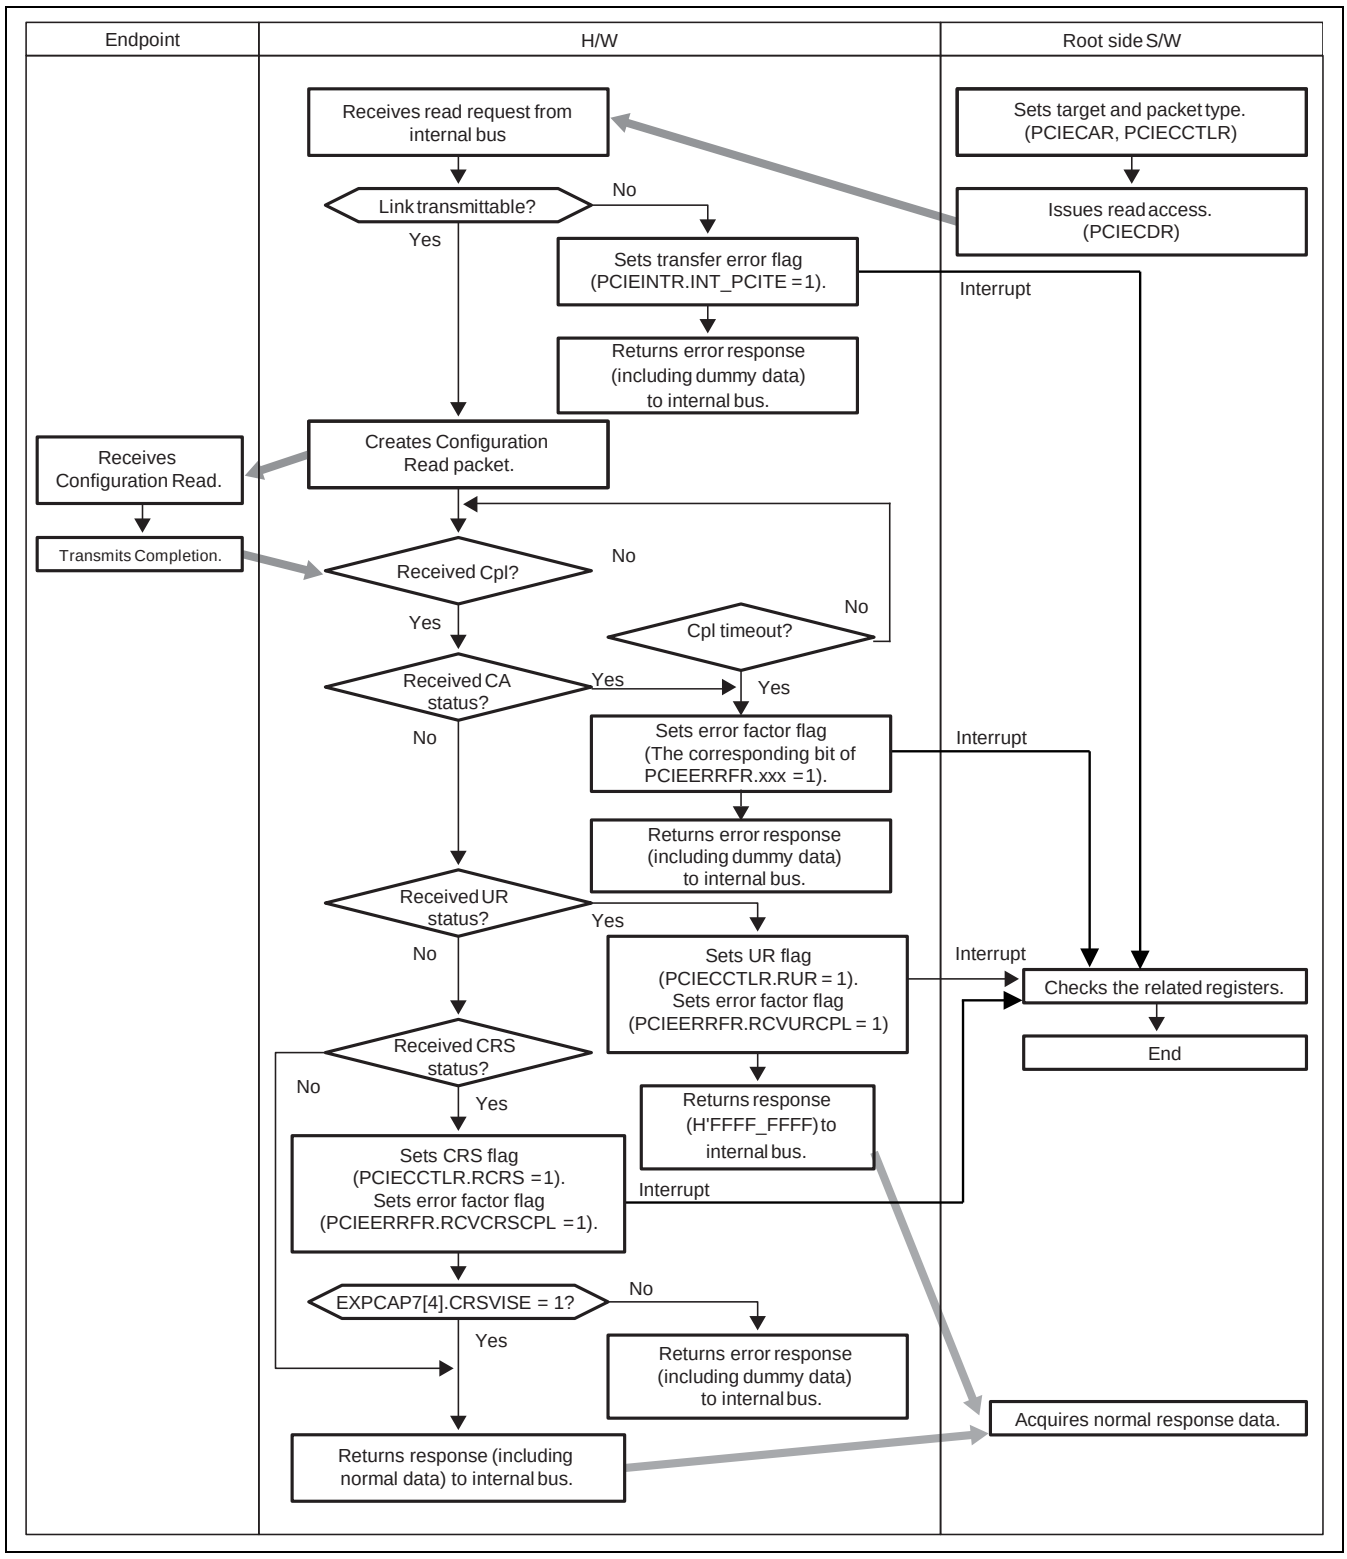

Figure 49.4 Configuration Read Operation

(2) Configuration Write Operation

Figure 49.5 shows a flow of configuration write operation.

The peer device should be the function for which configuration read has been succeeded (= the function from which CRS may never be returned).

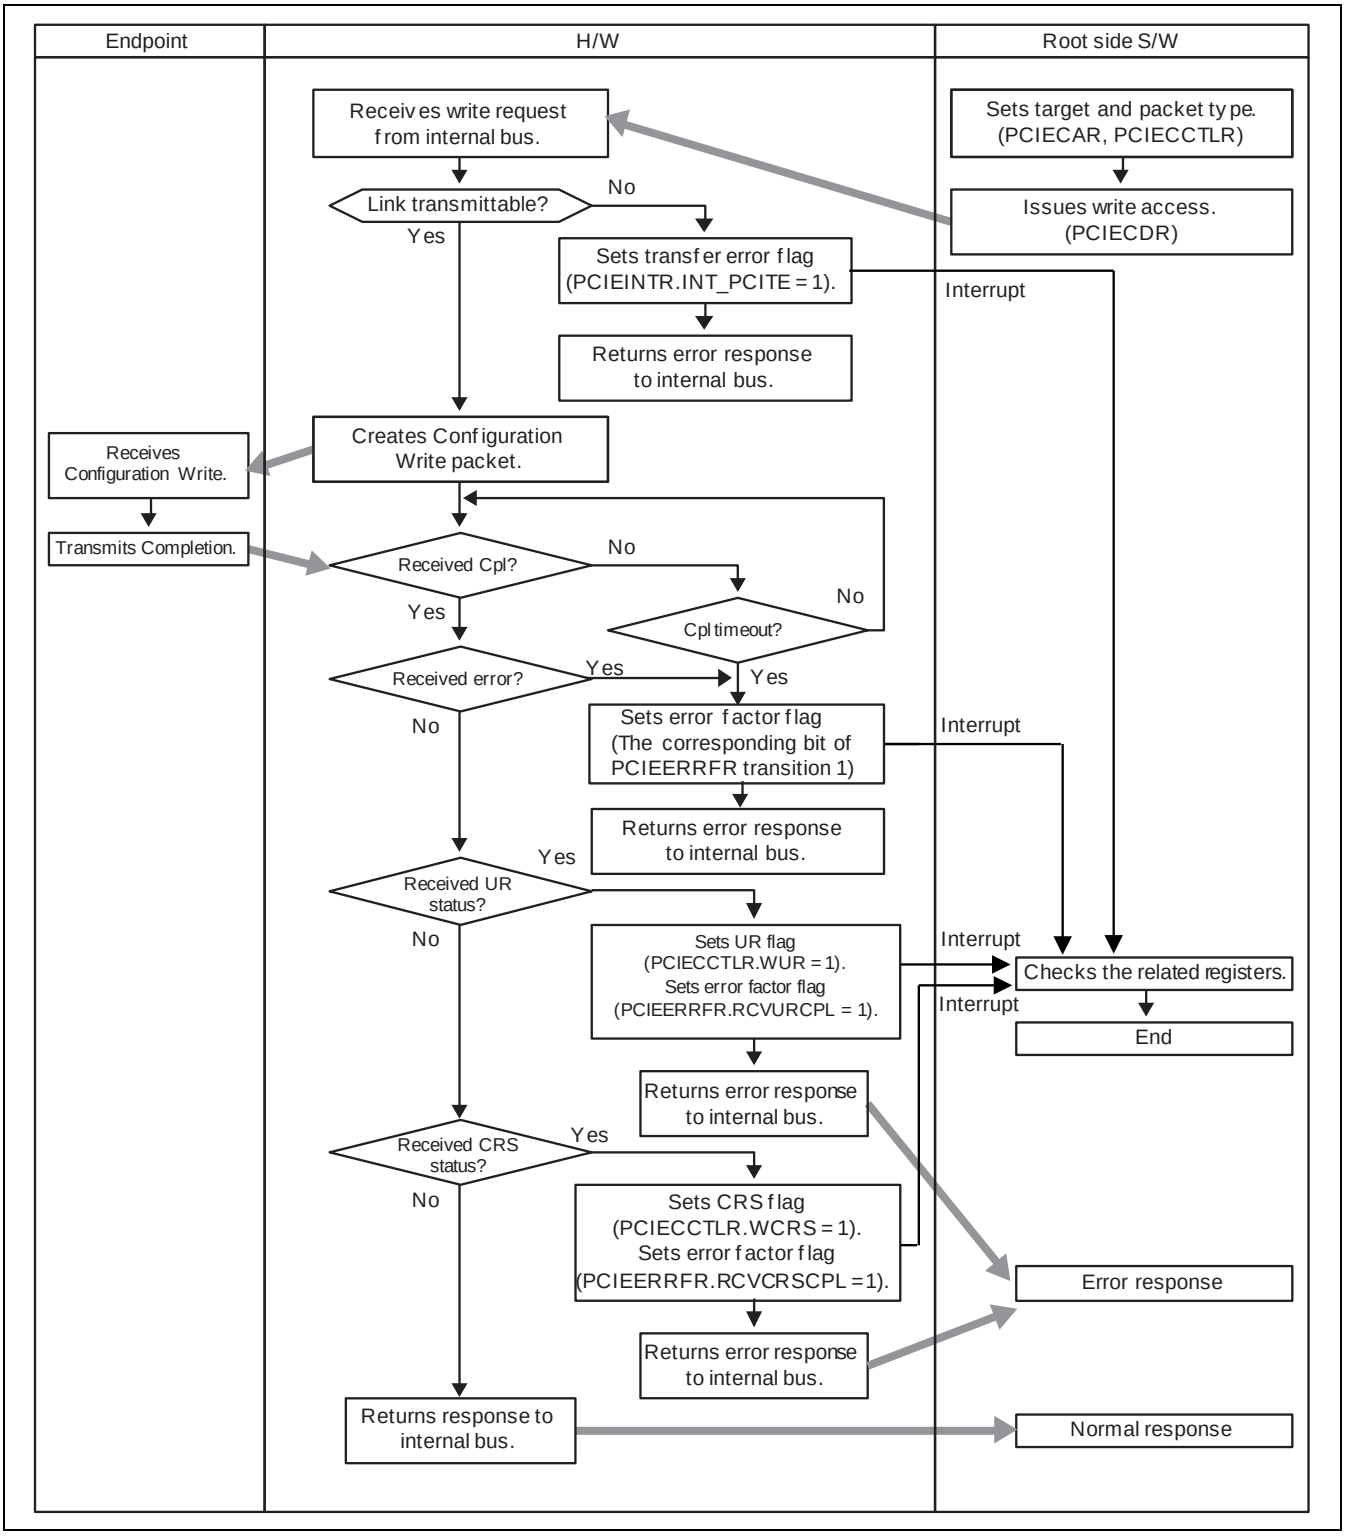

Figure 49.5 Configuration Write Operation

(3) Initialization of PCIEC in Root Port Mode

In Root Port mode, set all the Endpoints (indicated as system in the flow chart) connected to the PCIEC after link establishment. Figure 49.6 shows a sample setting flowchart.

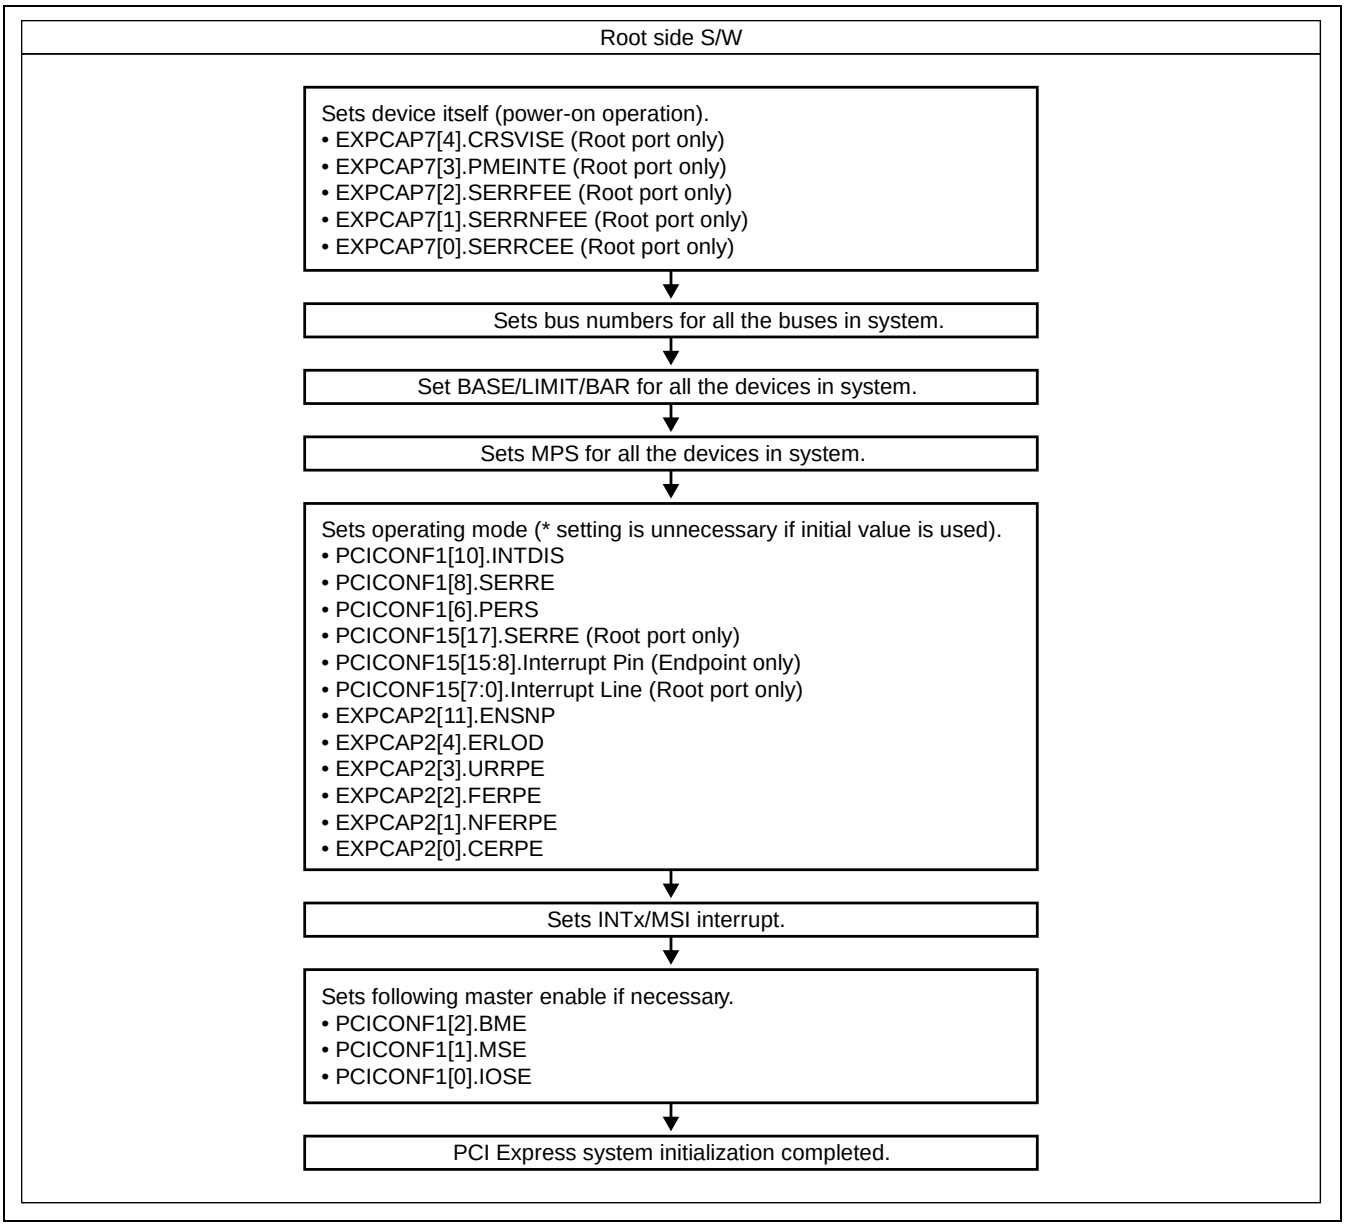

Figure 49.6 PCIEC Initialization in Root Port Mode

49.3.3 Messages and MSI

This module supports transmission and reception of the messages and MSI (Message Signaled Interrupt) defined in the PCI Express standard. The messages allow interrupt signaling, power management, error information notification, and unlocking. The MSI is used instead of INTx to signal interrupts. The following sections describe transmission and reception of the messages and MSI.

(1) Overview of Messages

This module automatically transmits and receives messages that indicate the error state of a link through hardware (Figure 49.7 (a) and 49.8 (a)). The other types of messages can be transmitted and received only by writing and reading the registers of this module (Figure 49.7 (b) and 49.8 (b)). The PM-related messages and INTx messages have separate 1-bit fields corresponding to the messages and simply writing to the pertinent bit allows this module to create and transmit a message. In message reception, reading the status of the pertinent bit completes reception.

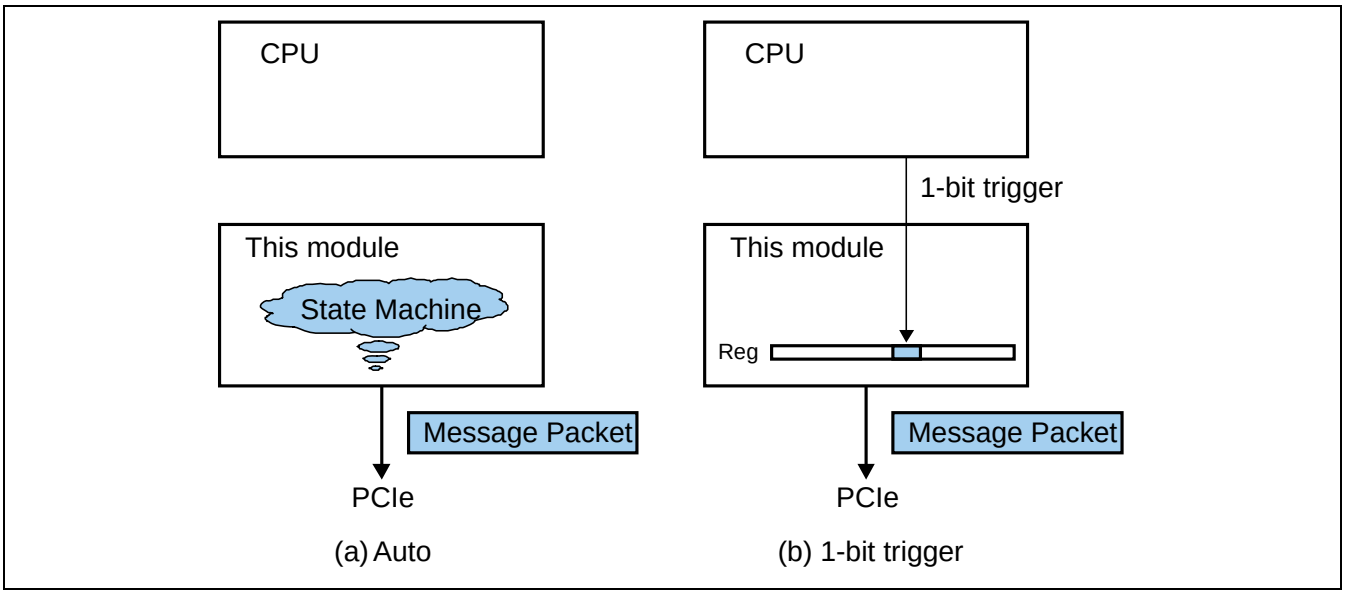

Figure 49.7 Message Transmission Methods

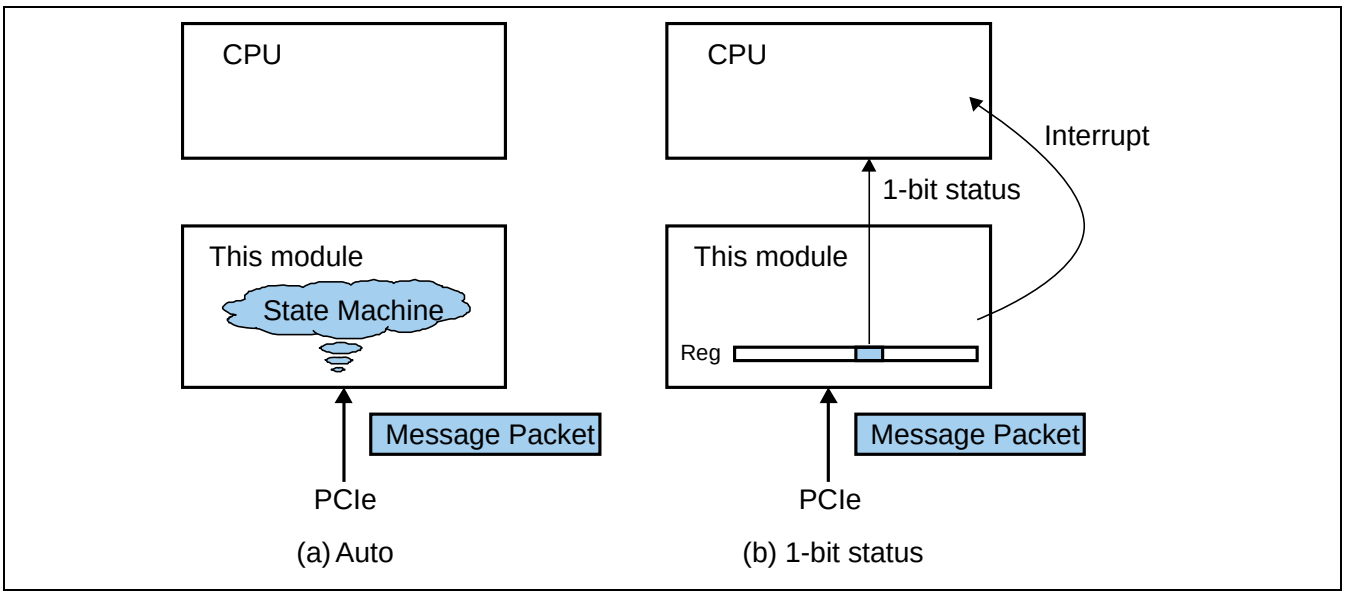

Figure 49.8 Message Reception Methods

(2) Message Transmission

Messages can be transmitted by either of the following two methods.

(a) Automatic Message Transmission by Hardware

This module automatically sends a necessary message when an error occurs. The following messages are automatically sent.

- ERR_COR: When transmission of the correctable error message is enabled, this message is automatically sent if a correctable error occurs.
- ERR_NONFATAL: When transmission of the non-fatal error message is enabled, this message is automatically sent if a non-fatal error occurs.
- ERR_FATAL: When transmission of the fatal error message is enabled, this message is automatically sent if a fatal error occurs.

(b) Initiation of Message Transmission by 1-bit Writing through Software

This module sends unlock or INTx interrupt messages under control by software. To send these messages, access the following registers.

- Unlocking (unlock message transmission): Writing 1 to PCIEUNLOCKCR[0].ASTUNLOCK allows transmission of the unlock message and unlocking. The unlock messages can be transmitted only by the Root Port.
- Power management message transmission (PME_* message transmission): Writing 1 to the bits corresponding to the messages in the power management message transmission control register allows transmission of the messages given below: PME_TO_ACK, PME_TOFF, and PM_PME.
- INTx interrupt generation and cancellation (Assert_INTx/Deassert_INTx message transmission: x = A, B, C, or D): Writing 1 to PCIEINTXR[16].ASTINTX allows transmission of the Assert_INTx message corresponding to the INTx specified with PCICONF15[15:8].Interrupt Pin thus allowing generation of the INTx interrupt. Writing 0 to PCIEINTXR[16].ASTINTX allows transmission of the Deassert_INTx message corresponding to the INTx specified with PCICONF15[15:8].Interrupt Pin thus allowing cancellation of the INTx interrupt. The INTx interrupts can be generated and canceled only by the Endpoint.

(3) Message Reception

In this module, reception of some messages is automatically handled by hardware. For the message reception processes not performed through hardware, refer to the status and process reception through software. Note that the messages except Vendor_Defined_Message are required by the PCI Express standard to be transmitted and received with TC0. If such a message is received with the other TC, the PCIEC considers it as a malformed TLP (fatal error) thus performing error processing automatically.

(a) Automatic Message Reception by Hardware

- Assert_INTx (x is A to D): When this message is received in Root Port mode, PCIEINTXR[0, 1, 2, 3].INTx are set. The INTx interrupt is generated here when PCICONF15[7:0].Interrupt Line is not H'FF. When received in Endpoint mode, this message is considered as a malformed TLP and error processing is performed.
- Deassert_INTx (x is A to D): When this message is received in Root Port mode, PCIEINTXR[0, 1, 2, 3].INTx are cleared. The INTx interrupt is canceled here (only in the Root Port) when PCICONF15[7:0].Interrupt Line is not H'FF. When received in Endpoint mode, this message is considered as a malformed TLP and error processing is performed.
- ERR_COR: When this message is received, the appropriate value is set to the configuration register to indicate reception of a correctable error and the INT_PCICERR interrupt is generated.
- ERR_NONFATAL: When this message is received, the appropriate value is set to the configuration register to indicate reception of a non-fatal error and the INT_PCINFERR interrupt is generated.
- ERR_FATAL: When this message is received, the appropriate value is set to the configuration register to indicate reception of a fatal error and the INT_PCIFERR interrupt is generated.

- Unlock: The unlock message is discarded since neither the PCI Express Endpoint nor Root Port accepts a lock request.
- Set_Slot_Power_Limit: (When this message is received, the power information specified with the message is automatically reflected to the configuration register (EXPCAP1[27:18]) through hardware.)

(b) Reception of Messages Requiring Software Processing

The module hardware detects reception of the following messages but does not automatically process them. Reception of these messages must be checked and processed by software as described below.

- PM_PME

A message reception can be checked via the following registers:

- PCIERMSGR
- PCIERMSGIER
- EXPCAP8

In the PCIERMSGR, bits are defined for each specified message, and 1 is set to a bit corresponding to the received message when a message is received. In this situation, if the corresponding bit in the PCIERMSGIER is set to 1 and if the PCIEINTER[5].INT_PCIMESE is set to 1, a PCIMES interrupt is generated.

Table 49.7 shows the messages, reception of which is detected by hardware and which are processed by software.

Table 49.7 Messages Whose Reception can be Detected by the PCIEC

Register	Bit No.	Register	Bit No.	Receive Message
PCIEINTR	5	PCIERMSGR	12	Set_Slot_Power_Limit
	30	EXPCAP8	17	PM_PME

(4) Overview of MSI

This section describes the MSI interrupts.

This module supports MSI interrupts. Whether the PCI Express system should use INTx or MSI interrupts is determined by the Root Port during a configuration cycle. When this module is to be used as a Root Port, whether INTx or MSI interrupt is used should be determined during a configuration cycle, and the results of the determination must be set in the configuration register.

When this module is used as a Root Port, a maximum of 32 interrupt vectors can be used as MSI interrupts. In addition, this module supports both Per Vector Masking and the transmission of 64-bit address messages.

(5) MSI Transmission

MSI can be transmitted only in Endpoint mode. Figure 49.9 shows an MSI transmission flow.

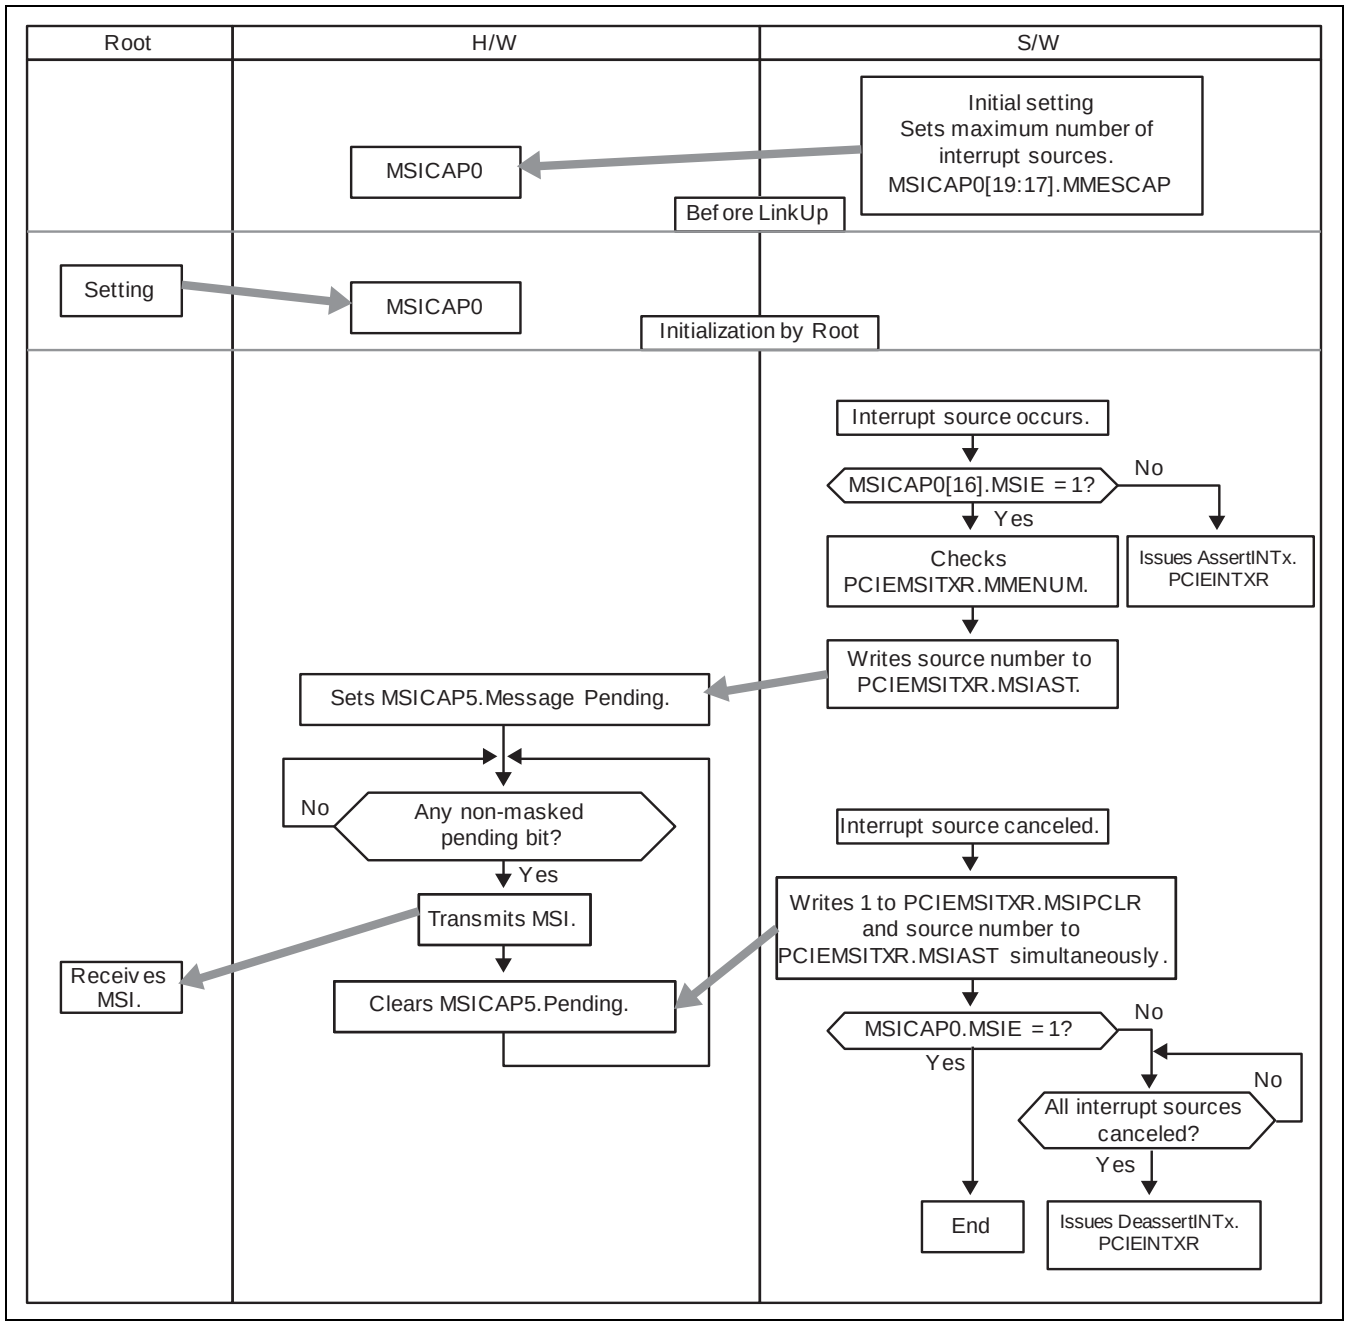

Figure 49.9 MSI Transmission

(6) MSI Reception

MSI can be received only in Root Port mode. The following describes a MSI reception flow.

(a) MSI Interrupt Setting (Root Port)

When this module is used as a Root Port, whether INTx or MSI interrupts are used should be determined during a configuration cycle. If MSI interrupts are selected, the following settings should be performed.

(1) Assigning Interrupt Vectors to Endpoints

Reference the MSICAP0[19:17].MMESCAP of the Endpoint device, and check the number of MSI interrupt vectors required by devices. Based on the result of the checking, the number of vectors to be assigned to the Endpoints is determined so that the number of vectors to be assigned to all devices is 32 or less, the number of vectors assigned to each Endpoint is 1 or greater and less than or equal to the requested number of assignments.

The number of vectors assigned to each Endpoint should be set in the MSICAP0[22:20].MMESE.

(2) Setting Receive Message Address

Specify the address to which the MSI is received to PCIEMSIAUR and PCIEMSIALR and also enable MSI address decoding.

Notes: 1. When there is a switch or bridge between the Endpoint and this module, set the address so that the memory write request to the address specified by the switch or bridge should be routed to the Root Port, or change the address specified by the switch or bridge and set the address so that the memory write request to the address specified by this module should be routed to the Root Port instead.

2. When the specified address falls within the target area, 1DW memory write request to the specified address is not handled as a target transfer, but as an MSI message.

(3) Setting Endpoint Message Address

Set the transmission destination address of the MSI message to MSICAP1[31:2].Lower Message Address and MSICAP2[31:0].Upper Message Address of the Endpoint device.

The transmission destination address of MSI message should be the address set to PCIEMSIAUR and PCIEMSIALR.

(4) Setting Message Data

Set the message data for transmission to the MSICAP3[15:0].Message Data of the Endpoint device.

In the 32-bit MSI vectors supported by this module, bits [12:8] in write data must specify the starting vector number of the MSI vectors assigned to the Endpoint, and all other bits must be cleared to 0. Figure 49.10 shows an example of an MSI message data to be set in an Endpoint.

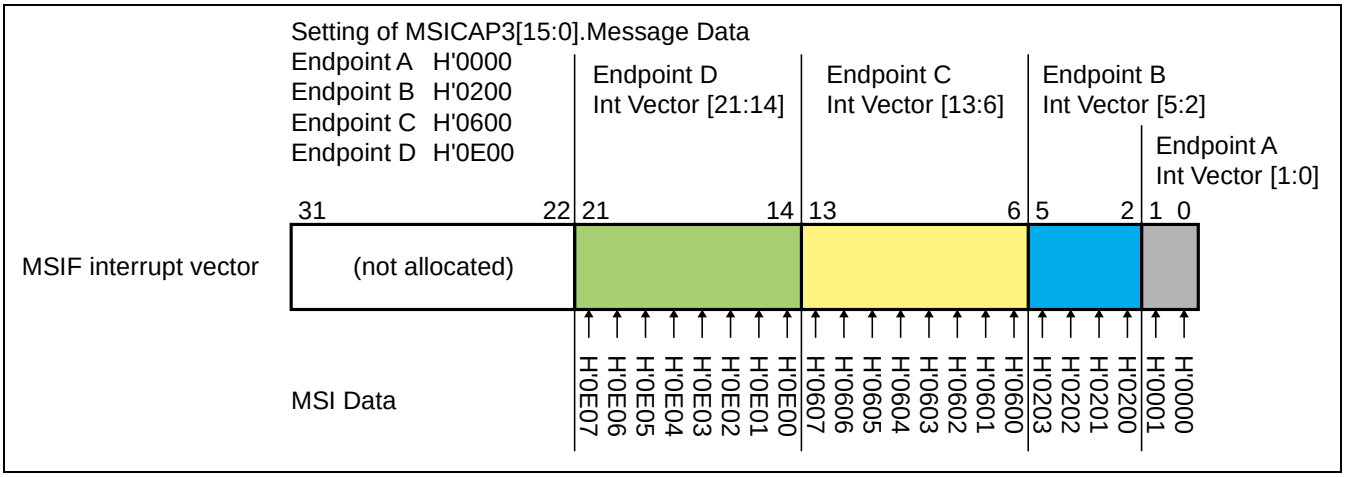

Figure 49.10 MSI Message Data to be Set in Endpoint (an example of setting where Vectors 2, 4, 8 and 8 are allocated to Endpoints A, B, C and D, respectively)

(5) Enabling MSI Interrupts of the Peer Device
Set MSICAP0[16].MSIE of all the devices to 1.

(6) Enabling MSI Interrupts
Set the MSIIE bits.

49.3.4 Overview of Transmission and Reception

PCI Express transfers are classified into two types of requests and one type of completion.

The following three methods are provided for PCI Express transactions. For details on each transfer, refer to the following sections.

1. PIO transfer: A request is issued from the internal bus side to a device on the PCI Express.
2. Target transfer: A request is received by the internal bus side from the PCI Express.
3. DMA transfer: A great quantity of data is automatically written and read between the PCI Express and the internal bus without intervention of the CPU.

Table 49.8 shows the relationship between two types of requests and PCI Express transactions and also shows the transaction issuance methods with this module.

Table 49.8 Relationship between Posted/Non-Posted Requests and PCI Express Transactions

Transaction Type	Transfer Type	Completion	Device Type that can Issue Transaction	Transaction Issuance Method with This Module	Operation
Memory Write	Posted	Not provided	Root Port &Endpoint	PIO, DMA, (MSI Endpoint only)	Data is written to the memory of the communication peer. 1 byte to 4 Kbytes of data not exceeding MPS*1 can be written.
Memory Read	Non-Posted	Provided	Root Port &Endpoint	PIO, DMA	A quantity of data not exceeding MRRS*2 is read from the memory of the communication peer. The read data is returned with a completion separately from this request; no data is included in this request.
I/O Write	Non-Posted	Provided	Root Port only	PIO	Data is written to I/O. Data size is 1 DW. A completion is necessary that indicates whether this request has succeeded.
I/O Read	Non-Posted	Provided	Root Port only	PIO	Data is read from I/O. No data is included. The read data and a completion that indicates whether this request has succeeded are necessary.
Configuration Write	Non-Posted	Provided	Root Port only	PCI Express transfer control register	Configuration write is performed. Data size is 1 DW. A completion is necessary that indicates whether this request has succeeded.
Configuration Read	Non-Posted	Provided	Root Port only	PCI Express transfer control register	Configuration read is performed. No data is included. The read data and a completion that indicates whether this request has succeeded are necessary.
Message	Posted	Not provided	Root Port & Endpoint	Issued by this IP, message transmit register, message transmit module	A message request is transmitted. This is used for power management and interrupt control.

Notes: 1. MPS: Max Payload Size
2. MRRS: Max Read Request Size

In Table 49.8, the transactions for which “Provided” is indicated in the “Completion” column, make a response with a completion. The data returned with a completion differs depending on the transaction. Table 49.9 shows the particulars of the completion contents returned. Specifically, the table shows whether completion data for each type of transactions is included or not, the devices that can issue the transaction, and some other related information.

Table 49.9 Relationship between Completion and PCI Express Transactions

Transaction Type	Completion Data	Device Type that can Issue Transaction	Transaction Issuance Method with This Module	Operation
Memory Read	Included	Root Port & Endpoint	Automatically issued by this module.	Data requested by memory read request and status are returned.
I/O Write	Not included	Root Port only	Automatically issued by this module.	No data is included. Status in response to I/O write is returned.
I/O Read	Included	Root Port only	Automatically issued by this module.	Data size is 1 DW. The read data and a completion that indicates whether this request has succeeded are returned.
Configuration Write	Not included	Root Port only	Automatically issued by this module.	No data is included. Status in response to configuration write is returned.
Configuration Read	Included	Root Port only	Automatically issued by this module.	Data size is 1 DW. The read data and a completion that indicates whether this request has succeeded are returned.

49.3.5 PIO Transfer (Data Transfer from Internal Bus → PCIEC → External Device)

This section describes PIO transfer. PIO transfer here refers to the transfer method to create a PCI Express packet by accessing the memory space assigned to the PCI Express via the internal bus.

(1) Overview of PIO Transfer

PIO transfer is the transfer method with which the device on the internal bus transmits a packet to the PCI Express by writing to (or reading from) the space assigned to the PCI Express. When a write access is made, the written data is stored in the data payload of the PCI Express packet. The maximum data size that can be transmitted equals to the maximum data size of an internal bus packet. The type of the PCI Express packet to be transmitted can be specified using the appropriate setting register and either memory read/write or IO read/write can be selected.

Before starting transfer, it is necessary to set the internal bus space that is transferred to the PCIEC and to set the particulars of the packet to be transmitted. Section (2) describes these settings and section (3) describes specific transfer operations.

(2) Initial Setting of PIO Transfer

The internal bus address cannot unequivocally define one transfer destination since the address space of the PCI Express, which is the transfer destination, is represented with 64 bits. Therefore, the upper address of the PCI Express space is specified using the PCIEC address upper register n ($0 \leq n \leq 3$) and PCIEC address lower register n ($0 \leq n \leq 3$). Set the PCI conversion control register n (PCIEPTCTLRn; $0 \leq n \leq 3$) [31].PARE to indicate that such area setting is valid. Set the PCIEC address upper and lower registers at initial setting.

Table 49.10 shows the PIO transfer control registers. The PCIEC memory areas 0 to 3 are mapped to the PCI memory space or I/O space according to the setting of these registers.

Table 49.10 PIO Transfer Control Registers

PCIEC address upper registers 0 to 3 (PCIEPAUR0 to PCIEPAUR3)	Address (upper 32 bits) of the PCI address space to which the PCIE memory areas 0 to 3 are to be mapped
PCIEC address lower registers 0 to 3 (PCIEPALR0 to PCIEPALR3)	Address (lower 32 bits) of the PCI address space to which the PCIE memory areas 0 to 3 are to be mapped
PCIEC address mask registers 0 to 3 (PCIEPAMR0 to PCIEPAMR3)	Specify the size in the PCIE memory areas 0 to 3 to be mapped to the PCI address space.
PCIEC conversion control registers 0 to 3 (PCIEPTCTLR0 to PCIEPTCTLR3)	Specify whether the PCI space is valid or invalid. Specify the transfer destination space (PCI memory space or PCI IO space). Specify attributes (TC, LOCK, ZLR, and ATTR) for conversion.

Table 49.11 shows the PCI Express memory area addresses on the AXI bus space.

Table 49.11 AXI Bus Space Address Map

Memory Area	Address	Physical Address Size
PCIE0 memory 0	H'00_FE10_0000 to H'00_FE1F_FFFF	1 Mbyte
PCIE0 memory 1	H'00_FE20_0000 to H'00_FE3F_FFFF	2 Mbytes
PCIE0 memory 2	H'00_3000_0000 to H'00_37FF_FFFF	128 Mbytes
PCIE0 memory 3	H'00_3800_0000 to H'00_3FFF_FFFF	128 Mbytes
PCIE1 memory 0	H’00_EE90_0000 to H’00_EE9F_FFFF	1Mbyte
PCIE1 memory 1	H’00_EEA0_0000 to H’00_EEBF_FFFF	2Mbytes
PCIE1 memory 2	H'00_C000_0000 to H'00_C7FF_FFFF	128 Mbytes
PCIE1 memory 3	H'00_C800_0000 to H'00_CFFF_FFFF	128 Mbytes

The following shows the example of mapping the internal bus space to the PCIEC address space.

Example of mapping the internal bus space to the PCIEC address space:

PCIEC address lower register 0[31:0] = H'0000_0000
PCIEC address lower register 1[31:0] = H'5640_0000
PCIEC address lower register 2[31:0] = H'2000_0000
PCIEC address lower register 3[31:0] = H'8000_0000
PCIEC address upper register 0[31:0] = H'0000_0000
PCIEC address upper register 1[31:0] = H'0000_0008
PCIEC address upper register 2[31:0] = H'0000_0000
PCIEC address upper register 3[31:0] = H'F000_0000
PCIEC address mask register 0[31:0] = H'0000_FF80
PCIEC address mask register 1[31:0] = H'001F_FF80
PCIEC address mask register 2[31:0] = H'1FFF_FF80
PCIEC address mask register 3[31:0] = H'1FFF_FF80
PCIEC conversion control register 0[31:0] = H'8000_0100
PCIEC conversion control register 1[31:0] = H'8000_0000
PCIEC conversion control register 2[31:0] = H'8000_0000
PCIEC conversion control register 3[31:0] = H'8000_0000

Figure 49.11 shows an example of mapping the internal bus space to the PCI Express space with the above setting.

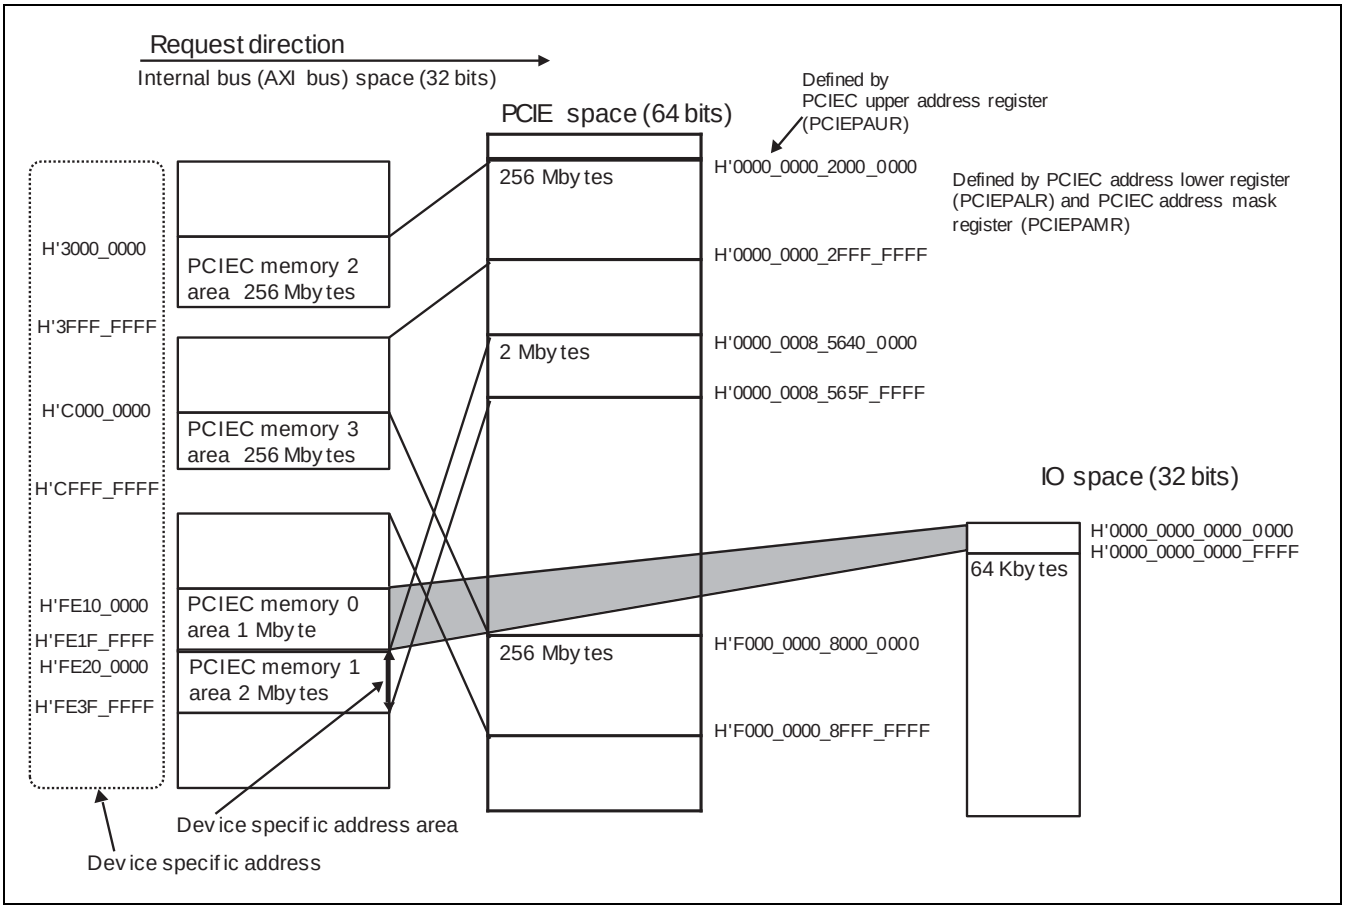

Figure 49.11 Example of Address Mapping for PIO Transfer

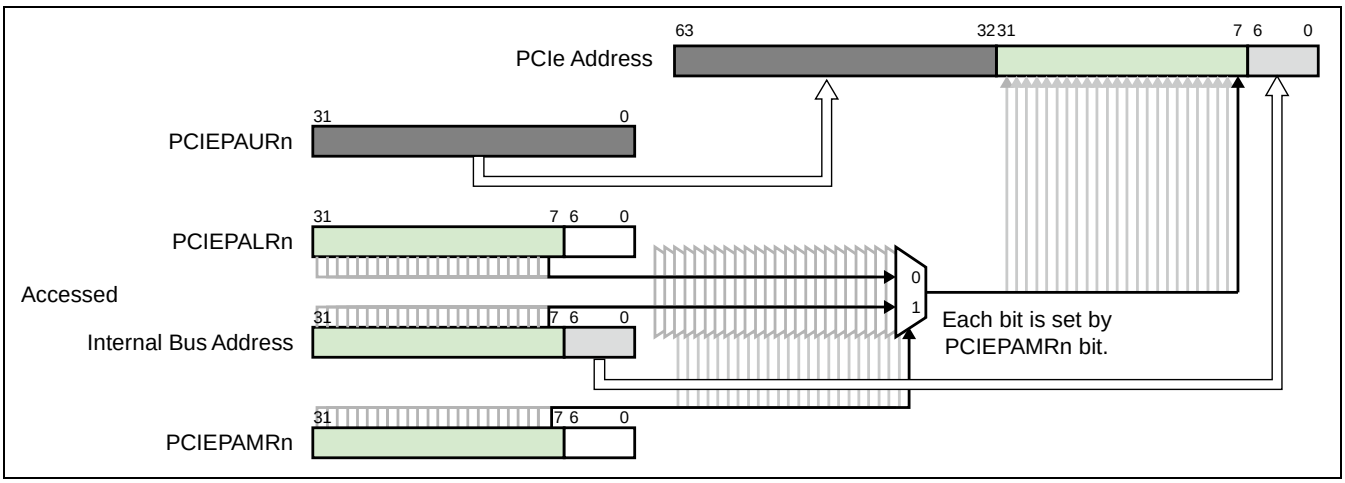

Figure 49.12 Address Translation for PIO Transfer

(3) PIO Transfer Operation

PIO transfer performs memory write/read to the corresponding memory/IO space on the PCI Express from the internal bus side. In reading, a read request is issued to the PCI Express, a completion from the device to be read is converted to data (response), and it is written to the area in the internal bus. Figures 49.13 and 49.14 show write and read operations of PIO transfer, respectively. In the figures, the processes for which “Check the related registers.” is indicated are software-dependent; perform appropriate processing for the application.

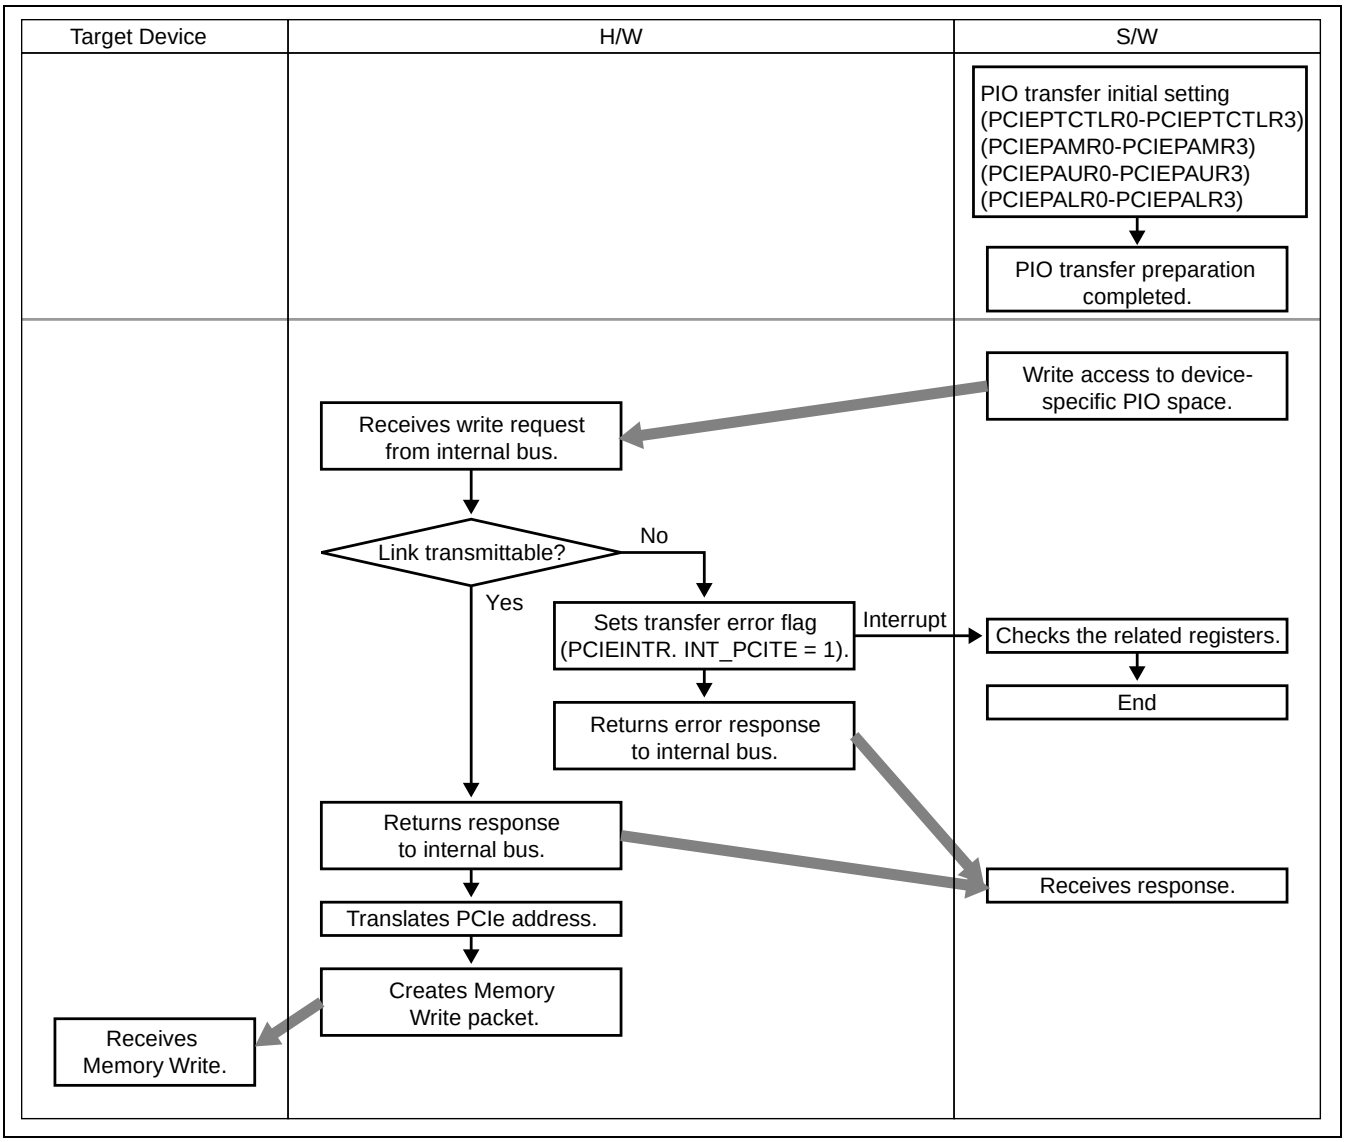

Figure 49.13 PIO Transfer Operation (memory write request)

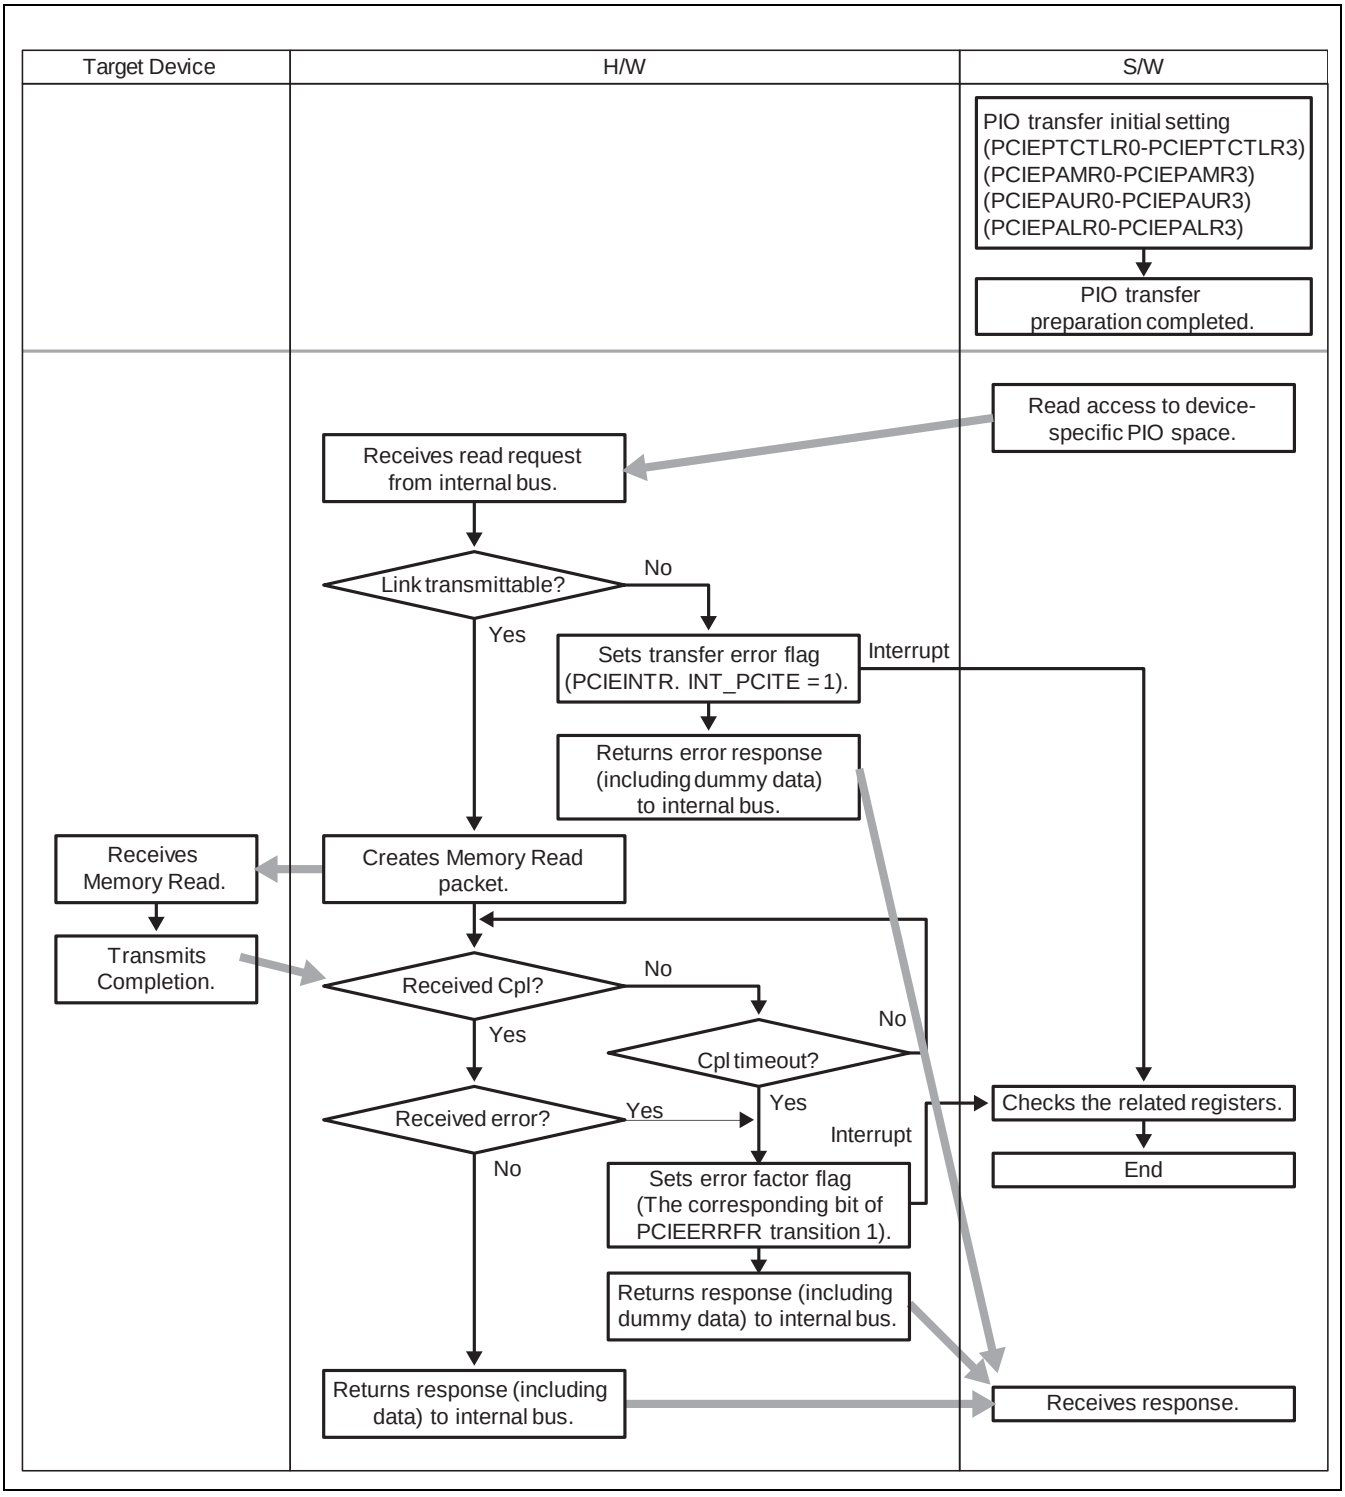

Figure 49.14 PIO Transfer Operation (memory read request)

49.3.6 Target Transfer (Data Transfer from External Device → PCIEC → Internal Bus)

With target transfer, the device on the PCI Express accesses the device on the internal bus of this module through a PCI Express request packet.

(1) Overview of Target Transfer

Using target transfer, the device on the PCI Express can send packets for memory read/write and I/O read/write to read from and write to the area in the internal bus.

In a target transfer, this module can receive packets of any data length less than or equal to the size specified in the MPS (Max Payload Size).

(2) Initial Setting of Target Transfer

The assignment of addresses in the PCI Express space is dynamically determined by the Root Port during a configuration cycle, based on the register settings at initialization. At initialization, the registers are set to specify the parameters such as the sizes of various areas and types of the areas (memory space, I/O space, or the other). When CFINIT is set to 1 and initialization is completed, the initial setting is reflected to BARn (Base Address Register n) of the configuration registers. In Root Port mode, PCIEPRARn is set through software. Here, BAR indicates the area to be released in response to the request from the downstream. In Endpoint mode, the BARn bits of configuration registers are set in the subsequent configuration cycle.

As an area in which memory space is to be allocated, this module supports either 64-bit PCI address space or 32-bit PCI address space (the first 4G area of the 64-bit space). When allocating an area in 32-bit address space, one BARn is used; when allocating an area in 64-bit address space, two contiguous BARn registers (BARn+1/BARn) are used. For this reason, a maximum of three 64-bit address space areas can be allocated.

In I/O space, areas are allocated using one PCIEPRAR or BAR register.

In Root Port mode, set the internal bus side space to be correlated to each of the PCIEPRAR registers in the PCI Express space to the local (internal bus) address registers 0 to 5 (PCIELAR0 to PCIELAR5). Also set the size to be allocated and the space type to the local (internal bus) address mask registers 0 to 5 (PCIELAMR0 to PCIELAMR5). Set these registers before a link is established (before setting CFINIT to 1). Although PCIEPRAR can be modified after a link is established, turn off the Master Enable of the communication peer or take other appropriate measures to prevent issuance of a request to the corresponding area during PCIEPRAR modification.

In Endpoint mode, set the internal bus side space to be correlated to each of the BAR registers in the PCI Express space to the local (internal bus) address registers 0 to 5 (PCIELAR0 to PCIELAR5). Also set the size to be allocated and the space type to the local (internal bus) address mask registers 0 to 5 (PCIELAMR0 to PCIELAMR5). Set these registers before a link is established (before setting CFINIT to 1).

The target transfer area must not be allocated to the internal bus space for the registers of this module or to the internal bus space for PIO transfer.

The following shows the example of mapping the PCI Express address space to the internal bus space.

Example of mapping the PCI Express address space to the internal bus space (Root Port):

Figure 49.15 shows an example of mapping the PCI Express space to the internal bus space (Root Port).

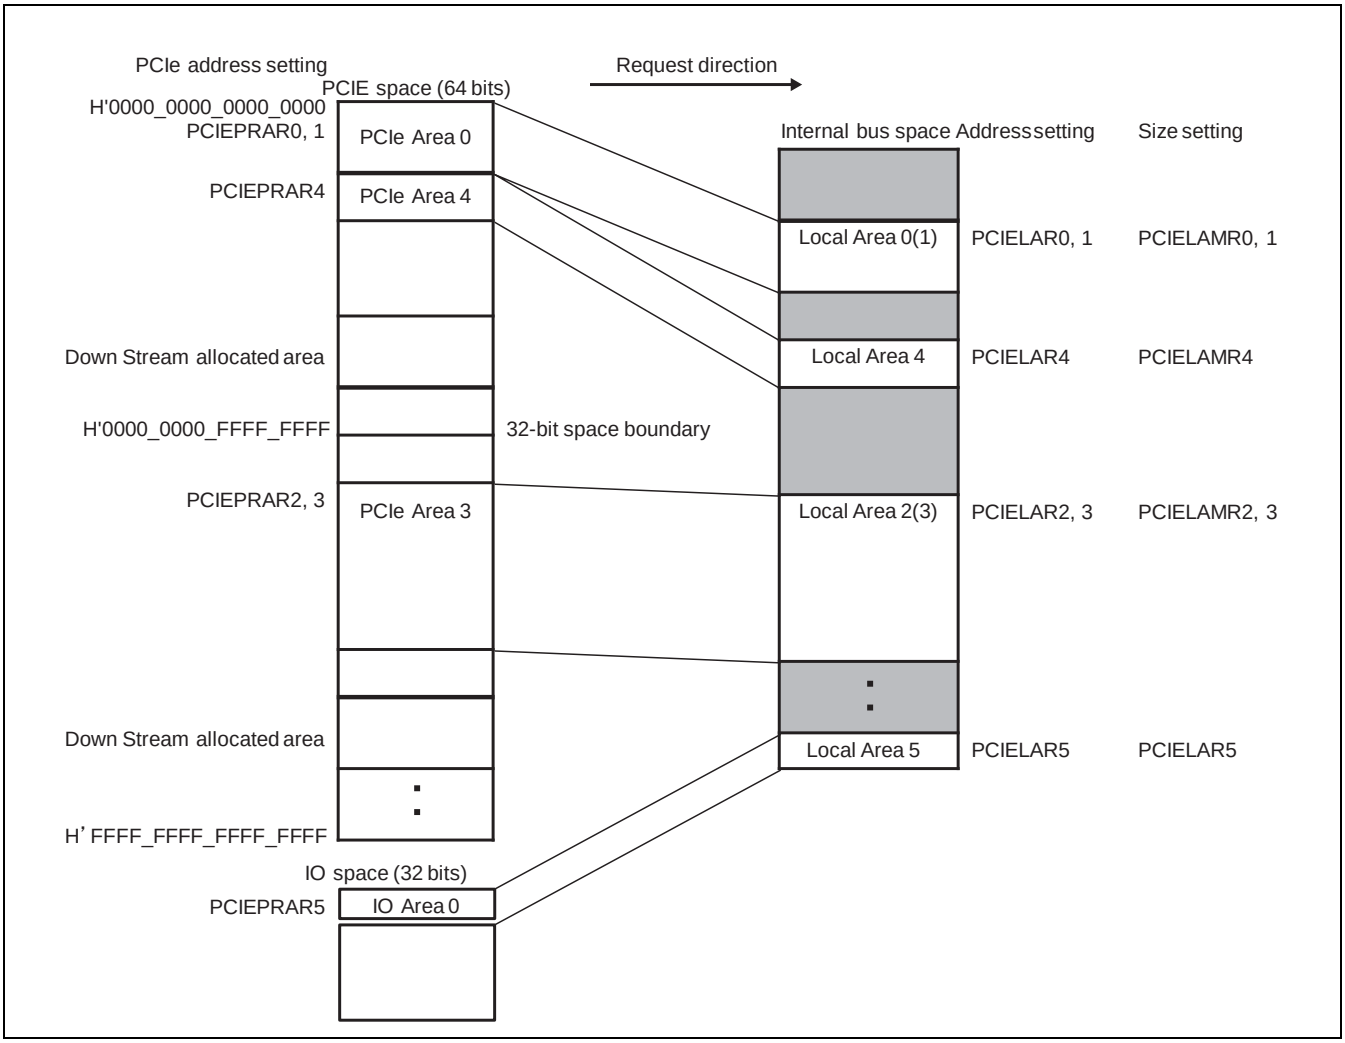

Figure 49.15 Example of Mapping PCI Express Address Space to Internal Bus Space (Root Port)

Example of mapping the PCI Express address space to the internal bus space (Endpoint):

Figure 49.16 shows an example of mapping the PCI Express space to the internal bus space (Endpoint)

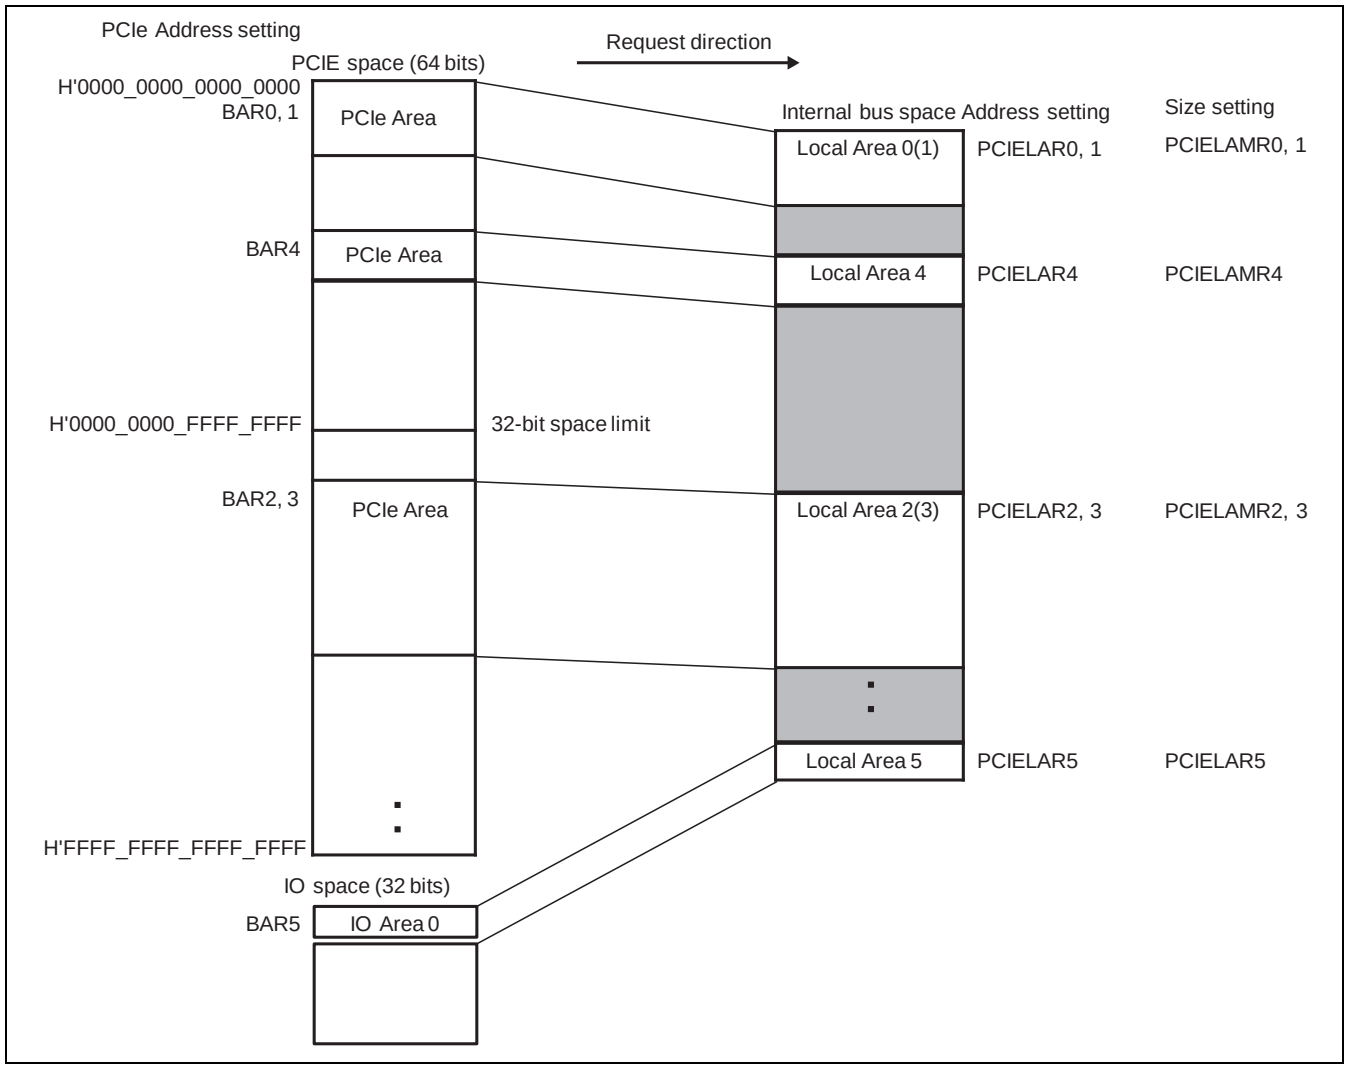

Figure 49.16 Example of Mapping PCI Express Address Space to Internal Bus Space (Endpoint)

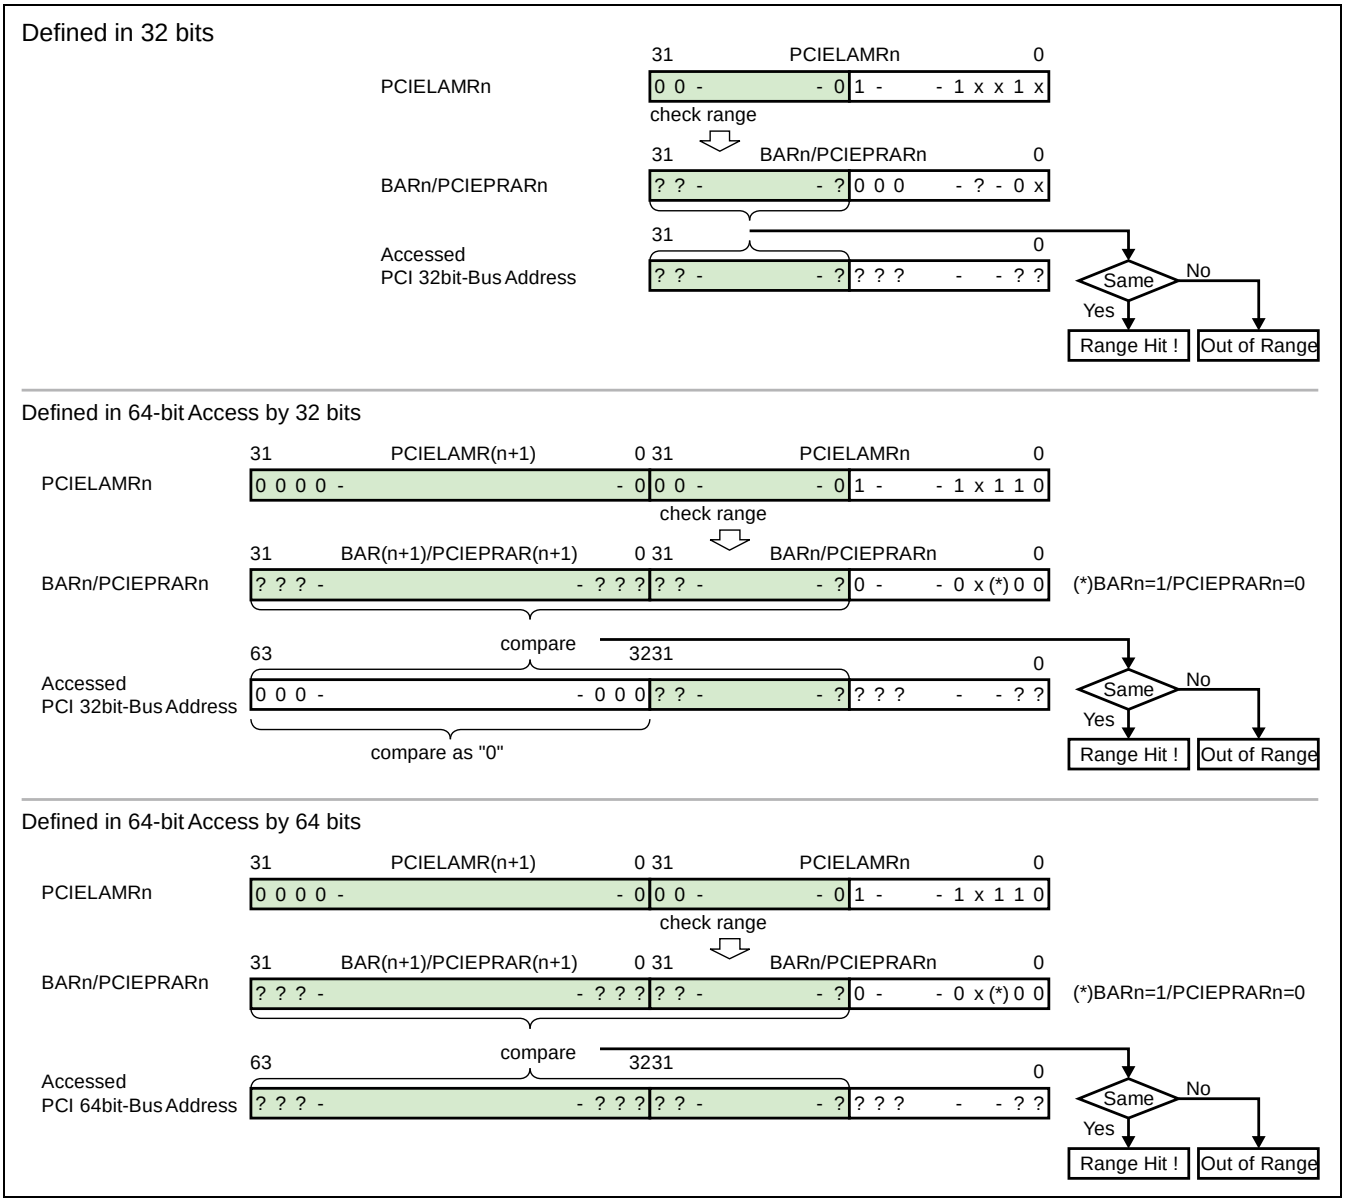

Figure 49.17 Address Comparison for Target Transfer

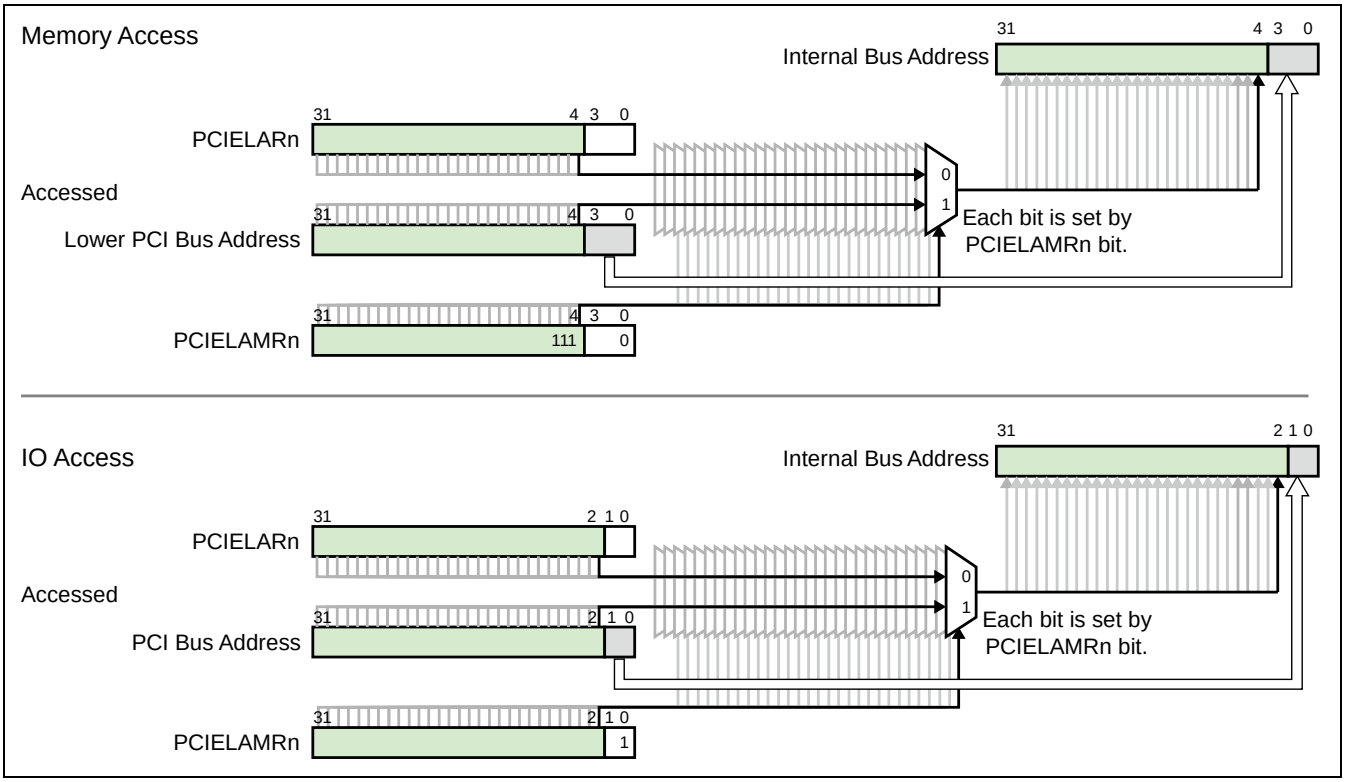

Figure 49.18 Address Translation for Target Transfer

(3) Target Transfer Operation

Figures 49.19 and 49.20 show the target transfer operations to receive a memory write request and the other request, respectively. In receiving a memory write request, the received data is written to the corresponding internal bus address. In receiving the other request, the internal bus is accessed, a completion packet is created and returned (note that when the internal bus is read, all the byte lanes are accessed irrespective of the PCIe space setting (prefetchable or non-prefetchable type) since the internal bus does not have a read strobe).

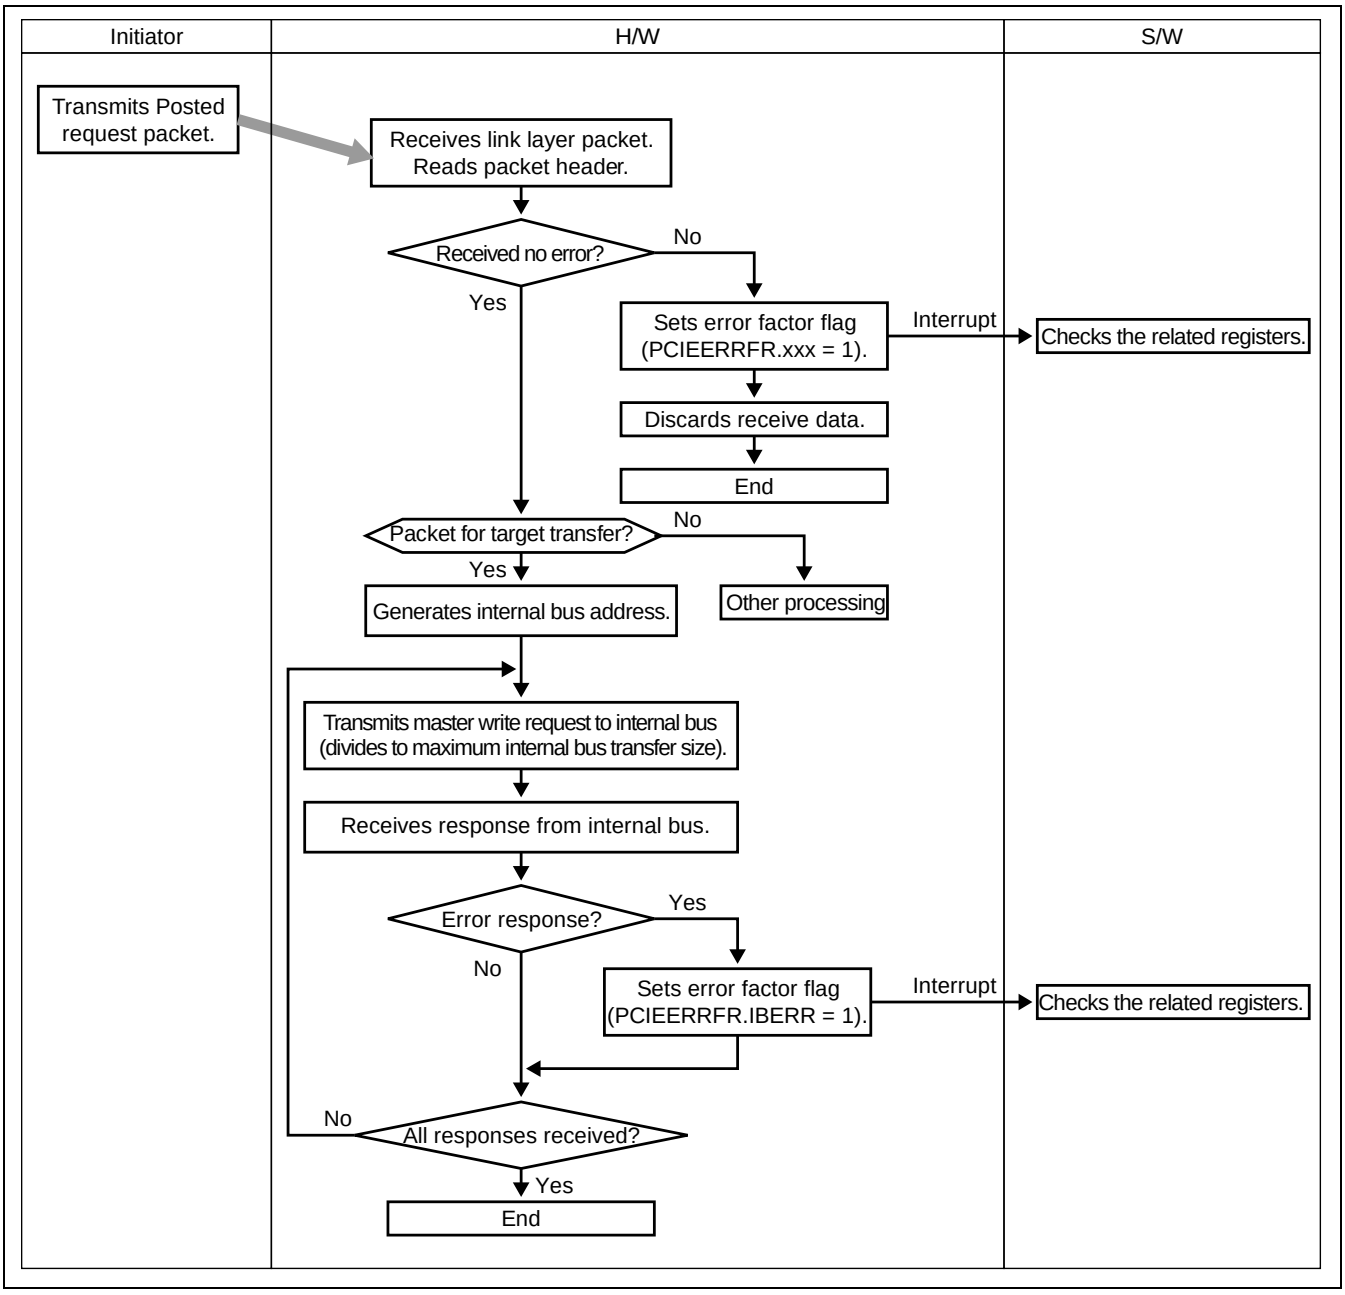

Figure 49.19 Target Transfer (Reception of a Memory Write Request)

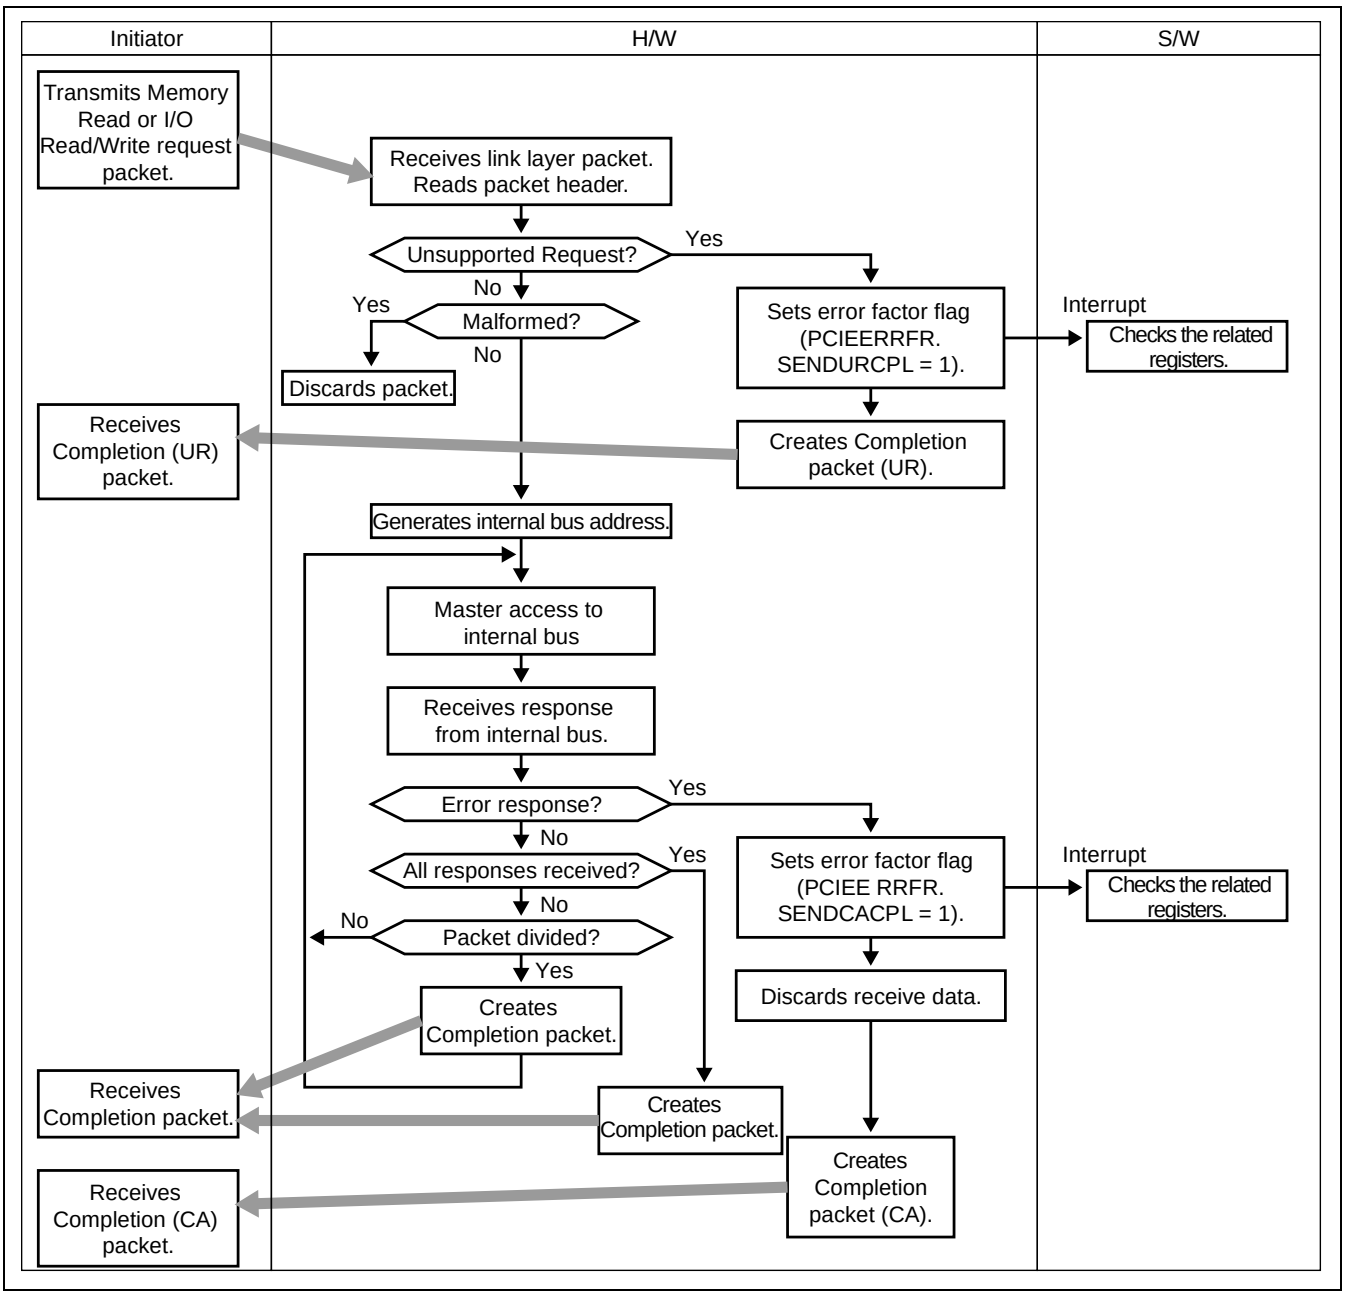

Figure 49.20 Target Transfer (Reception of a Request Other than a Memory Write Request)

49.3.7 DMA Transfer

This section describes the DMA transfer using the DMAC (PCIEC-DMAC) incorporated in this module.

(1) Overview of DMA Transfer

The PCIEC-DMAC enables effective data transfer between the PCI Express and the internal bus area. The PCIEC-DMAC can perform a maximum of 2^{29} count of transfer without intervention of the CPU.

The PCIEC-DMAC supports the command chain function, which allows consecutive execution of multiple transfer commands. With the command chain function, the DMAC-related setting information, such as the addresses of the transfer destination and source and transfer size, is considered as a command; by reading and executing these commands from the memory one by one, consecutive execution of multiple transfer units is provided without intervention of the CPU.

The PCIEC-DMAC has the following features.

- Number of channels: 8 channels
- Address space: PCI Express = 32/64 bits, internal bus = 32 bits
- Transfer data length: PCI Express = 8 to 128 bytes, internal bus = 8 to 128 bytes
- Maximum transfer count: 536,870,912 (2^{29})
- Address mode: Dual address mode
- Transfer request: Started by register control
- Data transfer: Normal mode (continuous transfer), command chain
- Priority: Either channel priority fixed mode or round-robin mode selectable
- Interrupt request: Interrupts can be requested to the INTC when a data transfer has completed or an error has occurred.

(2) Initial Setting of DMA Transfer

Set the PCI Express and internal bus addresses, byte count, transfer end interrupt. When the command chain is not used, set the PCIEDMCHCRn.CCE to 0. In the DMA transfer (internal bus side), access to the internal bus space for the registers and access to the internal bus space for PIO transfer are prohibited.

(3) DMA Transfer Operation

DMA transfer can be initiated by simultaneously setting the transfer direction and enabling the channels with PCIEDMCHCRn. Transfer end is detected by confirming PCIEDMCHSRn[0].TE = 1 or detecting a transfer end interrupt. After transfer is ended, transfer is completed by setting PCIEDMCHCRn[31].CHE to 0. Simultaneously, PCIEDMCHSRn[0].TE is set to 1 to clear this bit.

Figure 49.21 and 49.22 show DMA transfer from the internal bus to the PCI Express space and from the PCI Express space to the internal bus, respectively.

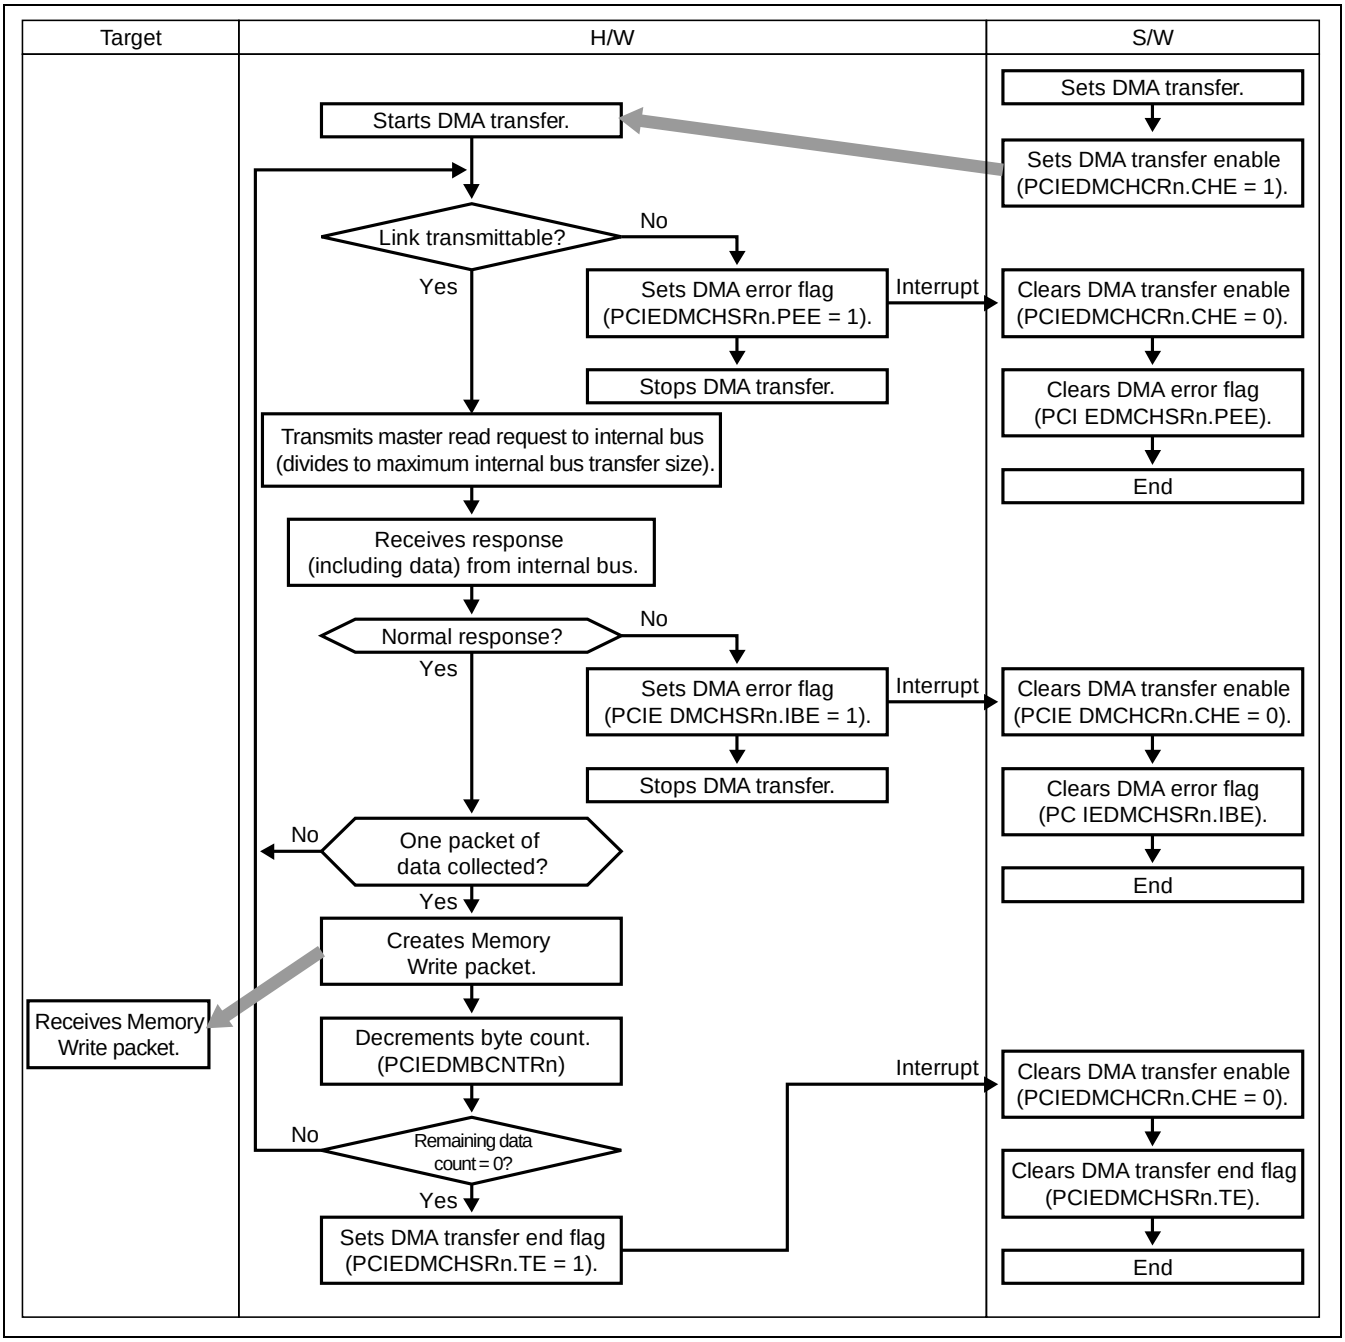

Figure 49.21 DMA Transfer (Internal Bus → PCI Express)

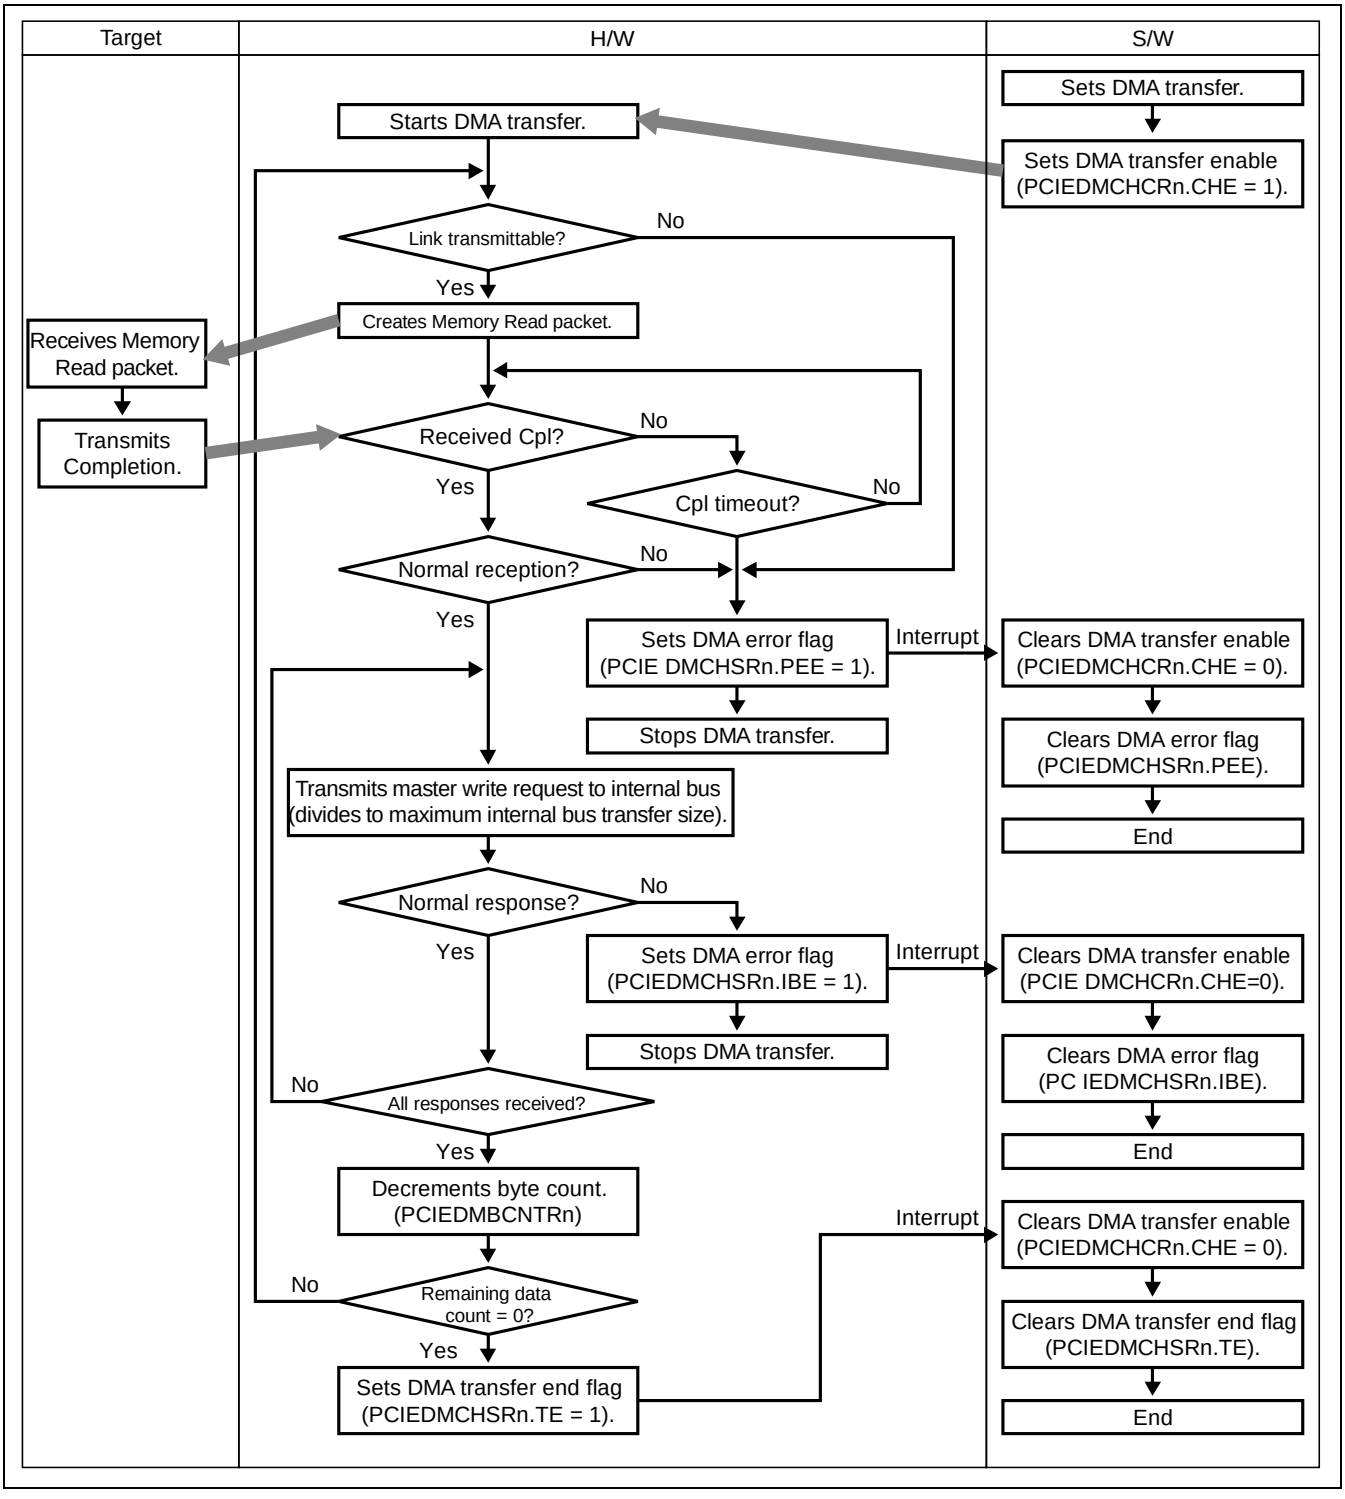

Figure 49.22 DMA Transfer (PCI Express → Internal Bus)

(4) DMA Channel Priority

When more than one DMA channel is used simultaneously, they are actually used according to the priority described in this section. The priority can be set with the PCIEDMAOR register. Set the relevant bit at the same time as setting PCIEDMAOR.DMAE to 1.

The channel priority is initialized to CH0 > CH1 > CH2 > CH3 > CH4 > CH5 > CH6 > CH7 while PCIEDMAOR.DMAE = 0.

(a) Arbitration Timing between DMA Channels

Arbitration is performed every transfer unit (128 bytes max.) of the DMA channel currently transferring data.

(b) Fixed Mode

When PCIEDMAOR.ABT is 0, the priority is fixed to the default setting.

(c) Round Robin Mode

When PCIEDMAOR.ABT is 1, round robin scheduling is applied to all the channels to determine the priority. When a certain channel completes transfer, the channel is given a bottom priority and the channels that have been given a lower priority than that channel are given a higher priority as shown in Figure 49.23.

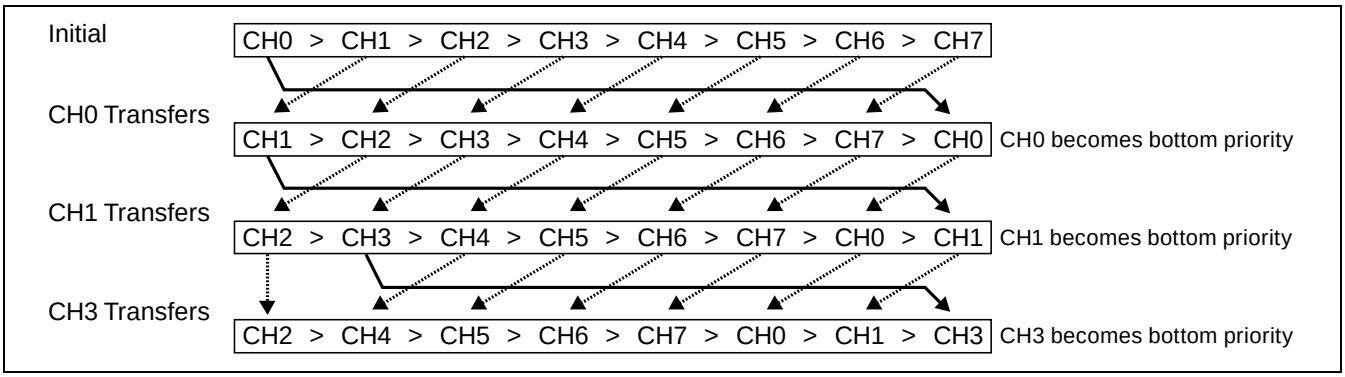

Figure 49.23 Round Robin Scheduling among All the Channels

(5) Dividing Packet at Address Boundary

If the PCI Express side address or internal bus address of a packet crosses the 4-Kbyte boundary, the packet is divided.

(6) Command Chain

(a) Overview of Command Chain Operation

A command chain allows this module to continuously execute multiple DMAC commands. A DMAC command refers to a set of information related to the PCIEC-DMAC transfer; that is, the information specified by PCIEDMPALRn, PCIEDMPAURn, PCIEDMIARn, PCIEDMBCNTRn, PCIEDMCCARn, and PCIEDMCHCRn. As well as in the PCIEC-DMA control register, the information can also be set in the memory in the format shown in Figure 49.24. With the command chain, each time a DMAC command execution is completed, the next DMAC command is read from memory and the content of the DMAC command is written to the relevant PCIEC-DMA control register, which allows execution of the DMAC command.

By specifying the next DMAC command in the DMAC command to be read, a command chain is created and thus data can be transferred consecutively.

During command chain operation, a DMAC command is read from the memory address indicated by PCIEDMCCARn and the content of the read command is written to the register of the relevant channel to execute the command. If the CCE bit in the read DMAC command is 1, the next command is read from memory again and executed upon completion of the current command. If the CCE bit in the read DMAC command is 0, completion of the command completes the command chain operation.

(b) Initial Setting of Command Chain

To start a command chain on a channel, enable the channel while PCIEDMCHCRn.CCE is set to 1. Before starting a command chain, store a chain of DMAC commands in a memory location accessible from the internal bus, and set the address of the first DMAC command in PCIEDMCCARn.

Note: As the setting (information) of the first transfer of the command chain, the information in the memory specified with PCIEDMCCARn is used; the setting in the PCI Express-DMA control registers is not used (here, any setting other than PCIEDMCCARn is ignored).

(c) DMAC Command Format

Figure 49.24 shows the format of DMAC commands to be stored in memory. Set each field of the commands as described below and store such commands.

- CHE field: Always set 1.
- CCE field: Set 0 for the command to be executed last; set 1 for the other commands.
- CCA field: Set 0 in all the bits for the command to be executed last; set the address of the next command for the other commands.
- Reserved field: Always set 0.

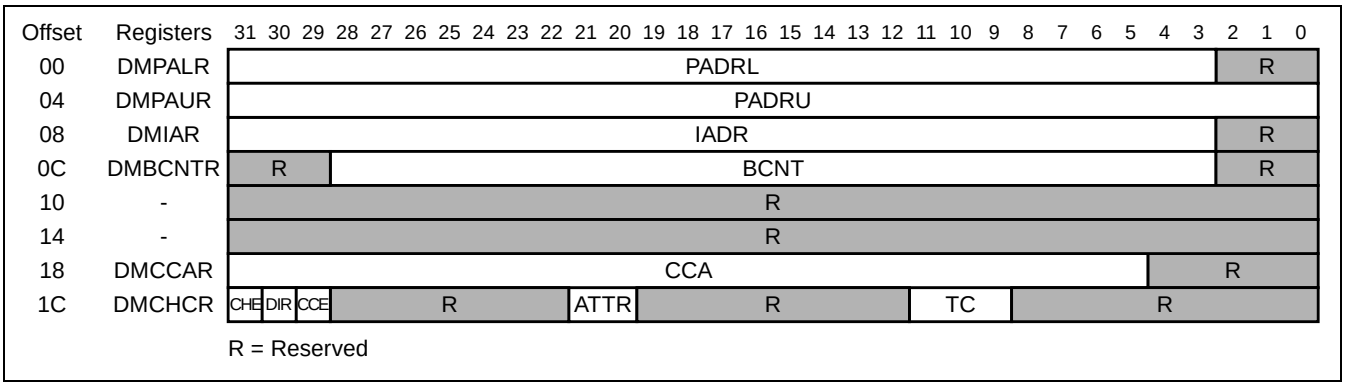

Figure 49.24 Formats of DMAC Commands

(d) Channel Priority for Command Read

While the command chain operation is in progress on multiple DMA channels, DMAC command read requests are issued from the multiple DMA channels; here, round robin scheduling is applied to all the channels to determine the priority (refer to section 49.3.7 (4)(c), Round Robin Mode).

Note: The channel priority here is different from the priority of the DMA transfer operation specified with PCIEDMAOR.

The channel priority is initialized to CH0 > CH1 > CH2 > CH3 > CH4 > CH5 > CH6 > CH7 while PCIEDMAOR.DMAE = 0.

(7) Notes on DMA Transfer

(a) Handling upon DL_Down / DL_Active

If a DL_Down occurs during DMA transfer, it is handled as a transfer error on the PCI Express side and thus transfer is ended after PCIEDMCHSRn.PEE is set. However, if a request is being made to the internal bus when a DL_Down occurs, a response to the request is first received and then flag is set and transfer is ended. Therefore, not all the operations are stopped immediately after a DL_Down.

When returned from a DL_Down to DL_Active, first read PCIEDMAOR.DMAACT = 0 to confirm that all the channels that have been operating before DL_Down have stopped operating, and then re-set DMA and perform transfer again.

49.3.8 Transfer Priority

This section describes the transfer priority.

(1) Arbitration (Transmission to PCI Express)

Accesses to transmit packets to the PCI Express include: DMA transfer, response processing to target transfer, PIO transfer, and Message transfer. The DMAC and the modules controlling PIO transfer output posted and non-posted requests, respectively.

Arbitration between these accesses is performed according to the priority shown below.

(High priority)
- Completion of target transfer (configuration)
- Completion of target transfer (memory, IO)
- PIO transfer (configuration, memory read, IO)
- PIO transfer (memory write)
- Various messages
- DMA transfer (memory read)
- DMA transfer (memory write)

(Low priority)

(2) Arbitration (Reception from PCI Express)

The completion receiver and request receiver receive packets from the PCI Express and make reception access requests.

Arbitration between these accesses is performed according to the priority shown below.

(High priority)
- PCIEC completion receiver
- PCIEC request receiver

(Low priority)

The PCIEC link of this module, which processes the PCIe protocol, processes packets received from the PCI Express one by one in order of reception. After that, the processed packets are sequentially distributed to the target receiver, DMA receiver, message receiver, and PIO receiver according to the type of the received packet and then processed one by one there. If the receiver corresponding to the processing target is waiting for a certain process to be completed (for example, waiting for a request to the internal bus or a response), the PCIe link starts the next reception process after completion of the process. Until completion, the next packet is suspended from being processed.

(3) PCI Express Transmit/Receive Ordering

The following describes the transaction ordering rules of this module.

Table 49.12 shows the transmit transaction ordering rules of this module.

Table 49.12 Transmit Transaction Ordering Rules of This Module

Row Pass Column	1st Posted	1st Non-Posted	1st Completion
2nd posted	No	Yes	Yes
2nd non-posted		No	Yes
2nd completion		Yes	No

Note: Yes: The second transaction can pass the first transaction.
No: The second transaction cannot pass the first transaction.

Table 49.13 shows the receive transaction ordering rules of this module.

Table 49.13 Receive Transaction Ordering Rules of This Module

			1st Transaction					
			Request					
			Posted	Non-Posted			Completion	
Row Pass Column			Memory Write/Message	Memory/ IO Read	IO Write	Configuration Write/Read	Read/Write	Memory Read (DMA)
2nd trans-action	Posted	Memory write/message	No*	Yes	Yes	Yes	Yes	Yes
	Non-posted	Memory/IO read	No	Yes	No	Yes	Yes	Yes
		IO write request	No*	Yes	No	Yes	Yes	Yes
		Configuration write/read	No	Yes	Yes	No	Yes	Yes
	Comple-tion	Read/write	Yes	Yes	Yes	Yes	No	Yes
		Memory read (DMA)	Yes	Yes	Yes	Yes	Yes	No

Notes: Yes: The second transaction can pass the first transaction.
No: The second transaction cannot pass the first transaction.
* For Memory/IO Write, the second request cannot pass the first request if they are issued to the same BAR space; the second request may pass the first request if issued to the different BAR spaces. For a combination of Memory Write and Message, the second request may pass the first request.

This module applies the ordering rules conforming to the standard to the transmission and reception sides. According to the rules, some packets cannot be passed by (to prevent an undesired influence on the order of sequential processing and such). Therefore, depending on the packet transfer order or combination, processing of a packet may be delayed until the previous packet processing is completed.

(4) Arbitration (Bus Master Request)

Accesses to output a master write request to the internal bus include: DMA transfer, target transfer, and message transfer.

Arbitration between these accesses is performed according to the priority shown below.

(High priority)
- Target transfer (reception of memory write and IO write)
- DMA transfer (reception of completion for memory read)

(Low priority)

Accesses to output a master read request to the internal bus include: DMA transfer, target transfer, and message transfer.

Arbitration between these accesses is performed according to the priority shown below.

(High priority)
- Target transfer (reception of memory read and IO read)
- DMA (command read)
- DMA (transmission of memory write)

(Low priority)

49.3.9 Link Function

(1) Changing Speed

The PCI Express 2.0 standard allows changing of the transfer speed intentionally or to handle the problem related to the link reliability. Figure 49.25 shows a flow of changing the transfer speed to 5.0 GT/s.

- Allow the factor of speed change to be generated while speed change is enabled. (According to the PCI Express 2.0 standard, if speed change is attempted by itself and ends in failure, starting of speed change by itself is prohibited for 200 ms.)
- If speed change is attempted while another speed change is in progress, it is impossible to know which speed change factor is used for judging the end of speed change. For reliable judgment of the end of speed change, do not make any attempt to change a speed during another speed change. (MACCTLR.SPCHG == 0 and MACSR.SPCHGFIN == 0 indicate that speed change has not been set or speed change processing is not in progress.)

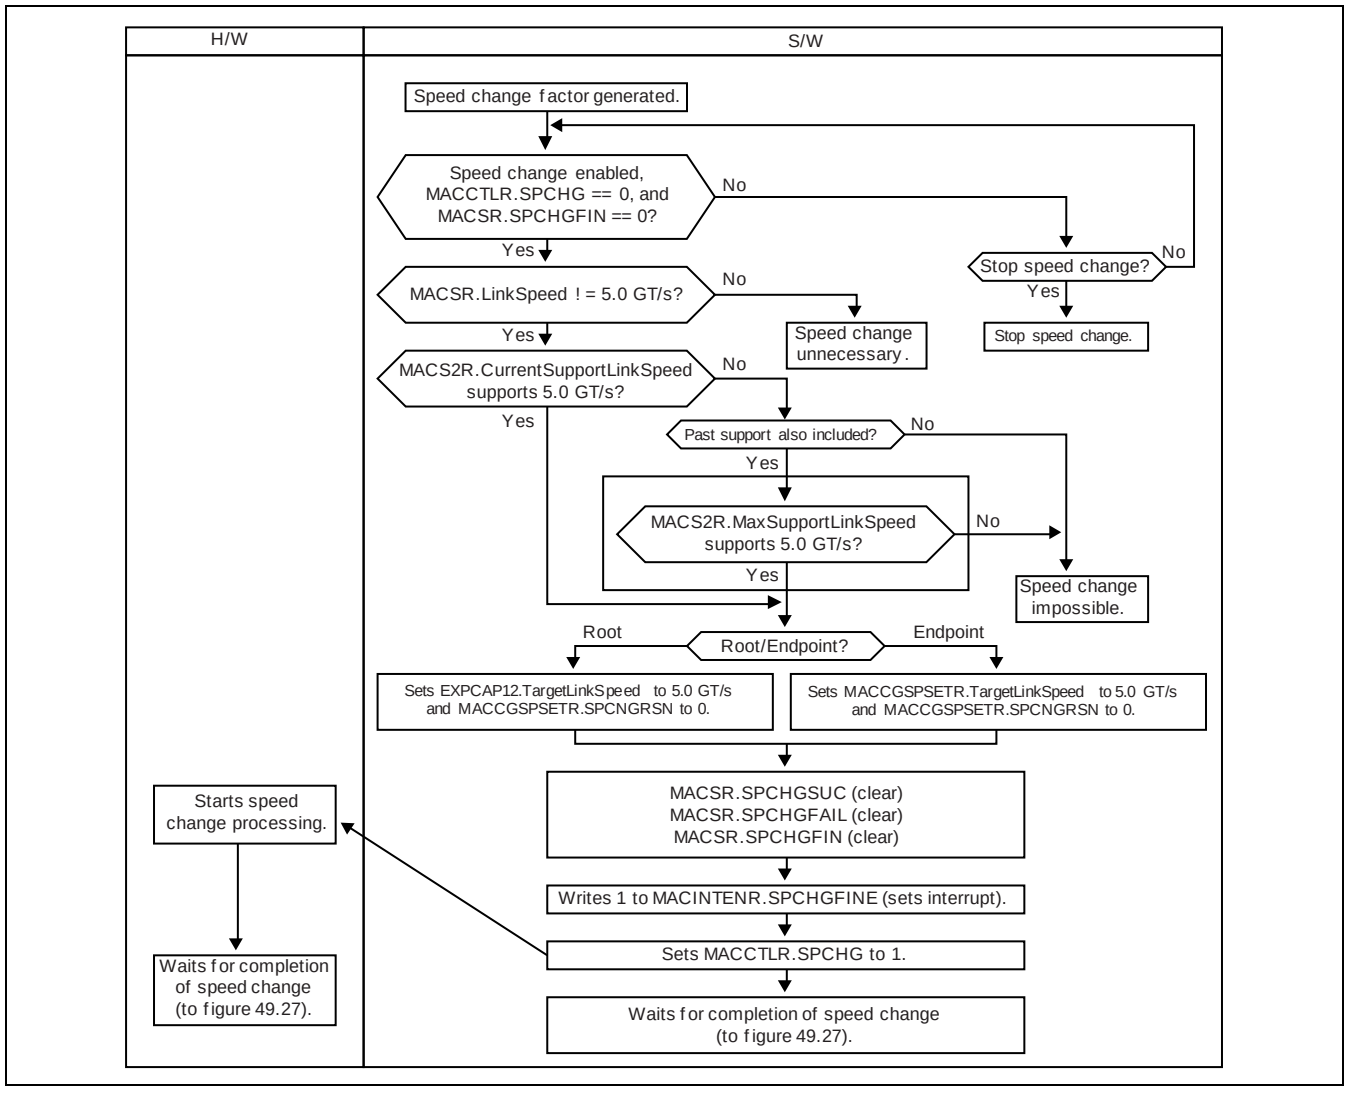

Figure 49.25 Changing Speed to 5.0 GT/s

Figure 49.26 shows a flow of changing the transfer speed to 2.5 GT/s.

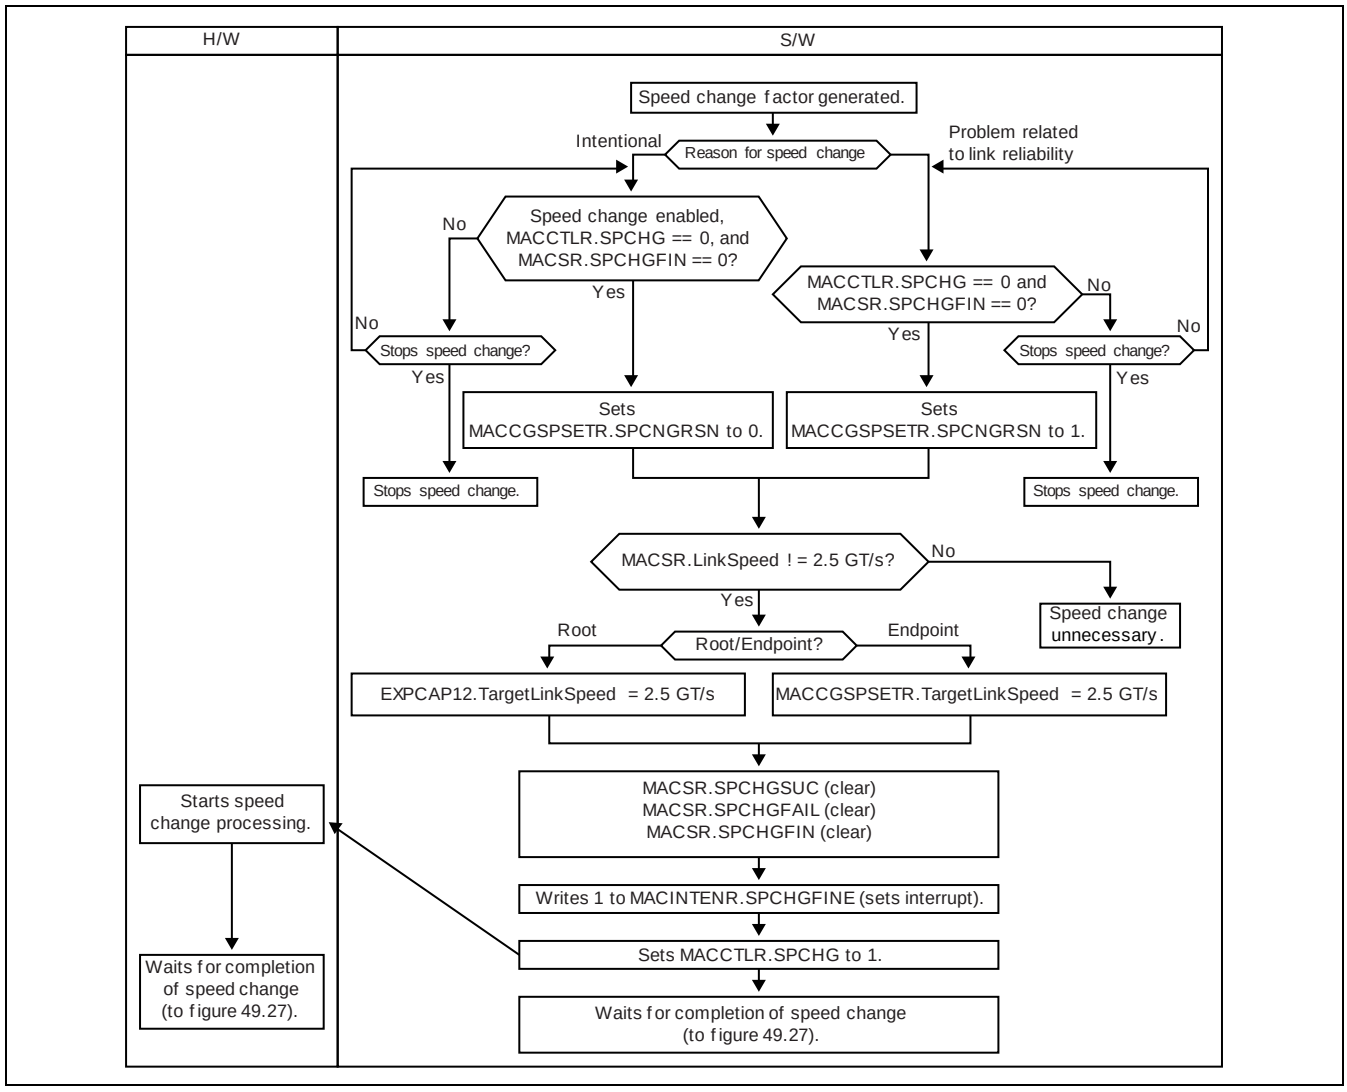

Figure 49.26 Changing Speed to 2.5 GT/s

Figure 49.27 shows a flow of the ending process for the transfer speed change.

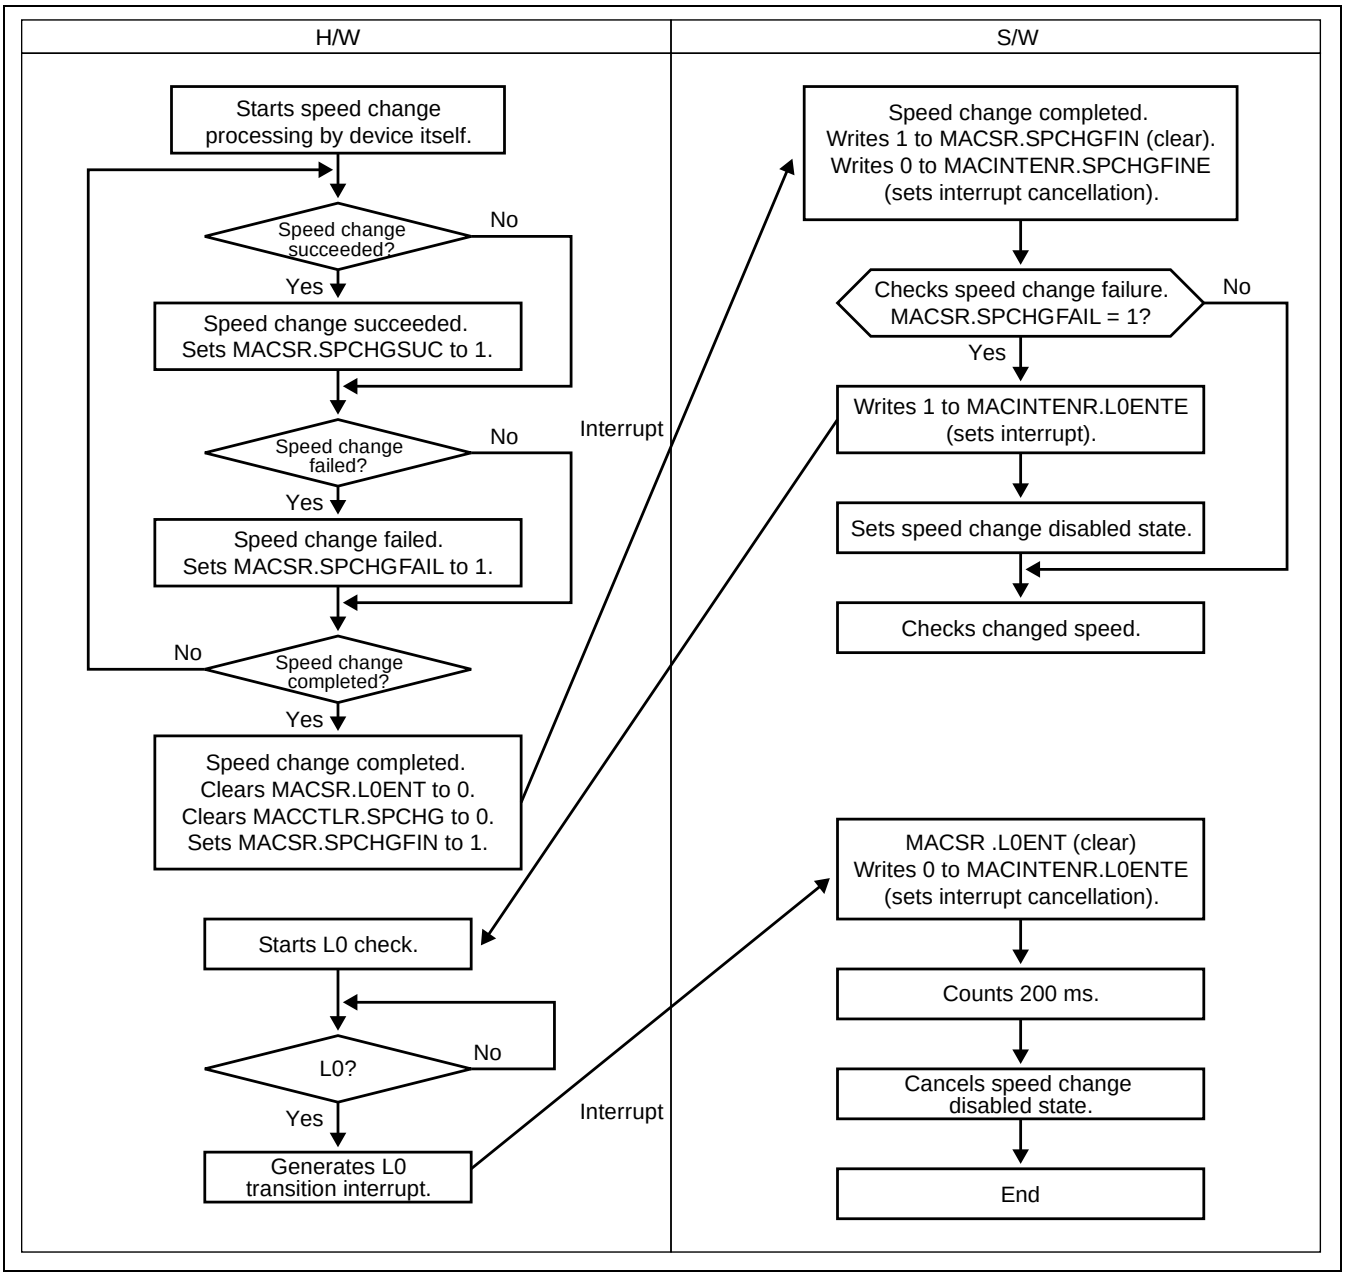

Figure 49.27 Ending Process of Speed Change

49.3.10 Power Management

This section describes power management of this module. This module has two power management modes below.

- PCI-PM
- ASPM (L0s)

PCI-PM is PCI-compatible and ASPM is specific to PCI Express. ASPM mode supports L0s only.

(1) PCI-PM

This section describes PCI-compatible power management mode. Table 49.14 shows power management operations in PCI-PM mode.

Table 49.14 PCI-PM Operations

No.	Transition	Target Device
1	L0 → L1 → L0	Endpoint
2		Root port

(a) L0 → L1 → L0 (Endpoint)

After modification of the Power State field, initiate the L1 transition sequence through software according to the flowchart shown in Figure 49.28.

After initiated through software, the L1 transition sequence is performed through hardware according to the following procedure.

1. Prepares for L1 transition.
2. Processes the handshake with the peer device for L1 transition.
3. Causes the LTSSM of this module to make an L1 transition.

- Triggered by a write of PMCTLR.L1IATN = 1, hardware initiates the L1 transition sequence. As preparation for causing L1 transition, this module first allows hardware to automatically perform the following. (1) Waits for the minimum amount of credits to be accumulated necessary to transmit the largest TLP for which all the types of credits are configured. (2) Waits for the retry buffer to be empty. (3) Waits for all the TLP to be transmitted.
- After completion of the above preparation, this module transmits PM_Enter_L1 DLLP and receives PM_Request_Ack DLLP to process the handshake with the peer device for L1 transition.
- After completion of the handshake for L1 transition, this module disables TLP/DLLP transmission and directs the LTSSM to make a transition to L1. If directions are given to make a transition to the detect or recovery state before the LTSSM completes L1 transition, this module gives priority to a transition to the detect or recovery state.
- Hardware clears the PMCTLR.L1IATN bit to 0 when the LTSSM makes a transition to the state other than L0, recovery, and configuration, that is, when the LTSSM makes a transition to L1 (PMSR.PMSTATE = L1) properly or LDn (PMSR.PMSTATE = LDn). Simultaneously, the PMSR.L1FAEG bit is set. Software can confirm that TLP write is again enabled and the transition destination by reading PMSR.L1FAEG = 1 and PMSR.PMSTATE. After confirming PMSR.L1FAEG = 1, write 1 to PMSR.L1FAEG to clear the bit.
- After initiation of the L1 transition sequence, if transitions are made as L0 → recovery → L0 or L0 → recovery → configuration → L0 before a transition to the L1 state is caused, hardware automatically initiates the L1 transition sequence again. Therefore, software has nothing to process. PMSR.L1FAEG is not set.

The sequence for a recovery from L1 is performed under the following conditions.

1. Cases in which recovery is initiated by this module itself (caused by software)

   Software gives directions to transmit the PM_PME message to prepare for communication again; or an error message is transmitted through software processing.

The message of the error caused by the PM_PME message is scheduled for transmission by software when the PM_PME message transmission is supported. Be sure to confirm that a transition to L1 has been properly made (PMSR.L1FAEG = 1 and PMSR.PMSTATE = L1) before scheduling.

2. Cases in which recovery is initiated by the peer

   The receive lane becomes no longer electrically idle.

   Typical example: The peer issues D0 configuration write for recovery and makes a transition to recovery itself.

3. Cases in which recovery is initiated by this module itself (caused by hardware)

   An error message is transmitted through hardware processing.

   Depending on the timing, an error message is transmitted after L1 transition and a recovery may be made.

   A completion of the TLP received before L1 transition is transmitted.

After a recovery to L0, if the device is in the non-D0 state and there is no TLP to be transmitted, software should confirm that hardware is in the L0 state (PMSR.PMSTATE = L0) and initiate the L1 transition sequence again (write 1 to PMCTLR.L1IATN). In this case, the sequence is: L0 → L1 → L0 recovery → L1 again.

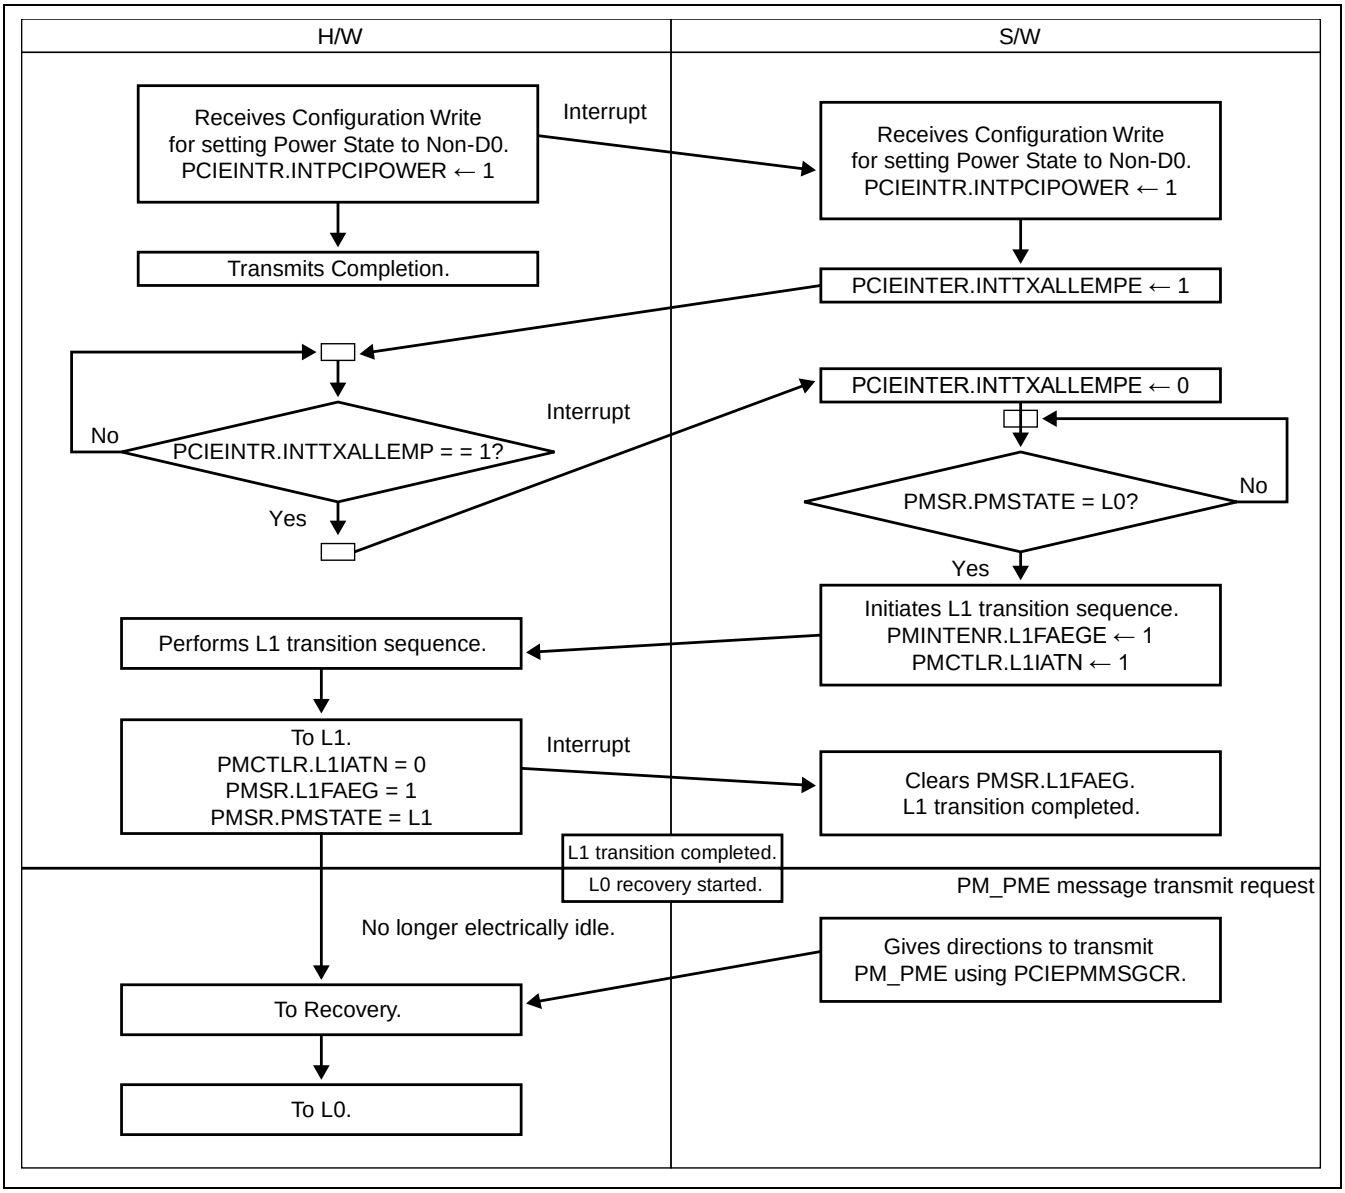

Figure 49.28 Transition from L0 to L1 to L0 (Endpoint)

(b) L0 → L1 → L0 (Root Port)

Initiate the L1 transition sequence through software according to the flowchart shown in Figure 49.29.

After initiated through software, the L1 transition sequence is performed through hardware according to the following procedure.

1. Prepares for L1 transition.
2. Processes the handshake with the peer device for L1 transition.
3. Causes the LTSSM of this module to make an L1 transition.

- Triggered by a write of PMCTLR.L1IATN = 1, hardware initiates the L1 transition sequence. As preparation for causing L1 transition, this module first allows hardware to automatically perform the following. (1) Waits for the retry buffer to be empty. (2) Waits for all the TLP to be transmitted.
- After completion of the above preparation, this module transmits PM_Request_Ack DLLP and receives the electrical idle ordered set to process the handshake for L1 transition.
- When having received the electrical idle ordered set on any lane, this module disables TLP/DLLP transmission. If directions are given to make a transition to the Detect or Recovery state before disabling TLP/DLLP transmission, this module gives priority to a transition to the Detect or Recovery state.
- After completion of the handshake for L1 transition, this module directs the LTSSM to make a transition to L1 and transmits the electrical idle ordered set.
- Hardware clears the PMCTLR.L1IATN bit to 0 when the LTSSM makes a transition to the state other than L0, Recovery, and Configuration, that is, when the LTSSM makes a transition to L1 (PMSR.PMSTATE = L1) properly or LDn (PMSR.PMSTATE = LDn). Simultaneously, the PMSR.L1FAEG bit is set. Software can confirm that TLP write is again enabled and the transition destination by reading PMSR.L1FAEG = 1 and PMSR.PMSTATE. After confirming PMSR.L1FAEG = 1, write 1 to PMSR.L1FAEG to clear the bit.
- After initiation of the L1 transition sequence, if transitions are made as L0 → Recovery → L0 or L0 → Recovery → Configuration → L0 before a transition to the L1 state is caused, hardware automatically initiates the L1 transition sequence again. Therefore, software has nothing to process. PMSR.L1FAEG is not set.

The sequence for a recovery from L1 is performed under the following conditions.

1. Cases in which recovery is initiated by this module itself

   Software performs configuration write to transmit TLP again.

   The request for configuration write is scheduled for transmission by software. Be sure to confirm that a transition to L1 has been properly made (PMSR.L1FAEG = 1 and PMSR.PMSTATE = L1) before scheduling.
2. Cases in which recovery is initiated by the peer

   The receive lane becomes no longer electrically idle.

   Typical example: The Endpoint issues a PME message for requesting a recovery itself and the peer makes a transition to Recovery.

After a recovery to L0, if the device is in the Non-D0 state and PM_Enter_L1 DLLP is transmitted from the downstream device, software should confirm that hardware is in the L0 state (PMSR.PMSTATE = L0) and initiate the L1 transition sequence again (write 1 to PMCTLR.L1IATN). In this case, the sequence is: L0 → L1 → L0 recovery → L1 again.

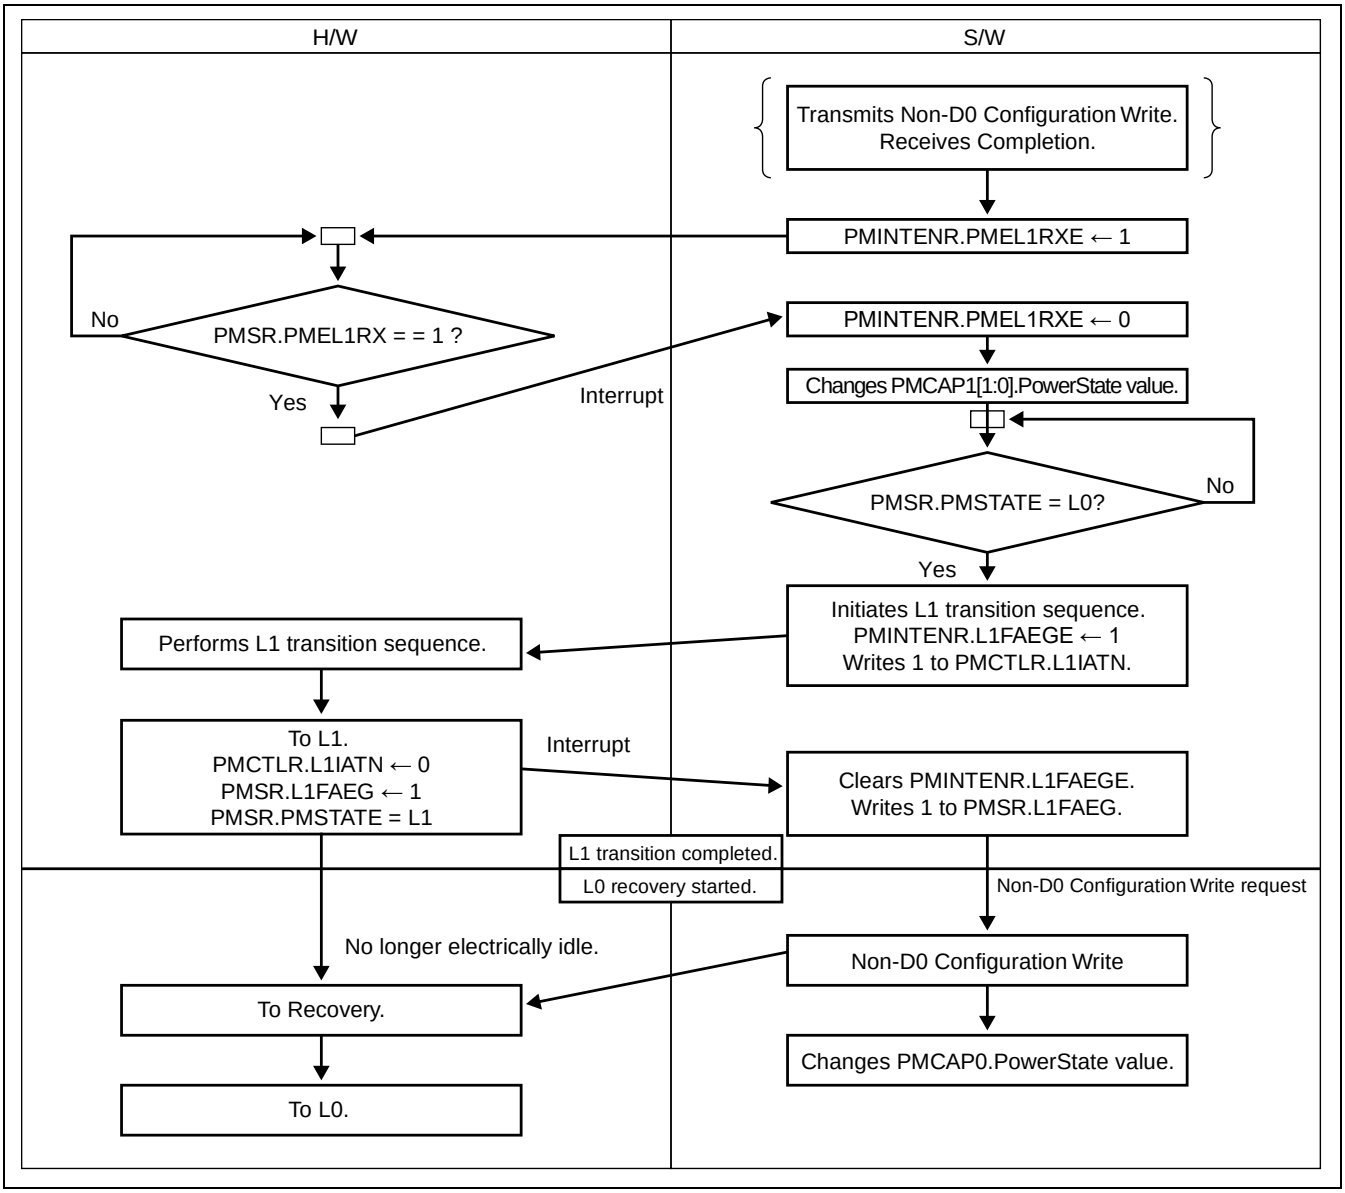

Figure 49.29 Transition from L0 to L1 to L0 (Root Port)

(2) Active State Power Management (ASPM)

This section describes PCI Express-specific power management mode. Table 49.15 shows power management operations in Active State Power Management (hereinafter referred to as ASPM) mode. ASPM is automatically controlled by hardware; software should take nothing particular into account.

Table 49.15 ASPM Operation

No.	Transition	Target Device
1	L0 → L0s → L0	Common to Endpoint and Root Port

(a) L0 → L0s → L0

When a link is in the idle state for 4 μs, hardware automatically initiates the L0s transition sequence. This module determines a link to be in the idle state in any of the following cases.

- Cases in which No TLP is transmitted
  1. No TLP to be transmitted is scheduled in the VC buffer.
  2. TLP is scheduled but there are not enough credits to transmit the TLP in the VC buffer.
  3. TLP is scheduled and there are enough credits but Non-posted cannot be issued according to the limitations on the number of Outstanding by this module.
- Cases in which no DLLP is scheduled for transmission

Figure 49.30 shows an overall overview of L0 → L0s → L0 transition.

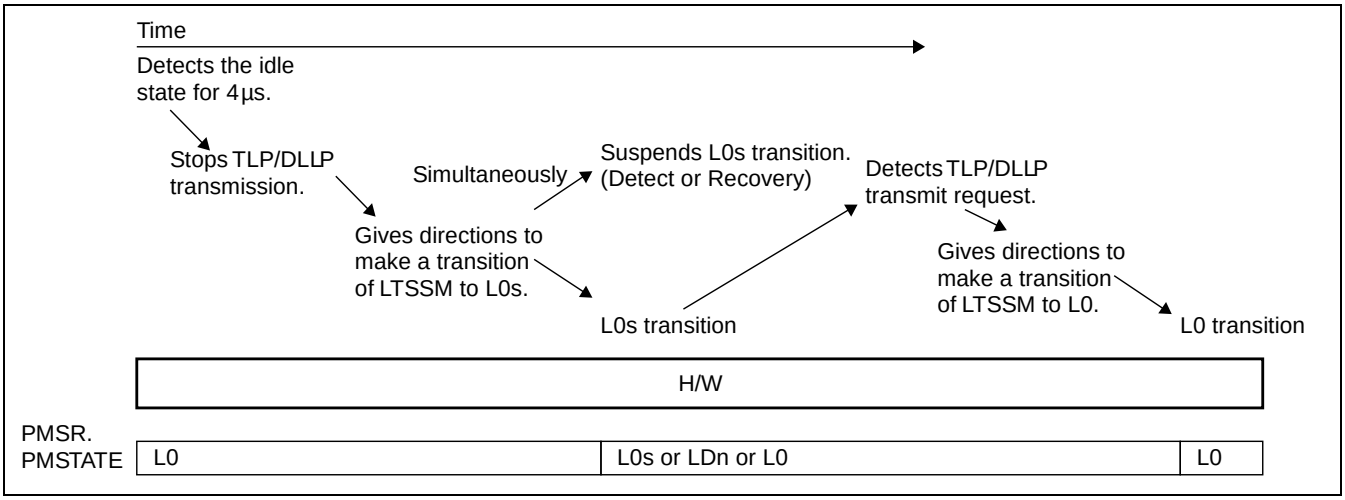

Figure 49.30 Overall Overview of L0 → L0s → L0 (Common to Endpoint/Root Port)

The L0s transition sequence is as follows.

1. Detects the idle state for 4 μs.
2. Stops TLP/DLLP transmission.
3. Gives directions to make a transition to L0s.

Note that if the directions to make a transition to L0s and the directions to make a transition to Detect or Recovery are given simultaneously in this module, the directions to make a transition to Detect or Recovery are given priority. If the directions are given to make a transition to L0s and then the directions are given to make a transition to the other state (such as Detect and Recovery), a transition to L0s is first made and then a transition to the designated state is made.

The sequence for a recovery from L0s is: when there is TLP/DLLP to be transmitted, recovery from L0s to L0 is automatically made. After recovery, TLP/DLLP is transmitted.

49.3.11 Error Handling

This section describes handling of the errors detected by this module.

(1) Error Types

This module classifies detected errors into four types: three types defined in the PCI Express standard (correctable errors, non-fatal errors, and fatal errors) and other errors (system errors). It reports each type of error through the corresponding interrupt.

(a) Correctable Error

Correctable errors are defined as the type of errors from which recovery is possible through the PCI Express protocol. Recovery from the errors is performed by hardware.

When the conditions described later are satisfied, occurrence of a correctable error is signaled by the INT_PCICERR interrupt.

(b) Non-Fatal Error

Non-fatal errors are defined as the type of errors from which recovery is impossible through the PCI Express protocol but which is not fatal. After this error, a single packet is discarded but the subsequent data communication can be continued. In most cases, error processing such as retransmission of the discarded packet is needed.

When the conditions described later are satisfied, occurrence of a non-fatal error is signaled by the INT_PCINFERR interrupt.

(c) Fatal Error

Fatal errors are defined as the type of errors from which recovery is impossible through the PCI Express protocol and which is fatal. Specifically, the errors that require resetting the communication path or other appropriate processing fall into this type. In most cases, this module must be initialized.

When the conditions described later are satisfied, occurrence of a fatal error is signaled by the INT_PCIFERR interrupt.

(d) Other Errors Detected by This Module (System Error)

The errors that do not fall into the above types are classified as system errors. The necessary processing depends on the cause of each error.

Occurrence of a system error is signaled by the INT_PCISERR interrupt.

(2) Priority of Errors

Upon detecting multiple errors during reception of a single packet, this module reports only one error that it determines as the most important according to the following priority among errors.

Receiver Overflow

Malformed TLP

Unsupported request (UR), or unexpected completion

Poisoned TLP received

(3) Correctable Error

Correctable errors are defined as the type of errors from which recovery is possible without loss of transfer data through hardware processing such as automatic retransmission request.

If a correctable error occurs, the EXPCAP2[16].CEDTCD bit is set to 1. If a correctable error occurs when the EXPCAP2[0].CERPE bit is 1 in Endpoint mode, the ERR_COR message is transmitted to the Root Port to notify occurrence of an error. In Root Port mode, the INT_PCICERR interrupt is generated if EXPCAP7[0].SERRCEE is 1.

In Root Port mode, if the ERR_COR message is received from an Endpoint when all of the PCICONF15[17].SERRE, EXPCAP2[0].CERPE, and EXPCAP7[0].SERRCEE bits are 1, the INT_PCICERR interrupt is generated.

The following errors are classified as correctable errors.

(a) Receiver error

8b/10b decode error

Disparity error

Elastic buffer overflow

Elastic buffer underflow

(b) BAD TLP

LCRC error

Sequence number error

(c) BAD DLLP

16-bit CRC error

(d) Replay timeout

Ack/Nak timeout

(e) Replay Num rollover

Replay Num rollover

(4) Non-Fatal Error

A non-fatal error cannot be corrected through hardware control and one packet of data will be lost. Therefore, recovery processing by software, such as retransmission processing, is needed.

If a non-fatal error occurs, the EXPCAP2[17].NFEDTCD bit is set to 1. If a non-fatal error occurs when PCICONF1[8].SERRE is 1, the PCICONF1[30].SSE bit is set to 1. If a non-fatal error occurs when the EXPCAP2[1].NFERPE bit or PCICONF1[8].SERRE bit is 1 in Endpoint mode, the ERR_NONFATAL message is transmitted to the Root Port to notify occurrence of an error. In Root Port mode, the INT_PCINFERR interrupt is generated if EXPCAP7[1].SERRNFEE is 1. However, if the error source is an unsupported request (described later), this module does not send the message or generate an interrupt when the conditions described later are satisfied.

In Root Port mode, if the ERR_NONFATAL message is received, PCICONF7[30].RSE is set to 1. If the ERR_NONFATAL message is received when the PCICONF15[17].SERRE and PCICONF1[8].SERRE bits are 1, the PCICONF1[30].SSE bit is set to 1. If the ERR_NONFATAL message is received from an Endpoint when the PCICONF15[17].SERRE bit is 1, the EXPCAP2[1].NFERPE or PCICONF1[8].SERRE bit is 1, and the EXPCAP7[1].SERRNFEE bit is 1, the INT_PCINFERR interrupt is generated. However, if the error source is an unsupported request (described later), this module does not generate an interrupt when the conditions described later are satisfied. In addition, if the non-fatal error comes under the advisory non-fatal error cases described later, separately defined processing is performed.

The following errors are classified as non-fatal errors.

(a) Poisoned TLP Reception

If a packet with the Poisoned attribute is written, it is handled as a non-fatal error.

This module does not transfer a write request of a packet from the PCI Express side to the internal bus side if the packet has the Poisoned attribute. If a request with the Poisoned attribute is received, the packet is discarded.

If the completion responding to the request issued by this module has the Poisoned attribute, the data in the completion is not transferred to the internal bus side.

If ConfigrationWrite Type0, I/O Write, Set_Slot_Power_Limit, or MSI has the Poisoned attribute, it is handled also as an unsupported request.

(b) Unsupported Request (UR) Reception

The following requests are handled as unsupported requests.

- Access to the area other than the PCI address area specified with BAR
- Reception of memory/IO request in Root Port mode when PCICONF1[2].BME = 0
- Access to memory space when PCICONF1[1].MSE = 0
- Access to IO space when PCICONF1[0].IOSE = 0
- Reception of a message with an undefined message code
- Reception of MsgD with message code Msg
- Reception of a message to be received only by an Endpoint in Root Port mode
- Reception of a message to be received only by a Root/Switch in Endpoint mode
- Reception of a Type0 Vendor Defined Message
- Reception of TLP other than configuration access and message in the Non-D0 state
- Access to a configuration register not implemented
- Reception of a Type1 Configuration Request
- Reception of a Configuration Request in Root Port mode
- Reception of a packet without the No Snoop attribute when acceptance of a snoop transaction is rejected by VCCAP4[15].RJCTSNPTR

- Reception of a MRdLk request

If an unsupported request is received, the EXPCAP2[19].URDTCD bit is set to 1.

If an unsupported request is received when both the EXPCAP2[3].URRPE and PCICONF1[8].SERRE bits are 0, neither transmission of a message nor generation of an interrupt is performed.

If an unsupported request is received, the packet is discarded.

(c) Completer Abort (CA)

If an error occurs on the internal bus when the packet is transferred from the PCI Express to the internal bus, this module considers it as a Completer Abort and performs error handling. When the packet received from the PCI Express is a Non-Posted request, this module returns a completion with the Completer Abort (CA)– Completion Status thus setting the PCICONF1[27].STA bit to 1.

If the packet received by this module from the PCI Express side violates the PCI Express standard or is considered to be damaged, it is handled as an unsupported request or malformed TLP, not as a Completer Abort.

(d) Unexpected Completion Reception

If the completion not corresponding to the request issued by this module is received, it is considered as an unexpected completion and error handling is performed.

Reception of an unexpected completion falls into the advisory non-fatal error cases described later.

(5) Fatal Error

Fatal errors are defined as the type of errors from which recovery is impossible through hardware and which usually require system-level error recovery processing such as initialization of the PCI Express.

If a fatal error occurs, the EXPCAP2[18].FEDTCD bit is set to 1. If a fatal error occurs when the PCICONF1[8].SERRE bit is 1, the PCICONF1[30].SSE bit is set to 1. If a fatal error occurs when the EXPCAP2[2].FERPE or PCICONF1[8].SERRE bit is 1, in Endpoint mode the ERR_FATAL message is transmitted to the Root Port to notify occurrence of an error. In Root Port mode, the INT_PCINFERR interrupt is generated if EXPCAP7[2].SERRFEE is 1.

In Root Port mode, if the ERR_FATAL message is received, PCICONF7[30].RSE is set to 1. If the ERR_FATAL message is received when both of the PCICONF15[17].SERRE and PCICONF1[8].SERRE bits are 1, the PCICONF1[30].SSE bit is set to 1. If the ERR_FATAL message is received from an Endpoint when the PCICONF15[17].SERRE bit is 1, the EXPCAP2[1].FERPE or PCICONF1[8].SERRE bit is 1, and the EXPCAP7[2].SERRFEE bit is 1, the INT_PCIFERR interrupt is generated.

The following errors are classified as fatal errors.

(a) Data Link Layer Protocol Error
(b) Reception of malformed TLP

The following packets are considered as malformed TLPs, which cause a fatal error when received. These packets are discarded when received.

- Reception of a packet with data size exceeding the Max Payload Size
- Reception of a packet with data of different length from the length specified in the size field
- Reception of a TLP with TD field in header = 0 and with the digest field
- Reception of a TLP with TD field in header = 1 and without the digest field
- Reception of an Assert_INTx/Deassert_INTx message of non TC0
- Reception of a power management message of non TC0
- Reception of an error signal message of non TC0

- Reception of an unlock message of non TC0
- Reception of a Set_Slot_Power_Limit message of non TC0
- Reception of a Set_Slot_Power_Limit message without data
- Reception of a completion with data of different size from the size specified in the Length field
- Reception of a completion with data size exceeding the Max Payload Size
- Reception of a TLP of undefined type or fmt
- Reception of a TLP of the unassigned TC
- Reception of an IO request of TC! = 0, Attr[1:0]! = 0, Length[9:0]! = 1, or Last DWBE[3:0]! = 0
- Reception of a configuration request of TC! = 0, Attr[1:0]! = 0, Length[9:0]! = 1, or Last DWBE[3:0]! = 0
- Reception of an Assert_INTx/Deassert_INTx message in Endpoint mode
- Reception of a memory request with illegal DWBE
- Reception of a memory request crossing a 4-Kbyte boundary

(6) System Error

System errors are defined as the errors that are not classified as any of the correctable, non-fatal, and fatal errors.

This module can signal the following events as the system errors by so setting PCIEERRFER.

- Internal bus error (reception of error response or disagreement of read data size)
- Posted/Non-Posted Buffer overflow
- CplLk reception
- Reception of an Unexpected Completion
- Disagreement of read data size requested and Completion data size
- Completion timeout
- Reception of a Completion with the CRS/CA/UR status
- Transmission of a Completion with the CA/UR status

If any system error occurs, the INT_PCISERR interrupt is generated.

(7) Advisory Non-Fatal Error Case

The PCI Express standard prescribes that some of non-fatal errors should not be processed when the applicable packet is received because the errors should be judged in terms of cause and significance by the packet transmission source, software, or system. These non-fatal errors are called advisory non-fatal error cases, which include the cases described in the following sections. If such a case is detected, general non-fatal error processing is not performed but processing prescribed individually is performed instead.

(a) Return of Completion with Unsupported Request/Completer Abort Status

If a completion with unsupported request/Completer Abort status is returned, this module does not perform non-fatal error processing defined in the PCI Express standard. This module records occurrence of an error in PCIEERRFR[0].SENDURCPL or PCIEERRFR[1].SENDCACPL, and generates an INT_PCISERR interrupt if the corresponding bit in PCIEERRFER is set to 1.

(b) Completion Timeout

If a completion timeout occurs, this module does not perform non-fatal error processing defined in the PCI Express standard. This module records occurrence of an error in PCIEERRFR[8].CPLTIMEOUT, and generates an INT_PCISERR interrupt if the corresponding bit in PCIEERRFER is set to 1. When software determines that further retransmission is impossible, allow the software to perform error processing such as transmission of ERR_COR.

(c) Reception of Unexpected Completion

If this module receives an unexpected completion, it does not perform non-fatal error processing defined in the PCI Express standard. This module records occurrence of an error in PCIEERRFR[12].UNEXPECTED COMPLETION, and generates an INT_PCISERR interrupt if the corresponding bit in PCIEERRFER is set to 1.

(d) Reception of Unsupported Request/Completer Abort Completion

If this module receives a completion of unsupported request/Completer Abort, it does not perform non-fatal error processing defined in the PCI Express standard. This module records occurrence of an error in PCIEERRFR[4].RECEIVEURCPL or PCIEERRFR[5].RECEIVECACPL, and generates an INT_PCISERR interrupt if the corresponding bit in PCIEERRFER is set to 1.

(e) Reception of Poisoned TLP

According to the PCI Express standard, the case in which a Poisoned TLP is received and reception is continued is also defined as an advisory non-fatal error case; however, an advisory non-fatal error of such a case does not occur with this module since this module prohibits continuation of Poisoned data processing. Although the cases related to the intermediate receiver are also defined by the standard, the corresponding processing is not performed since this module does not operate as an intermediate receiver.

49.3.12 Interrupts

Table 49.16 shows the interrupt signal lines of this module, definition, and the conditions under which interrupts are generated. The interrupt signals are synchronized with the internal bus clock.

Table 49.16 List of Interrupt Signal Lines

Name	Definition	Conditions of Generation	Related Registers
pci_int_serr	System error interrupt	• Occurrence of a system error • Completion with the UR status is transmitted. • Completion with the CA status is transmitted. • Completion with the UR status is received. • Completion with the CA status is received. • Completion with the CRS status is received. • Completion timeout occurs. • Size error occurs. • Unexpected Completion is received. • CplLk is received. • Posted buffer overflows. • Non-Posted buffer overflows. • Transfer error occurs on the internal bus.	• PCIEINTR[0].INT_PCISERR • PCIEERRFR[0].SENDURCPL • PCIEERRFR[1].SENDCACPL • PCIEERRFR[4].RCVURCPL • PCIEERRFR[5].RCVCACPL • PCIEERRFR[6].RCVCRSCPL • PCIEERRFR[8].CPLTOUT • PCIEERRFR[9].RCVSZECPL • PCIEERRFR[12].UNEXPCPL • PCIEERRFR[13].RCVCPLLK • PCIEERRFR[20].NPOVF • PCIEERRFR[21].POVF • PCIEERRFR[28].IBERR
pci_int_ferr	PCI Express Fatal error interrupt	Occurrence of a fatal error • Malformed TLP • Data Link Layer Protocol Error	PCIEINTR[1].INT_PCIFERR • EXPCAP2[18].FEDTCD
pci_int_nferr	PCI Express Non Fatal Error interrupt	Occurrence of a non-fatal error • Unsupported request • Poisoned TLP	PCIEINTR[2].INT_PCINFERR • EXPCAP2[17].NFEDTCD
pci_int_cerr	PCI Express Correctable Error interrupt	Occurrence of a correctable error • Receiver Error • Bad DLLP • Bad TLP • Replay Number Rollover • Replay Timeout	PCIEINTR[3].INT_PCICERR • EXPCAP2[16].CEDTCD
pci_int_power	Power-down interrupt	PMCAP1[1:0] is set to the Non-D0 state by Configuration Write.	PCIEINTR[4].INT_PCIPOWER
pci_int_mes	PCI Express message reception or error interrupt	Reception of a message or occurrence of an error • PM_PME is received. • Set_Slot_Power_Limit is received.	PCIEINTR[30].INT_PM_PME_RCV • EXPCAP8[16].PMEST • PCIEINTR[5].INT_PCIMES • PCIERMSGR[12].SLOTPOWER

Name	Definition	Conditions of Generation	Related Registers
pci_int_bw	PCI Express link bandwidth change interrupt	Change of link bandwidth • Change of bandwidth is caused by intentional factor. • Change of bandwidth is caused by reliability.	PCIEINTR[28].INT_PCIBW • EXPCAP4[31].LKAUTOBWSTS • EXPCAP4[30].LKBWMNGSTS
pci_int_txallemp	PCI Express all transmission buffer empty interrupt	All the PCI Express transmit buffers are empty.	PCIEINTR[29].INT_TXALLEMP
pci_int_te	PCI Express transfer error interrupt	Occurrence of a PCI Express transfer error • PCIECDR is accessed with PCIECCTLR[31].CCIE = 0. • The pertinent PIO space is accessed with PCIEPTCTLRn[31].PARE = 0. • Transfer is executed with TC being set that is not mapped to VC0. • PIO transfer is executed in Endpoint mode with PCICONF1[2].BME = 0. • Transfer is executed with the attribute being set that is not enabled with the configuration register. • Transfer other than PME message transfer is executed in the Non D0 state. • PM_PME message transfer is executed in Endpoint mode with PMCAP1[8].PMEE = 0.	PCIEINTR[31].INT_PCITE
pci_int_sc	PCI Express status change interrupt	Change of the following status • PHYRDY • INTx Disable (PCICONF1[10].INTDIS) • DL_Active· MSI Enable (MSICAP0[16].MSIE) • PM Status (PMCAP1[1:0].Power State)	PCIEPHYSR[16].PHYRDYC PCIETSTR[12].INTXDC PCIETSTR[16].DLLACTC PCIETSTR[28].MSIEC PCIEPMSR[24].PSTC
pci_int_pm	PCI Express-IP power management interrupt	Detection of PM status • PM_Enter_L1 DLLP is received. • L1 initiation sequence is completed/suspended.	PCIEINTR[12].INT_PM • PMSR[23].PMEL1RX • PMSR[31].L1FAEG
pci_int_mac	PCI Express IP MAC interrupt	Detection of MAC status • Transition of LTSSM to L0 is made. • Link speed change is completed. • Link speed change occurs. • Link speed change fails. • Link speed change succeeds. • Link training is in progress.	PCIEINTR[13].INT_MAC • MACSR[3].L0ENT • MACSR[4].SPCHGFIN • MACSR[5].SPCHG • MACSR[6].SPCHGFAIL • MACSR[7].SPCHGSUC • MACSR[30].LKTR

Name	Definition	Conditions of Generation	Related Registers
pci_int_dmace	PCI Express DMAC error interrupt	Occurrence of a PCI Express error • DMA transfer is initiated with DMAPCIEDMAOR.DMAE = 0. • DMA transfer is initiated while a link is not established. • DMA transfer is initiated in Non D0. • DMA transfer is initiated with TC being set that is not mapped to VC0. • DMA transfer is initiated in Endpoint mode with PCICONF1[2].BME = 0. • DMA transfer is initiated with the attribute being set that is not enabled with the configuration register. • A completion other than SC is received when PCI -> internal bus. • A completion timeout occurs when PCI -> internal bus. • A malformed completion is received when PCI -> internal bus. • A Poisoned Completion is received when PCI -> internal bus. Occurrence of an internal bus error • An error response is received. • A response with data size different from the requested size is received. Forced termination • Forced termination of DMA is completed.	PCIEDMCHSR0-7[11].PEE PCIEDMCHSR0-7[9].IBE PCIEDMCHSR0-7[12].CHTC
pci_int_dmac0	PCI Express DMAC0 interrupt	Completion of data transfer	PCIEDMCHSR0[0].TE
pci_int_dmac1	PCI Express DMAC1 interrupt	Completion of data transfer	PCIEDMCHSR1[0].TE
pci_int_dmac2	PCI Express DMAC2 interrupt	Completion of data transfer	PCIEDMCHSR2[0].TE
pci_int_dmac3	PCI Express DMAC3 interrupt	Completion of data transfer	PCIEDMCHSR3[0].TE
pci_int_dmac4	PCI Express DMAC4 interrupt	Completion of data transfer	PCIEDMCHSR4[0].TE
pci_int_dmac5	PCI Express DMAC5 interrupt	Completion of data transfer	PCIEDMCHSR5[0].TE
pci_int_dmac6	PCI Express DMAC6 interrupt	Completion of data transfer	PCIEDMCHSR6[0].TE
pci_int_dmac7	PCI Express DMAC7 interrupt	Completion of data transfer	PCIEDMCHSR7[0].TE
pci_int_msi[31:0]	MSI interrupt	MSI reception	PCIEMSIFR[31:0]
pci_int_intx[3:0]	INTx interrupt	Assert_INTx message reception	PCIEINTXR[3:0]

Figure 49.31 and 49.32 show the interrupts whose corresponding interrupt status and enable bits are located in the multiple registers.

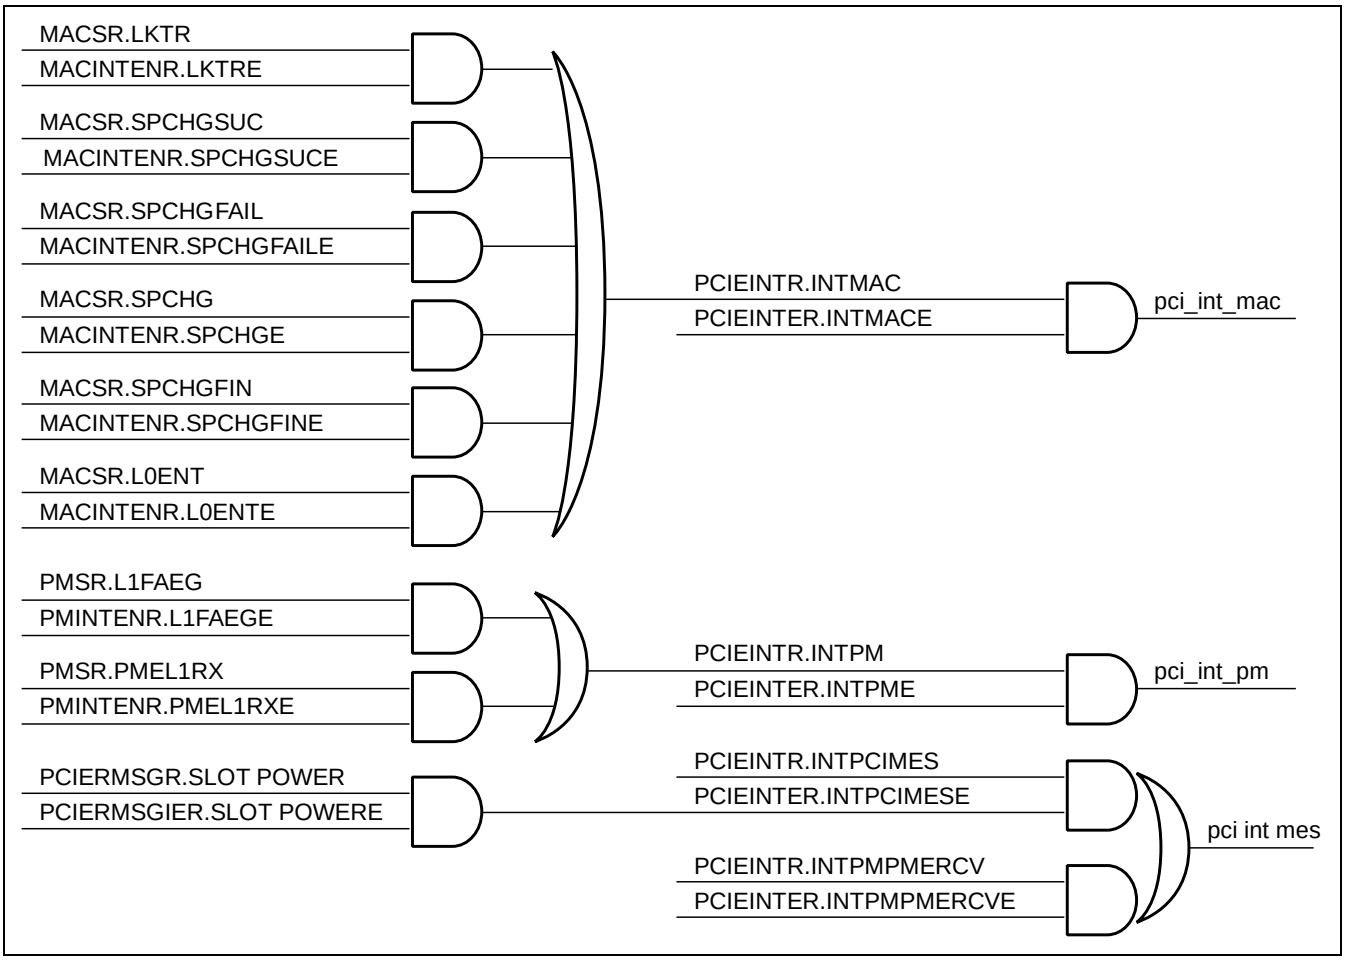

Figure 49.31 Interrupts Involving Multiple Registers (1)

49.3.13 Compliance Test

Test compliance according to the PCI Express standard.

49.3.14 Internal Reference Clock Supply

This section describes the internal reference clock supply. This specification applies from PCIE1 to PCIE0 and supports with RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, and RZ/G2N.

Reference clock supply sequence is as follows.

1. Cancel a reset and module standby for PCIE0. No need to cancel PCIE1.
2. Write 0 to PHY_REF_USE_PAD bit in PHY_CLK_RST register for PCIE0.

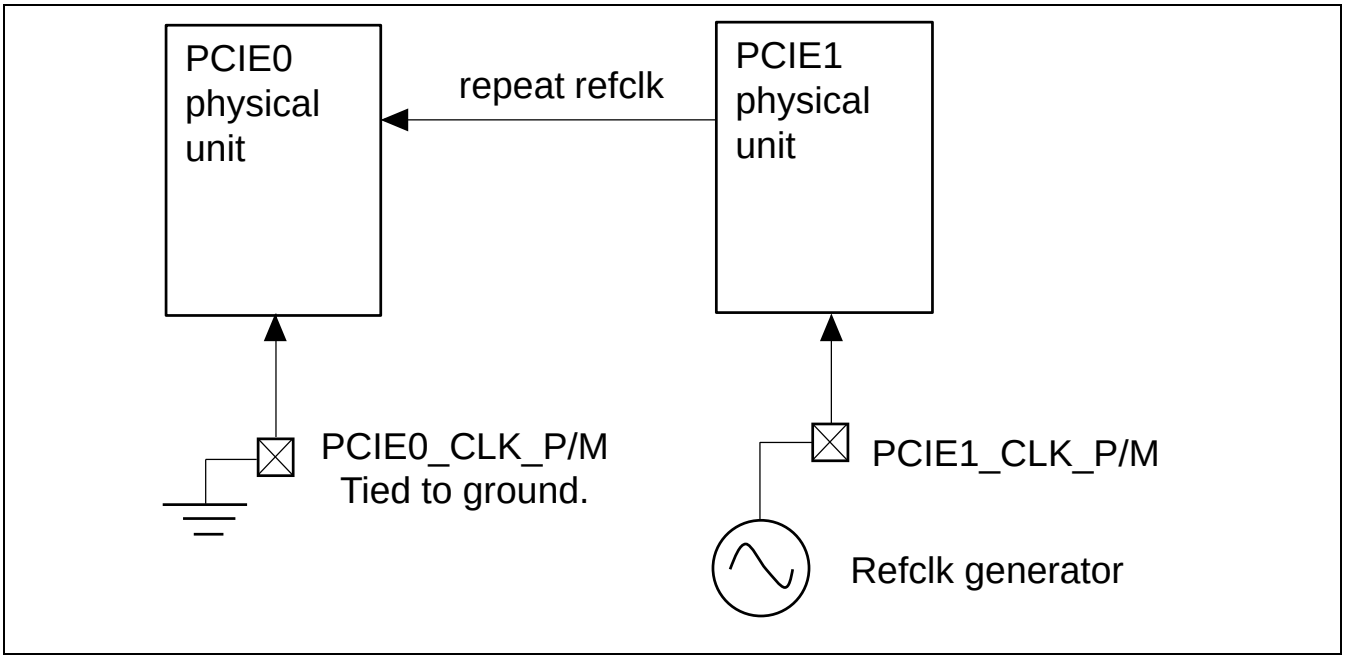

Figure 49.33 Internal Reference Clock Supply PCIE1 to PCIE0

49.4 Usage Notes

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

49.4.1 Write/Read Attributes of Configuration Registers

Although the registers in the configuration space have the register attributes defined by the PCI Express standard, these registers have different attributes when accessed by the internal bus. This section shows the attributes required for control. Software refers to the software running on the device (i.e., CPU) on the internal bus.

Table 49.17 Write/Read Attributes

Attributes of PCI Express Registers	Description	Attributes of IP Registers	Example
HWInit	Hardware initialized bit. Initialized by hardware or software.	R for fields initialized by hardware.	EXPCAP0[24].SLTI_MP
		RW for fields initialized by software.	EXPCAP3[31:24].Port Number
RO	Read-only bit. Cannot be modified by software.	R for fields initialized by hardware.	PCICONF0[31:16].Device ID
		RW for fields initialized by software.	EXPCAP0[23:20].Device Port Type
RW	Read/Write bit. Can be modified by software.	RW	PCICONF1[2].BME
RW1C	Read-only status bit. Writing 1 clears the bit. Writing 0 has no effect.	RW1C	PCICONF1[24].MDPE
ROS	Sticky-read-only bit. Cannot be modified by software. Not initialized by hot reset.	Applies to no IP registers.	—
RWS	Sticky-read write bit. Can be modified by software. Not initialized by hot reset.	RW	EXPCAP2[10].AUXPPME
RW1CS	Sticky-read-only status bit. Writing 1 clears the bit. Writing 0 has no effect. Not initialized by hot reset.	RW1C	PMCAP1[15].PMEST
RsvdP	Reserved bit. Read-only. May be used as a RW bit in the future. Reading the bit returns 0.	R	EXPCAP4[15:12]
RsvdZ	Reserved bit. Read-only. May be used as a RW1C bit in the future. Reading the bit returns 0.	R	EXPCAP2[31:22]

The following shows which PCI Configuration Capability is supported by this IP.

		Offset		Capability	Spec Requirements	Root Port Type01	Endpoint Type00
PCI Configuration Space	PCI3.0 Compatible Configuration Space	H'000		PCI Compatible Configuration Registers	Required	√	√
		H'03F					
		H'040		PCI Power Management Capability Structure	Required	√	√
				MSI or MSI-X Capability Structure	Required if an interrupt resource is required	—	√
				PCI Express Capability Structure	Required	√	√
		H'0FF					
	PCI Express Extended Configuration Space	H'0100		Virtual Channel Capability	Optional	√	√
				Device Serial Number Capability	Optional	x	x
				Advanced Error Reporting Capability	Optional	x	x
				PCI Express Root Complex Link Declaration Capability	Optional	x	x
				PCI Express Root Complex Internal Link Control Capability	Optional	x	x
				Power Budgeting Capability	Optional	x	x
				PCI Express Root Complex Event Collector Endpoint Association Capability	Optional	x	x
				Multi-Function Virtual Channel Capability	Optional	x	x
				Vendor-Specific Capability	Optional	x	x
				RCRB Header Capability	Optional	x	x
		H'0FFF					

49.4.2 Notes on Accessing Configuration Registers

- In Endpoint mode, writing to the configuration registers of this IP is prohibited except at initialization.
- “PCI RW” in the column header of the table in the description section of each register indicates the attribute of configuration access from the PCI Express bus in Endpoint mode; it is invalid in Root Port mode. For the registers with the same attribute shared in Endpoint mode and Root Port, “—” is indicated.

49.4.3 Registers Which Affect Hardware Internal Operation in Root Port Mode

Since the Endpoint configuration space may be accessed by the peer Root Port, it should be set appropriately. The registers implemented according to the Root Port configuration space are not accessed by Endpoint. Therefore, in Root Port mode, the user should appropriately set the registers that have influence on hardware operation shown in Table 49.18 at initialization. For details on register setting, refer to description of each register.

Table 49.18 Root Port Configuration Registers Which Affect Hardware Internal Operation

Register Name	Bit Name
PCICONF1	System Error Enable
	Parity Error Response
	Bus Master Enable
	Memory Space Enable
	IO Space Enable
PCICONF3	Header Type
PCICONF15	Secondary Bus Reset
	SERR Enable
	Parity Error Response

49.4.4 Power Management States

Do not stop inputting the reference clock signal in the power management states (L0s/L). Transition to the power management states (L0s/L1) is made from L0.

49.4.5 State Transition

Transition to the L2 state is prohibited since L2 is not supported.

50. Serial Communication Interface with FIFO (SCIF)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

50.1 Overview

This LSI has serial communication interfaces with FIFO buffers (SCIF) that handles asynchronous communication and clock synchronous serial communication. The SCIF has two 16-stage FIFO buffers separately for transmission and reception, which enables fast, efficient, and uninterrupted communication. The following table lists the functions of each interface.

The presence of the SCKn, RTSm#, and CTSm# pins depends on the product or channel. The synchronous mode and mode control functions are supported in the interface channel which has the pins related to these functions.

n = 0 to 5
m = 0, 1, 3, 4

Internal clock (PCK):

- RZ/G2H: S3D4ϕ
- RZ/G2M V1.3: S3D4ϕ
- RZ/G2M V3.0: S3D4ϕ
- RZ/G2N: S3D4ϕ.
- RZ/G2E: S3D4Cϕ.

Internal clock (SCKi):

- RZ/G2H: S3D1ϕ
- RZ/G2M V1.3: S3D1ϕ
- RZ/G2M V3.0: S3D1ϕ
- RZ/G2N: S3D1ϕ.
- RZ/G2E: S3D1Cϕ.

Table 50.1 Channel Information

						Second Generation RZ/G series products			
	Name	Function	Pin	Base Address	Remarks	RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
0	SCIF-0	Asynchronous mode (modem control is enabled) Clock synchronous mode	RX0, TX0, SCK0, RTS0#, and CTS0#	H'E6E6_0000	Transmission/reception clock can be supplied externally from SCK0 pin.	√	√	√	√

1	SCIF-1	Asynchronous mode (modem control is enabled) Clock synchronous mode	RX1, TX1, SCK1, RTS1#, and CTS1#	H'E6E6_8000	Transmission/reception clock can be supplied externally from SCK1 pin.	√	√	√	√
		Asynchronous mode Clock synchronous mode	RX1, TX1 and SCK1			√	√	√	√
2	SCIF-2	Asynchronous mode Clock synchronous mode	RX2, TX2 and SCK2	H'E6E8_8000	Transmission/reception clock can be supplied externally from SCK2 pin.	√	√	√	√
3	SCIF-3	Asynchronous mode (modem control is enabled) Clock synchronous mode	RX3, TX3, SCK3, RTS3#, and CTS3#	H'E6C5_0000	Transmission/reception clock can be supplied externally from SCK3 pin.	√	√	√	√
		Asynchronous mode Clock synchronous mode	RX3, TX3 and SCK3			√	√	√	√
4	SCIF-4	Asynchronous mode (modem control is enabled) Clock synchronous mode	RX4, TX4, SCK4, RTS4#, and CTS4#	H'E6C4_0000	Transmission/reception clock can be supplied externally from SCK4 pin.	√	√	√	√
		Asynchronous mode Clock synchronous mode	RX4, TX4 and SCK4			√	√	√	√
5	SCIF-5	Asynchronous mode Clock synchronous mode	RX5, TX5 and SCK5	H'E6F3_0000	Transmission/reception clock can be supplied externally from SCK5 pin.	√	√	√	√

50.1.1 Features

The SCIF has the following features.

- Asynchronous serial communication mode

  The SCIF performs serial data communication based on a character-by-character asynchronous system. This feature enables serial data communication with standard asynchronous communication chips that support Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA). There is a choice of eight serial data transfer formats.

  — Data length: 7 or 8 bits
  — Stop bit length: 1 or 2 bits
  — Parity: Even/odd/none
  — Receive error detection: Parity, framing, and overrun errors
  — Break detection:

    A break is detected when a framing error lasts for more than 1 frame length at Space 0 (low level).

    When a framing error occurs, a break can also be detected by reading the RX pin level directly from the serial port register (SCSPTR).
- Clock synchronous serial communication mode

  The SCIF performs serial data communication synchronized with a clock. This feature enables serial data communication with other LSIs that support synchronous communication. There is a single serial data communication format for clock synchronous serial communication.

  — Data length: 8 bits
  — Receive error detection: Overrun errors
- Full-duplex communication capability

  The SCIF has an independent transmitter and receiver that enable simultaneous transmission and reception. The transmitter and receiver both have a 16-stage FIFO buffer structure, enabling continuous serial data transmission and reception.
- On-chip baud rate generator, enabling any bit rate to be selected

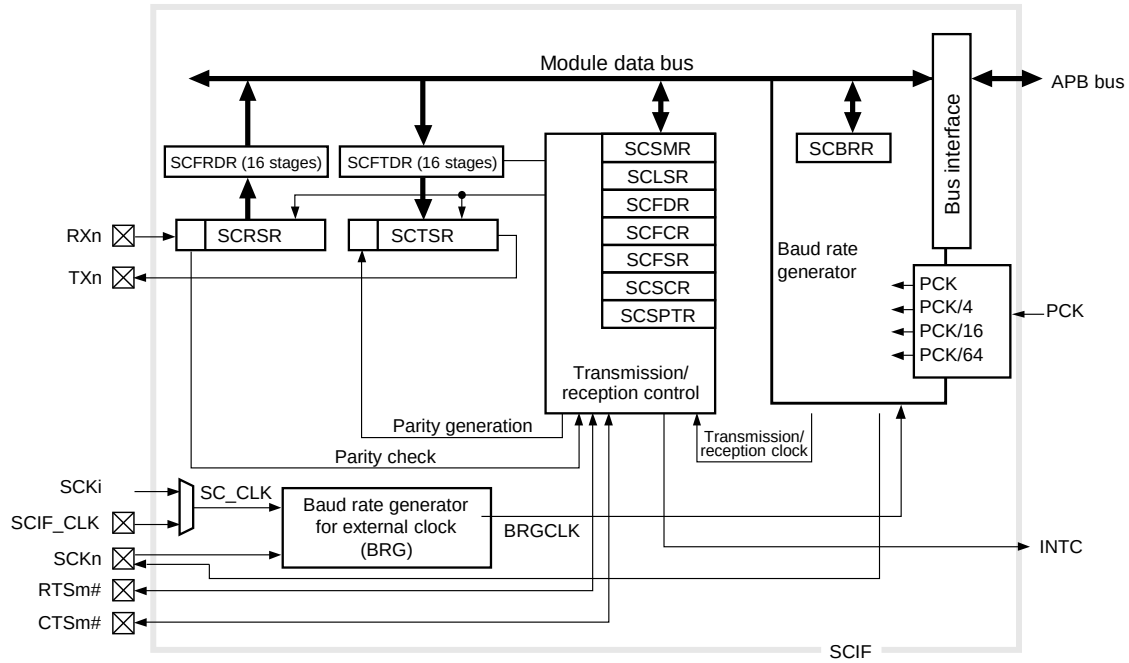
  The SCIF enables choice of a clock source for transmission/reception: a clock from the on-chip baud rate generator based on the internal clock or an external clock.
- Eight interrupt sources

  The SCIF has eight types of interrupt sources – receive-data-ready, receive-FIFO-data-full, break, transmit-FIFO-data-empty, transmit-end, receive-error, overrun-error and time-out and enables any of them to be requested independently.
- DMA data transfer

  When the transmit FIFO register is empty or the receive FIFO register has received data, issuing a DMA transfer request activates the DMA controller (DMAC) to execute a data transfer.
- The amount of data in the transmit/receive FIFO registers and the number of receive errors in receive data in the receive FIFO register are available.
- In asynchronous mode, a receive data ready (DR) or a timeout error (TO) can be detected during reception.

50.1.2 Block Diagram

Figure 50.1 shows the SCIF block diagram.



[Legend]

Notes: 1. Only 0 can be written to bits 7 to 4, 1, and 0 to clear the flags. Bits 15 to 8, 3, and 2 are read-only bits and cannot be modified.
2. Only 0 can be written to bits 2 and 0 to clear the flags. Bits 15 to 3, and 1 are read-only bits and cannot be modified.
3. The initial values of SCSPTR bits 6, 4, 2, and 0 are undefined.

The table below lists the registers used in asynchronous mode, asynchronous mode with modem control, and clock synchronous mode. When setting up the registers, set the bits related to unsupported modes in each interface to their initial values. Otherwise, the SCIF may malfunction. Do not write to any registers other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from registers other than listed below are undefined.

Table 50.4 Register Settings in Each Mode

[Legend]

* : Used in any mode.

A : Used in asynchronous mode.

M : Used in asynchronous mode (modem control is enabled) (in addition to A).

C : Used in clock synchronous mode.

0 : Reserved (the write value should always be 0.)

— : Undefined

50.1.5 Connected Module

Table 50.5 shows the connected modules to the SCIF.

Table 50.5 Connected modules

Module name	Connected module name	Function of connected module
SCIF	AP-System Core	Access the Register
	CPG	Output Clocks
	PFC	Select External pins
	Module Standby	Control to stop clocks
	Software Reset	Execute software reset
	INTC	Control to interrupt
	SYS-DMAC	Control Direct Memory Access

50.2 Register Description

Explanation of abbreviation of register

Initial value: Value of the register after power-on reset

—: Undefined value

R/W: The bit or field is readable and writable.

R/WC0: The bit or field is readable and writable. Writing 0 to the bit initializes the bit. Writing 1 to the bit is ignored.

R: The bit or field is readable only. When writing to the register, write 0 to it.

—/WB: The bit or field is writable. Note that values read from write-only bits are not guaranteed.

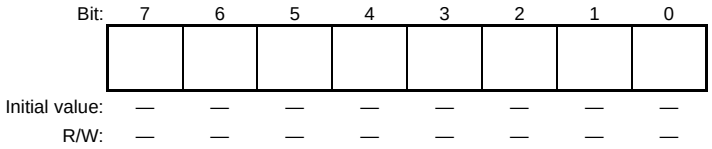
50.2.1 Receive Shift Register (SCRSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SCRSR is a register that receives serial data.

The SCIF sets serial data input to the SCRSR from the RX pin in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is transferred to the receive FIFO data register SCFRDR, automatically.

SCRSR cannot be read from and written to by the CPU.



50.2.2 Receive FIFO Data Register (SCFRDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SCFRDR is a 16-stage FIFO register that stores received serial data.

When the SCIF has received one byte of serial data, it transfers the received data from the receive shift register (SCRSR) to SCFRDR for storage, and reception is thus completed. SCRSR is then ready for reception, and is capable of receiving up to 16 consecutive bytes of data before SCFRDR is full.

SCFRDR is a read-only register and cannot be modified by the CPU. Note that the read value will be undefined while there is no receive data in SCFRDR. When SCFRDR is full of receive data, subsequent serial data is lost.

SCFRDR is read as an undefined value after a power-on reset.

Bit:	7	6	5	4	3	2	1	0
Initial value:	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R

50.2.3 Transmit Shift Register (SCTSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SCTSR is a register that transmits serial data.

To perform serial data transmission, the SCIF first transfers transmit data from the transmit FIFO data register (SCFTDR) to SCTSR, then sends the data to the TX pin starting with the LSB (bit 0). When transmission of one byte is completed, the SCIF transfers the next transmit data from SCFTDR to SCTSR automatically, then starts transmission.

SCTSR cannot be read from and written to directly by the CPU.

Bit:	7	6	5	4	3	2	1	0
Initial value:	—	—	—	—	—	—	—	—
R/W:	—	—	—	—	—	—	—	—

50.2.4 Transmit FIFO Data Register (SCFTDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SCFTDR is an 8-bit FIFO register of 16 stages that stores data for serial transmission.

If SCTSR is empty after transmit data has been written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR and starts serial transmission.

SCFTDR is a write-only register and cannot be read from by the CPU. Writing further data to SCFTDR is no longer possible when it is full (contains 16 bytes of transmit data). Attempts at writing data to the register in this situation are ignored.

SCFTDR is read as an undefined value on a power-on reset.

Bit:	7	6	5	4	3	2	1	0
Initial value:	—	—	—	—	—	—	—	—
R/W:	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB

50.2.5 Serial Mode Register (SCSMR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	C/A#	CHR	PE	O/E#	STOP	—	CKS[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W

SCSMR is a 16-bit register that sets the SCIF's serial transfer format and selects the baud rate generator clock source.

SCSMR can always be read from and written to by the CPU.

SCSMR is initialized to H'0000 by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	C/A#	B’0	R/W	Communication Mode Selects asynchronous mode or clock synchronous mode for the SCIF operation. 0: Asynchronous mode 1: Clock synchronous mode Note: Whether clock synchronous mode can be selected or not depends on the interface.
6	CHR	B’0	R/W	Character Length Selects 7 or 8 bits for asynchronous mode data length. In clock synchronous mode, the data length is fixed at 8 bits regardless of the CHR bit setting. 0: 8 bits 1: 7 bits* Note: * When the 7-bit data is selected, the MSB (bit 7) in the transmit FIFO data register (SCFTDR) is not transmitted.
5	PE	B’0	R/W	Parity Enable Determines whether parity bit is added in transmission or not, and parity bit is checked in reception in asynchronous mode or not. In clock synchronous mode, the parity bit is not added and checked regardless of the PE bit setting. When bit PE is set to 1, the parity (even or odd) specified by bit O/E# is added to transmit data. In reception, the parity bit is checked for the parity (even or odd) specified by bit O/E#. 0: Disables parity bit addition and check. 1: Enables parity bit addition and check.

Bit	Bit Name	Initial Value	R/W	Description
4	O/E#	B’0	R/W	Parity Mode Selects either even or odd parity to use in parity addition and check. In asynchronous mode, the O/E# bit setting is valid only when bit PE is set to 1, enabling parity bit addition and check. In clock synchronous mode or when parity addition or check is disabled in asynchronous mode, the O/E# bit setting is invalid. 0: Even parity*1 1: Odd parity*2 Notes: 1. When even parity is set, the parity bit is added in transmission so that the total number of 1-bits in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is even. 2. When odd parity is set, the parity bit is added in transmission so that the total number of 1-bits in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is odd.
3	STOP	B’0	R/W	Stop Bit Length Selects 1 bit or 2 bits as the stop bit length in asynchronous mode. The stop bit setting is valid only in asynchronous mode. Since the stop bit is not added in clock synchronous mode, the STOP bit setting is invalid in this mode. In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit. If it is 0, it is treated as the start bit of the next transmit character. 0: 1 stop bit*1 1: 2 stop bits*2 Notes: 1. In transmission, high level of 1 bit (stop bit) is added to the end of a transmit character before it is sent. 2. In transmission, high level of 2 bits (stop bits) are added to the end of a transmit character before it is sent.
2	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	CKS[1:0]	B’00	R/W	Clock Select 1 and 0 These bits select the clock source for the on-chip baud rate generator. The clock source can be selected from PCK, PCK /4, PCK /16, and PCK /64, according to the setting of bits CKS1 and CKS0. B’00: PCK B’01: PCK /4 B’10: PCK /16 B’11: PCK /64

50.2.6 Serial Control Register (SCSCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SCSCR is a register that enables or disables transmission/reception by the SCIF, enables or disables interrupt requests, and selects transmission/reception clock source for the SCIF.

SCSCR can always be read from and written to by the CPU.

SCSCR is initialized to H'0000 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	TEIE	—	—	—	TIE	RIE	TE	RE	REIE	TOIE	CKE[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	TEIE	B’0	R/W	Transmit End Interrupt Enable When a transmit-end request is enabled by the TIE bit, the TEIE bit selects the source of the transmit end interrupt request from the following: • Setting the TDFE flag in SCFSR • Setting the TEND flag in SCFSR 0: The transmit FIFO data empty (TDFE) interrupt request is used. 1: The transmit end (TEND) interrupt request is used.
10 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	B'0	R/W	Transmit Interrupt Enable Enables or disables a transmit-FIFO-data-empty interrupt (TDFE) request when the TEIE bit in SCSCR is pulled 0, if all of the following conditions are satisfied: • Serial transmit data has been transferred from SCFTDR to SCTSR. • The number of data bytes in SCFTDR is equal to or less than the transmit trigger count. • The TDFE flag in SCFSR is set to 1. Enables or disables a transmit-end interrupt (TEND) request when the TEIE bit of SCSCR is set to 1, if both of the following conditions are satisfied: • Transmission was ended because there is no valid data in SCFTDR when the last bit of the transmit character in SCTSR was transmitted. • The TEND flag of SCFSR is set to 1. 0: When the TEIE bit is 0, disables transmit-FIFO-data-empty interrupt (TDFE) request. When the TEIE bit is 1, disables transmit-end interrupt (TEND) request. 1: When the TEIE bit is 0, enables transmit-FIFO-data-empty interrupt (TDFE) request. When the TEIE bit is 1, enables transmit-end interrupt (TEND) request.
6	RIE	B'0	R/W	Receive Interrupt Enable Enables or disables a receive-FIFO-data-full interrupt request when the RDF flag in SCFSR is set to 1, a receive-data-ready interrupt request when the DR flag in SCFSR is set to 1, a receive-error interrupt request when the ER flag in SCFSR is set to 1, a break interrupt request when the BRK flag in SCFSR is set to 1, and an overrun error interrupt request when the ORER flag in SCLSR is set to 1. 0: Disables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests. 1: Enables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests.
5	TE	B'0	R/W	Transmit Enable Enables or disables the start of SCIF serial transmission. The SCIF starts serial transmission when transmit data is written to the SCFTDR while TE is 1. Before setting TE to 1, set SCSMR and SCFCR to specify the transmission format and reset the transmit FIFO. 0: Disables transmission. 1: Enables transmission.

Bit	Bit Name	Initial Value	R/W	Description
4	RE	B'0	R/W	Receive Enable Enables or disables the start of SCIF serial reception. When RE is 1, the SCIF starts serial reception by detecting a start bit in asynchronous mode or by detecting a synchronization clock input in clock synchronous mode. Before setting RE to 1, set SCSMR and SCFCR to specify the reception format and reset the receive FIFO. 0: Disables reception.* 1: Enables reception. Note: Even if RE is cleared to 0, the DR, ER, BRK, RDF, FER, PER, TO and ORER flags are not affected, and retain their states.
3	REIE	B'0	R/W	Receive Error Interrupt Enable Enables or Disables generation of receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests. 0: Disables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.* 1: Enables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests. Note: * When REIE is 1, ER, BRK or ORER interrupt requests will occur even if RIE is cleared to 0. This setting is used to notify the interrupt controller of ER, BRK, and ORER interrupt requests during DMAC transfer.
2	TOIE	B'0	R/W	Timeout Interrupt Enable Enables or disables generation of timeout interrupt (TO) requests when the TO flag in SCLSR is set to 1. 0: Disables timeout interrupts (TO). 1: Enables timeout interrupts (TO).
1, 0	CKE[1:0]	B'00	R/W	Clock Enable 1 and 0 These bits select the SCIF clock source and enables or disables the clock output from the SCK pin. Whether the SCK pin functions as a serial clock output pin or a serial clock input pin is determined by combination of the CKE [1:0] bits settings. To specify synchronization clock output in clock synchronous mode, set C/A# to 1 in SCSMR then set CKE [1:0]. See table 50.5 for the bit settings.

Table 50.6 Clock Selection

CKE[1:0]	Mode	Clock Source	SCK Pin
B’00	Asynchronous mode	Internal clock (PCK, PCK /4, PCK/16, PCK/64)	The SCK pin is not used. The SCK pin functions as an input pin (Input signals are ignored). (Initial value)
	Clock synchronous mode		The SCK pin outputs the synchronization clock. (Initial value)
B’01	Asynchronous mode		The SCK pin outputs the clock (with a frequency 16 times the bit rate).
	Clock synchronous mode		The SCK pin outputs the synchronization clock.
B’10	Asynchronous mode	Baud rate generator output for external clock or SCK	When SC_CLK is selected: The SCK pin is an input pin (Input signals are ignored). Set the SC_CLK frequency so that the frequency of BRGCLK is 16 times the bit rate.
			When SCK is selected: The SCK pin inputs the clock (with a frequency 16 times the bit rate).
	Clock synchronous mode	SCK*	The SCK pin inputs the synchronization clock.
B’11	Prohibited	—	—

Note: * It is not allowed to set synchronous communication using SC_CLK for input.

50.2.7 Serial Status Register (SCFSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PER[3:0]				FER[3:0]				ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/WC0	R/WC0	R/WC0	R/WC0	R	R	R/WC0	R/WC0

SCFSR is a 16-bit register. The lower 8 bits are a status flag that indicates the operating status of the SCIF, and the upper 8 bits indicate the number of reception errors of data in the receive FIFO register.

SCFSR can always be read from and written to by the CPU. However, the flags ER, TEND, TDFE, BRK, RDF, and DR cannot be written by 1. The FER and PER flags are read-only flags and cannot be modified.

SCFSR is initialized to H'0060 by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	PER[3:0]	All 0	R	Parity Error Count These bits indicate the number of parity errors of receive data stored in the receive FIFO data register (SCFRDR). After the ER is set in SCFSR, the value represented by bits 15 to 12 indicates the number of parity errors. If a parity error occurs in all 16-byte receive data in SCFRDR, PER3 to PER0 are cleared to 0.
11 to 8	FER[3:0]	All 0	R	Framing Error Count These bits indicate the number of framing errors of receive data stored in the receive FIFO data register (SCFRDR). After the ER bit is set in SCFSR, the value represented by bits 11 to 8 indicates the number of framing errors. If a framing error occurs in all 16-byte receive data in SCFRDR, FER3 to FER0 are cleared to 0.

Bit	Bit Name	Initial Value	R/W	Description
7	ER	B'0	R/WC0	Receive Error Indicates that a framing error or a parity error has occurred in reception.*1 The ER flag is not affected by an error and retains its previous state when the RE bit is 0 in SCSCR. If a receive error occurs, receive data will be transferred to SCFRDR and reception operation will be continued. Whether there is a receive error in data read from SCFRDR can be determined by the FER and PER bits in SCFSR. 0: Indicates that no framing or parity error has occurred in reception. [Clearing conditions] • A power-on reset is executed. • 0 is written to ER. 1: Indicates that a framing error or a parity error has occurred in reception. [Setting conditions] • The SCIF checks whether the stop bit at the end of receive data is 1, but the stop bit is 0.*2 • The number of 1-bits in receive data plus the parity bit does not match the parity setting (even or odd) specified by the O/E# bit in SCSMR during reception. Note: In the 2-stop-bit mode, only the first stop bit is checked that the value is 1; the second stop bit is not checked.
6	TEND	B'1	R/WC0	Indicates that transmission has been ended * because there was no valid data in SCFTDR when the last bit of the transmit character was transmitted. 0: Indicates that transmission is in progress. [Clearing conditions] • Transmit data is written to SCFTDR, and 0 is written to TEND. • Data is written to SCFTDR by the DMAC. 1: Indicates that transmission has been ended. [Setting conditions] • A power-on reset is executed. • The TE bit in SCSCR is 0. • There is no transmit data in SCFTDR when the last bit of a 1-byte serial transmission character is transmitted. Note: When transmit data is written to SCFTDR by the DMAC in clock synchronous mode, the TEND flag may not be cleared. Therefore, if the DMAC is used for transmission in clock synchronous mode, the TEND flag should be read using the following procedure. 1. Check that data transfer is completed in the DMAC. 2. Read the TEND flag. 3. If TEND = 1, clear the TEND flag to 0. 4. Read the TEND flag again. 5. Use the second read TEND flag.

Bit	Bit Name	Initial Value	R/W	Description
5	TDFE	B’1	R/WC0	Transmit FIFO Data Empty Indicates that the SCIF has transferred data from SCFTDR to SCTSR, the number of data bytes in SCFTDR becomes equal to or less than the transmit trigger count specified by the TTRG1 and TTRG0 bits in SCFCR, and SCFTDR is ready to be written by new transmit data. SCFTDR is a 16-byte FIFO register. The maximum number of bytes that can be written to when TDFE = 1 is “16 – [the transmit trigger count]”. If data exceeding this value is attempted to be written, the data will be ignored. The number of data bytes in SCFTDR is indicated by the upper bits of SCFDR. If the number of data written in SCFTDR is equal to or less than the transmit trigger count, this bit will be set to 1 even if it is cleared to 0 after it is read as 1. 0: Indicates that the number of transmit data written to SCFTDR exceeds the transmit trigger count. [Clearing conditions] • Transmit data exceeding the specified transmit trigger count have been written to SCFTDR, and 0 is written to TDFE. • Transmit data exceeding the specified transmit trigger count have been written to SCFTDR by the DMAC. 1: Indicates that the number of transmit data in SCFTDR is equal to or less than the transmit trigger count. [Setting conditions] • A power-on reset is executed. • The number of transmit data in SCFTDR is equal to or less than the transmit trigger count after transmission.
4	BRK	B’0	R/WC0	Break Detect Indicates that a receive data break signal has been detected. If a break signal is detected, receive data (H'00) transfer to SCFRDR is stopped. After the break is canceled and the receive signal returns to 1, the receive data transfer resumes. 0: Indicates that no break signal has been received. [Clearing conditions] • A power-on reset is executed. • 0 is written to BRK. 1: Indicates that a break signal has been received. [Setting condition] • Data with a framing error is received, followed by the space "0" (low level) for at least one frame length.
3	FER	B’0	R	Framing Error Indicates that a framing error has been found in the data that is to be read next from SCFRDR in asynchronous mode. 0: Indicates that there is no framing error in the receive data that is to be read from SCFRDR. [Clearing conditions] • A power-on reset is executed. • There is no framing error in the data that is to be read next from SCFRDR. 1: Indicates that there is a framing error in the receive data that is to be read from SCFRDR. [Setting condition] • There is a framing error in the data that is to be read next from SCFRDR.

Bit	Bit Name	Initial Value	R/W	Description
2	PER	B'0	R	Parity Error This bit indicates that a parity error has been found in the data that is to be read next from SCFRDR in asynchronous mode. 0: Indicates that there is no parity error in the receive data that is to be read from SCFRDR. [Clearing conditions] • A power-on reset is executed. • There is no parity error in the data that is to be read next from SCFRDR. 1: Indicates that there is a parity error in the receive data that is to be read from SCFRDR. [Setting condition] • There is a parity error in the data that is to be read next from SCFRDR.
1	RDF	B'0	R/WC0	Receive FIFO Data Full Indicates that the received data has been transferred from SCRSR to SCFRDR, and the number of receive data bytes in SCFRDR becomes equal to or more than the receive trigger count specified by the RTRG1 and RTRG0 bits in SCFCR. SCFRDR is a 16-byte FIFO register. When RDF = 1, data equal to or more than the number of receive trigger data bytes can be read. When SCFRDR is empty, SCFRDR is read as an undefined value. The number of receive data bytes in SCFRDR is indicated by the lower bits of SCFDR. If the number of data in SCFRDR is equal to or more than the trigger count, this bit will be set to 1 even if it is cleared to 0. At this time, read receive data until the number of data in SCFRDR is less than the trigger count, read RDF as 1, and then clear RDF. 0: Indicates that the number of receive data bytes in SCFRDR is less than the specified receive trigger count. [Clearing conditions] • A power-on reset is executed. • SCFRDR is read until the number of receive data bytes in SCFRDR is less than the receive trigger count, and 0 is written to RDF. • SCFRDR is read by the DMAC until the number of receive data bytes in SCFRDR is less than the receive trigger count. 1: Indicates that the number of receive data bytes in SCFRDR is equal to or more than the specified receive trigger count. [Setting condition] • Receive data more than the receive trigger count have been stored in SDFRDR.

Bit	Bit Name	Initial Value	R/W	Description
0	DR	B'0	R/WC0	Receive Data Ready Indicates that the number of data bytes in SCFRDR is less than the receive trigger count and that no further data has been received for at least 15 etu after the stop bit of the data received last in asynchronous mode. This bit is not set in clock synchronous mode. 0: Indicates that data is being received or has been successfully received, and there is no receive data in SCFRDR. [Clearing conditions] • A power-on reset is executed. • All the receive data in SCFRDR has been read, and 0 is written to DR. • All the receive data in SCFRDR has been read by the DMAC. 1: Indicates that no further receive data has been received. [Setting condition] • The receive FIFO data register (SCFRDR) has the number of data byte that is below the receive trigger number of data bytes and no further data has arrived for at least 15 etu after the stop bit of the data received last. Note: etu: Elementary Time Unit (time for transfer of 1 bit) Equivalent to 1.5 frames with an 8-bit, 1-stop-bit format.

50.2.8 Bit Rate Register (SCBRR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	7	6	5	4	3	2	1	0
Initial value:	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

SCBRR is an 8-bit register that sets the serial transmission/reception bit rate in accordance with the baud rate generator operating clock selected by the CKS1 and CKS0 bits in SCSMR. This baud rate generator is intended for PCK, PCK/4, PCK/16, and PCK/64. For details on the baud rate generator for external clock, see section 50.3.3, Baud Rate Generator for External Clock (BRG).

SCBRR can always be read from and written to by the CPU except for during transfer.

SCBRR is initialized to H'FF by a power-on reset.

The SCBRR setting is determined by the following equation:

[Asynchronous mode]

$$N = \frac{PCK}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

[Clock synchronous mode]

$$N = \frac{PCK}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$$

B: Bit rate (bit/s)

N: SCBRR setting for the baud rate generator ($0 \leq N \leq 255$) (which satisfies the electrical characteristics)

PCK: Peripheral module operating frequency (MHz)

n: Baud rate generator input clock (n = 0, 1, 2, 3)
(See the table 50.6 for the relation between n and the clock.)

Table 50.7 SCSMR Settings

n	Clock	SCSMR.CKS[1:0] Setting
0	PCK	B'00
1	PCK/4	B'01
2	PCK/16	B'10
3	PCK/64	B'11

The bit rate error in asynchronous mode is determined by the following equation:

$$\text{error (\%)} = \left\{ \frac{PCK \times 10^6}{(N+1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100$$

50.2.9 FIFO Control Register (SCFCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SCFCR is a register that resets data counts and sets the number of trigger data bytes for the transmit and receive FIFO registers. It also has a loopback test enable bit.

SCFCR can always be read from and written to by the CPU except for during transfer.

SCFCR is initialized to H'0000 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	RSTRG[2:0]			RTRG[1:0]		TTRG[1:0]		MCE	TFRST	RF RST	LOOP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	RSTRG[2:0]	B’000	R/W	RTS Output Active Trigger The RTS# signal is high when the number of receive data bytes stored in SCFRDR is equal to or more than the specified trigger number shown below: B’000: 15 B’001: 1 B’010: 4 B’011: 6 B’100: 8 B’101: 10 B’110: 12 B’111: 14
7, 6	RTRG[1:0]	B’00	R/W	Receive FIFO Data Count Trigger These bits specify the number of receive data bytes that makes the RDF (receive data full) flag to be set in SCFSR. The RDF flag is set when the number of receive data bytes in SCFRDR is equal to or more than the specified trigger number shown below:

RTRG[1:0]	Asynchronous Mode	Clock Synchronous Mode
B’00	1	1
B’01	4	2
B’10	8	8
B’11	14	14

Bit	Bit Name	Initial Value	R/W	Description
5, 4	TTRG[1:0]	B'00	R/W	Transmit FIFO Data Count Trigger These bits specify the number of remaining transmit data bytes that makes the transmit FIFO data register empty (TDFE) flag to be set in SCFSR. The TDFE flag is set when the number of transmit data bytes in SCFTDR is equal to or less than the specified trigger count shown below, after transmission: B'00: 8 (8) B'01: 4 (12) B'10: 2 (14) B'11: 0 (16) Note: Values in parentheses indicate the empty space in SCFTDR in bytes.
3	MCE	B'0	R/W	Modem Control Enable Enables or disables modem control signals CTS# and RTS#. This bit should always be set to 0 in clock synchronous mode. Whether modem control can be selected or not depends on the interface. 0: Disables modem signals.* 1: Enables modem signals. Note: CTS# and RTS# control ports.
2	TFRST	B'0	R/W	Transmit FIFO Data Register Reset Enables or disables a transmit FIFO data register reset that empties the register. 0: Disables the reset.* 1: Enables the reset. Note: The register is reset by a power-on reset.
1	RFRST	B'0	R/W	Receive FIFO Data Register Reset Enables or disables a receive FIFO data register reset that empties the register. 0: Disables the reset.* 1: Enables the reset. Note: The register is reset by a power-on reset.
0	LOOP	B'0	R/W	Loopback Test Enables or disables the loopback test by internally connecting the transmit output pin (TX) and receive input pin (RX), and the RTS# pin and CTS# pin. If the loopback test is specified, the signal on the RTS# pin is internally conveyed to CTS# pin, and data transmission is automatically suspended when RTS# is asserted. 0: Disables the loopback test. 1: Enables the loopback test. Even if loopback test is specified by this bit, SCSPTR.RTSDT and SCSPTR.CTSDT bits does not reflect signal on loopback path, because those registers shows signals on RTS#/CTS# pins.

50.2.10 FIFO Data Count Register (SCFDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SCFDR is a 16-bit register that indicates the number of data bytes stored in SCFTDR and that in SCFRDR.

The upper 8 bits indicate the number of transmit data bytes in SCFTDR, and the lower 8 bits indicates the number of receive data bytes in SCFRDR.

SCFDR can always be read by the CPU.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	T[4:0]					—	—	—	R[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 8	T[4:0]	H'00	R	These bits show the number of data bytes untransmitted and still stored in SCFTDR. H'00 indicates that there is no transmit data in SCFTDR. H'10 indicates that SCFTDR is full of transmit data.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	R[4:0]	H'00	R	These bits show the number of receive data stored in SCFRDR in bytes. H'00 indicates that there is no receive data in SCFRDR. H'10 indicates that SCFRDR is full of receive data.

50.2.11 Serial Port Register (SCSPTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SCSPTR controls multiplexed input/output and data on the serial communication interface (SCIF) ports. Bits 1 and 0 control breaks in serial transmission/reception by reading input data from the RX pin and writing output data to the TX pin. Bits 3 and 2 read input data from and write output data to the SCK pin. Bits 5 and 4 read input data from and write output data to the CTS# pin. Bits 7 and 6 read input data from and write output data to the RTS# pin.

SCSPTR is a 16-bit register that can always be read from and written to by the CPU.

All SCSPTR bits except bits 6, 4, 2, and 0 are initialized to 0 by a power-on reset. The values of bits 6, 4, 2, and 0 are undefined.

Note: Whether modem control can be selected or not depends on the interface.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RTSIO	RTSDT	CTSIO	CTSDT	SCKIO	SCKDT	SPB2IO	SPB2DT
Initial value:	0	0	0	0	0	0	0	0	0	—	0	—	0	—	0	—
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	RTSIO	B'0	R/W	Serial Port RTS# Pin Input/output Specifies input or output for the serial port RTS# pin. To actually set the RTS# pin as a port output pin to output the value set by the RTSDT bit, the MCE bit in SCFCR should be cleared to 0. 0: Indicates that this bit does not output the value of the RTSDT bit to the RTS# pin. 1: Indicates that this bit outputs the value of the RTSDT bit to the RTS# pin.
6	RTSDT	—	R/W	Serial Port RTS# Pin Data Specifies the input/output data level of the serial port RTS# pin. Whether the pin is set for input or output is determined by the RTSIO bit. When the pin is set for output, the value of the RTSDT bit is output to the RTS# pin. Regardless of the value of the RTSIO bit, the value of the RTS# pin is read from the RTSDT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
5	CTSIO	B'0	R/W	Serial Port CTS# Pin Input/output Specifies input or output for the serial port CTS# pin. To actually set the CTS# pin as a port output pin to output the value set by the CTSDT bit, the MCE bit in SCFCR should be cleared to 0. 0: Indicates that the CTSDT bit value is not output to the CTS# pin. 1: Indicates that the CTSDT bit value is output to the CTS# pin.

Bit	Bit Name	Initial Value	R/W	Description
4	CTSDT	—	R/W	Serial Port CTS# Pin Data Specifies the input/output data level of the serial port CTS# pin. Whether the pin is set for input or output is determined by the CTSIO bit. When the pin is set for output, the value of the CTSDT bit is output to the CTS# pin. Regardless of the value of the CTSIO bit, the value of the CTS# pin is read from the CTSDT bit. The initial value of this bit is undefined after a power-on. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
3	SCKIO	B'0	R/W	Serial Port Clock Pin Input/output Specifies input or output for the serial port SCK pin. To actually set the SCK pin as a port output pin to output the value set by the SCKDT bit, the CKE [1:0] bits in SCSCR should be cleared to 0. 0: Indicates that the SCKDT bit value is not output to the SCK pin. 1: Indicates that the SCKDT bit value is output to the SCK pin.
2	SCKDT	—	R/W	Serial Port Clock Pin Data Specifies the input/output data level of the serial port SCK pin. Whether the pin is set for input or output is determined by the SCKIO bit. When the pin is set for output, the value of the SCKDT bit is output to the SCK pin. Regardless of the value of the SCKIO bit, the value of the SCK pin is read from the SCKDT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
1	SPB2IO	B'0	R/W	Serial Port Break Input/Output Specifies the output condition of the serial port TX pin. To actually set the TX pin as a port output pin to output the value set by the SPB2DT bit, the TE bit in SCSCR should be cleared to 0. 0: Indicates that the SPB2DT bit value is not output to the TX pin. 1: Indicates that the SPB2DT bit value is output to the TX pin.
0	SPB2DT	—	R/W	Serial Port Break Data Specifies the input level of the serial port RX pin and the output level of the TX pin. The TX pin output conditions are determined by the SPB2IO bit. When the TX pin is set for output, the value of the SPB2DT bit is output to the TX pin. Regardless of the value of the SPB2IO bit, the value of the RX pin is read from the SPB2DT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.

Figures 50.2 to 50.6 show the block diagrams of the SCIF I/O ports.

50.2.12 Line Status Register (SCLSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TO	—	ORER
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/WC0	R	R/WC0

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	TO	B’0	R/WC0	Timeout Indicates that the number of data bytes in SCFRDR is less than the receive trigger count, and that no further data has been received for at least 15 etu after the stop bit of the last receive data in asynchronous mode. This bit is not set in clock synchronous mode. 0: Indicates that data is being received or has been successfully received and that there is no receive data in SCFRDR. [Clearing conditions] • A power-on reset is executed. • All the receive data in the SCFRDR has been read, and 0 is written to TO. 1: Indicates that no further receive data has been received (receive timeout). [Setting condition] • The number of data bytes in SCFRDR is less than the receive trigger count and no further data has been received for at least 15 etu after the stop bit of the last receive data.* Note: etu: Elementary Time Unit (time for transfer of 1 bit) Equivalent to 1.5 frames with an 8-bit, 1-stop-bit format.
1	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	ORER	B'0	R/WC0	Overrun Error Indicates that an overrun error has occurred in reception and abnormal termination is caused. If an overrun error occurs, the receive data prior to the overrun error is retained in SCFRDR and the data received subsequently is discarded. Any subsequent serial reception is disabled while the ORER flag is 1. To resume data reception after clearing the ORER flag, be sure to first read (or clear) data in the receive FIFO and handle the error, then clear the ORER flag. 0: Indicates that data is being received or has been successfully received. [Clearing conditions] • A power-on reset is executed. • 0 is written to ORER. 1: Indicates that an overrun error has occurred in reception. [Setting condition] • The next serial reception has been completed while SCFRDR is full of 16-byte data. Note: When bit RE in SCSCR is cleared to 0, the ORER flag is not affected and its previous state is retained.

50.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

50.3.1 Operation in Asynchronous Mode

In asynchronous mode, the SCIF performs serial communication, in which data is transmitted/received in character units using the attached start bit indicating the start of communication and stop bit indicating the end of communication.

Figure 50.7 shows the general format for asynchronous serial communication.

In asynchronous serial communication, the transmission line is usually kept marked (high level). The SCIF monitors the transmission line, and when it finds a space (low level), it regards the space as a start bit and starts serial communication.

One character in serial communication consists of a start bit (low level), followed by transmit/receive data (LSB-first; from the lowest bit), a parity bit (high or low level), and a stop bit (high level).

During reception in asynchronous mode, the SCIF performs synchronization at the falling edge of the start bit. Communication data is acquired at the center of each bit because the SCIF samples data at the eighth pulse of the clock which has a frequency of 16 times the bit rate.

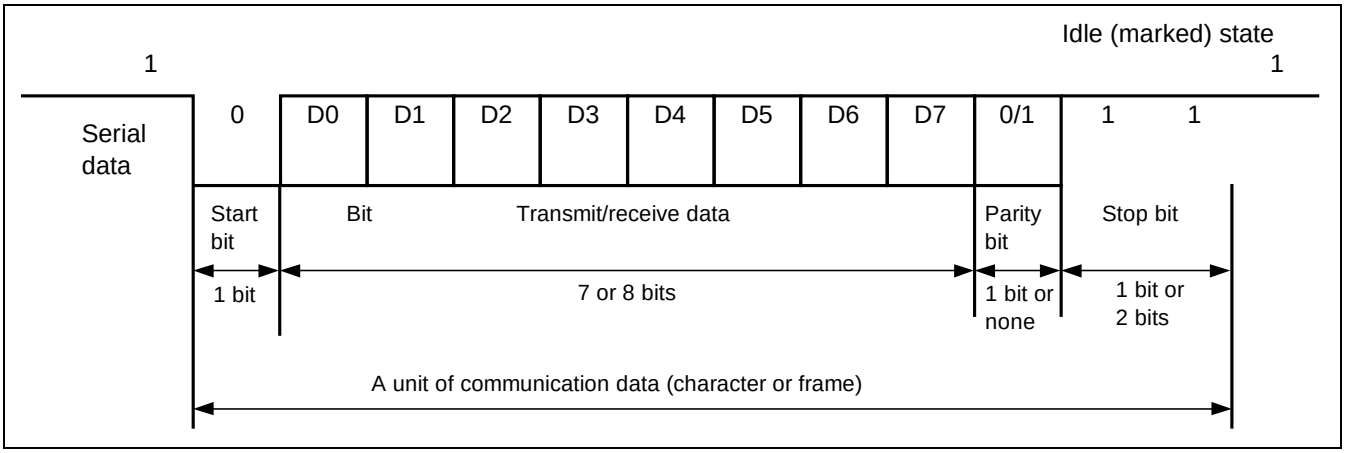

Figure 50.7 Data Format in Asynchronous Mode (Example of 8-Bit Data with Parity and Two Stop Bits)

(1) Transmission/Reception Format

Table 50.8 shows available data transfer formats. The SCIF supports 8 transfer formats, which can be specified by SCSMR.

Table 50.8 Serial Transmission/Reception Formats (Asynchronous Mode)

SCSMR Settings			Serial Transmission/Reception Format and Frame Length											
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	S	8-bit data								STOP		
		1	S	8-bit data								STOP	STOP	
	1	0	S	8-bit data								P	STOP	
		1	S	8-bit data								P	STOP	STOP
1	0	0	S	7-bit data							STOP			
		1	S	7-bit data							STOP	STOP		
	1	0	S	7-bit data							P	STOP		
		1	S	7-bit data							P	STOP	STOP	

[Legend]
S: Start bit
STOP: Stop bit
P: Parity bit

(2) Clock

The transfer clock can be selected from the following two clocks using the CKE [1:0] bits in SCSCR:

- Internal clock generated by the on-chip baud rate generator
- External clock generated by an external clock baud rate generator

(3) Data Transmission/Reception

(a) Initialization of SCIF (Asynchronous Mode)

Before transmitting/receiving data or changing the operating mode or communication format, the SCIF should be initialized using the sample flowchart for SCIF initialization shown in Figure 50.8.

[Notes]

Clearing the TE bit to 0 initializes SCTSR. However, SCFSR, SCFTDR, and SCFRDR contents are retained even if the TE and RE bits are cleared to 0.

The TE bit should be cleared to 0 after all transmit data has been sent and the TEND flag has been set in SCFSR. The TE bit can be cleared to 0 during transmission, but the data being transmitted will enter the marked state after clearing. In addition, before setting the TE bit to 1 to restart the transmission, set the TFRST bit to 1 in SCFCR to reset SCFTDR.

When an external clock is used, do not stop the clock during operation or initialization. If stopped, the operation will be unreliable. Furthermore, when the baud rate generator for external clock is also to be used, be sure to make settings for it before starting initialization of the SCIF.

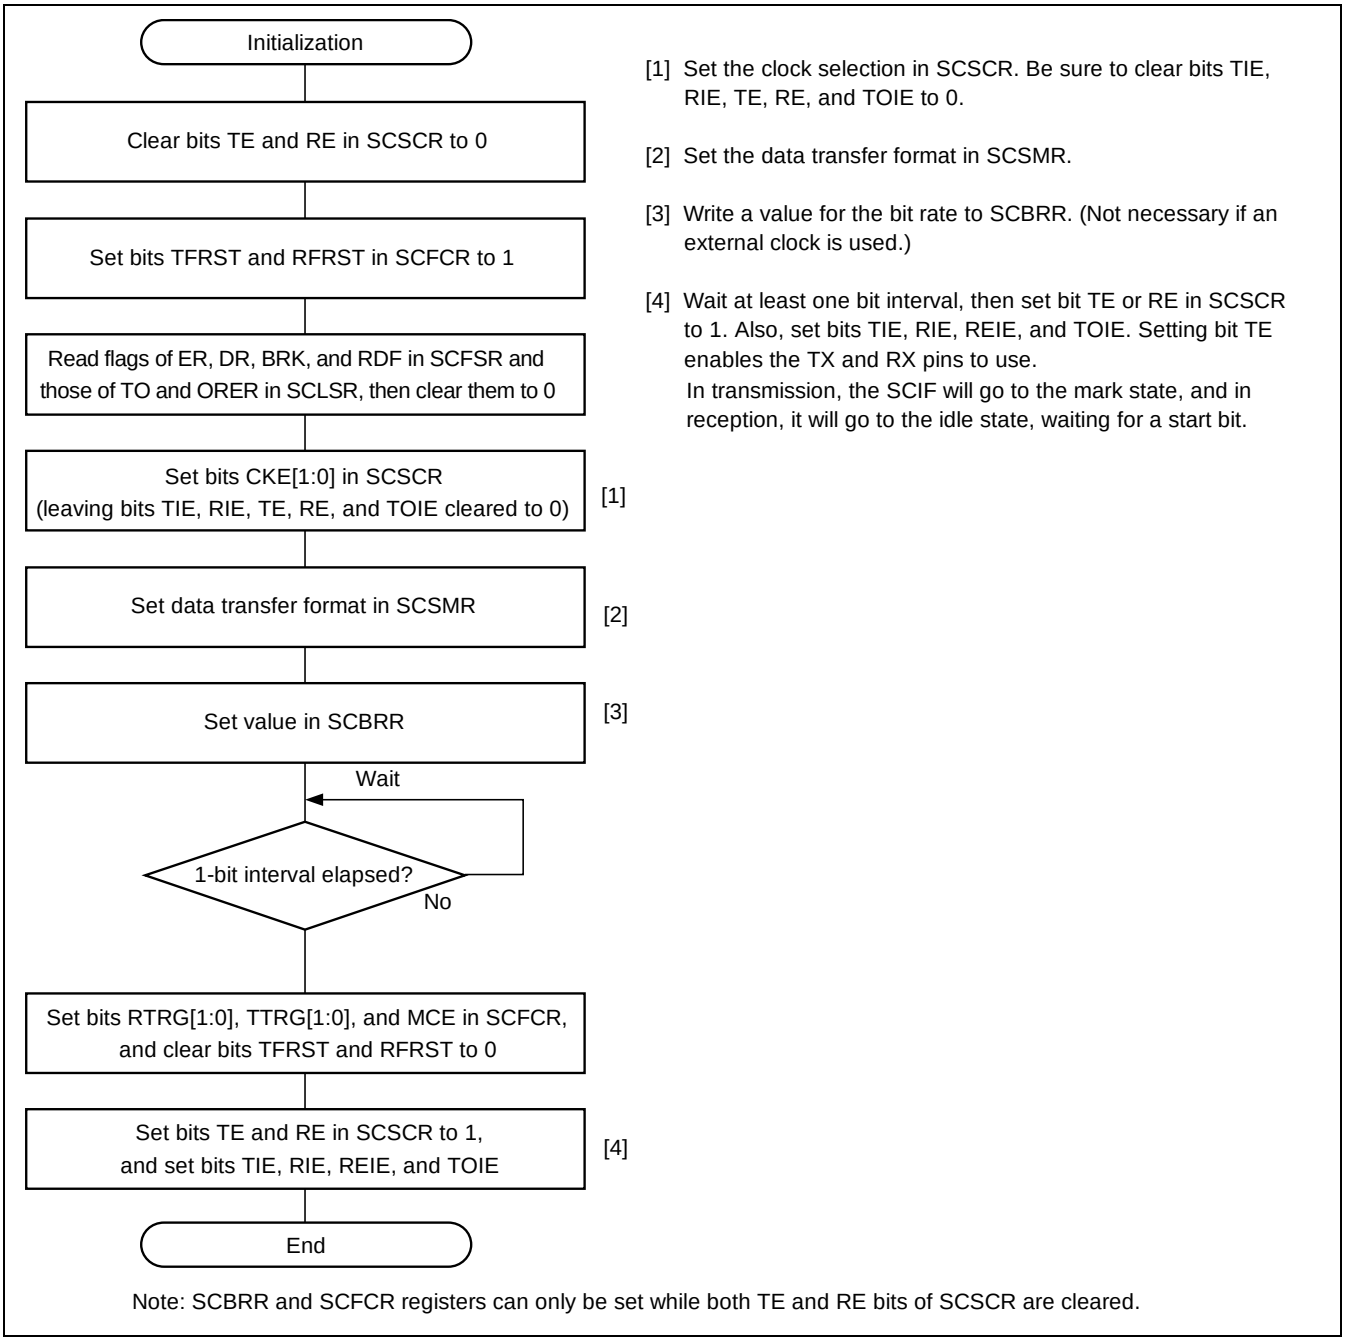

Figure 50.8 Sample Flowchart for Initializing the SCIF

(b) Serial Data Transmission (Asynchronous Mode)

Figure 50.9 shows a sample flowchart for serial transmission.

After the SCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

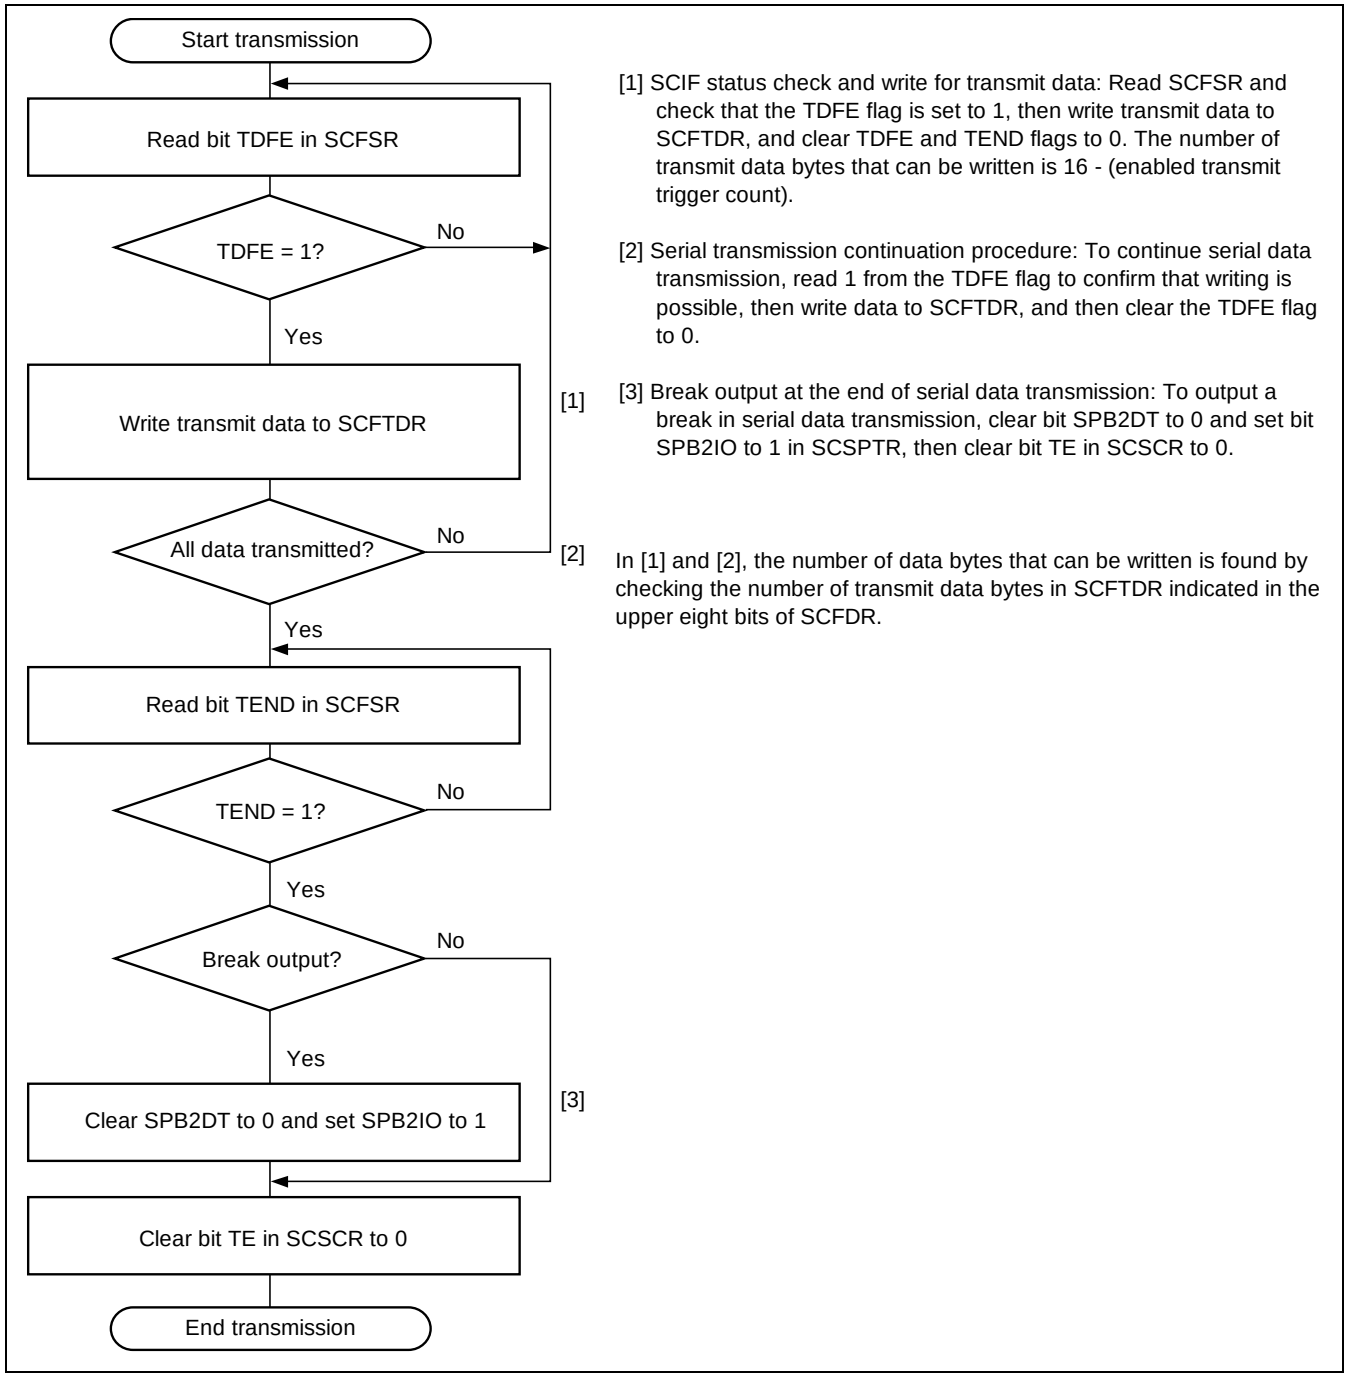

Figure 50.9 Sample Flowchart for Serial Transmission

In serial transmission, the SCIF operates as follows:

1. When data is written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR and starts transmitting. Confirm that the TDFE flag in SCFSR is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is at least (16- (transmit trigger count)).
2. When data is transferred from SCFTDR to SCTSR and the SCIF starts transmission, consecutive transmission is performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR is equal to or less than the transmit trigger count specified in SCFCR, the TDFE flag is set. If the TIE and TEIE bits in SCSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. The serial transmit data is sent from the TX pin in the following order:
   A. Start bit: One 0-bit is output.
   B. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
   C. Parity bit: One parity bit (even or odd parity) is output.
      A format that does not output a parity bit can also be selected.
   D. Stop bit(s): One or two stop bits are output.
   E. Marked state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The SCIF checks transmit data in SCFTDR when sending the stop bit. If there is data in it, the SCIF transfers the data from SCFTDR to SCTSR, sends the stop bit, and then starts serial transmission of the next frame. If there is no transmit data, the SCIF sets the TEND flag to 1 in SCFSR and sends out the stop bit, and then the marked state is entered to output 1 continuously. At this time, if the TIE and TEIE bits in SCSCR are set to 1, a transmit-end interrupt (TEND) request occurs.

Figure 50.10 shows an example of transmission in asynchronous mode.

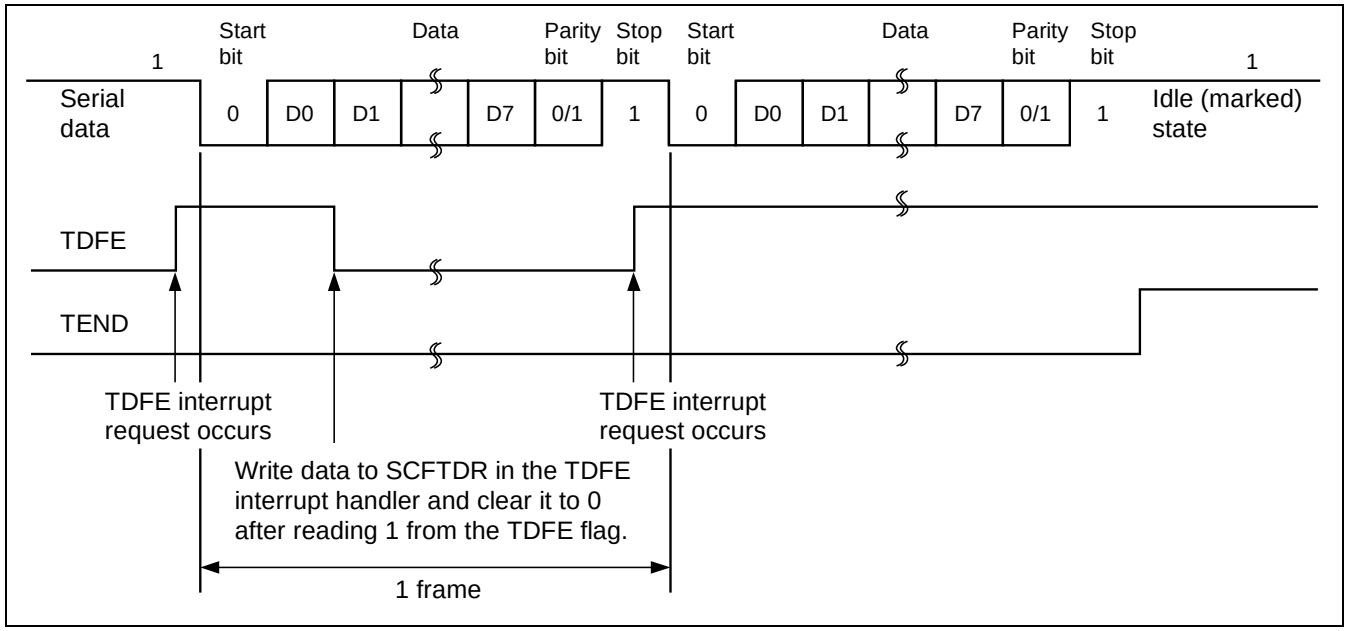

Figure 50.10 Sample SCIF Transmission Operation (Example of 8-Bit Data with Parity and One Stop Bit)

4. When modem control is enabled, transmission can be stopped or resumed in accordance with the CTS# input value. When CTS# is set to 1 during transmission, the marked state is entered after one frame of data transmission is ended. Setting CTS# to 0 restarts outputting the next transmit data from the start bit. Figure 50.11 shows an example of the operation with modem control enabled.

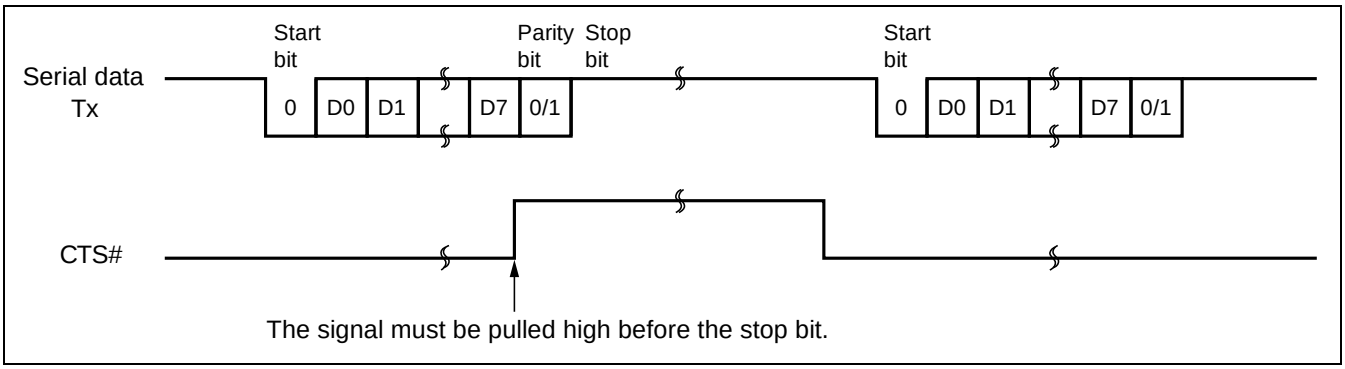

Figure 50.11 Sample Operation with Modem Control Enabled (CTS#)

(c) Serial Data Reception (Asynchronous Mode)

Figures 50.12 and 50.13 show sample flowcharts for serial reception.

After the SCIF reception operation is enabled, serial data reception can be performed using the following procedure:

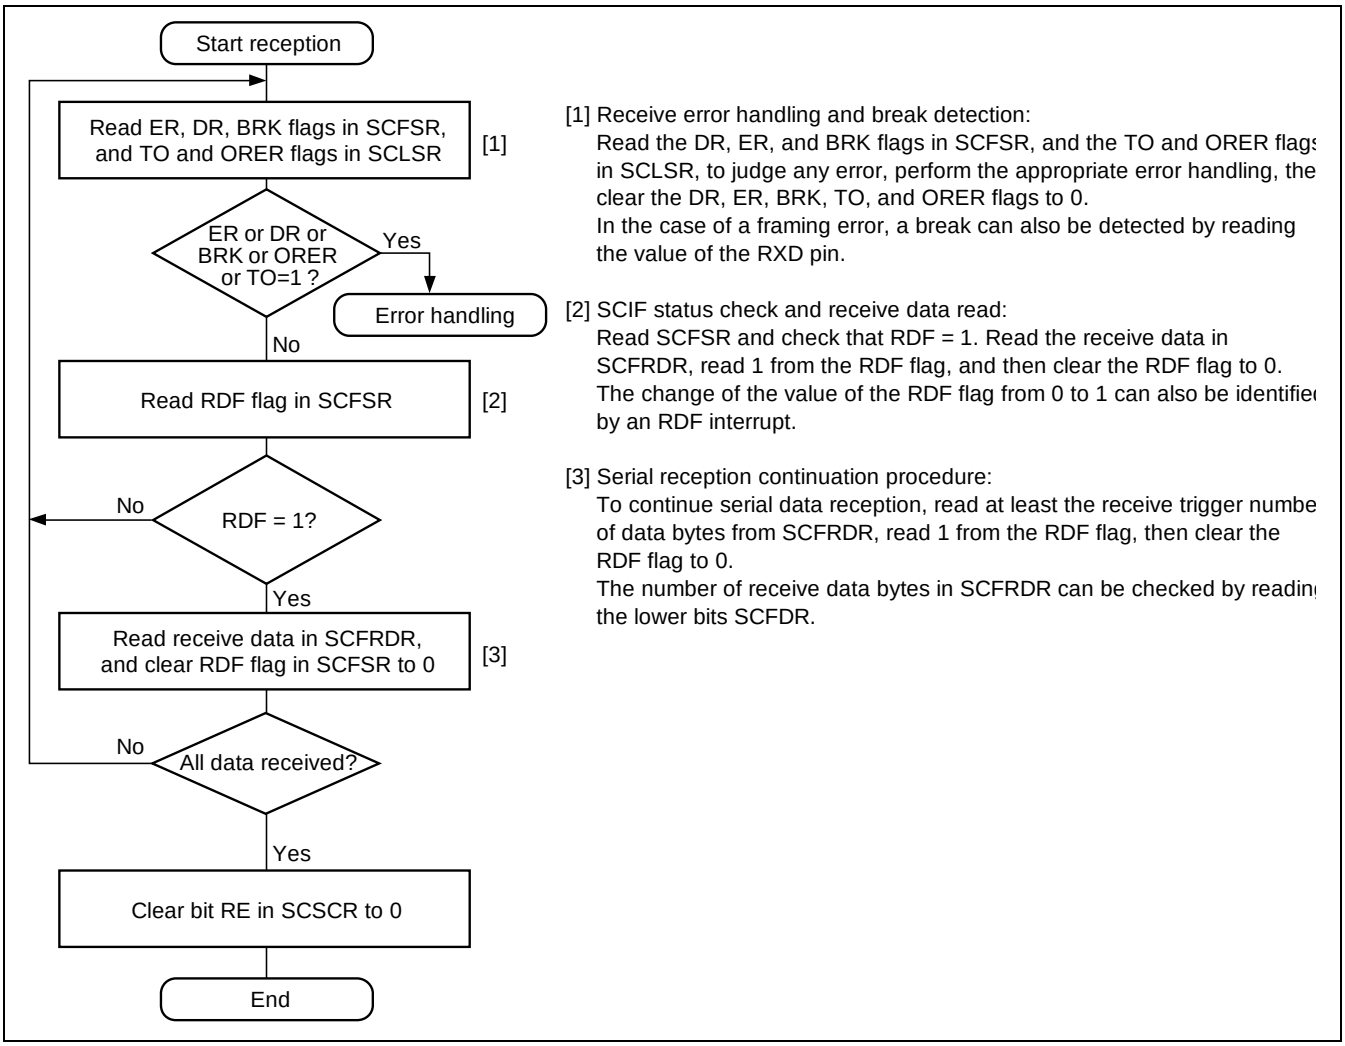

Figure 50.12 Sample Flowchart for Serial Reception (1)

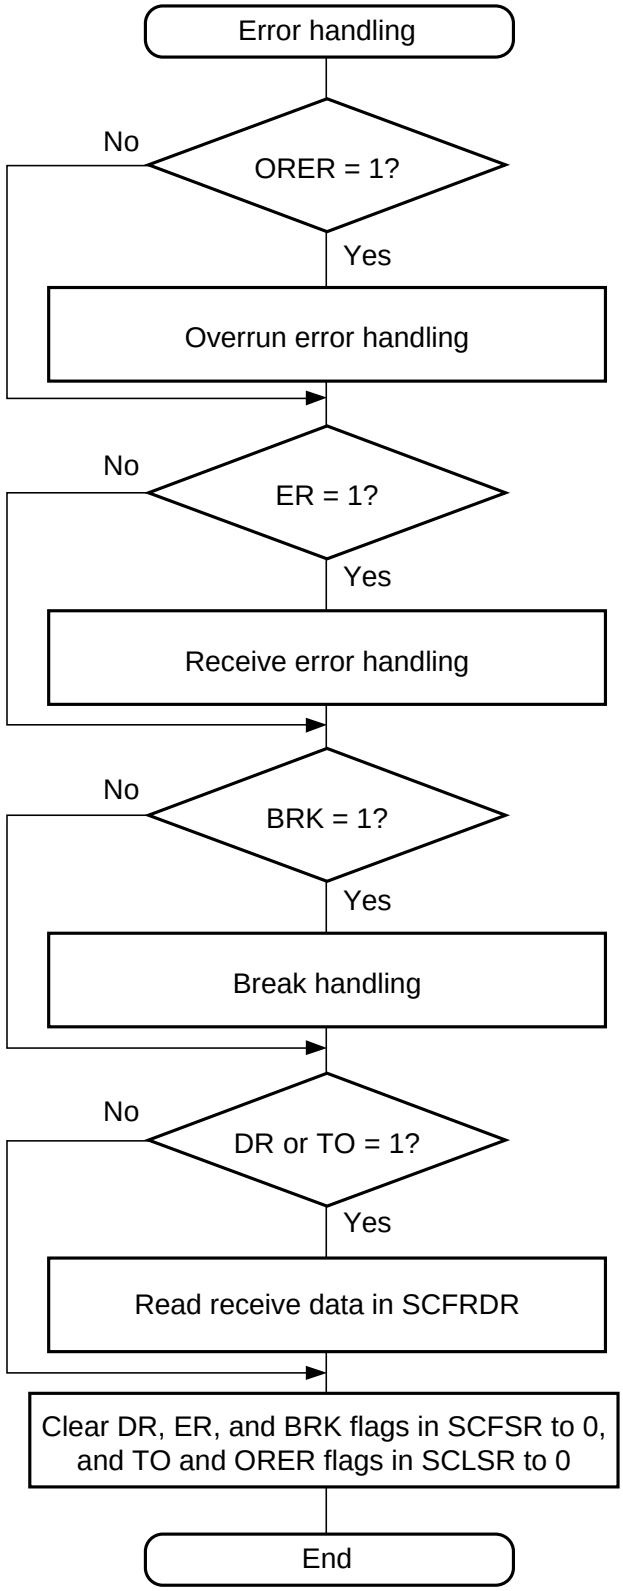

Whether a framing error or parity error has occurred in the receive data that is to be read from SCFRDR can be determined by checking bits FER and PER in SCFSR.

Figure 50.13 Sample Flowchart for Serial Reception (2)

In serial reception, the SCIF operates as follows:

1. The SCIF monitors the transmission line, and when detecting the start bit 0, it performs internal synchronization and starts reception.
2. The SCIF stores the received data in SCRSR in LSB-to-MSB order.
3. The SCIF receives the parity bit and stop bit.
   After receiving these bits, the SCIF performs the following checks:
   A. Stop bit: The SCIF checks whether the stop bit is 1.
      If there are two stop bits, it checks only the first stop bit.
   B. Receive data: The SCIF checks that receive data can be transferred from the receive shift register (SCRSR) to SCFRDR.
   C. Overrun error: The SCIF checks that the ORER flag is 0, indicating that no overrun error has occurred.
   D. Break state: The SCIF checks that the BRK flag is 0, indicating that the break state is not set.
   If the SCIF can confirm the conditions of (b), (c), and (d), it stores the receive data in SCFRDR.

   Note: The SCIF continues to receive data even when a parity error or a framing error occurs.

4. If the RDF flag changes to 1 while the RIE bit in SCSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs.
   If the DR flag changes to 1 while the RIE bit in SCSCR is 1, a receive-data-ready interrupt (DR) request occurs.
   If the TO flag changes to 1 while the TOIE bit in SCSCR is 1, a timeout interrupt (TO) request occurs.
   If the ER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a receive-error interrupt (ER) request occurs.
   If the BRK flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a break interrupt (BRK) request occurs.
   If the ORER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, an overrun-error interrupt (ORER) request occurs.

Figure 50.14 shows an example of reception in asynchronous mode.

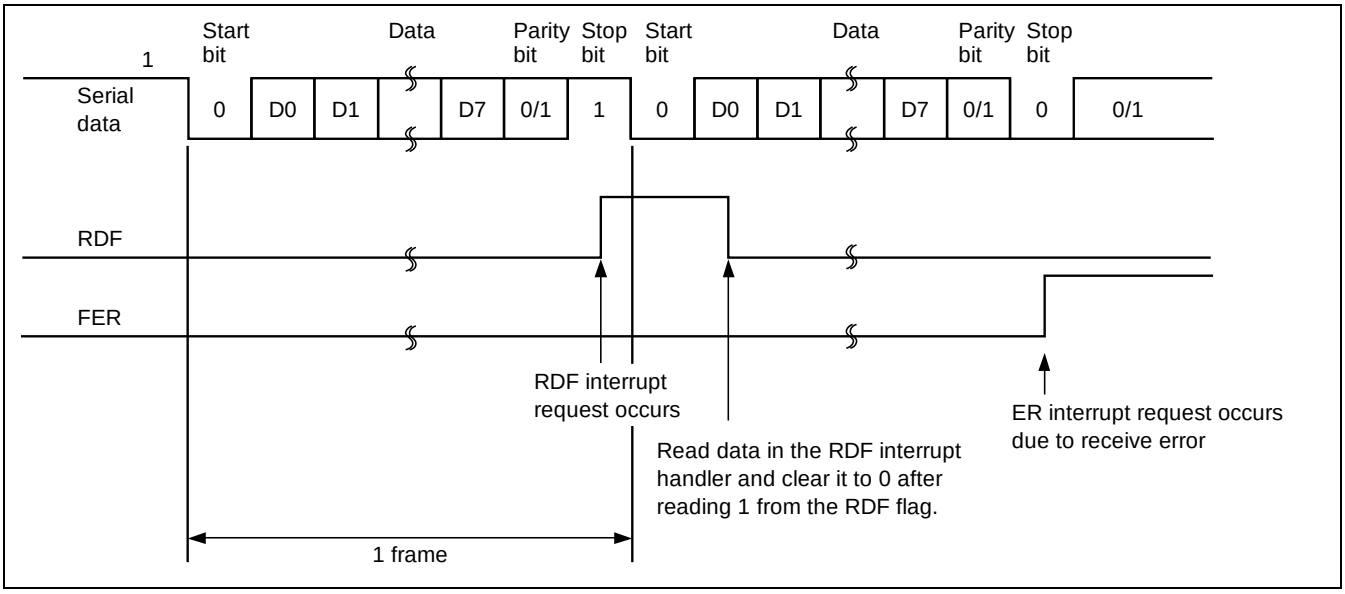

Figure 50.14 Sample SCIF Receive Operation (Example of 8-Bit Data with Parity and One Stop Bit)

5. When modem control is enabled, the RTS# signal is output when SCFRDR is empty. When RTS# is 0, data can be received. When RTS# is set to 1, the number of data bytes in SCFRDR is equal to or more than the RTS# output active trigger count.

Figure 50.15 shows an example of the operation with modem control enabled.

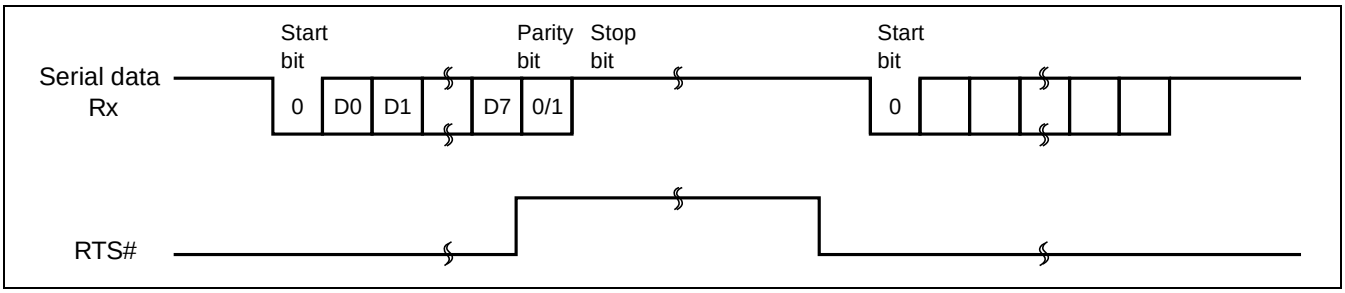

Figure 50.15 Example of the Operation with Modem Control Enabled (RTS#)

50.3.2 Operation in Clock Synchronous Mode

Clock synchronous mode, in which data is transmitted and received in synchronization with clock pulses, is suitable for fast serial communication.

Figure 50.16 shows the general format for clock synchronous serial communication. In the clock synchronous serial communication, data on the communication line is output between one falling edge of the synchronization clock and the next falling edge. The data decision is done at the rising edge of the clock.

In serial communication, each character is output starting with the LSB and ending with the MSB. After the MSB is output, the communication line retains the state of the last data.

In clock synchronous mode, the SCIF receives data in synchronization with a rising edge of the synchronization clock.

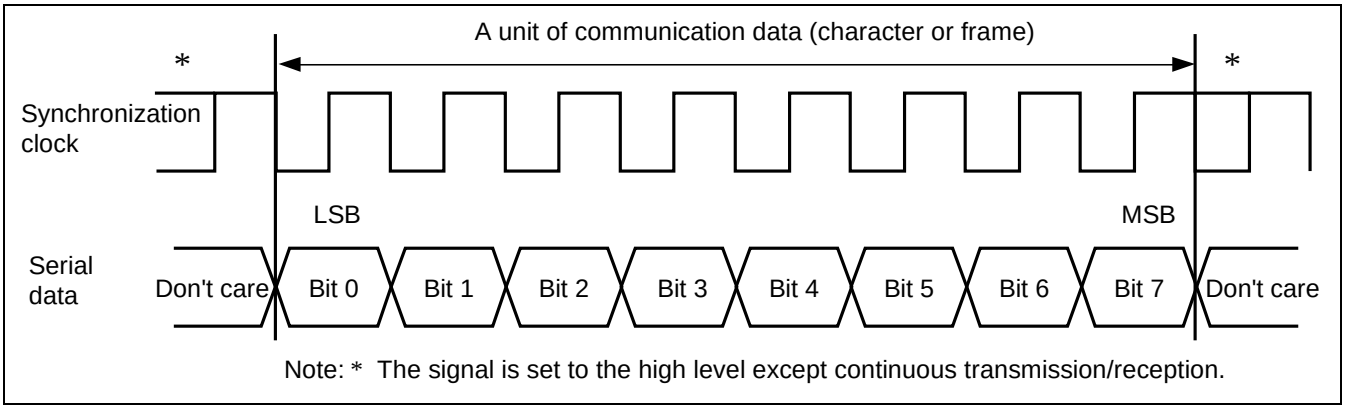

Figure 50.16 Data Format for Clock Synchronous Communication

(1) Data Transfer Format

The data transfer format is fixed to 8 bits. No parity bit can be added.

(2) Clock

The clock can be selected from the following two clocks using the C/A# bit in SCSMR and the CKE [1:0] bits in SCSCR:

- Internal clock generated by the on-chip baud rate generator
- External synchronization clock input at the SCK pin

When the SCIF is operated on an internal clock, the synchronization clock is output from the SCK pin. Eight synchronization clock pulses are output in one-character transfer, and when no transfer is performed the clock is fixed high. When only reception operation is performed, selecting an internal clock outputs clock pulses until the number of data bytes in the receive FIFO reaches the specified receive trigger count, while the RE bit in SCSCR is 1.

(3) Data Transmission/Reception

(a) Initialization of SCIF (Synchronous Mode)

Before transmitting/receiving data or changing the operating mode or communication format, the TE and RE bits in SCSCR to 0 and then the SCIF should be initialized using the sample flowchart for SCIF initialization shown in Figure 50.17.

[Note]

Clearing the TE bit to 0 initializes SCTSR. However, clearing the RE bit to 0 does not affect the RDF, PER, FER, and ORER flags and SCFRDR contents.

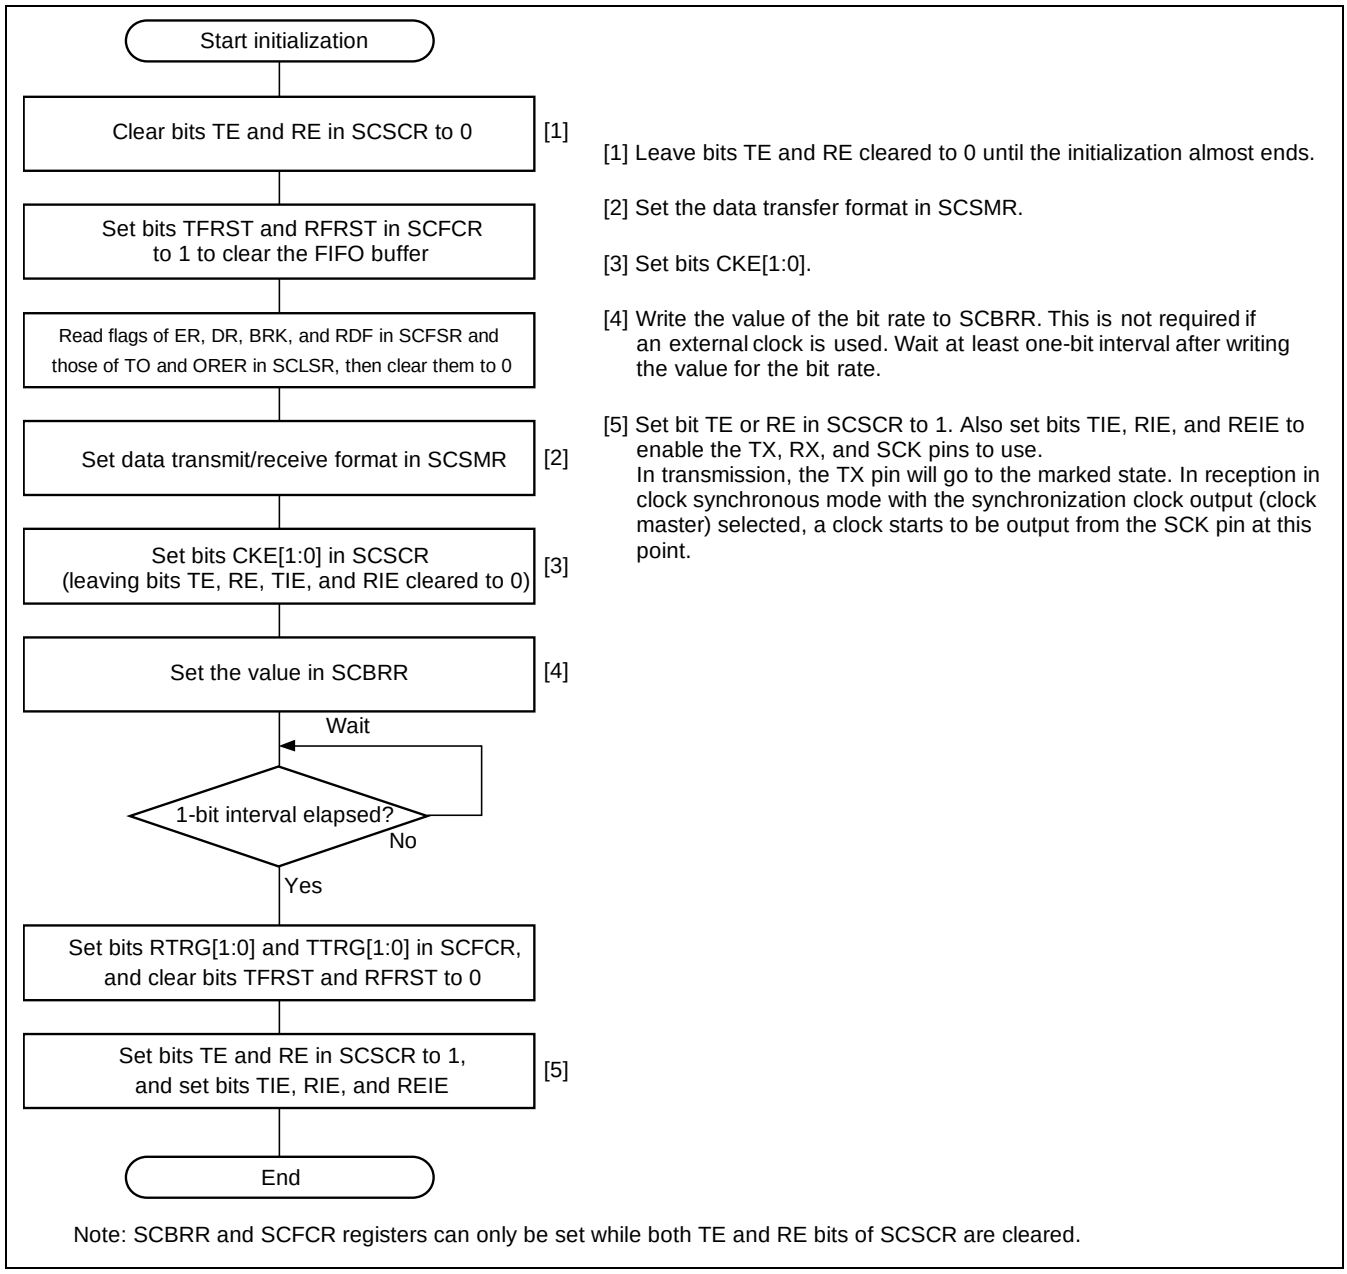

Figure 50.17 Sample Flowchart for SCIF Initialization

(b) Serial Data Transmission (Clock Synchronous mode)

Figure 50.18 shows a sample flowchart for serial transmission.

After the SCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

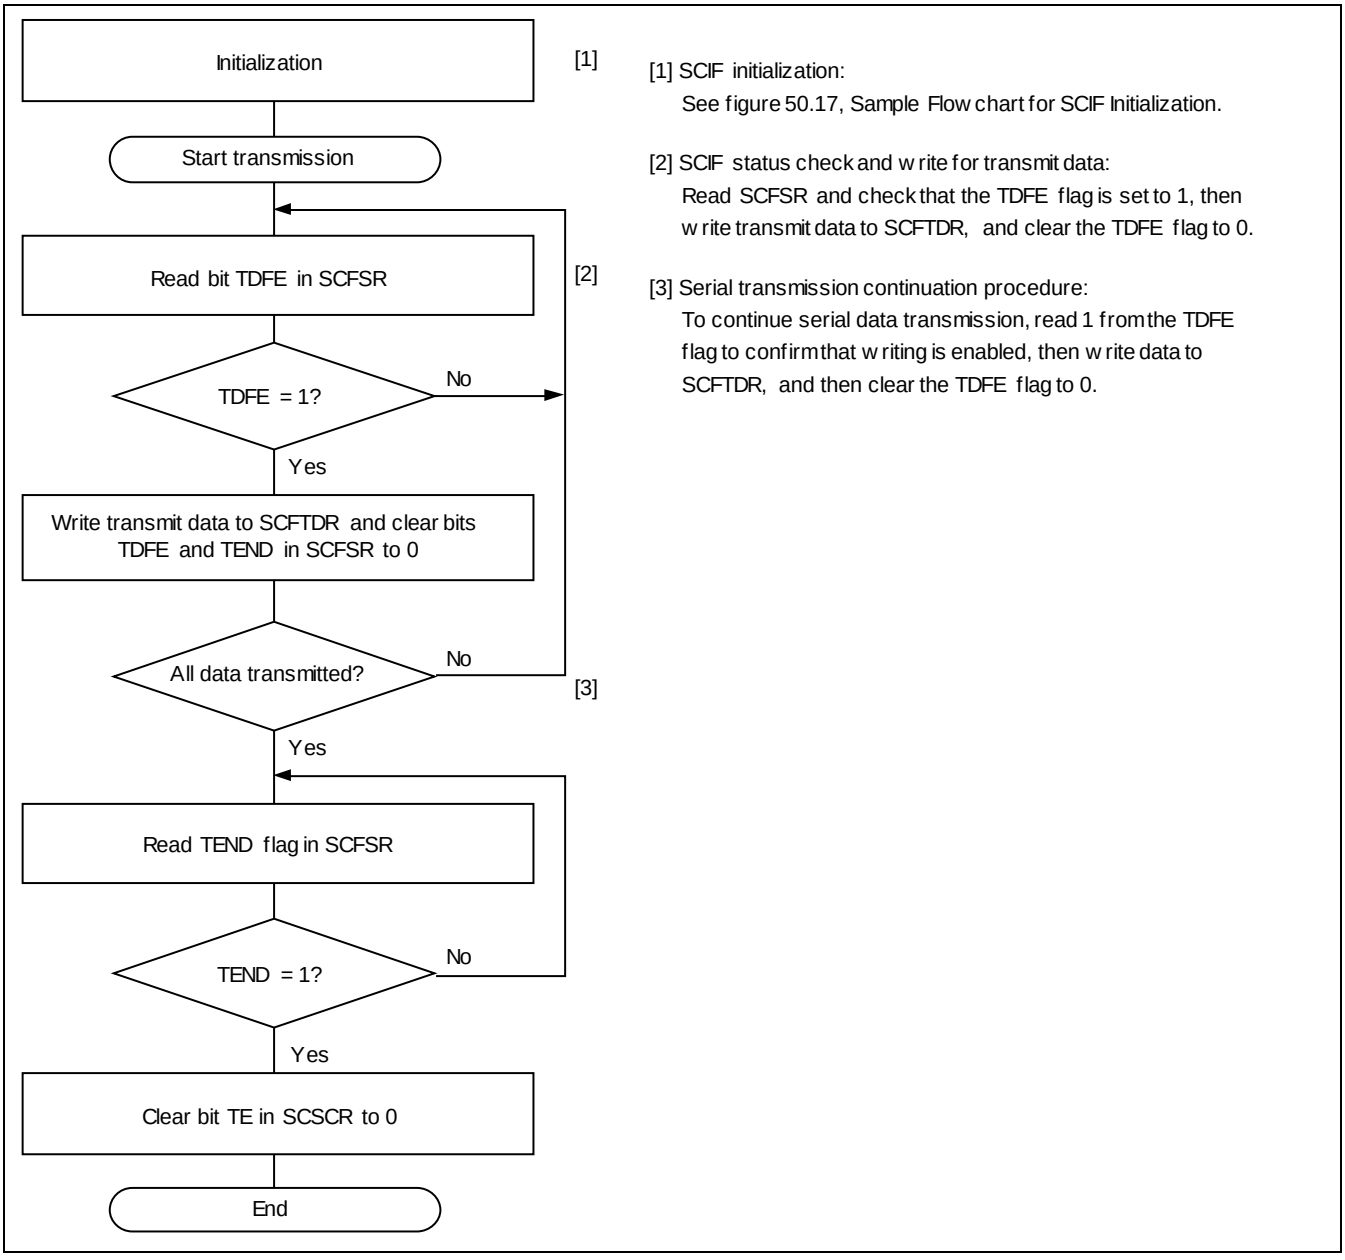

Figure 50.18 Sample Flowchart for Serial Transmission

In serial data transmission, the SCIF operates as described below:

1. When data is written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR to start transmission. Confirm that the TDFE flag in SCFSR is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is at least (16- (the transmit trigger count)).
2. After the SCIF transfers data from SCFTDR to SCTSR and starts data serial transmission, the SCIF consecutively transmits it until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR is equal to or less than the transmit trigger count set in SCFCR, the TDFE flag is set. If the TIE and TEIE bits in SCSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. When the external clock is selected, data is output in synchronization with the input clock. The serial transmit data is output at the TX pin in the LSB-first order.
3. The SCIF checks transmit data in SCFTDR when sending the last bit. If there is transmit data, the SCIF transfers the data to SCTSR, and starts serial transmission of the next frame. If there is no transmit data left, the TEND flag in SCFSR is set to 1, and the transmit data pin (TX pin) retains its state after the last bit is sent. At this time, if the TIE and TEIE bits in SCSCR are set to 1, a transmit-end interrupt (TEND) request occurs.
4. After serial transmission ends, the SCK pin is fixed high.

Note: In clock synchronous mode, when transmit data is written to SCFTDR by the DMAC, the TEND flag may not be cleared. Therefore, if the DMAC is used for transmission in clock synchronous mode, read the TEND flag in the following method.
   1. Confirm that data transfer is completed in the DMAC.
   2. Read the TEND flag.
   3. Clear the TEND flag to 0 if TEND = 1.
   4. Read the TEND flag again.
   5. Use the second-read TEND flag.

Figure 50.19 shows an example of SCIF serial transmission in clock synchronous mode.

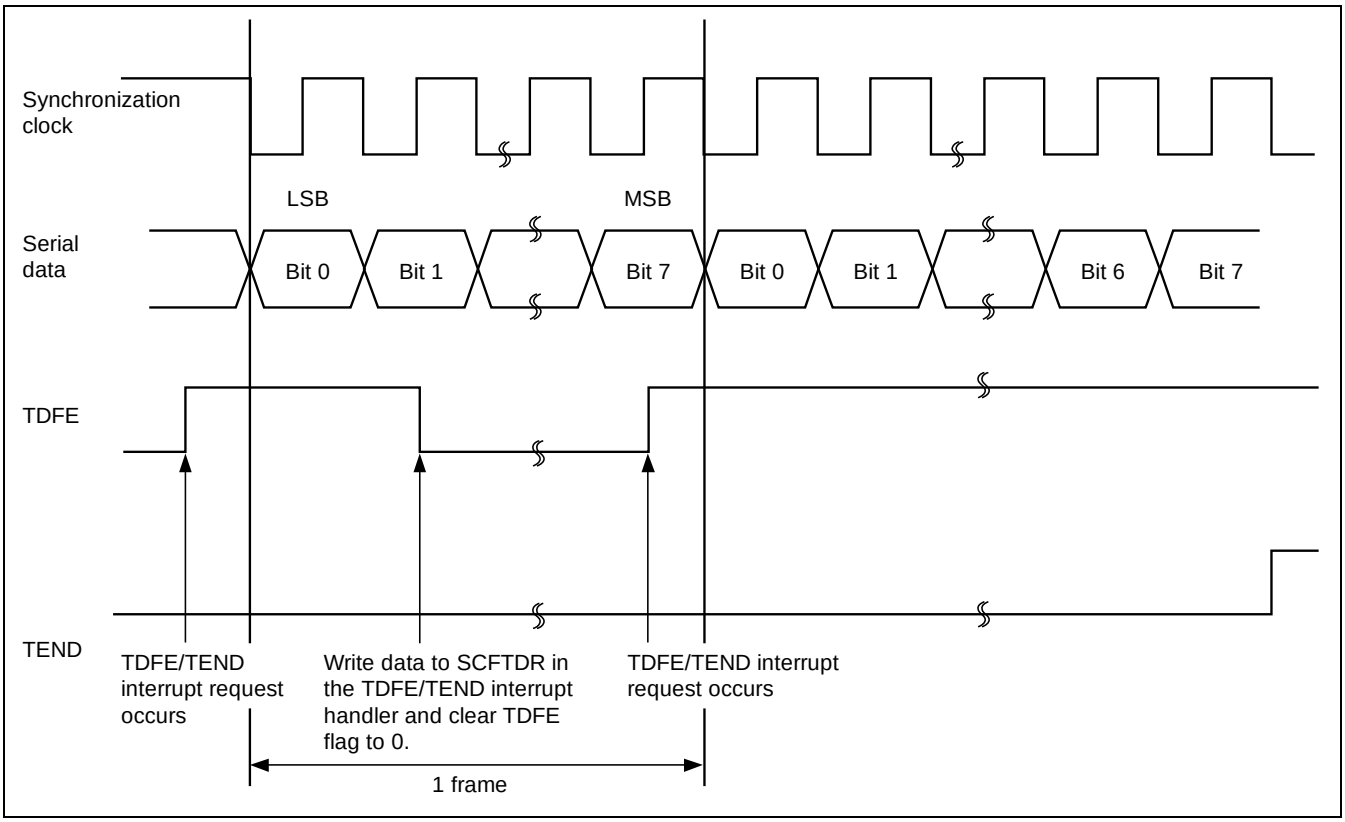

Figure 50.19 Example of SCIF Serial Transmission in Clock Synchronous Mode

(c) Serial Data Reception (Clock Synchronous Mode)

Figures 50.20 and 50.21 show sample flowcharts for serial reception.

The SCIF reception should be enabled before taking the following steps for serial data reception.

When switching operating mode from asynchronous mode to clock synchronous mode without initializing the SCIF, check that the ORER, PER3 to PER0, and FER3 to FER0 flags are cleared to 0.

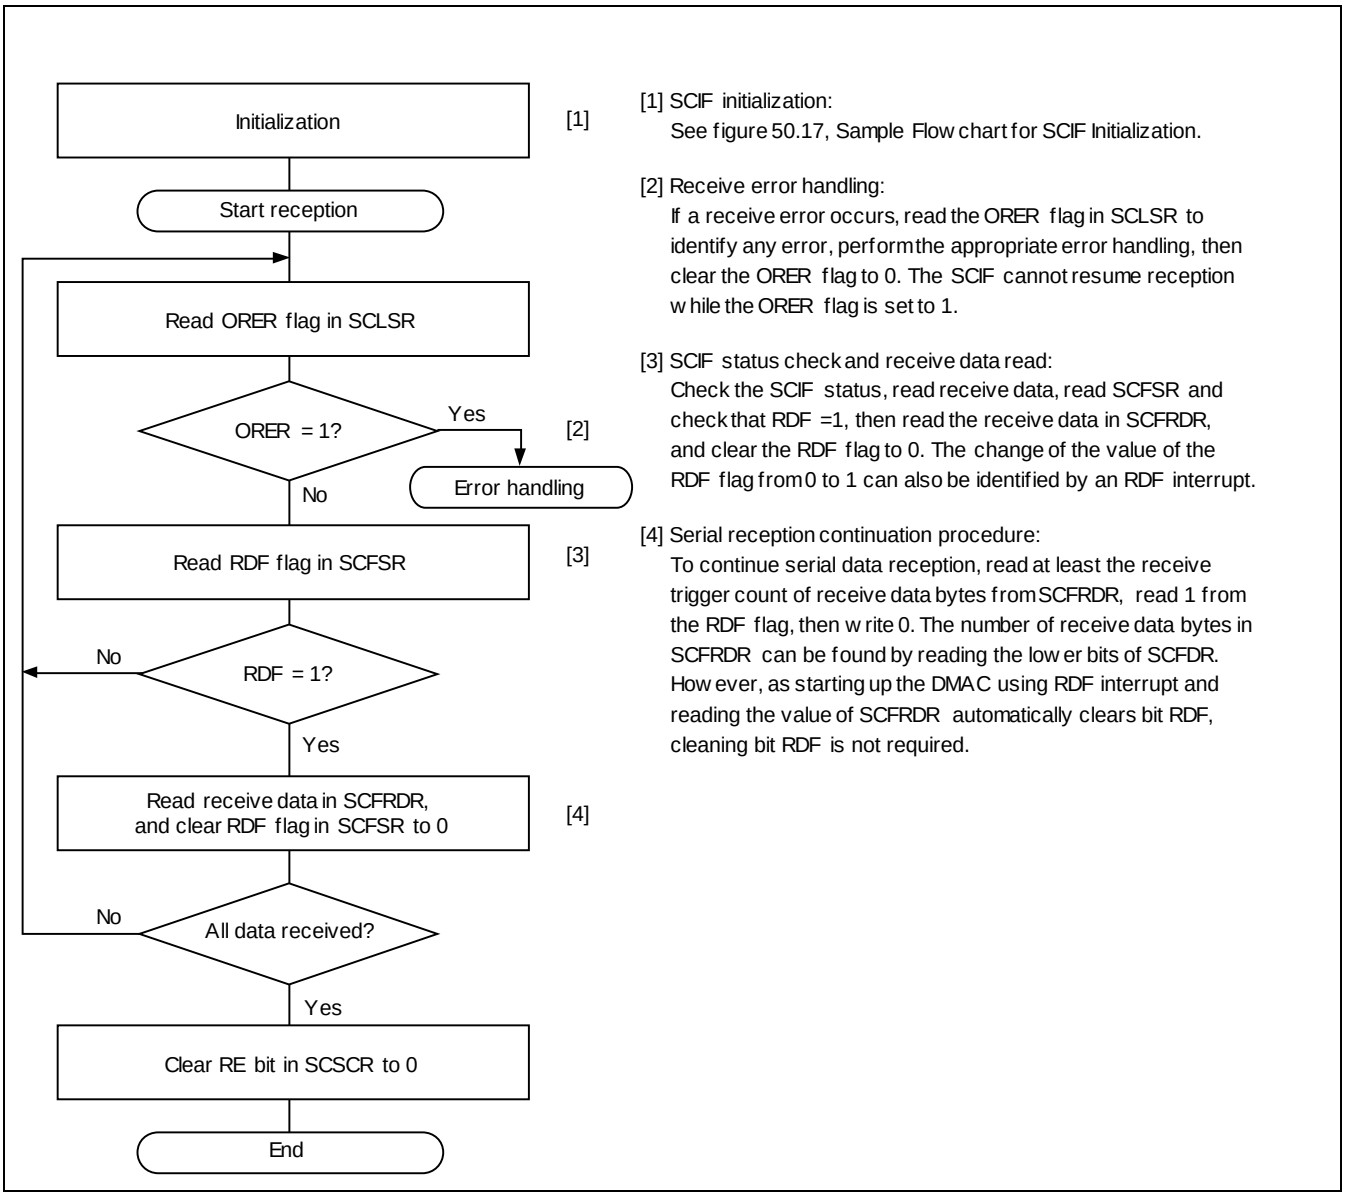

Figure 50.20 Sample Flowchart for Serial Data Reception

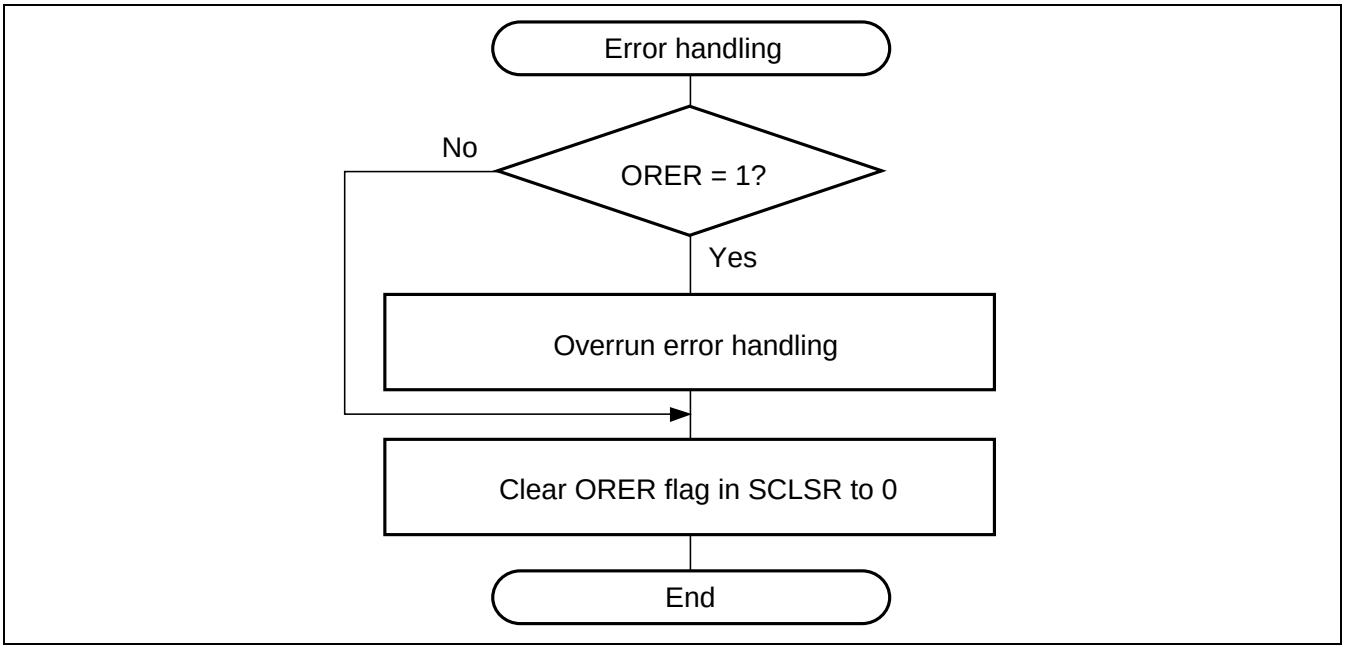

Figure 50.21 Sample Flowchart for Serial Data Reception

In serial data reception, the SCIF operates as described below:

1. The SCIF starts receiving data in synchronization with synchronization clock input or output.
2. The SCIF stores receive data in SCRSR in LSB-to-MSB order.
   After receiving the data, the SCIF first checks if the receive data can be transferred from SCRSR to SCFRDR, then starts storing the receive data in SCFRDR.
   If the SCIF detects an overrun error, the SCIF cannot receive subsequent data.
3. If the RDF flag changes to 1 while the RIE bit in SCSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs. If the ORER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a break interrupt (BRI) request occurs.

Figure 50.22 shows an example of SCIF reception in clock synchronous mode.

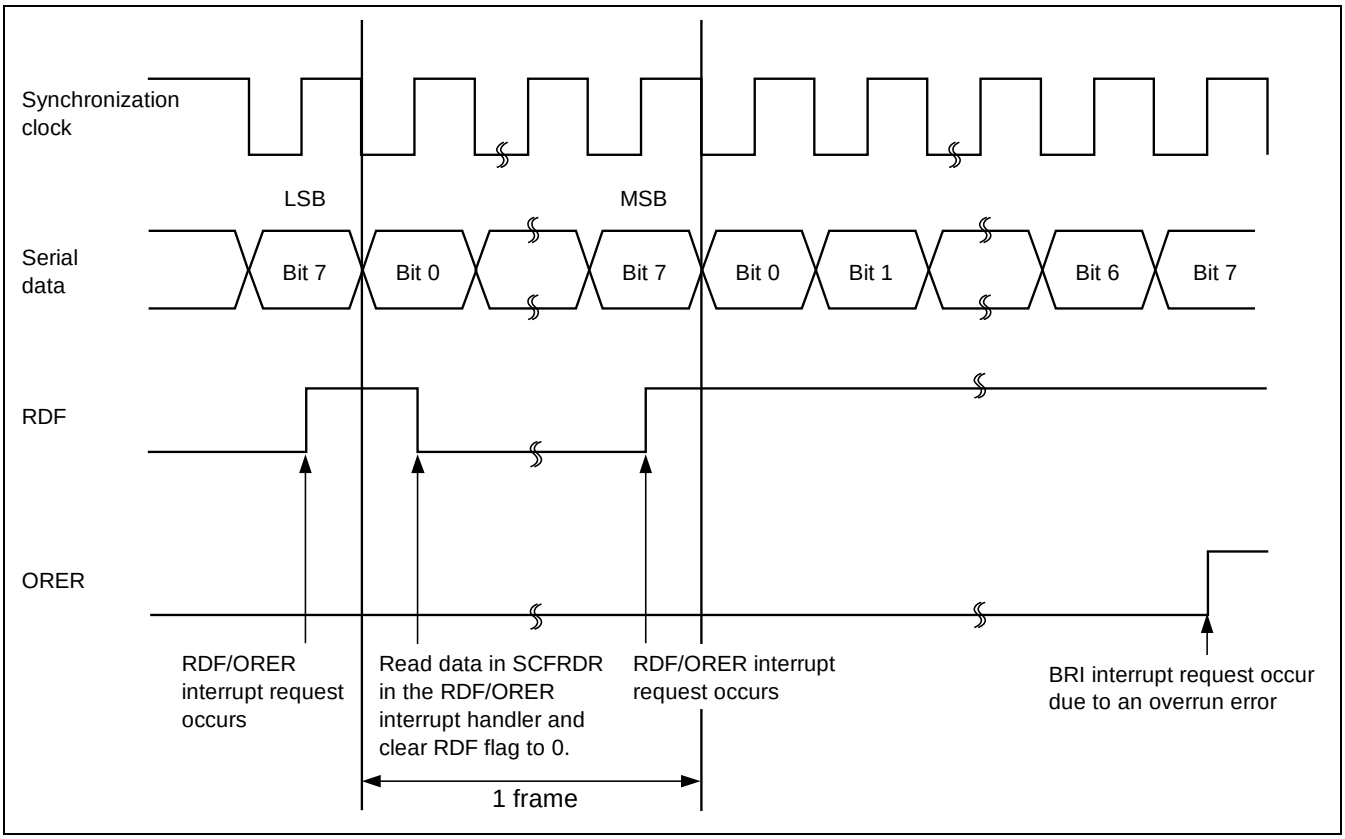

Figure 50.22 Example of SCIF Reception in Clock Synchronous Mode

(d) Simultaneous Serial Data Transmission/Reception (Clock Synchronous Mode)

Figure 50.23 shows a sample flowchart for simultaneous serial data transmission/reception.

The SCIF transmission and reception should be enabled before taking the following steps for simultaneous serial data transmission/reception.

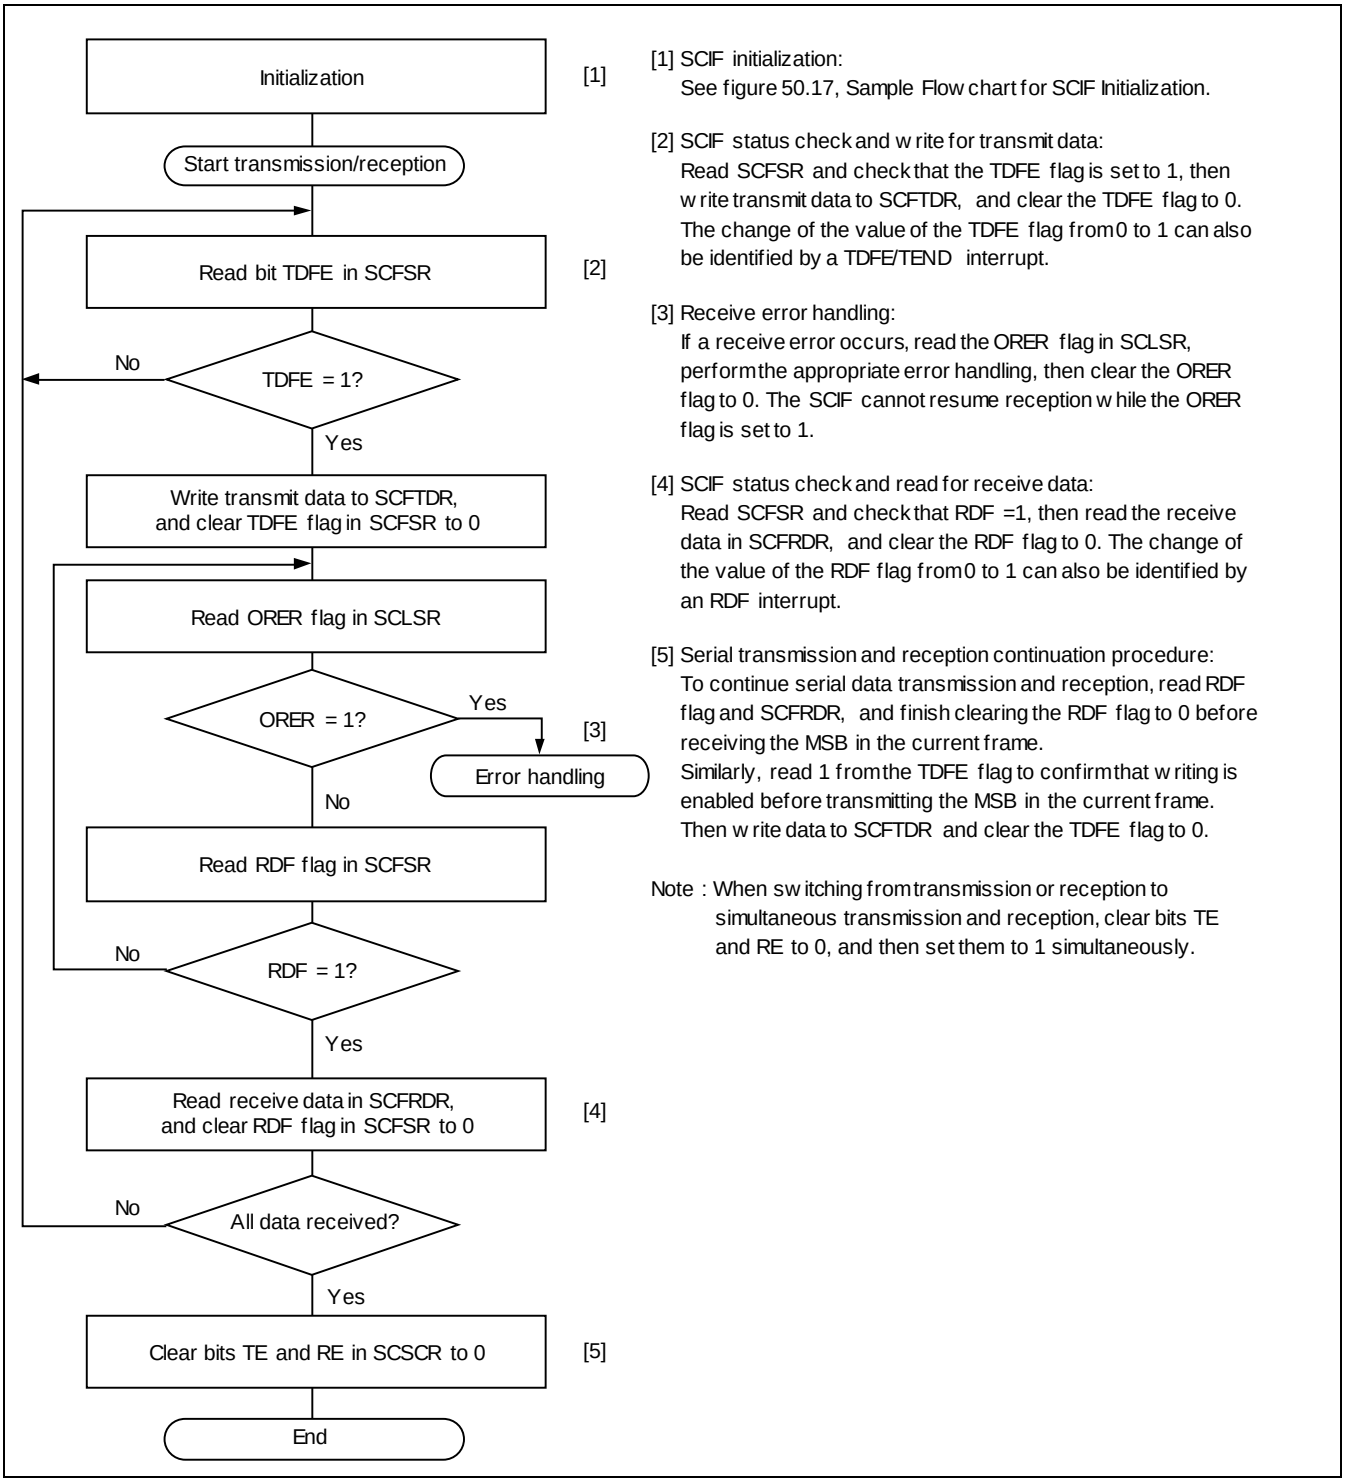

Figure 50.23 Sample Flowchart for Simultaneous Serial Data Transmission/Reception

50.3.3 Baud Rate Generator for External Clock (BRG)

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

(1) Overview

The SCIF incorporates a baud rate generator for external clock (abbreviated as BRG, hereafter). The BRG supplies a sampling clock (BRGCLK) to the SCIF core by dividing the external clock SC_CLK (selectable between SCIF_CLK and SCKi) by 1 to $2^{16} - 1$. In addition, the BRG switches the output between the external clock SCK and divided clock.

Figure 50.24 shows a block diagram of the BRG.

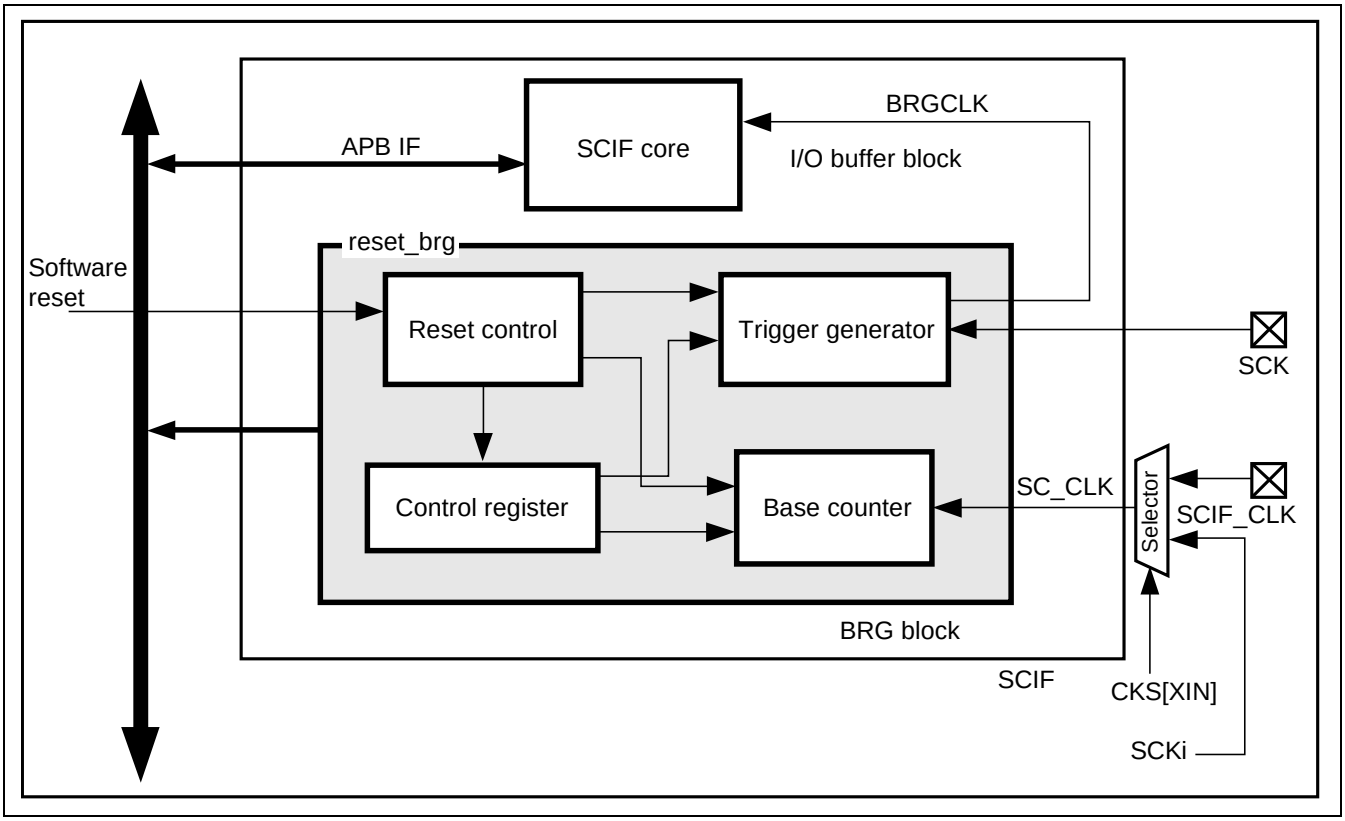

Figure 50.24 BRG Block Diagram

(a) Reset Controller:

The reset controller handles resetting the control register, base counter, and trigger generator.

(b) Control Register:

The control register has the frequency division register and clock select register.

(c) Base Counter:

The base counter is a 16-bit CLK synchronization counter that is used to determine the timing for generating a frequency divided clock.

(d) Trigger Generator:

The trigger generator generates rising-edge/falling-edge triggers for a frequency divided clock with the timing according to values of the frequency division register and base counter. The triggers are used to generate the frequency divided clock. In addition, the trigger generator switches the output between the SCK (external clock input) and frequency divided clock.

(2) Register Configuration

Table 50.9 shows the registers in the BRG block.

Table 50.9 List of Registers

Name	Abbreviation	R/W	Initial Value	Relative Address	Access Size
Frequency division register	DL	R/W	H'0000	H'30	16
Clock select register	CKS	R/W	H'0000	H'34	16

(3) Frequency Division Register (DL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register specifies the value of frequency division for the frequency divided clock generated by the BRG.

This register supports a 16-bit binary format that allows specifying a value in the rage of 1 to 65535.

Setting all 0s in this register makes the BRG output the frequency divided clock at the low level.

The value of frequency division is given by the following formula:

The value of frequency division = (clock input frequency)/ (required baud rate × 16)

Table 50.10 shows how to use the baud rate generator with a 3.6864-MHz crystal resonator.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DL[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DL[15:0]	All 0	R/W	Specifies a division value of frequency clock generated in BRG. The value settings enabled in the range of 1 to 65535.

Table 50.10 Baud Rate (3.6864-MHz clock)

Baud Rate	Value of Frequency Division	Error Rate (*)
50	4608	—
75	3072	—
110	2095	–0.022
134.5	1713	0.001
150	1536	—
300	768	—
600	384	—
1200	192	—
1800	128	—
2000	115	0.174
2400	96	—
3600	64	—
4800	48	—
7200	32	—
9600	24	—
14400	16	—
19200	12	—
38400	6	—
76800	3	—
115200	2	—

Note: —: Indicates that the error rate is 0.

(4) Clock Select Register (CKS)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register switches the output between the frequency divided clock and specifies a source clock for the external baud rate.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CKS	XIN	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	CKS	B’0	R/W	This bit switches the output between the frequency divided clock (SC_CLK) and external clock (SCK). 0: Selects the frequency divided clock. 1: Selects the external clock.
14	XIN	B’0	R/W	Selects the baud rate generator clock source for the external clock between SCIF_CLK and SCKi. 0: Selects the external clock (SCIF_CLK). 1: Selects the internal clock (SCKi).
13 to 0	—	All 0	R	Reserved These bits are always read as 0. Only 0 should be written to these bits.

(5) Restrictions in BRG

Notes on Setting Frequency Division Register

1. For the initial setting of the register after a reset, at least one bit of waiting period is required to secure the clock stabilization time.
   (Example) One bit period when DL = 2

   $3.68\ (\text{MHz}) \times 1/2 \times 1/16 = 0.115\ (\text{MHz}) \rightarrow 8695\ (\text{ns})$

2. For modifying the register value after the setting stated in <1> above, at least one bit of waiting period at the maximum bit rate (DL = '65535') is required.
   The SCIF registers and BRG registers should be set as the following table:

- Asynchronous mode (SC_CLK external input)

SCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
SCSMR.C/A#	B’0	CKS	H’0000
SCSCR.CKE[1:0]	B’10	DL	H’0001 to H’FFFF

- Asynchronous mode (SCK external input)

SCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
SCSMR.C/A#	B’0	CKS	H’8000
SCSCR.CKE[1:0]	B’10	DL	Don’t care

- Clock synchronous mode (external input)

SCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
SCSMR.C/A#	B’1	CKS	H’8000
SCSCR.CKE[1:0]	B’10	DL	Don’t care

- Asynchronous mode (SC_CLK internal input)

SCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
SCSMR.C/A#	B’0	CKS	H’4000
SCSCR.CKE[1:0]	B’10	DL	H’0001 to H’FFFF

3. The register settings for the baud rate generator for external clock should be made before starting initialization of the SCIF.

50.3.4 SCIF Interrupt Sources and the DMAC

If the DMAC is used for transmission/reception, set and enable the DMAC before setting the SCIF.

Transmission Interrupts and DMA Transfer:

If the TDFE/TEND flag in SCFSR is set to 1 when the TDFE/TEND interrupt is enabled by the TIE bit, a TDFE/TEND interrupt request and a transmit-FIFO-data-empty DMA transfer request will occur. If the TDFE/TEND flag is set to 1 when TDFE/TEND interrupt is disabled by the TIE bit, only the transmit-FIFO-data-empty DMA transfer request will occur. (A transmit-FIFO-data-empty DMA transfer request is generated when the TDFE flag is set while TEIE is 0, or when the TEND flag is set while TEIE is 1. DMA transfer requests are not affected by the TEIE bit.)

When TDFE/TEND interrupt requests are enabled, the interrupt requests are cleared by the DMAC regardless of the interrupt handling program.

Reception Interrupts and DMA Transfer:

If the RDF/DR flag in SCFSR is set to 1 when RDF/DR interrupt is enabled by the RIE bit, an RDF/DR interrupt request occurs. If the RDF/DR flag is set to 1, a receive-FIFO-data-full DMA transfer request occurs. If the RDF/DR flag is set to 1 when RDF/DR interrupt is disabled by the RIE bit, and only a receive-FIFO-data-full DMA transfer request occurs and DMAC can be activated to perform data transfer.

Setting the RIE bit in SCSCR to 0 and the REIE it to 1 generates the ER/BRK/ORER interrupt requests without generating RDF/DR interrupt requests. When the BRK flag in SCFSR or the ORER flag in SCLSR is set to 1, BRK/ORER interrupt requests occur.

If the TO flag is set to 1 in SCLSR when TO interrupts are enabled by the TOIE bit, TO interrupt requests occur.

DR/TO interrupt requests generated by setting the DR or TO flag to 1 or receive-FIFO-data-full DMA transfer requests occur only in asynchronous mode.

When DR/TO interrupt requests are enabled to be issued, interrupt requests generated by the DR flag are cleared by the DMAC regardless of the interrupt handling program, however, those generated by the TO flag are not cleared by the DMAC. Therefore, the TO flag interrupt requests need to be cleared with the interrupt handling program. (The DR and TO flags are set at the same time, but cleared separately.)

Table 50.11 SCIF Interrupt Sources

Interrupt Source	DMAC Activation	Priority on Reset Release
Interrupts generated by receive error flag (ER)	Disabled	High
Interrupts generated by receive-FIFO-data-full (RDF), receive-data-ready (DR) or timeout (TO) *	Enabled	↕
Interrupts generated by break (BRK) or overrun error (ORER)	Disabled	↕
Interrupts generated by transmit FIFO data empty (TDFE)	Enabled	Low

Note: * RXI interrupts by means of the DR or TO flag are available only in asynchronous mode.

50.4 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

Note the following on use of the SCIF.

50.4.1 Break Detection and Operation

Break signals can also be detected by reading the RX pin value directly when a framing error (FER) is detected. In the break state, the input values from the RX pin are all 0s. So, the parity error flag (PER) may be set after the FER flag is set to 1.

Although the SCIF stops receive data transfer to SCFRDR after detecting a break, it continues data reception.

50.4.2 Sending a Break Signal

The input/output condition and level of the TX pin are determined by the SPB2IO and SPB2DT bits in SCSPTR. This enables to send a break signal.

The pin does not function as the TX pin from the initialization of the serial transmitter to setting of the TE bit (enabling transmission). In this period, the marked state is substituted by the value of the SPB2DT bit. Therefore, the SPB2IO and SPB2DT bits should be set to 1 (designating output and high level) beforehand.

To send a break signal during serial transmission, clear the SPB2DT bit to 0 (low level), and then clear the TE bit to 0 (halting transmission). When the TE bit is cleared, the transmitter is initialized regardless of the current transmission state, and the TX pin outputs 0.

50.4.3 Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCIF operates on the base clock with a frequency 16 times the bit rate.

In reception, the SCIF performs the internal synchronization by sampling the fall edge of the start bit using the base clock. In addition, the SCIF takes receive data at the rising edge of the eighth pulse on the base clock.

Figure 50.25 shows the timing of this operation.

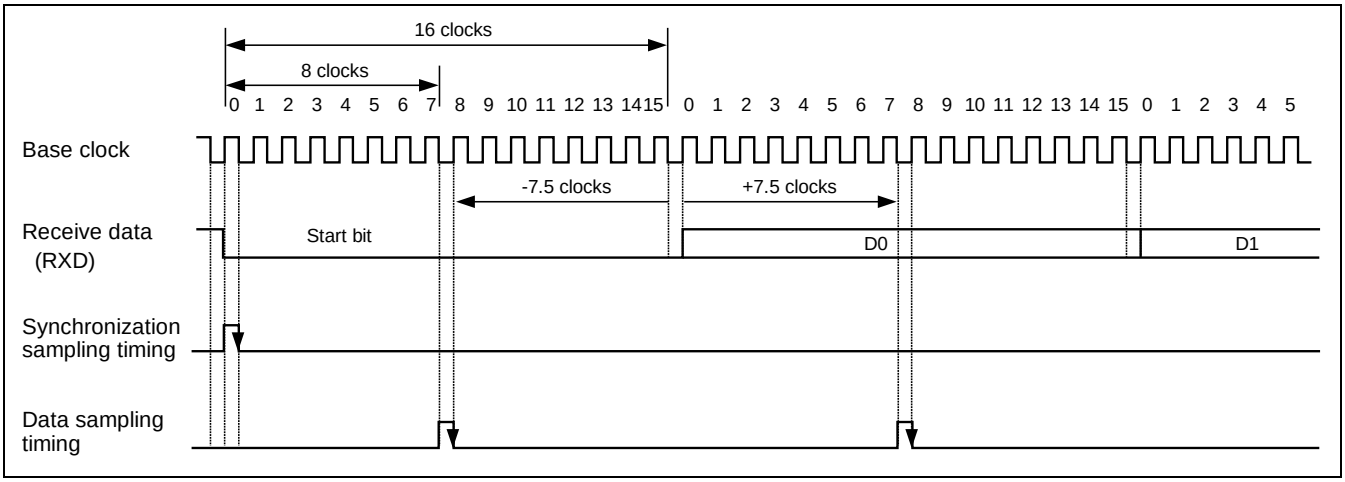

Figure 50.25 Timing Chart of Receive Data Sampling

The reception margin in asynchronous mode is given by formula (1).

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\% \quad \text{Expression (1)}$$

M: Receive margin (%)

N: Ratio of bit rate to clock (N = 16)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute value of clock frequency deviation

Assuming F = 0 and D = 0.5 for expression (1), the reception margin obtained with expression (2) is 46.875% as shown below:

Assuming D = 0.5 and F = 0

$M = (0.5 - 1/(2 \times 16)) \times 100\%$

$= 46.875\%$ ……expression (2)

This is a theoretical value. A reasonable margin allowed in system designs is 20% to 30%.

50.4.4 Reception Margin and Baud Rate Error

The value of 46.875% obtained by the above expression (2) indicates the reception margin when the baud rate error is 0 (F = 0). If there is no error in the reception and transmission baud rates, reception is possible even with misalignment of approx. 1/2 bit. If there is an error in the reception and transmission baud rates, the errors are accumulated up to the stop bit reception, which reduces the reception margin. The allowable baud rate error can be obtained by modifying the F in expression (1). When D= 0.5:

$F = \{(15/32 - M)/(L - 0.5)\} \times 100\ (\%)$……expression (3)

By using expression (3), the relationship between the allowable error and reception margin with the frame length = 12 can be summarized as follows:

Allowed Error (%)	Reception Margin (%)
4.07	0
3.64	5
3.20	10
2.33	20
1.46	30

51. High Speed Serial Communication Interface with FIFO (HSCIF)

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

51.1 Overview

The Second generation RZ/G series products have a high speed serial communication interface with built-in FIFO buffers (high-speed serial communication interface with FIFO: HSCIF) that handles asynchronous communication. The HSCIF has two 128-stage FIFO buffers separately for transmission and reception, which enables fast, efficient, and uninterrupted communication. RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N, RZ/G2E have 5 channels of HSCIF. All functions of each channel are same.

Internal clock:

— RZ/G2H: S3D1ϕ
— RZ/G2M V1.3: S3D1ϕ
— RZ/G2M V3.0: S3D1ϕ
— RZ/G2N: S3D1ϕ.
— RZ/G2E: S3D1Cϕ.

51.1.1 Features

The HSCIF has the following features.

- Asynchronous serial communication mode
  The HSCIF performs serial data communication based on a character-by-character asynchronous system. This feature enables serial data communication with standard asynchronous communication chips that support universal asynchronous receiver/transmitter (UART) or asynchronous communication interface adapter (ACIA). There is a choice of eight serial data transfer formats.
  — Data length: 7 or 8 bits
  — Stop bit length: 1 or 2 bits
  — Parity: Even/odd/none
  — Receive error detection: Parity, framing, and overrun errors
  — Break detection:
    A break is detected when a framing error lasts for more than 1 frame length at space 0 (low level).
    When a framing error occurs, a break can also be detected by reading the HRX pin level directly from the serial port register (HSSPTR).
  — Sampling rate: Variable (integer number from 8 to 32)
- Capable of full-duplex communication
  The HSCIF has an independent transmitter and receiver that enable simultaneous transmission and reception. The transmitter and receiver both have a 128-stage FIFO buffer structure, enabling continuous serial data transmission and reception.
- On-chip baud rate generator, enabling any bit rate to be selected
  The HSCIF enables choice of a clock source for transmission/reception: a clock from the on-chip baud rate generator based on the internal clock or an external clock.
- Eight interrupt sources
  The HSCIF has eight types of interrupt sources: receive-data-ready, receive-FIFO-data-full, break detection, transmit-FIFO-data-empty, transmit-end, receive-error, overrun-error and time-out, and enables any of them to be requested independently.

- DMA data transfer

  When the transmit FIFO register is empty or the receive FIFO register has received data, issuing a DMA transfer request activates the DMA controller (DMAC) to execute a data transfer.
- Modem control functions (HRTS# and HCTS#) are stored.
- The amount of data in the transmit/receive FIFO registers and the number of receive errors in receive data in the receive FIFO register are available.
- A receive data ready (DR) or a timeout error (TO) can be detected during reception.

51.1.2 Block Diagram

Figure 51.1 shows the HSCIF block diagram.

51.2 Register Description

Registers in the HSCIF are allocated to and arranged in the address space of the internal bus.

[Legend for Register Description]

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

R: Read-only. When the bit is reserved, the write value should always be 0. Writing 1 to these bits can cause a malfunction of HSCIF.

—/WB: Write-only. The read value is undefined.

51.2.1 Receive Shift Register (HSRSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

HSRSR is a register that receives serial data.

The HSCIF sets serial data input to the HSRSR from the HRX pin in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is transferred to the receive FIFO register HSFRDR, automatically.

HSRSR cannot be read from and written to by the CPU.

Bit:	7	6	5	4	3	2	1	0
Initial value:	—	—	—	—	—	—	—	—
R/W:	—	—	—	—	—	—	—	—

51.2.2 Receive FIFO Data Register (HSFRDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

HSFRDR is a 128-stage FIFO register that stores received serial data.

When HSCIF has received one byte of serial data, it transfers the received data from the receive shift register (HSRSR) to HSFRDR for storage, and reception is thus completed. HSRSR is then ready for reception, and is capable of receiving up to 128 consecutive bytes of data before HSFRDR is full.

HSFRDR is a read-only register and cannot be modified by the CPU. Note that the read value will be undefined while there is no receive data in HSFRDR. When HSFRDR is full of receive data, subsequent serial data is lost.

HSFRDR is read as an undefined value after a power-on reset.

Bit:	7	6	5	4	3	2	1	0
Initial value:	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R

51.2.3 Transmit Shift Register (HSTSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

HSTSR is a register that transmits serial data.

To perform serial data transmission, the HSCIF first transfers transmit data from the transmit fifo data register (HSFTDR) to HSTSR, and then sends the data to the HTX pin starting with the LSB (bit 0). When transmission of one byte is completed, the HSCIF transfers the next transmit data from HSFTDR to HSTSR automatically, then starts transmission.

HSTSR cannot be read from and written to directly by the CPU.

Bit:	7	6	5	4	3	2	1	0
Initial value:	—	—	—	—	—	—	—	—
R/W:	—	—	—	—	—	—	—	—

51.2.4 Transmit FIFO Data Register (HSFTDR)

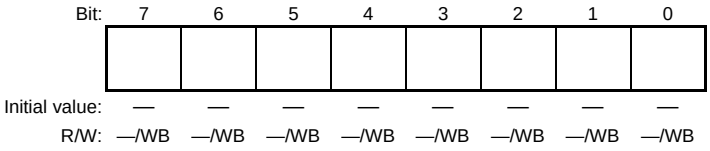
RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

HSFTDR is an 8-bit FIFO register of 128 stages that stores data for serial transmission.

If HSTSR is empty after transmit data has been written to HSFTDR, the HSCIF transfers the data from HSFTDR to HSTSR and starts serial transmission.

HSFTDR is a write-only register and cannot be read from by the CPU. Writing further data to HSFTDR is no longer possible when it is full. Attempts at writing data to the register in this situation are ignored.

HSFTDR is read as an undefined value on a power-on reset.



51.2.5 Serial Mode Register (HSSMR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CHR	PE	O/E#	STOP	—	CKS[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W

HSSMR is a 16-bit register that sets the HSCIF's serial transfer format and selects the baud rate generator clock source.

HSSMR can always be read from and written to by the CPU.

HSSMR is initialized to H'0000 by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	CHR	B’0	R/W	Character Length Selects 7 or 8 bits for data length. When the 7-bit data is selected, the MSB (bit 7) in the transmit FIFO data register (HSFTDR) is not transmitted. 0: 8 bits 1: 7 bits
5	PE	B’0	R/W	Parity Enable Determines whether parity bit is added in transmission or not, and parity bit is checked in reception or not. When bit PE is set to 1, the parity (even or odd) specified by bit O/E# is added to transmit data. In reception, the parity bit is checked for the parity (even or odd) specified by bit O/E#. 0: Disables parity bit addition and check. 1: Enables parity bit addition and check.
4	O/E#	B’0	R/W	Parity Mode Selects either even or odd parity to use in parity addition and check. The O/E# bit setting is valid only when bit PE is set to 1, enabling parity bit addition and check. 0: Even parity 1: Odd parity When even parity is set, the parity bit is added in transmission so that the total number of 1-bit in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bit in the receive character plus the parity bit is even. When odd parity is set, the parity bit is added in transmission so that the total number of 1-bit in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bit in the receive character plus the parity bit is odd.

Bit	Bit Name	Initial Value	R/W	Description
3	STOP	B'0	R/W	Stop Bit Length Selects 1 bit or 2 bits as the stop bit length. In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit. If it is 0, it is treated as the start bit of the next transmits character. 0: 1 stop bit*1 1: 2 stop bits*2 Notes: 1. In transmission, high level of 1 bit (stop bit) is added to the end of a transmit character before it is sent. 2. In transmission, high level of 2 bits (stop bits) are added to the end of a transmit character before it is sent.
2	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	CKS[1:0]	B'00	R/W	Clock Select 1 and 0 These bits select the clock source for the on-chip baud rate generator. The clock source can be selected from Internal clock, Internal clock/4, Internal clock/16, and Internal clock/64, according to the setting of bits CKS [1:0]. B'00: Internal clock B'01: Internal clock/4 B'10: Internal clock/16 B'11: Internal clock/64

51.2.6 Serial Control Register (HSSCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

HSSCR is a register that enables or disables transmission/reception by the HSCIF, enables or disables interrupt requests, and selects transmission/reception clock source for the HSCIF.

HSSCR can always be read from and written to by the CPU.

HSSCR is initialized to H'0000 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOT[1:0]		—	—	TEIE	—	—	—	TIE	RIE	TE	RE	REIE	TOIE	CKE[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15, 14	TOT[1:0]	B'00	R/W	Set the time for a data ready (DR) or a timeout (TO) to be set in asynchronous mode. B'00: 15 etu* B'01: 31 etu B'10: 47 etu B'11: 63 etu Note: * ETU: Elementary Time Unit (time for transfer of one bit) Equivalent to 1.5 frames with an 8-bit, 1-stop-bit format.
13, 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	TEIE	B'0	R/W	Transmit End Interrupt Enable When a transmit-end request is enabled by the TIE bit, the TEIE bit selects the source of the transmit end interrupt request from the following: • Setting the TDFE flag in HSFSR • Setting the TEND flag in HSFSR 0: The transmit FIFO data empty (TDFE) interrupt request is used. 1: The transmit end (TEND) interrupt request is used.
10 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	B'0	R/W	Transmit Interrupt Enable Enables or disables a transmit-FIFO-data-empty interrupt (TDFE) request when the TEIE bit in HSSCR is pulled 0, if all of the following conditions are satisfied: • Serial transmit data has been transferred from HSFTDR to HSTSR. • The number of data bytes in HSFTDR is equal to or less than the transmit trigger count. • The TDFE flag in HSFSR is set to 1. Enables or disables a transmit-end interrupt (TEND) request when the TEIE bit of HSSCR is set to 1, if both of the following conditions are satisfied: • Transmission was ended because there is no valid data in HSFTDR when the last bit of the transmit character in HSTSR was transmitted. • The TEND flag of HSFSR is set to 1. 0: When the TEIE bit is 0, disables transmit-FIFO-data-empty interrupt (TDFE) request. When the TEIE bit is 1, disables transmit-end interrupt (TEND) request. 1: When the TEIE bit is 0, enables transmit-FIFO-data-empty interrupt (TDFE) request. When the TEIE bit is 1, enables transmit-end interrupt (TEND) request.
6	RIE	B'0	R/W	Receive Interrupt Enable Enables or disables a receive-FIFO-data-full interrupt request when the RDF flag in HSFSR is set to 1, a receive-data-ready interrupt request when the DR flag in HSFSR is set to 1, a receive-error interrupt request when the ER flag in HSFSR is set to 1, a break interrupt request when the BRK flag in HSFSR is set to 1, and an overrun error interrupt request when the ORER flag in HSLSR is set to 1. 0: Disables receive-FIFO-data-full interrupts (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests. 1: Enables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests.
5	TE	B'0	R/W	Transmit Enable Enables or disables the start of HSCIF serial transmission. The HSCIF starts serial transmission when transmit data is written to the HSFTDR while TE is 1. Before setting TE to 1, set HSSMR and HSFCR to specify the transmission format and reset the transmit FIFO. 0: Disables transmission. 1: Enables transmission.

Bit	Bit Name	Initial Value	R/W	Description
4	RE	B'0	R/W	Receive Enable Enables or disables the start of HSCIF serial reception. When RE is 1, the HSCIF starts serial reception by detecting a start bit. Before setting RE to 1, set HSSMR and HSFCR to specify the reception format and reset the receive FIFO. 0: Disables reception.* 1: Enables reception. Note: * Even if RE is cleared to 0, the DR, ER, BRK, RDF, FER, PER, TO and ORER flags are not affected, and retain their states.
3	REIE	B'0	R/W	Receive Error Interrupt Enable Enables or Disables generation of receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests. 0: Disables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.* 1: Enables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests. Note: * When REIE is 1, ER, BRK or ORER interrupt requests will occur even if RIE is cleared to 0. This setting is used to notify the interrupt controller of ER, BRK, and ORER interrupt requests during DMAC transfer.
2	TOIE	B'0	R/W	Timeout Interrupt Enable Enables or disables generation of timeout interrupt (TO) requests when the TO flag in HSLSR is set to 1. 0: Disables timeout interrupts (TO). 1: Enables timeout interrupts (TO).
1, 0	CKE[1:0]	B'00	R/W	Clock Enable 1 and 0 See Table 51.3 for the bit settings.

Table 51.3 Clock Selection

CKE[1]	CKE[0]	Clock Source	HSCK Pin
B'0	B'0	Internal clock (Internal clock, Internal clock/4, Internal clock/16, and Internal clock/64)	The HSCK pin is not used. The HSCK pin functions as an input pin (input signals are ignored). (Initial value)
B'0	B'1	Prohibited	—
B'1	B'0	Baud rate generator output for external clock or HSCK	When SC_CLK is selected: The HSCK pin is an input pin (input signals are ignored). Set the SC_CLK frequency so that the frequency of BRGCLK is multiplied by the sampling rate.
			When HSCK is selected: The HSCK pin inputs the clock (with the bit rate multiplied by the sampling rate).
	B'1	Prohibited	

Note: It is not allowed to set synchronous communication using SC_CLK for input.

51.2.7 Serial Status Register (HSFSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

HSFSR is a 16-bit register. The lower 8 bits are status flags that indicate the operating status of the HSCIF, and the upper 8 bits are all reserved.

HSFSR can always be read from and written to by the CPU. However, the flags ER, TEND, TDFE, BRK, RDF, and DR cannot be written by 1. The FER and PER flags are read-only flags and cannot be modified.

HSFSR is initialized to H'0060 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/WC0	R/WC0	R/WC0	R/WC0	R	R	R/WC0	R/WC0

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	ER	B’0	R/WC0	Receive Error Indicates that a framing error or a parity error has occurred in reception. The ER flag is not affected by an error and retains its previous state when the RE bit is 0 in HSSCR. If a receive error occurs, receive data will be transferred to HSFRDR and reception operation will be continued. Whether there is a receive error in data read from HSFRDR can be determined by the FER and PER bits in HSFSR. 0: Indicates that no framing or parity error has occurred in reception. [Clearing conditions] • A power-on reset is executed. • 0 is written to ER. 1: Indicates that a framing error or a parity error has occurred in reception. [Setting conditions] • The HSCIF checks whether the stop bit at the end of receive data is 1, but the stop bit is 0.* • The number of 1-bit in receive data plus the parity bit does not match the parity setting (even or odd) specified by the O/E# bit in HSSMR during reception. Note: * In the 2-stop-bit mode, only the first stop bit is checked that the value is 1; the second stop bit is not checked.

Bit	Bit Name	Initial Value	R/W	Description
6	TEND	B'1	R/WC0	Transmit End Indicates that transmission has been ended because there was no valid data in HSFTDR when the last bit of the transmit character was transmitted. 0: Indicates that transmission is in progress. [Clearing conditions] • Transmit data is written to HSFTDR, and 0 is written to TEND. • Data is written to HSFTDR by the DMAC. 1: Indicates that transmission has been ended. [Setting conditions] • A power-on reset is executed. • The TE bit in HSSCR is 0. • There is no transmission data in HSFTDR when the last bit of a 1-byte serial transmission character is transmitted.
5	TDFE	B'1	R/WC0	Transmit FIFO Data Empty Indicates that the HSCIF has transferred data from HSFTDR to HSTSR, the number of data bytes in HSFTDR becomes equal to or less than the transmit trigger count specified by the HSTTRGR, and HSFTDR is ready to be written by new transmit data. HSFTDR is a 128-byte FIFO register. The maximum number of bytes that can be written to when TDFE = 1 is "128 − [the transmit trigger count]". If data exceeding this value is attempted to be written, the data will be ignored. The number of data bytes in HSFTDR is indicated by the upper bits of HSFDR. If the number of data written in HSFTDR is equal to or less than the transmit trigger count, this bit will be set to 1 even if it is cleared to 0 after it is read as 1. 0: Indicates that the number of transmit data written to HSFTDR exceeds the transmit trigger count. [Clearing conditions] • Transmit data exceeding the specified transmit trigger count have been written to HSFTDR, and 0 is written to TDFE. • Transmit data exceeding the specified transmit trigger count have been written to HSFTDR by the DMAC. 1: Indicates that the number of transmit data in HSFTDR is equal to or less than the transmit trigger count. [Setting conditions] • A power-on reset is executed. • The number of transmit data in HSFTDR is equal to or less than the transmit trigger count after transmission.

Bit	Bit Name	Initial Value	R/W	Description
4	BRK	B’0	R/WC0	Break Detect Indicates that a receive data break signal has been detected. If a break signal is detected, receive data (H'00) transfer to HSFRDR is stopped. After the break is canceled and the receive signal returns to 1, the receive data transfer resumes. 0: Indicates that no break signal has been received. [Clearing conditions] • A power-on reset is executed. • 0 is written to BRK. 1: Indicates that a break signal has been received. [Setting condition] • Data with a framing error is received, followed by the space "0" (low level) for at least one frame length.
3	FER	B’0	R	Framing Error Indicates that a framing error has been found in the data that is to be read next from HSFRDR. 0: Indicates that there is no framing error in the receive data that is to be read from HSFRDR. [Clearing conditions] • A power-on reset is executed. • There is no framing error in the data that is to be read next from HSFRDR. 1: Indicates that there is a framing error in the receive data that is to be read from HSFRDR. [Setting condition] • There is a framing error in the data that is to be read next from HSFRDR.
2	PER	B’0	R	Parity Error This bit indicates that a parity error has been found in the data that is to be read next from HSFRDR. 0: Indicates that there is no parity error in the receive data that is to be read from HSFRDR. [Clearing conditions] • A power-on reset is executed. • There is no parity error in the data that is to be read next from HSFRDR. 1: Indicates that there is a parity error in the receive data that is to be read from HSFRDR. [Setting condition] • There is a parity error in the data that is to be read next from HSFRDR.

Bit	Bit Name	Initial Value	R/W	Description
1	RDF	B'0	R/WC0	Receive FIFO Data Full Indicates that the received data has been transferred from HSRSR to HSFRDR, and the number of receive data bytes in HSFRDR becomes equal to or more than the receive trigger count specified by the HSRTRGR. HSFRDR is a 128-byte FIFO register. When RDF = 1, data equal to or more than the number of receive trigger data bytes can be read. When HSFRDR is empty, HSFRDR is read as an undefined value. The number of receive data bytes in HSFRDR is indicated by the lower bits of HSFDR. If the number of data in HSFRDR is equal to or more than the trigger count, this bit will be set to 1 even if it is cleared to 0. At this time, read receive data until the number of data in HSFRDR is less than the trigger count, read RDF as 1, and then clear RDF. 0: Indicates that the number of receive data bytes in HSFRDR is less than the specified receive trigger count. [Clearing conditions] • A power-on reset is executed. • HSFRDR is read until the number of receive data bytes in HSFRDR is less than the receive trigger count, and 0 is written to RDF. • HSFRDR is read by the DMAC until the number of receive data bytes in HSFRDR is less than the receive trigger count. 1: Indicates that the number of receive data bytes in HSFRDR is equal to or more than the specified receive trigger count. [Setting condition] • Receive data more than the receive trigger count have been stored in HSFRDR.

Bit	Bit Name	Initial Value	R/W	Description
0	DR	B'0	R/WC0	Receive Data Ready Indicates that the receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received. 0: Indicates that data is being received or has been successfully received, and there is no receive data in HSFRDR. [Clearing conditions] • A power-on reset is executed. • All the receive data in HSFRDR has been read, and 0 is written to DR. • All the receive data in HSFRDR has been read by the DMAC. 1: Indicates that no further receive data has been received. [Setting condition] The receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received. Note: * When the setting is 00, the time is 15 etu. This is equivalent to 1.5 frames in an 8-bit, 1-stop-bit format. etu: Elementary Time Unit (time for transfer of one bit)

51.2.8 Bit Rate Register (HSBRR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

HSBRR is an 8-bit register that sets the serial transmission/reception bit rate in accordance with the baud rate generator operating clock selected by the CKS [1:0] bits in HSSMR. This baud rate generator is intended for Internal clock, Internal clock/4, Internal clock/16, and Internal clock/64. For details on the baud rate generator for external clock, see section 51.5, Baud Rate Generator for External Clock (BRG).

HSBRR can always be read from and written to by the CPU except for during transfer.

HSBRR is initialized to H'FF by a power-on reset.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—
Initial value:	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

The HSBRR setting is determined by the following equation:

[Asynchronous mode]

$$N = \frac{\text{Internal clock}}{Sr \times 2^{2n+1} \times B} \times 10^6 - 1$$

B: Bit rate (bit/s)

N: HSBRR setting for the baud rate generator ($0 \le N \le 255$) (which satisfies the electrical characteristics)

Internal clock: AXI bus clock operating frequency (MHz)

n: Baud rate generator input clock (n = 0, 1, 2, 3)
(See the Table 51.4 for the relation between n and the clock.)

Sr: Sampling rate (8 to 32)

Table 51.4 HSSMR Settings

n	Baud Rate Generator Input Clock	HSSMR Setting CKS[1]	CKS[0]
0	Internal clock	B'0	B'0
1	Internal clock/4	B'0	B'1
2	Internal clock/16	B'1	B'0
3	Internal clock/64	B'1	B'1

The bit rate error in asynchronous mode is determined by the following equation:

$$\text{error (\%)} = \left\{ \frac{\text{Internal clock} \times 10^6}{(N+1) \times B \times Sr \times 2^{2n+1}} - 1 \right\} \times 100$$

51.2.9 FIFO Control Register (HSFCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

HSFCR is a register that resets data counts for transmit and receive FIFO registers. It also has a modem control and a loopback test enable bit.

HSFCR can always be read from and written to by the CPU except for during transfer.

HSFCR is initialized to H'0000 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	MCE	B'0	R/W	Modem Control Enable Enables or disables modem control signals HCTS# and HRTS#. 0: Disables modem signals.* 1: Enables modem signals. Note: * HCTS# and HRTS# control ports.
2	TFRST	B'0	R/W	Transmit FIFO Data Register Reset Enables or disables a transmit FIFO data register reset that empties the register. 0: Disables the reset.* 1: Enables the reset. Note: * The register is reset by a power-on reset.
1	RFRST	B'0	R/W	Receive FIFO Data Register Reset Enables or disables a receive FIFO data register (HSFRDR) reset that empties the register. 0: Disables the reset.* 1: Enables the reset. Note: * The register is reset by a power-on reset.
0	LOOP	B'0	R/W	Loopback Test Enables or disables the loopback test by internally connecting the transmit output pin (HTX) and receive input pin (HRX), and the HRTS# pin and HCTS# pin. 0: Disables the loopback test. 1: Enables the loopback test.

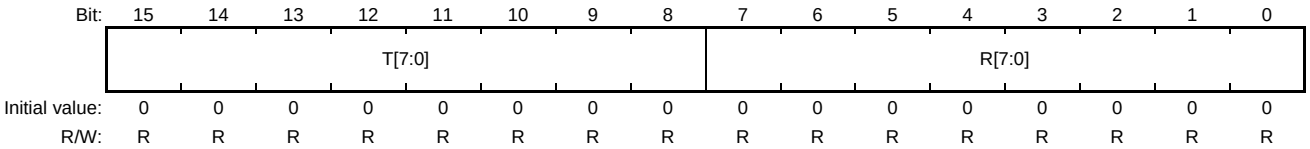
51.2.10 FIFO Data Count Register (HSFDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

HSFDR is a 16-bit register that indicates the number of data bytes stored in HSFTDR and that in HSFRDR.

The upper 8 bits indicate the number of transmit data bytes in HSFTDR, and the lower 8 bits indicates the number of receive data bytes in HSFRDR.

HSFDR can always be read by the CPU.



Bit	Bit Name	Initial Value	R/W	Description
15 to 8	T[7:0]	H'00	R	These bits indicate the number of data bytes un-transmitted and still stored in HSFTDR. H'00 indicates that there is no transmit data in HSFTDR, and H'80 indicates that HSFTDR is full of transmit data.
7 to 0	R[7:0]	H'00	R	These bits indicate the number of receive data stored in HSFRDR. H'00 indicates that there is no receive data in HSFRDR, and H'80 indicates that HSFRDR is full of receive data.

51.2.11 Serial Port Register (HSSPTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

HSSPTR controls multiplexed input/output and data on the high speed serial communication interface (HSCIF) ports. Bits 1 and 0 control breaks in serial transmission/reception by reading input data from the HRX pin and writing output data to the HTX pin. Bits 3 and 2 read input data from and write output data to the HSCK pin. Bits 5 and 4 read input data from and write output data to the HCTS# pin. Bits 7 and 6 read input data from and write output data to the HRTS# pin.

HSSPTR is a 16-bit register that can always be read from and written to by the CPU.

All HSSPTR bits except bits 6, 4, 2, and 0 are initialized to 0 by a power-on reset. The values of bits 6, 4, 2, and 0 are undefined.

Note: Whether modem control can be selected or not depends on the channel.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RTSIO	RTSDT	CTSIO	CTSDT	SCKIO	SCKDT	SPB 2IO	SPB 2DT

R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	RTSIO	B'0	R/W	Serial Port – RTS Port Input/output Specifies input or output for the serial port HRTS# pin. To actually set the HRTS# pin as a port output pin to output the value set by the RTSDT bit, the MCE bit in HSFCR should be cleared to 0. 0: Indicates that this bit does not output the value of the RTSDT bit to the HRTS# pin. 1: Indicates that this bit outputs the value of the RTSDT bit to the HRTS# pin.
6	RTSDT	—	R/W*	Serial Port – RTS Port Data Specifies the input/output data level of the serial port HRTS# pin. Whether the pin is set for input or output is determined by the RTSIO bit. When the pin is set for output, the value of the RTSDT bit is output to the HRTS# pin. Regardless of the value of the RTSIO bit, the value of the HRTS# pin is read from the RTSDT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
5	CTSIO	B'0	R/W	Serial Port – CTS Port Input/output Specifies input or output for the serial port HCTS# pin. To actually set the HCTS# pin as a port output pin to output the value set by the CTSDT bit, the MCE bit in HSFCR should be cleared to 0. 0: Indicates that the CTSDT bit value is not output to the HCTS# pin. 1: Indicates that the CTSDT bit value is output to the HCTS# pin.

Bit	Bit Name	Initial Value	R/W	Description
4	CTSDT	—	R/W*	Serial Port – CTS Port Data Specifies the input/output data level of the serial port HCTS# pin. Whether the pin is set for input or output is determined by the CTSIO bit. When the pin is set for output, the value of the CTSDT bit is output to the HCTS# pin. Regardless of the value of the CTSIO bit, the value of the HCTS# pin is read from the CTSDT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
3	SCKIO	B'0	R	Serial Port – Clock Port Input
2	SCKDT	—	R	Serial Port – Clock Port Data The initial value of this bit is undefined after a power-on reset.
1	SPB2IO	B'0	R/W	Serial Port – Break Input/output Specifies the output condition of the serial port HTX pin. To actually set the HTX pin as a port output pin to output the value set by the SPB2DT bit, the TE bit in HSSCR should be cleared to 0. 0: Indicates that the SPB2DT bit value is not output to the HTX pin. 1: Indicates that the SPB2DT bit value is output to the HTX pin.
0	SPB2DT	—	R/W*	Serial Port – Break Data Specifies the input level of the serial port HRX pin and the output level of the HTX pin. The HTX pin output conditions are determined by the SPB2IO bit. When the HTX pin is set for output, the value of the SPB2DT bit is output to the HTX pin. Regardless of the value of the SPB2IO bit, the value of the HRX pin is read from the SPB2DT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.

Note: * The value written to these bits can't be read because the value of the pin is read.

51.2.12 Line Status Register (HSLSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TO	—	ORER
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/WC0	R	R/WC0

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	TO	B'0	R/WC0	Timeout Indicates that the receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received. 0: Indicates that data is being received or has been successfully received and that there is no receive data in HSFRDR. [Clearing conditions] • A power-on reset is executed. • All the receive data in the HSFRDR has been read, and 0 is written to TO. 1: Indicates that no further receive data has been received (receive timeout). [Setting condition] • The receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received.* Note: * When the setting is 00, the time is 15 etu. This is equivalent to 1.5 frames in an 8-bit, 1-stop-bit format. etu: Elementary Time Unit (time for transfer of one bit)
1	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	ORER	B'0	R/WC0	Overrun Error Indicates that an overrun error has occurred in reception and abnormal termination is caused. If an overrun error occurs, the receive data prior to the overrun error is retained in HSFRDR and the data received subsequently is discarded. Any subsequent serial reception is disabled while the ORER flag is 1. To resume data reception after clearing the ORER flag, be sure to first read (or clear) data in the receive FIFO and handle the error, then clear the ORER flag. 0: Indicates that data is being received or has been successfully received. [Clearing conditions] • A power-on reset is executed. • 0 is written to ORER. 1: Indicates that an overrun error has occurred in reception. [Setting condition] • The next serial reception has been completed while HSFRDR is full of 128-byte data. Note: When bit RE in HSSCR is cleared to 0, the ORER flag is not affected and its previous state is retained.

51.2.13 Sampling Rate Register (HSSRR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SRE	SRDE	—	—	SRHP[3:0]				—	—	—	SRCYC[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	SRE	B’0	R/W	Sampling Rate Register Enable (SRE) 0: Set the SRCYC [4: 0] bits to 15 (initial value). 1: Validates the setting of the SRCYC [4:0] bits.
14	SRDE	B’0	R/W	Sampling Point Register Enable (SRDE) 0: Invalidates the setting of the SRHP [3:0] bits and the sampling point will be (S+1)/2 for an odd sampling rate (S) and S/2 for an even sampling rate. 1: Validates the setting of the SRHP [3: 0] bits.
13, 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	SRHP[3:0]	B’0000	R/W	Sampling Point Register (SRHP) The sampling point can be moved by setting the SDRE bit to 1 and setting a value in these bits. Normally, the sampling point is the point of S/2 or (S+1)/2 for a sampling rate of S. By setting a signed 4-bit integer in these bits, the sampling point can be shifted by the amount of the specified sampling clock cycles. This will improve the receive margin. When setting a value in these bits, take notice that the sampling point does not become a negative value or it does not exceed the sampling rate. The shifted sampling point must satisfy the setup margin and hold margin.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	SRCYC[4:0]	B’0_1111	R/W	Bits 4 to 0: Sampling Rate Register (SRCYC) Data transfer at a desired sampling rate can be enabled by setting the SRE bit to 1 and setting a value in these bits. Set a value of "S - 1" in these bits for a sampling rate of S. Note that the sampling rate must be from 8 to 32 (a value from 7 to 31 can be set in these bits). Set these bits to 15 (initial value) when the SRE bit is set to 0.

51.2.14 Serial Error Register (HSRER)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	PER[6:0]							—	FER[6:0]

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 8	PER[6:0]	H'00	R	Parity Error Count These bits indicate the number of data items in which a parity error occurred in the receive data stored in the receive FIFO data register (HSFRDR). After the ER bit in HSFSR is set, the value in bits 14 to 8 will be the number of data items in which a parity error occurred. If all 128 bytes of receive data in HSFRDR have parity errors, bits PER [6:0] will have the value 0.
7	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 0	FER[6:0]	H'00	R	Framing Error Count These bits indicate the number of data items in which a framing error occurred in the receive data stored in the receive FIFO data register (HSFRDR). After the ER bit in HSFSR is set, the value in bits 6 to 0 will be the number of data items in which a framing error occurred. If all 128 bytes of receive data in HSFRDR have framing errors, bits FER [6:0] will have the value 0.

51.2.15 RTS Output Active Trigger Register (HSRTGR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	RSTRG[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	RSTRG[6:0]	H'0F	R/W	RTS Output Active Trigger Count The HRTS# signal goes high when the number of receive data items stored in the receive FIFO data register (HSFRDR) exceeds the value set in these bits. The initial value is 15.

51.2.16 Receive FIFO Data Count Trigger Register (HSRTRGR)

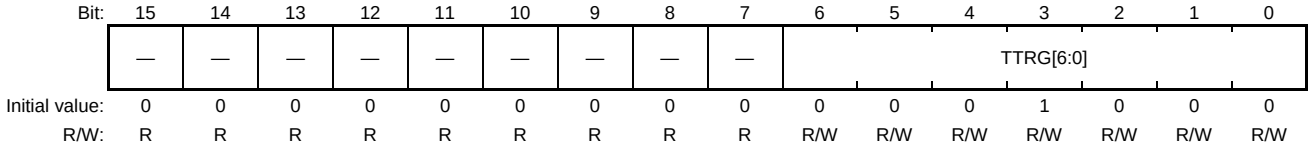
RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	RTRG[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	RTRG[6:0]	H'01	R/W	Receive FIFO Data Count Trigger These bits set the receive data item count at which the receive data full (RDF) flag in the serial status register (HSFSR) is set. The RDF flag is set when the number of receive data items stored in the receive FIFO data register (HSFRDR) equals or exceeds the value set in these bits. The initial value is 1.

51.2.17 Transmit FIFO Data Count Trigger Register (HSTTRGR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	TTRG[6:0]	H'08	R/W	Transmit FIFO Data Count Trigger These bits set the un-transmitted data item count at which the transmit FIFO data register empty (TDFE) flag in the serial status register (HSFSR) is set. The TDFE flag is set when the number of transmit data items in the transmit FIFO data register (HSFTDR) falls under the value set in these bits due to transmit operations. The initial value is 8.

51.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

51.3.1 Operation in Asynchronous Serial Communication Mode

In asynchronous serial communication mode, the HSCIF performs serial communication, in which data is transmitted or received in character units using the attached start bit indicating the start of communication and stop bit indicating the end of communication.

Figure 51.2 shows the general format for asynchronous serial communication.

In asynchronous serial communication, the transmission line is usually kept marked (high level). The HSCIF monitors the transmission line, and when it finds a space (low level), it regards the space as a start bit and starts serial communication.

One character in serial communication consists of a start bit (low level), followed by transmit/receive data (LSB-first; from the lowest bit), a parity bit (high or low level), and a stop bit (high level).

During reception in asynchronous mode, the HSCIF performs synchronization at the falling edge of the start bit. Transferred data is acquired at the center of each bit because the HSCIF samples on *S/2*th cycles of the clock which has a frequency of S times the bit rate, when the sampling rate as set in the sampling rate register (HSSRR) is S (if the sampling-rate setting is an odd number, the data is sampled on every *(S+1)/2*th pulse).

In addition, when the setting of the SRDE bit makes the setting of the sampling point bits effective, the point where the bits are latched can be intentionally moved from the centers of each bit.

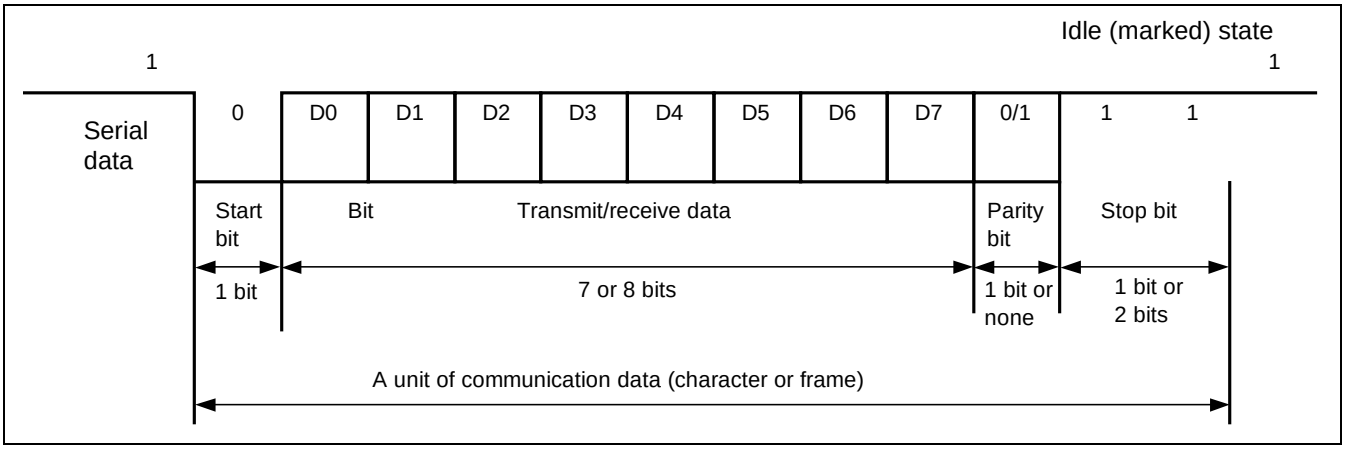


Figure 51.2 Data Format in Asynchronous Mode
(Example of 8-Bit Data with Parity and Two Stop Bits)

(1) Transmission/reception format

Table 51.5 shows available data transfer formats. The HSCIF supports 8 transfer formats, which can be specified by HSSMR.

Table 51.5 Serial Transmission/Reception Formats (Asynchronous Mode)

SCSMR settings			Serial transmission/reception format and frame length											
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	S	8-bit data								STOP		
0	0	1	S	8-bit data								STOP	STOP	
0	1	0	S	8-bit data								P	STOP	
0	1	1	S	8-bit data								P	STOP	STOP
1	0	0	S	7-bit data							STOP			
1	0	1	S	7-bit data							STOP	STOP		
1	1	0	S	7-bit data							P	STOP		
1	1	1	S	7-bit data							P	STOP	STOP	

[Legend]
S : Start bit
STOP : Stop bit
P : Parity bit

(2) Clock

The transfer clock can be selected from the following two clocks using the CKE[1:0] bits in HSSCR:

- Internal clock generated by the on-chip baud rate generator
- External clock generated by an external clock baud rate generator

(3) Data transmission/reception

(a) Initialization of HSCIF (asynchronous mode)

Before transmitting/receiving data or changing the operating mode or communication format, the HSCIF should be initialized using the sample flowchart for HSCIF initialization shown in Figure 51.3.

[Notes]

Clearing the TE bit to 0 initializes HSTSR. However, HSFSR, HSFTDR, and HSFRDR contents are retained even if the TE and RE bits are cleared to 0.

The TE bit should be cleared to 0 after all transmit data has been sent and the TEND flag has been set in HSFSR. The TE bit can be cleared to 0 during transmission, but the data being transmitted will enter the marked state after clearing. In addition, before setting the TE bit to 1 to restart the transmission, set the TFRST bit to 1 in HSFCR to reset HSFTDR.

When an external clock is used, do not stop the clock during operation or initialization. If stopped, the operation will be unreliable. Furthermore, when the baud rate generator for external clock is also to be used, be sure to make settings for it before starting initialization of the HSCIF.

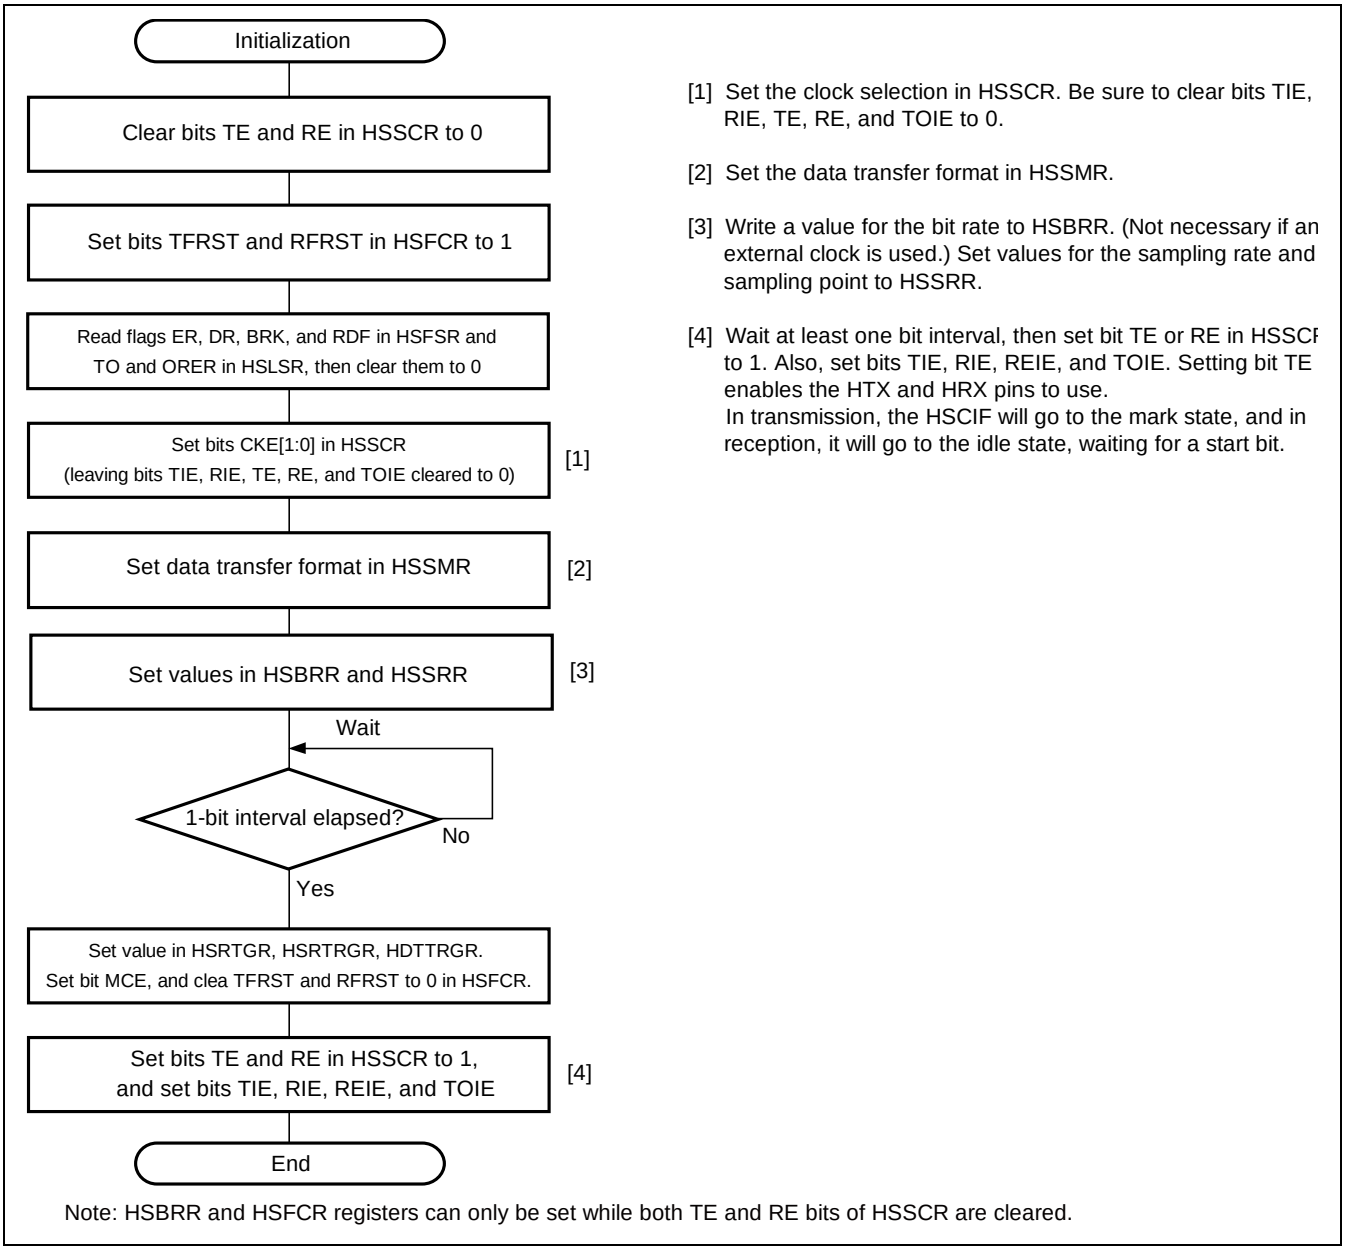

Figure 51.3 Sample Flowcharts for Initializing the HSCIF

(b) Serial data transmission (asynchronous mode)

Figure 51.4 shows a sample flowchart for serial transmission.

After the HSCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

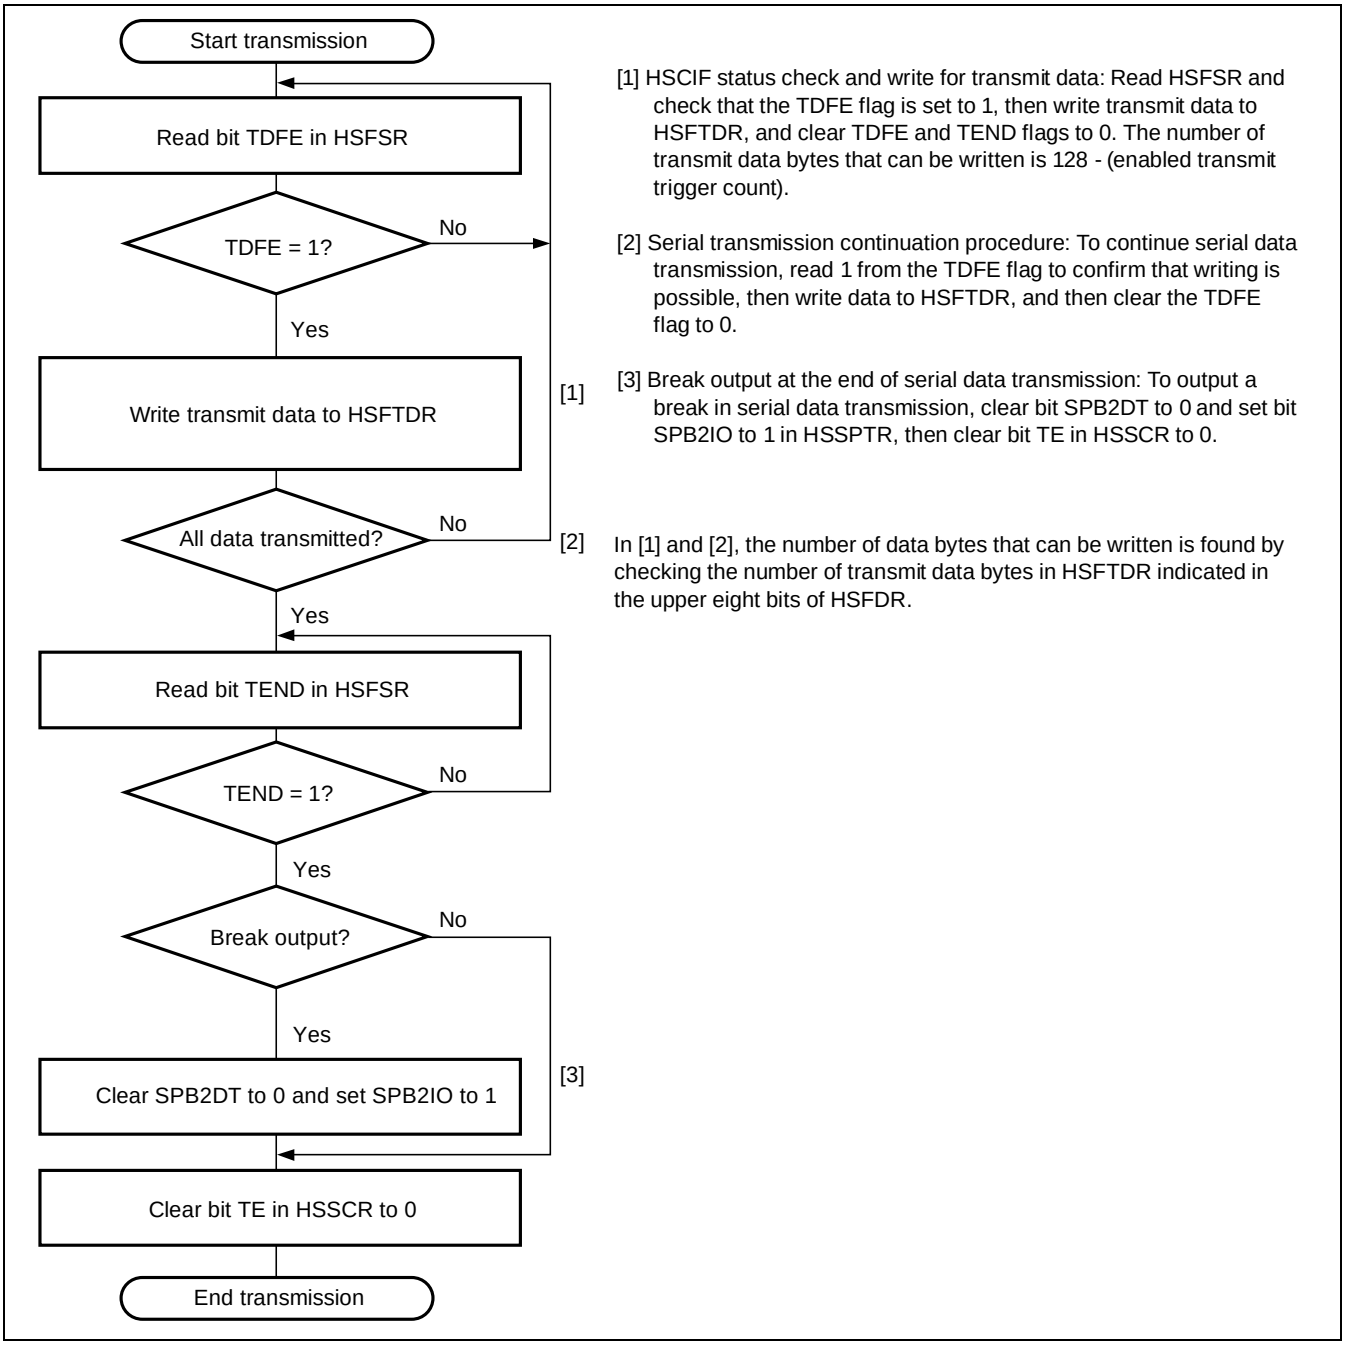

Figure 51.4 Sample Flowcharts for Serial Transmission

In serial transmission, the HSCIF operates as follows:

1. When data is written to HSFTDR, the HSCIF transfers the data from HSFTDR to HSTSR and starts transmitting. Confirm that the TDFE flag in HSFSR is set to 1 before writing transmit data to HSFTDR. The number of data bytes that can be written is at least 128 - (transmit trigger count).

2. When data is transferred from HSFTDR to HSTSR and the HSCIF starts transmission, consecutive transmission is performed until there is no transmit data left in HSFTDR. When the number of transmit data bytes in HSFTDR is equal to or less than the transmit trigger count specified in HSTTRGR, the TDFE flag is set. If the TIE and TEIE bits in HSSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. The serial transmit data is sent from the HTX pin in the following order:
   A. Start bit: One 0-bit is output.
   B. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
   C. Parity bit: One parity bit (even or odd parity) is output.
      A format that does not output a parity bit can also be selected.
   D. Stop bit(s): One or two stop bits are output.
   E. Marked state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The HSCIF checks transmit data in HSFTDR when sending the stop bit. If there is data in it, the HSCIF transfers the data from HSFTDR to HSTSR, sends the stop bit, and then starts serial transmission of the next frame. If there is no transmit data, the HSCIF sets the TEND flag to 1 in HSFSR and sends out the stop bit, and then the marked state is entered to output 1 continuously. At this time, if the TIE and TEIE bits in HSSCR are set to 1, a transmit-end interrupt (TEND) request occurs.

Figure 51.5 shows an example of transmission in asynchronous mode.

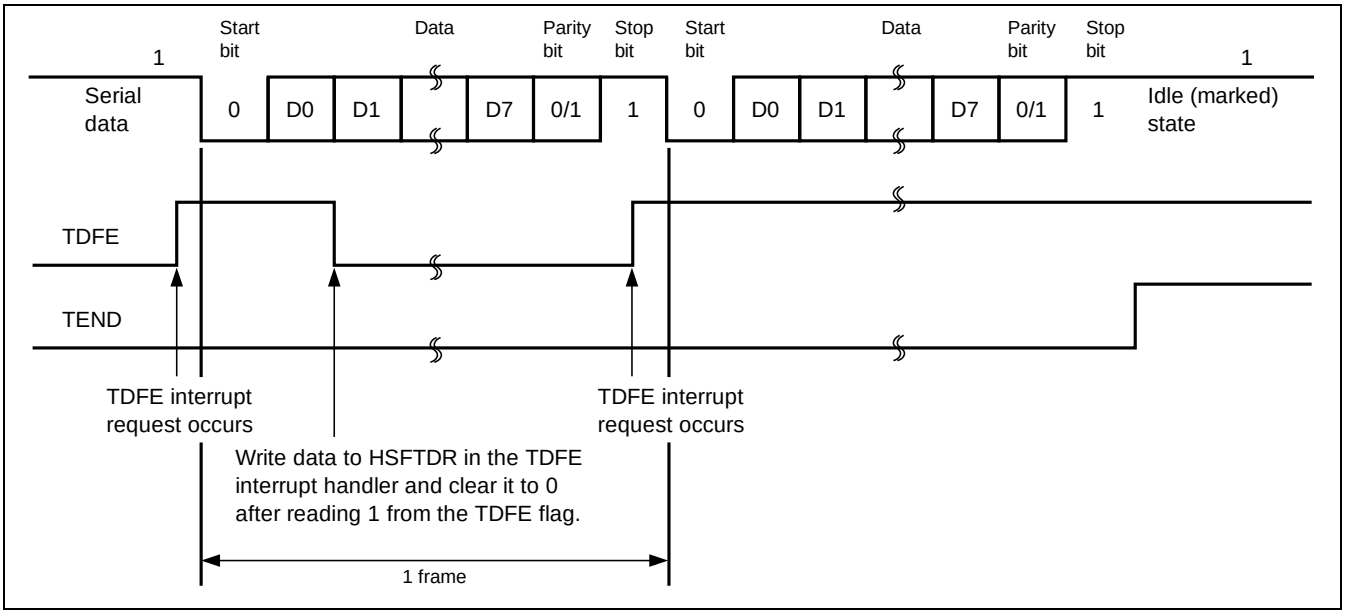

Figure 51.5 Sample HSCIF Transmission Operation (Example of 8-Bit Data with Parity and One Stop Bit)

4. When modem control is enabled, transmission can be stopped or resumed in accordance with the HCTS# input value. When HCTS# is set to 1 during transmission, the marked state is entered after one frame of data transmission is ended. Setting HCTS# to 0 restarts outputting the next transmit data from the start bit. Figure 51.6 shows an example of the operation with modem control enabled.

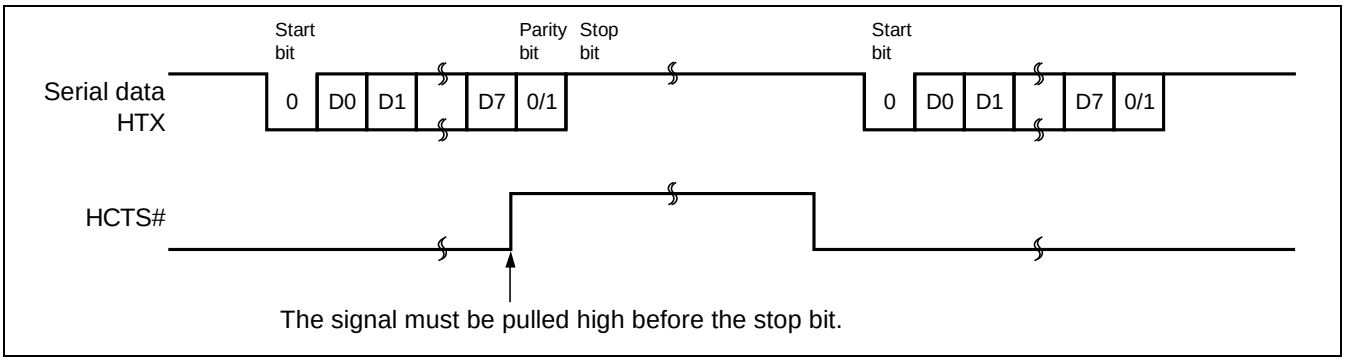

Figure 51.6 Sample Operation with Modem Control Enabled (HCTS#)

(c) Serial data reception (asynchronous mode)

Figures 51.7 and 51.8 show sample flowcharts for serial reception.

After the HSCIF reception operation is enabled, serial data reception can be performed using the following procedure:

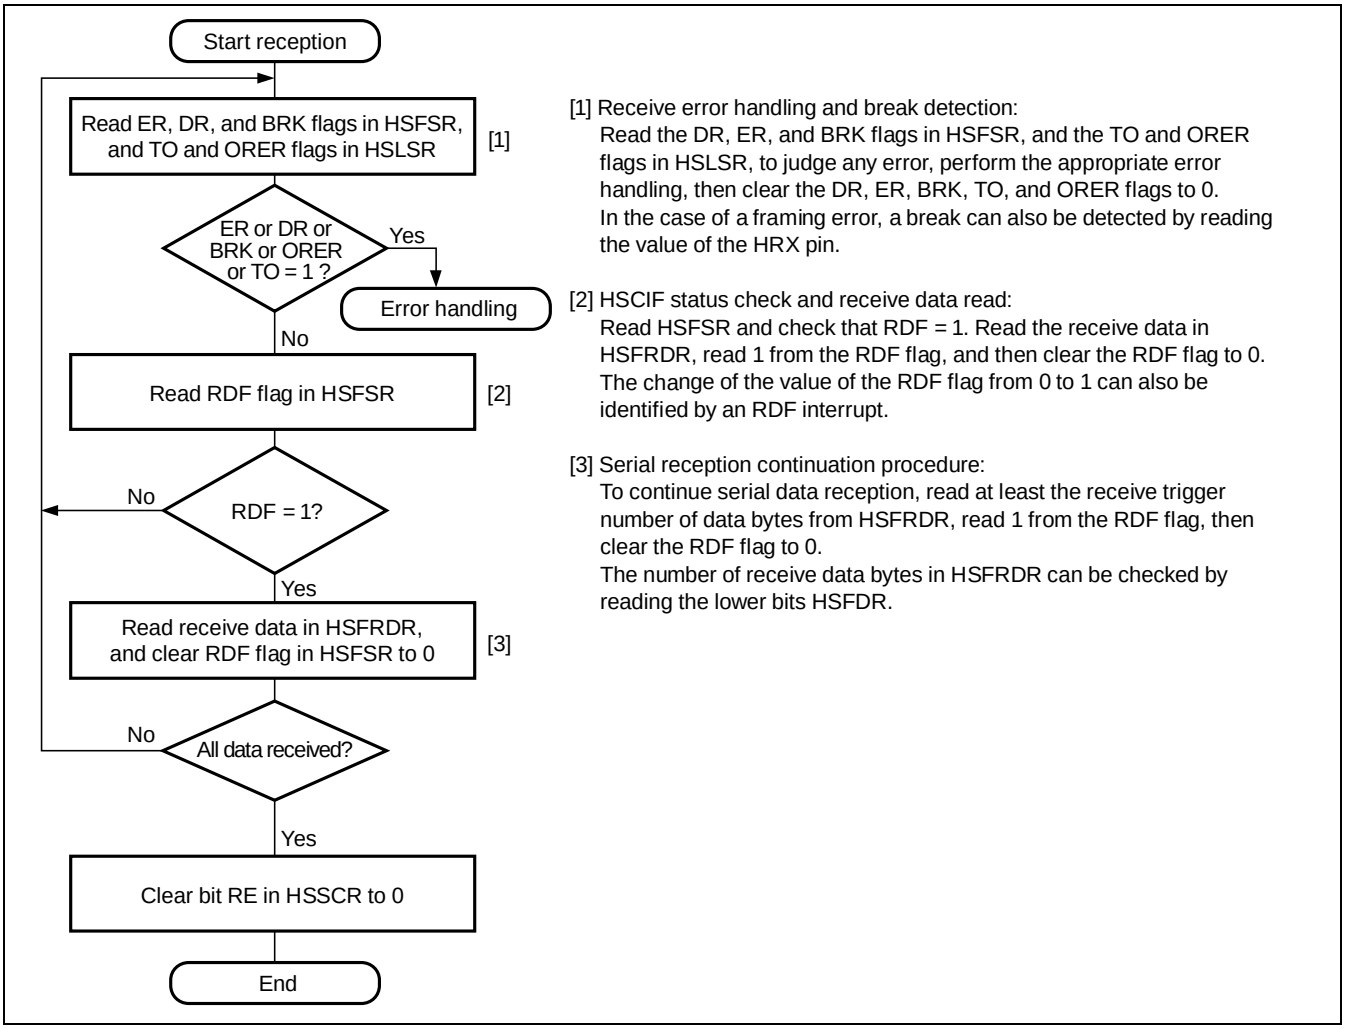

Figure 51.7 Sample Flowcharts for Serial Reception (1)

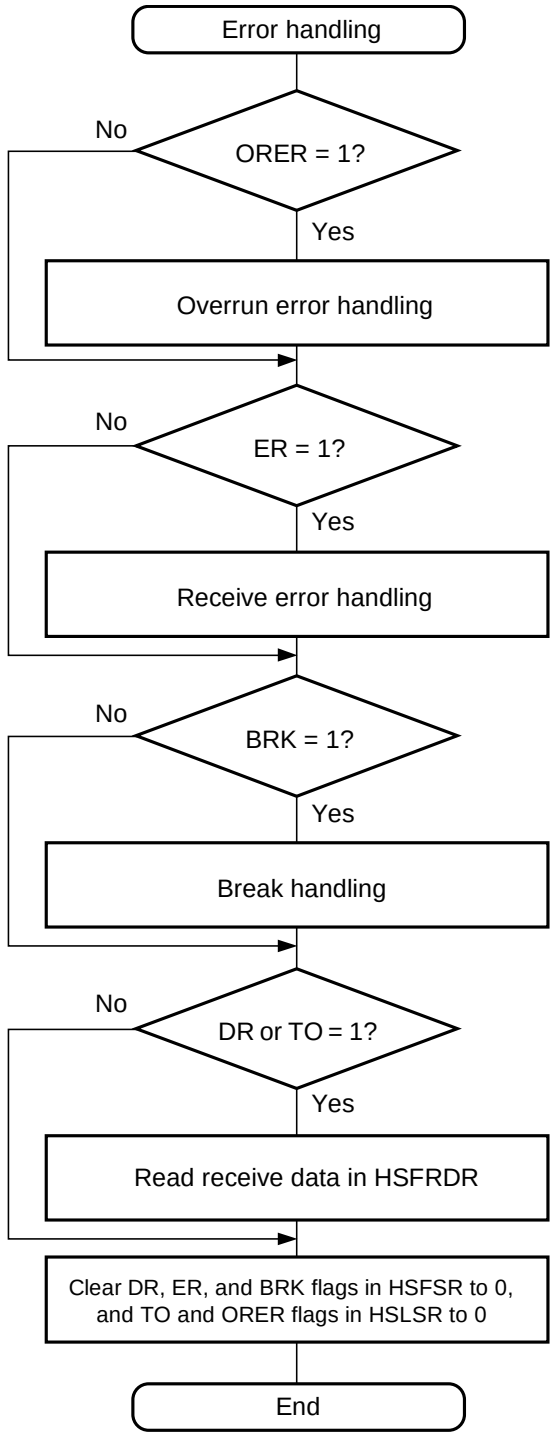

Whether a framing error or parity error has occurred in the receive data that is to be read from HSFRDR can be determined by checking bits FER and PER in HSRER.

Figure 51.8 Sample Flowcharts for Serial Reception (2)

In serial reception, the HSCIF operates as follows:

1. The HSCIF monitors the transmission line, and when detecting the start bit 0, it performs internal synchronization and starts reception.
2. The HSCIF stores the received data in HSRSR in LSB-to-MSB order.
3. The HSCIF receives the parity bit and stop bit.
   After receiving these bits, the HSCIF performs the following checks:

A. Stop bit: The HSCIF checks whether the stop bit is 1.
   If there are two stop bits, it checks only the first stop bit.
B. Receive data: The HSCIF checks that receive data can be transferred from the receive shift register (HSRSR) to HSFRDR.
C. Overrun error: The HSCIF checks that the ORER flag is 0, indicating that no overrun error has occurred.
D. Break state: The HSCIF checks that the BRK flag is 0, indicating that the break state is not set.

If the HSCIF can confirm the conditions of (b), (c), and (d), it stores the receive data in HSFRDR.

Note: The HSCIF continues to receive data even when a parity error or a framing error occurs.

4. If the RDF flag changes to 1 while the RIE bit in HSSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs.
   If the DR flag changes to 1 while the RIE bit in HSSCR is 1, a receive-data-ready interrupt (DR) request occurs.
   If the TO flag changes to 1 while the TOIE bit in HSSCR is 1, a timeout interrupt (TO) request occurs.
   If the ER flag changes to 1 while the RIE or REIE bit in HSSCR is 1, a receive-error interrupt (ER) request occurs.
   If the BRK flag changes to 1 while the RIE or REIE bit in HSSCR is 1, a break interrupt (BRK) request occurs.
   If the ORER flag changes to 1 while the RIE or REIE bit in HSSCR is 1, an overrun-error interrupt (ORER) request occurs.

Figure 51.9 shows an example of reception in asynchronous mode.

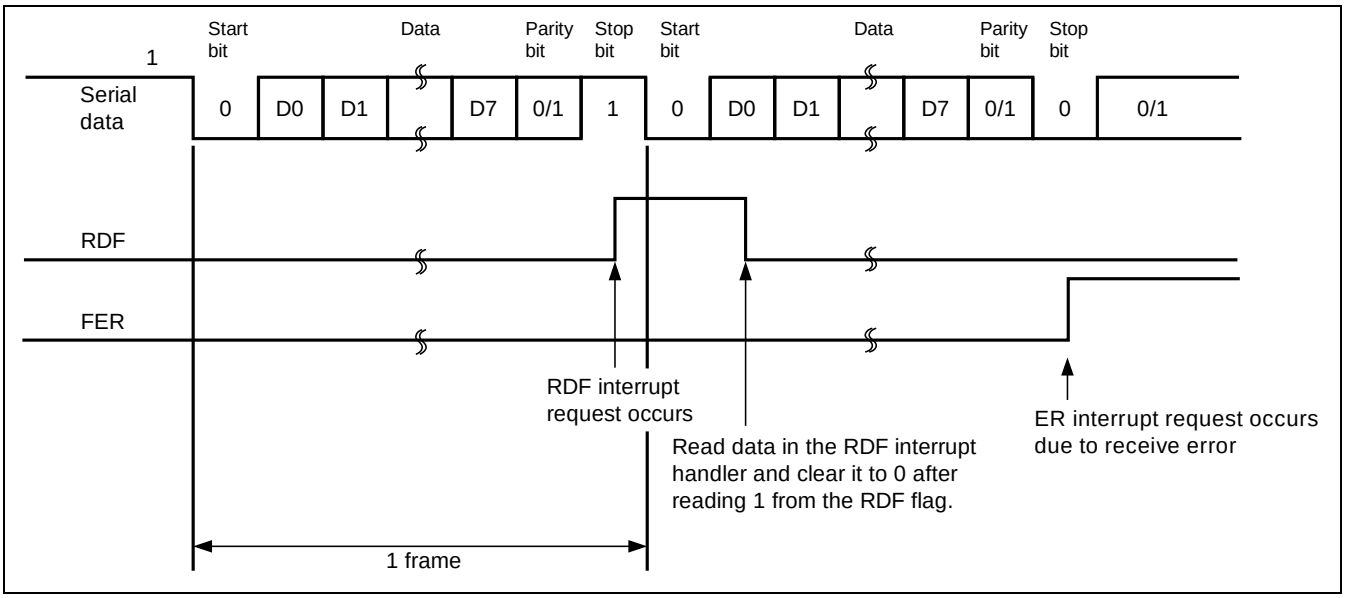

Figure 51.9 Sample HSCIF Receive Operation
(Example of 8-Bit Data with Parity and One Stop Bit)

5. When modem control is enabled, the HRTS# signal is output when HSFRDR is empty. When HRTS# is 0, data can be received. When HRTS# is set to 1, the number of data bytes in HSFRDR is equal to or more than the RTS output active trigger count (HSRTGR.RSTRG).

Figure 51.10 shows an example of the operation with modem control enabled.

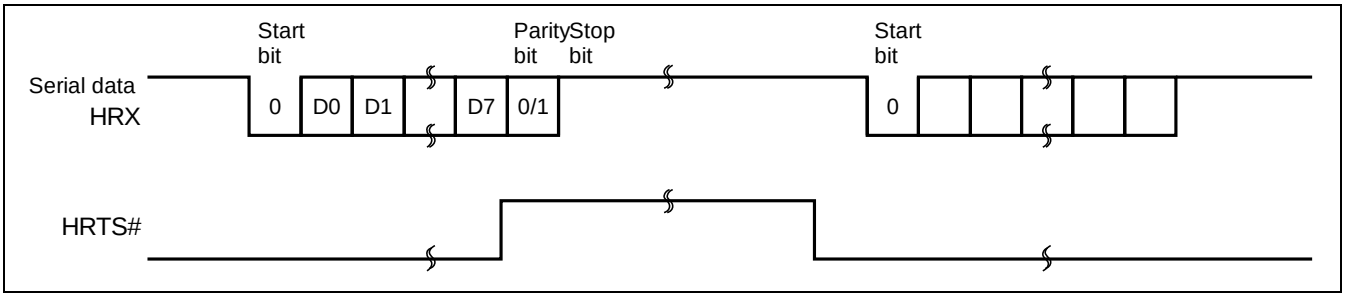

Figure 51.10 Example of the Operation with Modem Control Enabled (HRTS#)

51.3.2 HSCIF Interrupt Sources and the DMAC

If the DMAC is used for transmission/reception, set and enable the DMAC before setting the HSCIF.

Transmission interrupts and DMA transfer:

If the TDFE/TEND flag in HSFSR is set to 1 when the TDFE/TEND interrupt is enabled by the TIE bit, a TDFE/TEND interrupt request and a transmit-FIFO-data-empty DMA transfer request will occur. If the TDFE/TEND flag is set to 1 when TDFE/TEND interrupt is disabled by the TIE bit, only the transmit-FIFO-data-empty DMA transfer request will occur. (A transmit-FIFO-data-empty DMA transfer request is generated when the TDFE flag is set while TEIE is 0, or when the TEND flag is set while TEIE is 1. DMA transfer requests are not affected by the TEIE bit.)

When TDFE/TEND interrupt requests are enabled, the interrupt requests are cleared by the DMAC regardless of the interrupt handling program.

Reception interrupts and DMA transfer:

If the RDF/DR flag in HSFSR is set to 1 when RDF/DR interrupt is enabled by the RIE bit, an RDF/DR interrupt request occurs. If the RDF/DR flag is set to 1, a receive-FIFO-data-full DMA transfer request occurs. If the RDF/DR flag is set to 1 when RDF/DR interrupt is disabled by the RIE bit, and only a receive-FIFO-data-full DMA transfer request occurs and DMAC can be activated to perform data transfer.

Setting the RIE bit in HSSCR to 0 and the REIE bit to 1 generates the ER/BRK/ORER interrupt requests without generating RDF/DR interrupt requests. When the BRK flag in HSFSR or the ORER flag in HSLSR is set to 1, BRK/ORER interrupt requests occur.

If the TO flag is set to 1 in HSLSR when TO interrupts are enabled by the TOIE bit, TO interrupt requests occur.

When DR/TO interrupt requests are enabled to be issued, interrupt requests generated by the DR flag are cleared by the DMAC regardless of the interrupt handling program, however, those generated by the TO flag are not cleared by the DMAC. Therefore, the TO flag interrupt requests need to be cleared with the interrupt handling program. (The DR and TO flags are set at the same time, but cleared separately.)

Table 51.6 HSCIF Interrupt Sources

Interrupt Source	DMAC Activation
Interrupts generated by receive error flag (ER)	Disabled
Interrupts generated by receive-FIFO-data-full (RDF), receive-data-ready (DR) or timeout (TO)	Enabled
Interrupts generated by break (BRK) or overrun error (ORER)	Disabled
Interrupts generated by transmit FIFO data empty (TDFE)	Enabled

51.4 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

Note the following on use of the HSCIF.

(1) Break detection and operation

Break signals can also be detected by reading the HRX pin value directly when a framing error (FER) is detected. In the break state, the input values from the HRX pin are all 0s. So, the parity error flag (PER) may be set after the FER flag is set to 1.

Although the HSCIF stops receive data transfer to HSFRDR after detecting a break, it continues data reception.

(2) Sending a break signal

The input/output condition and level of the HTX pin are determined by the SPB2IO and SPB2DT bits in HSSPTR. This enables to send a break signal.

The pin does not function as the HTX pin from the initialization of the serial transmitter to setting of the TE bit (enabling transmission). In this period, the marked state is substituted by the value of the SPB2DT bit. Therefore, the SPB2IO and SPB2DT bits should be set to 1 (designating output and high level) beforehand.

To send a break signal during serial transmission, clear the SPB2DT bit to 0 (low level), and then clear the TE bit to 0 (halting transmission). When the TE bit is cleared, the transmitter is initialized regardless of the current transmission state, and the HTX pin outputs 0.

(3) Data sampling timing and reception margin in asynchronous mode

The HSCIF operates on the base clock with a frequency multiplied by the number which is set as a sampling rate for the bit rate.

In reception, the HSCIF performs the internal synchronization by sampling the falling edge of the start bit using the base clock. In addition, the HSCIF takes receive data at the rising edge of the S/2 pulse (when S is an even number) or (S+1)/2 pulse (when S is an odd number) on the base clock when sampling rate is S.

Figure 51.11 shows the timing of this operation when S = 16.

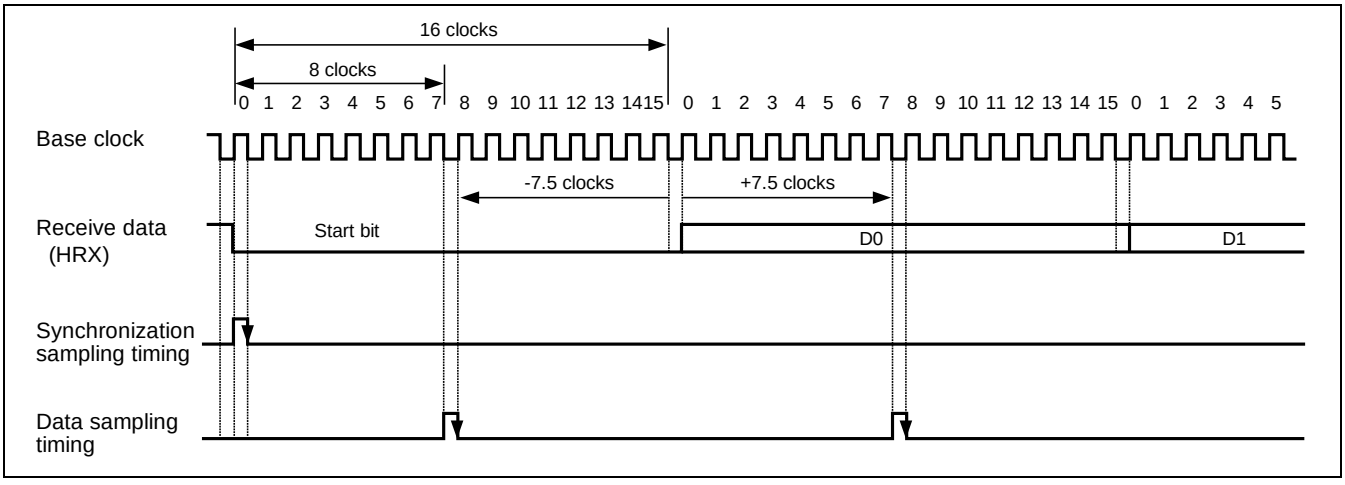

Figure 51.11 Timing Chart of Receive Data Sampling

The reception margin in asynchronous mode is given by formula (1).

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\% \quad \text{Expression (1)}$$

M: Receive margin (%)

N: Ratio of bit rate to clock (N = sampling rate)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute value of clock frequency deviation

Assuming F = 0, D = 0.5 and sampling rate = 16 for expression (1), the reception margin obtained with expression (2) is 46.875% as shown below:

Assuming D = 0.5 and F = 0

$$M = (0.5 - 1/(2 \times 16)) \times 100\%$$

$$= 46.875\% \ldots\ldots \text{expression (2)}$$

This is a theoretical value. A reasonable margin allowed in system designs is 20% to 30%.

(4) Reception margin and baud rate error

The value of 46.875% obtained by the above expression (2) indicates the reception margin when the baud rate error is 0 (F = 0). If there is no error in the reception and transmission baud rates, reception is possible even with misalignment of approx. 1/2 bit. If there is an error in the reception and transmission baud rates, the errors are accumulated up to the stop bit reception, which reduces the reception margin. The allowable baud rate error can be obtained by modifying the F in expression (1). When D = 0.5:

$$F = \{(15/32 - M)/(L - 0.5)\} \times 100\ (\%) \ldots\ldots \text{expression (3)}$$

By using expression (3), the relationship between the allowable error and reception margin with the frame length = 12 can be summarized as follows:

Allowed Error (%)	Reception Margin (%)
4.07	0
3.64	5
3.20	10
2.33	20
1.46	30

(5) Usage method of SRHP bits

The method for using the SRHP bits in the sampling rate register is described below.

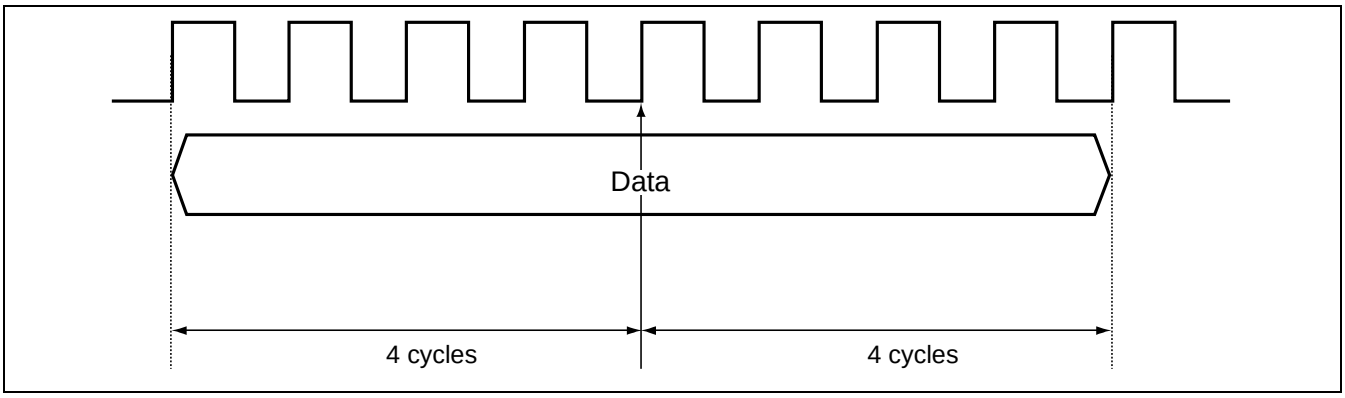

Figure 51.12 Sampling with Invalid SRHP Bits

Figure 51.12 shows a sampling example in which the SRHP bits are invalid (sampling rate = 8). In this case, the HSCIF samples data at half of the sampling rate, which is at the rising edge of the fourth pulse of the clock. This allows a setup margin and hold margin of 50% each to be provided.

However, if the ratio between the baud rate and sampling clock is not 1:1, either the setup margin or hold margin is omitted in data reception of a single frame. If the setup margin is omitted, the hold margin increases. On the other hand, if the hold margin is omitted, the setup margin increases. Figure 51.13 and 51.14 show examples.

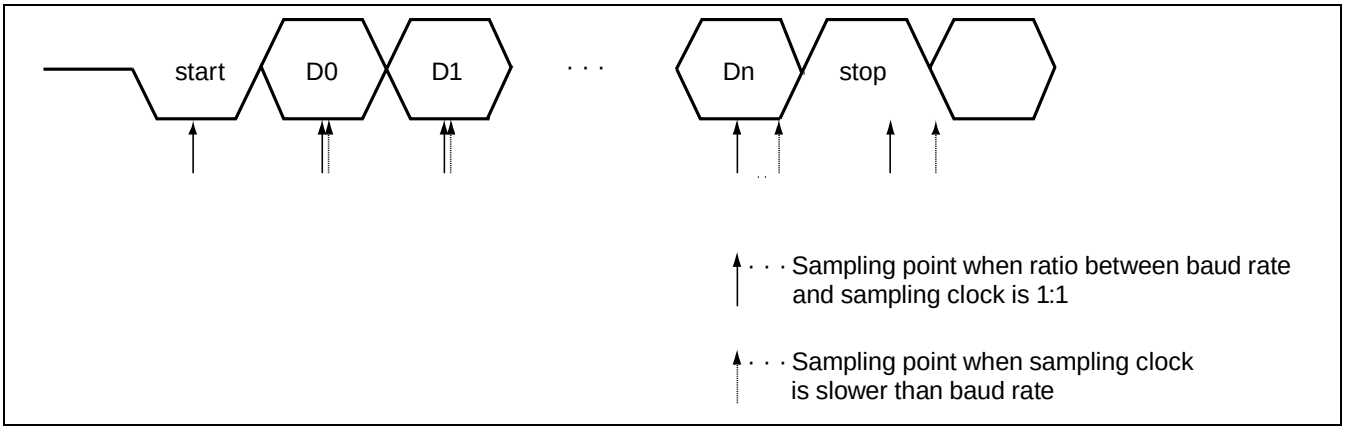

Figure 51.13 Sampling Point with Sampling Clock Slower Than Baud Rate

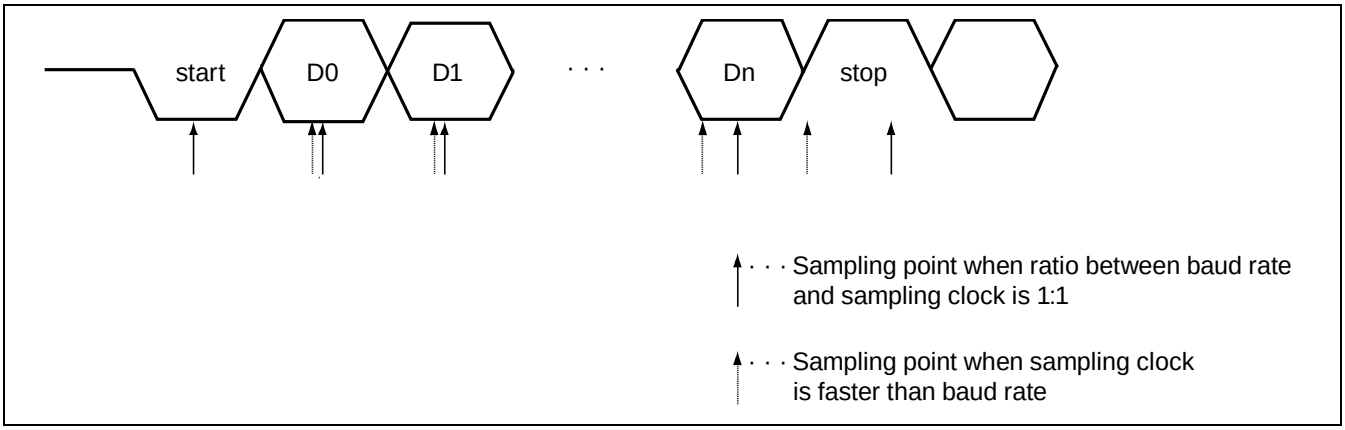

Figure 51.14 Sampling Point with Sampling Clock Faster Than Baud Rate

The ratio between the baud rate and sampling clock can be used to determine which margin among the setup margin and hold margin is to be omitted and which is to be increased. Based on this, the margin within a single frame can be increased by intentionally increasing the margin to be omitted in advance. The sampling point can be moved by setting a value in the SRHP bits. Figure 51.15 shows an example.

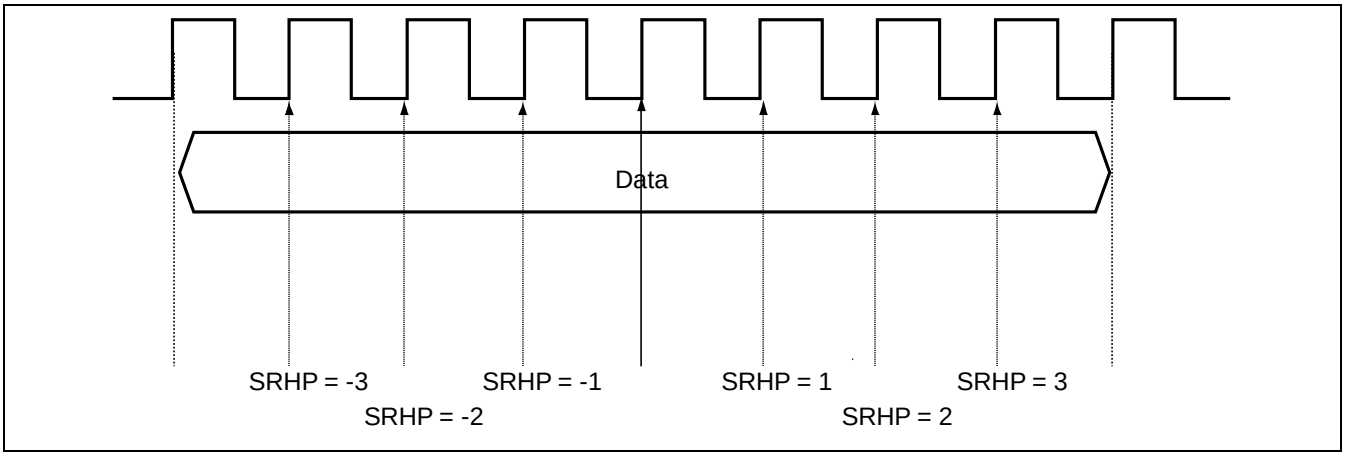

Figure 51.15 Sampling Point Moved by SRHP Bits

(6) Sampling rate and bit rate settings and respective margin

To set the baud rate in the HSCIF, in addition to setting the clock division ratio, the two registers, bit rate register (HSBRR) and sampling rate register (HSSRR), need to be set. These registers must be set so that the margin calculated by expression (1) in section 51.4 (3) will be a sufficient value.

The bit rate error is small when the value obtained by dividing the divided clock frequency used in the HSCIF with the sampling rate is near the desired baud rate. If there are many combinations of bit rate and sampling rate with the same bit rate error, choosing a combination with a large sampling rate provides a large margin. This is because when the bit rate error is constant in expression (1) in section 51.4 (3), that is, when the "absolute value of clock frequency deviation (F)" is constant, the margin (M) increases in accordance with the sampling rate (N).

If the sampling rate is made larger in a combination of bit rate and sampling rate with different bit rate errors, the bit rate error is increased. Accordingly, the "absolute value of clock frequency deviation (F)" on the right side in expression (1) in section 51.4 (3) gets larger and the margin (M) smaller.

Refer to the following procedure when selecting the sampling rate and bit rate settings.

1. Obtain the bit rate with the smallest bit rate error for sampling rates from 8 to 32.
2. Using expression (1) in section 51.4 (3), calculate the margin for each combination of sampling rate and bit rate which was obtained in step 1.
3. Select the combination with the largest margin among the combinations of sampling rate and bit rate.

51.5 Baud Rate Generator for External Clock (BRG)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

51.5.1 Overview

The HSCIF incorporates a baud rate generator for external clock (abbreviated as BRG, hereafter). The BRG supplies a sampling clock (BRGCLK) to the HSCIF core by dividing the external clock SC_CLK (selectable between SCIF_CLK and Internal clock) by 1 to $2^{16} - 1$. In addition, the BRG switches the output between the external clock HSCK and divided clock.

51.5.2 Block Diagram

Figure 51.16 shows a block diagram of the BRG.

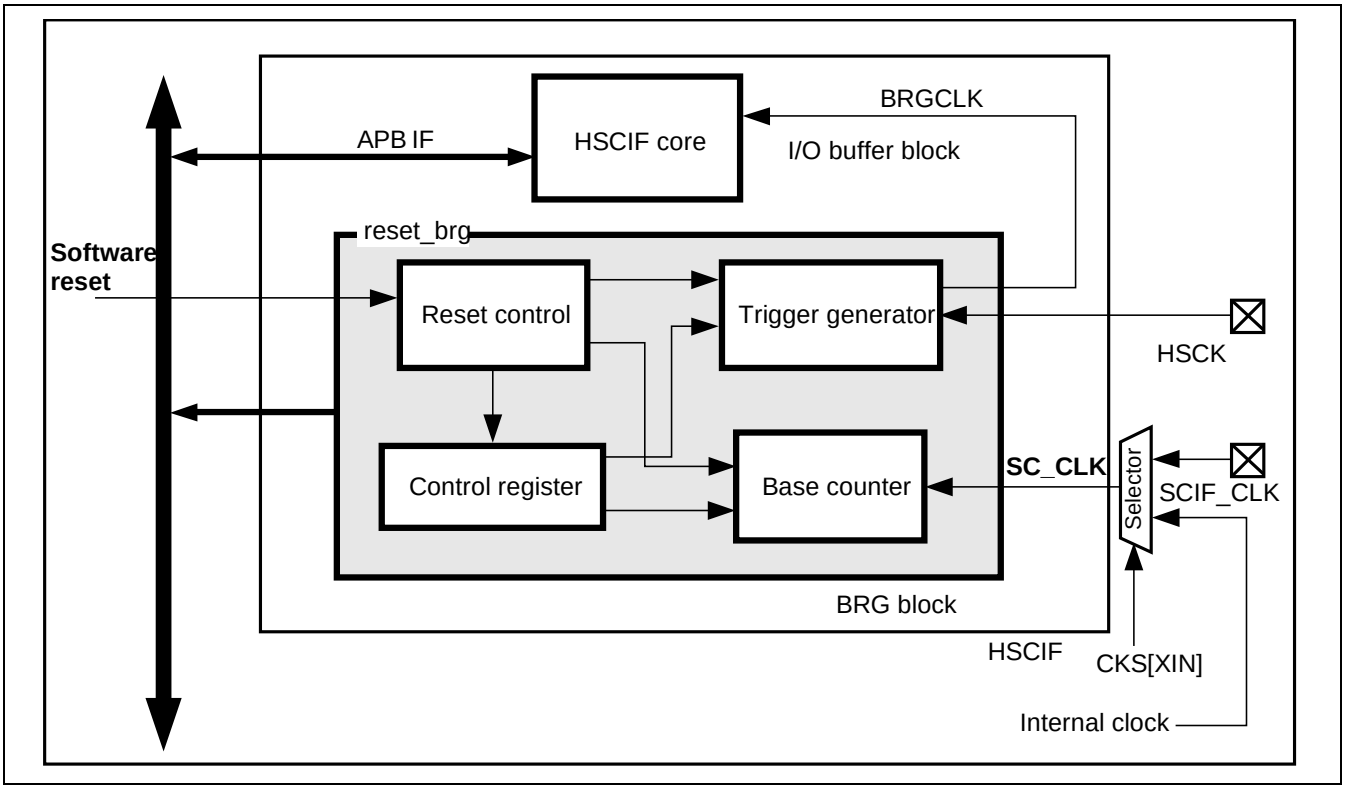

Figure 51.16 BRG Block Diagram

(1) Reset controller:

The reset controller handles resetting the control register, base counter, and trigger generator.

(2) Control register:

The control register has the frequency division register and clock select register.

(3) Base counter:

The base counter is a 16-bit CLK synchronization counter that is used to determine the timing for generating a frequency divided clock.

(4) Trigger generator:

The trigger generator generates rising-edge/falling-edge triggers for a frequency divided clock with the timing according to values of the frequency division register and base counter. The triggers are used to generate the frequency divided clock. In addition, the trigger generator switches the output between the HSCK (external clock input) and frequency divided clock.

51.5.3 BRG Register Configuration

Table 51.7 shows the registers in the BRG block.

Table 51.7 List of Registers

Name	Code	R/W	Initial Value	Offset From Base Address	Access Size	Second Generation RZ/G Series Products: RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
Frequency division register	DL	R/W	H'00	H'30	16	√	√	√	√
Clock select register	CKS	R/W	H'00	H'34	16	√	√	√	√

51.5.3.1 Frequency Division Register (DL)

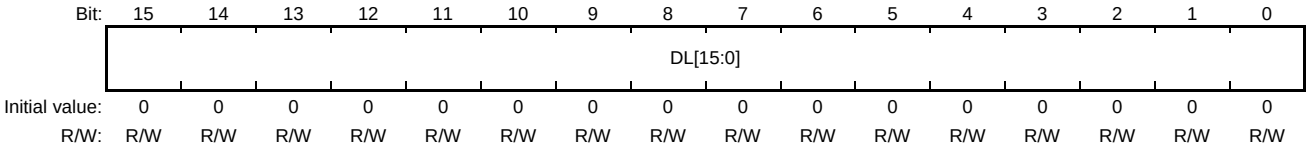
This register specifies the value of frequency division for the frequency divided clock generated by the BRG.

This register supports a 16-bit binary format that allows specifying a value in the range of 1 to 65535.

Setting all 0s in this register makes the BRG output the frequency divided clock at the low level.

The value of frequency division is given by the following formula:

The value of frequency division = (clock input frequency)/ (required baud rate × sampling rate)



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DL[15:0]	All 0	R/W	Specifies a division value of frequency clock generated in BRG. The setting value is enabled in the range of 1 to 65535.

Table 51.8 and Table 51.9 show how to use the baud rate generator with a 3.6864-MHz crystal resonator, and a 26-MHz crystal resonator.

Table 51.8 Baud Rate (3.6864-MHz clock)

Baud Rate	Value of Frequency Division	Sampling Rate	Error Rate*
50	4608	16	—
75	3072	16	—
110	4189	8	-0.002
134.5	1713	16	0.001
150	1536	16	—
300	768	16	—
600	384	16	—
1200	192	16	—

Baud Rate	Value of Frequency Division	Sampling Rate	Error Rate*
1800	128	16	—
2000	123	15	0.098
2400	96	16	—
3600	64	16	—
4800	48	16	—
7200	32	16	—
9600	24	16	—
14400	16	16	—
19200	12	16	—
38400	6	16	—
76800	3	16	—
115200	2	16	—

Note: * "—" Indicates that the error rate is 0.

Table 51.9 Baud Rate (26-MHz clock)

Baud Rate	Value of Frequency Division	Sampling Rate	Error Rate*
9600	129	21	0.025
19200	52	26	-0.160
38400	26	26	-0.160
57600	15	30	-0.309
115200	9	25	-0.309
230400	4	28	-0.756
460800	2	28	-0.756
921600	1	28	-0.756
1843200	1	14	-0.756
3250000	1	8	—

Note: * "—" Indicates that the error rate is 0.

51.5.3.2 Clock Select Register (CKS)

This register switches the output between the frequency divided clocks and specifies a source clock for the external baud rate.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CKS	XIN	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	CKS	B’0	R/W	This bit switches the output between the frequency divided clock (SC_CLK) and external clock (HSCK). 0: Selects the frequency divided clock. 1: Selects the external clock.
14	XIN	B’0	R/W	Selects the baud rate generator clock source for the external clock between SCIF_CLK and Internal clock. 0: Selects the external clock (SCIF_CLK). 1: Selects the internal clock (Internal clock).
13 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

51.5.4 Restrictions in BRG

(1) Notes on setting frequency division register

1. For the initial setting of the register after a reset, at least one bit of waiting period is required to secure the clock stabilization time.

   (Example) One bit period when DL = 2

   3.68 (MHz) × 1/2 × 1/16 = 0.115 (MHz) → 8695 (ns)

2. For modifying the register value after the setting stated in <1> above, at least one bit of waiting period at the maximum bit rate (DL = '65535') is required.

   The HSCIF registers and BRG registers should be set as the following table:

- Asynchronous mode (SC_CLK external input)

HSCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
HSSCR.CKE[1:0]	B'10	CKS	H'0000
		DL	H'1 to H'FFFF

- Asynchronous mode (HSCK external input)

HSCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
HSSCR.CKE[1:0]	B'10	CKS	H'8000
		DL	Don't care

- Asynchronous mode (SC_CLK internal input)

HSCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
HSSCR.CKE[1:0]	B'10	CKS	H'4000
		DL	H'1 to H'FFFF

3. The register settings for the baud rate generator for external clock should be made before starting initialization of the HSCIF.

52. I2C Bus Interface (I2C)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

52.1 Overview

52.1.1 Features

Second generation RZ/G series products have up to seven I2C bus interfaces conformant with the Philips Semiconductors (now NXP Semiconductors) I2C bus (Inter-IC bus) specification. However, the configuration of registers that control the I2C bus differs partly from the NXP Semiconductors register configuration. The I2C bus interface has the following features. Note that "module clock (MOD_CLK)" refers to the peripheral module clock in this section.

[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N]: module clock is S3D2ϕ for channels I2C0/1/2 and S0D6ϕ for channels I2C3/4/5/6. S3D2ϕ and S0D6ϕ have the same frequency (133.33 MHz).

[RZ/G2E]: module clock is S3D2ϕ (133.33 MHz) for all channels.

- The I2C interfaces support the I2C bus specification from NXP Semiconductors
- Multi-master compatible
- Seven- or ten-bit address compatible master
- Seven-bit slave address
- Fast mode compatible
- Variable clock frequencies
- DMA transfer support for Master/Slave Transmission Master/Slave Reception.

Figure 52.1 shows a block diagram of the I2C bus interface.

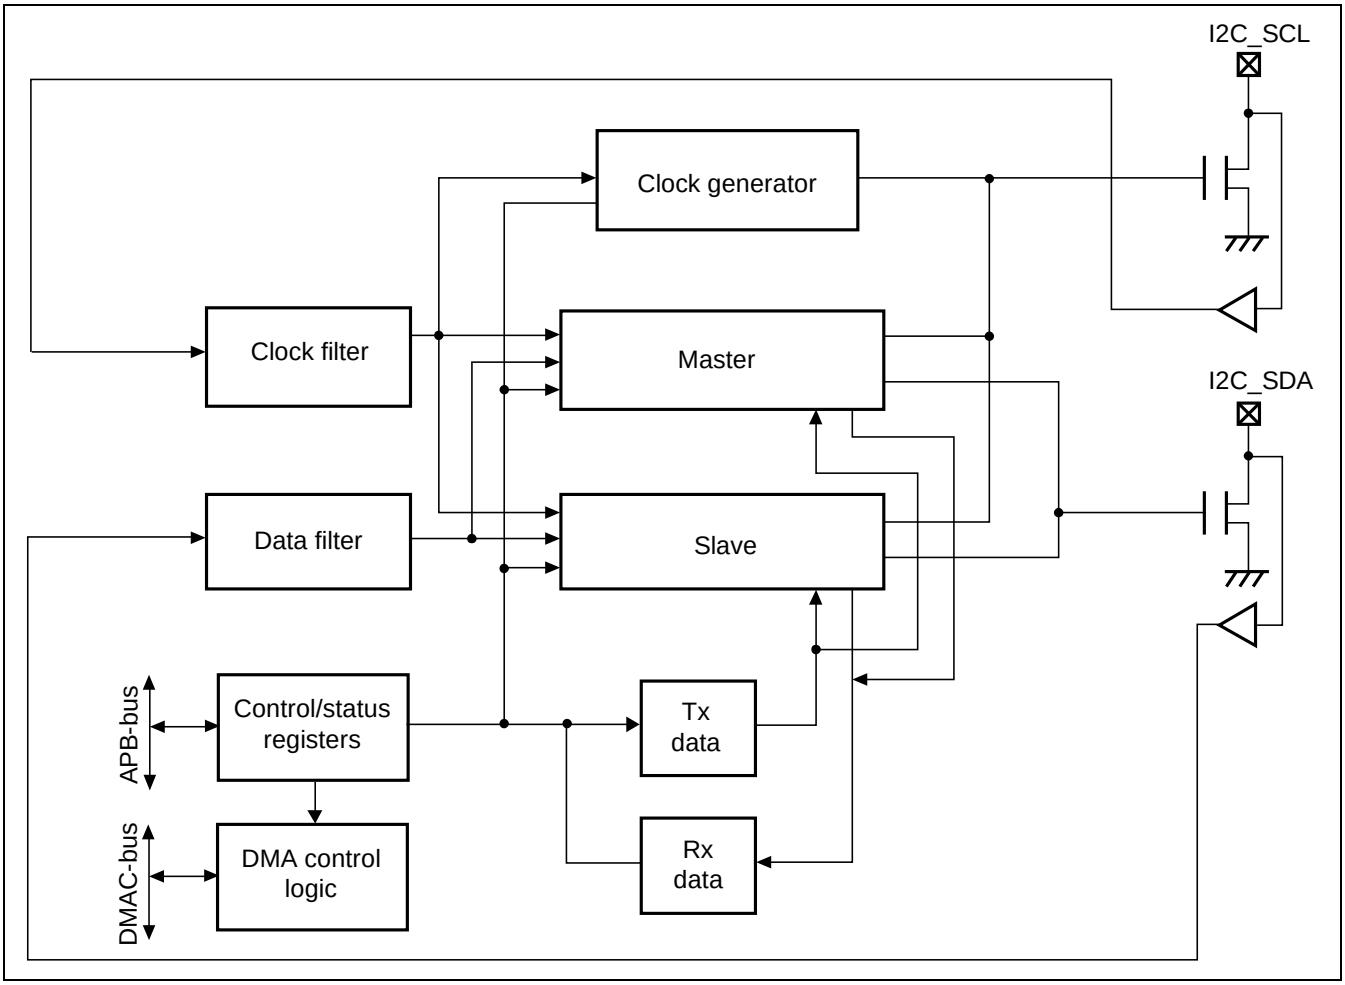


Figure 52.1 Block Diagram of I2C Bus Interface

52.1.2 External Pins

Table 52.1 lists the pins used in the I2C bus interface.

Table 52.1 I2C Bus Interface

				Second Generation RZ/G Series Products			
				RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
Channel Number	Pin Name *1	I/O	Function	Output Buffer Type*2			
0	SCL	I/O	SCL: I2C serial clock input/output pin SDA: I2C serial data input/output pin	OD	OD	OD	OD
	SDA						
1	SCL			LVTTL	LVTTL	LVTTL	LVTTL
	SDA						
2	SCL			LVTTL	LVTTL	LVTTL	LVTTL
	SDA						
3	SCL			OD	OD	OD	OD
	SDA						
4	SCL			OD	OD	OD	LVTTL
	SDA						
5	SCL			OD	OD	OD	LVTTL
	SDA						
6	SCL			LVTTL	LVTTL	LVTTL	LVTTL
	SDA						
7	SCL			—	—	—	LVTTL
	SDA						

Notes: 1. The actual pin names are I2Cn_SCL and I2Cn_SDA (n = 0 to 6 for RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N, n = 0 to 7 for RZ/G2E)). These are referred to as I2C_SCL and I2C_SDA in this section.

2. Output buffer type: "OD" is open drain buffer and "LVTTL" is low level drive only LVTTL buffer. OD assigned channel pins are 1.8 V I/O and input/output 3.3 V tolerant; LVTTL assigned channel pins are 3.3 V I/O.

The I2C buffer in this LSI is not compliant with the 5V-input. When turning off the I/O power source (3.3 V) of this LSI, turn off the power source of the pull-up resistors connected to the I2C pins.

Note: When using 1.8V I2C pins (OD assigned channel) as 3.3 V tolerant, all the external pull-up voltage power supply to the I2C of this LSI must keep the same power on/off sequence as the VCCQ (3.3 V) of this LSI.

52.1.3 Register Configuration

The base address for each channel of registers of the I2C bus interface is as follows:

- I2C0: H'E650_0000
- I2C1: H'E650_8000
- I2C2: H'E651_0000
- I2C3: H'E66D_0000
- I2C4: H'E66D_8000
- I2C5: H'E66E_0000
- I2C6: H'E66E_8000
- I2C7: H’E669_0000 (RZ/G2E)

Note: Number of I2C channels:
7 channels for RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N (channels 0 to 6)
8 channels for RZ/G2E (channels 0 to 7)

Each channel of the I2C bus interface has the registers below.

Table 52.2 Register Configuration

Register Name	Abbreviation	R/W	Offset Address from Base Address	Initial Value	Size	Second Generation RZ/G Series Products			
						RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
Slave control register	ICSCR	R/W	H'00	H'0000_0000	32	√	√	√	√
Master control register	ICMCR	R/W	H'04	H'0000_0000*3	32	√	√	√	√
Slave status register	ICSSR	R/(W)*1	H'08	H'0000_0000	32	√	√	√	√
Master status register	ICMSR	R/(W)*2	H'0C	H'0000_0000	32	√	√	√	√
Slave interrupt enable register	ICSIER	R/W	H'10	H'0000_0000	32	√	√	√	√
Master interrupt enable register	ICMIER	R/W	H'14	H'0000_0000	32	√	√	√	√
Clock control register	ICCCR	R/W	H'18	H'0000_0000	32	√	√	√	√
Slave address register	ICSAR	R/W	H'1C	H'0000_0000	32	√	√	√	√
Master address register	ICMAR	R/W	H'20	H'0000_0000	32	√	√	√	√
Receive data register	ICRXD	R	H'24	H'0000_0000	32	√	√	√	√

DMA enable register	ICDMAER	R/W	H'3C	H'0000_0000	32	√	√	√	√
First bit setup cycle register	ICFBSCR	R/W	H'38	H'0000_0004	32	√	√	√	√

Notes: Do not write to any addresses other than listed above. Operations cannot be guaranteed if writing is attempted.
Values read from addresses other than those listed above are undefined.
Although the actual register name and its abbreviation have channel number as a suffix respectively, it is omitted in this section (the number "2" of ICCCR2 is not channel number).
Operation cannot be guaranteed if the register is not accessed as a longword(32bit)

1. Only 0 can be written to bits 4 to 0 to clear the flags.
2. Only 0 can be written to bits 6 to 0 to clear the flags.
3. Bits 30, 29, 22, 21, 14, 13, 6, and 5 are undefined.

52.2 Register Description

Registers in the I2C are allocated to and arranged in the address space of the internal bus.

Legend for Register Description

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

R: Read-only. When the bit is reserved, the write value should always be 0. Writing 1 to these bits can cause a malfunction of I2C.

—/W: Write-only. The read value is undefined.

52.2.1 Slave Control Register (ICSCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	SDBS	SIE	GCAE	FNA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved When these bits are read,, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
7 to 4	—	All 0	R	Reserved The write value should always be 0.
3	SDBS	B’0	R/W	Slave Data Buffer Select This bit is used to select the data buffer. Select the single-buffer mode supported in this module. When this bit is set to 1, the single-buffer mode is selected. SCL will be held low from the timing when the receive data register acquires the data packet until the SDR flag is cleared. 0: Setting prohibited 1: Single-buffer mode
2	SIE	B’0	R/W	Slave Interface Enable This bit must be set for the slave operation. If this bit is low, the slave interface is reset.
1	GCAE	B’0	R/W	General Call Acknowledgement Enable When slave devices are to issue an acknowledgement in response to a general call address sent from a master, this bit must be set to 1.
0	FNA	B’0	R/W	Forced Non Acknowledgement In the slave receive mode, the level of this bit is sent to the transmitting device as the acknowledge signal. This bit is set to 0 during the period that the data packet is being received, and set to 1 on completion of data reception. Forced non acknowledgement is returned to the master during slave reception. When the slave has received the last byte of data in a data packet, the slave communicates with the master by sending a NACK, meaning that the acknowledgement is not driven. The master issues a stop on the bus after receiving a NACK. The setting of this bit does not affect the acknowledgement of the slave address.

52.2.2 Slave Status Register (ICSSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bits 0 to 4 among the status bits in the slave status register are cleared by writing 0 to the respective status bit positions. The individual bits are held 1 until 0 is written to (other than the GCAR and STM bits).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	GCAR	STM	SSR	SDE	SDT	SDR	SAR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
7	—	B'0	R	Reserved The write value should always be 0.
6	GCAR	B'0	R	General Call Address Received Indicates that the address received from the bus is a general call address (H'00). This status bit does not cause an interrupt. This bit is automatically cleared by hardware when the SIE bit (bit 2 in the slave control register) is set to 0 or when the SSR bit (bit 4 in this register) is set to 1.
5	STM	B'0	R	Slave Transmit Mode Indicates whether the current slave transmit mode is read or write. When this bit is set to 0, the mode is write (slave reception). When this bit is set to 1, the mode is read (slave transmission). This status bit does not cause an interrupt. This bit is automatically cleared by hardware when the SIE bit (bit 2 in the slave control register) is set to 0 or when the SSR bit (bit 4 in the slave status register) is set to 1.
4	SSR	B'0	R/W*	Slave Stop Received A stop condition has been output on the bus. This status bit becomes active after the rising edge of SDA during reception of a stop bit.

Bit	Bit Name	Initial Value	R/W	Description
3	SDE	B'0	R/W*	Slave Data Empty Indicates that data to be transmitted has been loaded into the shift register. At the start of byte data transmission, the contents of the ICTXD register are loaded into a shift register ready for outputting data on the bus. This status bit indicates that data has been loaded and the ICTXD register is again ready for further data. This status bit becomes active on the falling edge of SCL before reception of the first data bit. - When bit SDE = 1 & bit TSDMAE = 0, the interrupt SDE is issued to CPU, so the transmit data register is to accept further data. - When bit SDE = 1 & bit TSDMAE = 1, enable DMA transfer request to DMAC. During the single-buffer mode, this bit must be reset every time new data has been written to ICTXD. If not, the slave will hold SCL low after the current data transfer has finished to stop the bus. During DMA transmit mode, the SDE bit is also set after data is loaded into the shift register. In this case, this bit is cleared by DMA logic control. This mechanism to assure the continuous data transfer without software control. For the last byte data transmitted, this bit is cleared by software.
2	SDT	B'0	R/W*	Slave Data Transmitted A byte of data has been transmitted to the bus. This bit becomes active after the falling edge of SCL during reception of the last data bit.
1	SDR	B'0	R/W*	Slave Data Received A byte of data has been received from the bus and is ready for reading from the receive data register. This bit becomes active after the falling edge of SCL during reception of the last data bit. During the single-buffer mode, this bit must be reset after data has been read from the ICRXD register. - When bit SDR = 1 & bit RSDMAE = 0, the interrupt SDR is issued to CPU, so the transmit data register is to accept further data. - When bit SDR = 1 & bit RSDMAE = 1, enable DMA transfer request to DMAC. When SDBS is set to 1, SCL will be held low from the timing when the receive data register acquires the data packet until the SDR flag is cleared. During DMA receive mode, the SDR bit is also set after data is received into RXD register. In this case, this bit is cleared by DMA logic control. This mechanism to assure the continuous data transfer without software control.
0	SAR	B'0	R/W*	Slave Address Received Indicates that the slave has recognized its own address on the bus (defined by the contents of the slave address register). If the general call acknowledgement enable bit is enabled in the slave control register, then this status bit is also set to 1 even if the address on the bus is a general call address. In this case, the GCAR bit in this register is used to determine whether or not the address is a general call address. The STM bit indicates whether the access is read (high) or write (low). This status becomes active after the falling edge of SCL during reception of the last address bit. The slave holds the SCL signal low from the start of the ACK phase until the software resets this status bit.

Note: * This bit can be read from or written to. Writing 0 clears this bit to 0 and writing 1 is ignored.

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	MDBS	FSCL	FSDA	OBPC	MIE	TSBE	FSB	ESG
Initial value:	0	—	—	0	0	0	0	0	0	—	—	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0, except bits 30, 29, 22, 21, 14, and 13, in which case, initial value is undefined.	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
7	MDBS	B'0	R/W	Master Data Buffer Select This bit is used to select the data buffer mode. Select the single-buffer mode supported in this module. When this bit is set to 1, the single-buffer mode is selected. SCL will be held low from the timing when the receive data register acquires the data packet until the MDR flag is cleared. 0: Setting prohibited 1: Single-buffer mode
6	FSCL	—	R/W	Forced SCL This bit controls the status of the I2C_SCL pin (reading reflects the current status of the I2C_SCL pin). When the OBPC bit is set, this bit directly controls the SCL line on the bus. During a read cycle, the level on this bit (which includes the reset level) will change depending on the level on I2C_SCL since it directly reflects the level on the I2C_SCL.
5	FSDA	—	R/W	Forced SDA This bit controls the status of the I2C_SDA pin (reading reflects the busy status level on the I2C bus). When the OBPC bit is set, then this bit directly controls the SDA line on the bus. During a read cycle, the level on this bit (which includes the reset level) will show the busy status of the I2C bus (1 for busy; 0 for not busy).
4	OBPC	B'0	R/W	Override Bus Pin Control When this bit is set to 1, the FSDA and FSCL bits in this register control SDA and SCL directly.
3	MIE	B'0	R/W	Master Interface Enable When this bit is set to 1, the master interface is enabled. The master interface is disabled when this interface loses in arbitration of bus mastership even MIE bit indicates 1. If 0 is not subsequently written to the bit, the master interface is restored on detection of a STOP condition on the I2C bus. Regarding the state following a loss in arbitration of bus mastership, see the description of the MAL bit in ICMSR.

Bit	Bit Name	Initial Value	R/W	Description
2	TSBE	B'0	R/W	Start Byte Transmission Enable The write value for this bit should always be 0.
1	FSB	B'0	R/W	Forced Stop onto the Bus When this bit is set to 1, the master transmits a STOP condition on the bus at the end of the current transfer. If ESG is also set, the master immediately transmits a START condition and begins transmitting a new data packet. If ESG is not set, the master enters the idle state.
0	ESG	B'0	R/W	Enable Start Generation When this bit is set to 1, the master starts transmission of a data packet. If the bus is idle when ESG is set, the master transmits a START condition on the bus and then transmits the slave address. If the master is transferring data when ESG is set, at the end of that data byte transfer, the master transmits a repeated START condition before transmitting the slave address. When transmitting a data packet, the software must reset this bit when the slave address has been transmitted, otherwise a repeated START condition is transmitted after every transmission is completed.

52.2.6 Master Status Register (ICMSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The status bits (bits 0 to 6) in the master status register are cleared by writing 0 to the respective status bit positions. The individual status bits are held 1 until a reset by writing 0 to the appropriate bit position.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	MNR	MAL	MST	MDE	MDT	MDR	MAT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
7	—	B'0	R	Reserved The write value should always be 0
6	MNR	B'0	R/W*	Master NACK Received When this bit is set to 1, this bit indicates that the master has received a NACK response (the SDA line is high during the acknowledge cycle on the bus) to either an address or data transmission. To restart the address transmission from idle state on Master, this bit must be cleared.
5	MAL	B'0	R/W*	Master Arbitration Lost In a multi-master system, when this bit is set to 1, it indicates that the master has lost arbitration to other masters on the bus. At this point, the master interface is disabled then Master enters the idle state again. To restart the address transmission from idle state on Master, this bit must be cleared. [except RZ/G2M V1.3, RZ/G2M V3.0]
4	MST	B'0	R/W*	Master Stop Transmitted When this bit is set to 1, it indicates that the master has sent a STOP condition on the bus. A STOP condition can be sent either as a result of the setting of the forced stop bit in the control register, or from a NACK being received from a slave during a slave receive data packet.

Bit	Bit Name	Initial Value	R/W	Description
3	MDE	B'0	R/W*	Master Data Empty At the start of a byte data transmission, the contents of the transmit data register are loaded into a shift register ready for transmitting on the bus. This status bit becomes active: - When bit MDE = 1, MAT = 0 & bit TMDMAE = 0, the interrupt MDE is issued to CPU, so the transmit data register is to accept further data. - When bit MDE = 1, MAT = 0 & bit TMDMAE = 1, enable DMA transfer request to DMAC. During master transmission, the MDE bit is also set at the same time as the MAT bit is set after transmission of the slave address. In this case, you need to clear the MDE and MAT bits after the ICMCR's ESG bit is cleared. The clearing will restart the data transmission. During DMA transmit mode, the MDE bit is also set after data is loaded into the shift register. In this case, this bit is cleared by DMA logic control. This mechanism to assure the continuous data transfer without software control. For the last byte data transmitted, this bit cleared by software.
2	MDT	B'0	R/W*	Master Data Transmitted Byte data has been sent to the slave on the bus. This status bit becomes active after the falling edge of SCL during reception of the last data bit.
1	MDR	B'0	R/W*	Master Data Received Byte data has been received from the bus and is in the receive data register. This status bit becomes active after the falling edge of SCL during reception of the last data bit. During single-buffer mode, this status bit must be reset after data has been read from the receive data register. - When bit MDR = 1, MAT = 0 & bit RMDMAE = 0, the interrupt MDR is issued to CPU, so the receive data register is to accept further data. - When bit MDR = 1, MAT = 0 & bit RMDMAE = 1, enable DMA transfer request to DMAC. When MDBS is set to 1, SCL will be held low from the timing when the receive data register acquires the data packet until the MDR flag is cleared. During master reception mode, the MDR bit is also set at the same time as the MAT bit is set after transmission of the slave address. In this case, you must clear the MDR and MAT bits after the ICMCR's ESG bit is cleared. Clearing will start the data reception. During DMA receive mode, the MDR bit is also set after data is received into RXD register. In this case, this bit is cleared by DMA logic control. This mechanism to assure the continuous data transfer without software control.
0	MAT	B'0	R/W*	Master Address Transmitted The master has been transmitted the slave address byte of a data packet. This bit becomes active after the falling edge of SCL during reception of the ACK bit following transmission of the address.

Note: * This bit can be read from or written to. Writing 0 clears this bit to 0 and writing 1 is ignored.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SCGD						CDF		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
8 to 3	SCGD	All 0	R/W	SCL Clock Generation Divider When operation is in master mode, the SCL clock is generated from the internal clock by using SCGD as the ratio. This is also the operating clock in slave-mode operation while SCL is being held low to stop the bus after an overflow has occurred. SCGD must be specified in both master and slave modes. The formula expressing the relationship is: Equation 2: SCL rate calculation SCLfreq = I2Cck/(20 + SCGD × 8 + F[(tICF + tr + IntDelay) × I2Cck]) I2Cck: I2C internal clock frequency tICF: I2C SCL falling time (depending on external load) tr: I2C SCL rising time (depending on external load) IntDelay: LSI internal delay corresponds to output buffer type. Open drain buffer: 50 ns (typ.), 110 ns (max.) LVTTL (low drive only) buffer: 5 ns (typ.), 6 ns (max.). F[n]: n rounded down to an integer Suggested settings for CDF and SCGD for CPU speeds and the two I2C bus speeds are given in Table 52.3.
2 to 0	CDF	All 0	R/W	Clock Division Factor The internal clock used in most blocks in the I2C module is a divided module clock. The internal I2C clock is generated from the module clock using the CDF as the division ratio: Equation 1: I2C internal clock frequency calculation I2Cck = MOD_CLK/(1 + CDF) MOD_CLK: module clock frequency Ensure that minimum values for setup and hold times of the SDA signal relative to the SCL signal on the bus are satisfied. The clock frequency is to ensure that the glitch filtering will operate with glitches of up to 50 ns as described in the fast mode I2C specification. Note: CDF must be set so that the clock frequency (I2Cck) is lower than 20 MHz.

Table 52.3 Recommended Settings for CDF and SCGD*1

- Recommended register values for open drain buffer

	100 kHz		400 kHz	
Module Clock Frequency	**CDF(*2)**	**SCGD(*3)**	**CDF(*2)**	**SCGD(*3)**
133.33 MHz	6	21	6	3
Error		-0.80%		-0.80%

- Recommended register values for LVTTL buffer (low drive only)

	100 kHz		400 kHz	
Module Clock Frequency	**CDF(*2)**	**SCGD(*3)**	**CDF(*2)**	**SCGD(*3)**
133.33 MHz	6	21	6	3
Error		-0.28%		+1.31%

Notes: 1. These recommended values are for the SCL rate with an external load that produces tICF = 3 ns and tr = 150 ns.
Recalculate to obtain the actual values after measuring tICF and tr under actual conditions of usage.
2. Recommended value for CDF bit of ICCCR.
3. Recommended value for SCGD bit of ICCCR.

52.2.10 Receive and Transmit Data Registers (ICRXD and ICTXD)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Reading from or writing to these registers access different physical internal registers. When data is to be transmitted, the contents of the shift register are loaded via TXD. After data has been received into the shift register from the I2C bus, it is then loaded into RXD.

(1) Receive data register (ICRXD)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 to 0	TXD	All 0	W	Write Transmit Data Data to be transmitted by master or slave.

52.2.11 Clock Control Register 2 (ICCCR2)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	CDFD	HLSE	SME
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved When these bits are read, the value in bits 7 to 0 is set to bits 31 to 24, bits 23 to 16, and bits 15 to 8. The write value should always be 0.
7 to 3	—	All 0	R	Reserved The write value should always be 0.
2	CDFD	B'0	R/W	CDF Disable When this bit is set to 1, the module clock is used for internal clocks except the clock filter. For SCL rate computation, see equation 3 in Note 2. The clock filter always operates at a clock frequency divided by the CDF value.
1	HLSE	B'0	R/W	HIGH/LOW Separate Control Enable When this bit is set to 1, the SCGD setting is ignored and SCL is generated with the division ratio set by ICHPR during a high period and with the division ratio set by ICLPR during a low period. For SCL rate computation, see equation 3 in Note 2. The program should be prepared so that ICHPR and ICLPR should be written to before setting this bit.
0	SME	B'0	R/W	SCL Mask Enable When this bit is set to 1, a change of internal SCL is ignored after an SCL external input pin changes during the time equal to the number of internal clock cycles specified by ICMPR. For SCL rate computation, see equation 3 in Note 2. The program should be prepared so that ICMPR should be written to before setting this bit.

Notes: 1. The control bits should be set to "CDFD = 0, HLSE = 0, and SME = 0" or "CDFD = 1, HLSE = 1, and SME = 1". Otherwise, operation cannot be guaranteed. ICCCR2 should be written to prior to writing ICCCR.

2. Equation 3: SCL Rate Computation (CDFD = 1, HLSE = 1, and SME = 1)

SCL freq = MOD_CLK/(8 + 2 × SMD + SCLD + SCHD + F[(tICF + tr + IntDelay) × MOD_CLK])

MOD_CLK: Module Clock Frequency

SMD: SCL masked period (set by the SCL mask control register)

SCLD: I2C SCL low clock period (set by the SCL HIGH control register)

SCHD: I2C SCL high clock period (set by the SCL LOW control register)

tICF: I2C SCL falling time (depending on external load)

tr: I2C SCL rising time (depending on external load)

IntDelay: LSI internal delay corresponds to output buffer type.
Open drain buffer: 50 ns (typ.), 110 ns (max.)
LVTTL (low drive only) buffer: 5 ns (typ.), 6 ns (max.).

F[n]: n rounded down to an integer

Table 52.4 shows recommended register values for two types of I2C bus speeds.

Table 52.4 Recommended Register Values when CDFD = 1, HLSE = 1, and SME = 1

- Recommended Register Values for open drain buffer

	100 kHz					400 kHz				
Module Clock Frequency	**CDF (*1)**	**SCGD (*2)**	**SMD (*3)**	**SCHD (*4)**	**SCLD (*5)**	**CDF (*1)**	**SCGD (*2)**	**SMD (*3)**	**SCHD (*4)**	**SCLD (*5)**
133.33 MHz	6 (*6)	0	20	632	653	6 (*6)	0	21	133	150
Error			-1.53%					-5.84%		

- Recommended Register Values for LVTTL buffer (low drive only)

	100 kHz					400 kHz				
Module Clock Frequency	**CDF (*1)**	**SCGD (*2)**	**SMD (*3)**	**SCHD (*4)**	**SCLD (*5)**	**CDF (*1)**	**SCGD (*2)**	**SMD (*3)**	**SCHD (*4)**	**SCLD (*5)**
133.33 MHz	6 (*6)	0	14	639	658	6 (*6)	0	16	138	155
Error			-0.43%					-1.67%		

Note: tICF = 20ns, tr = 35ns, and IntDelay = 110ns(open drain buffer)/6ns(LVTTL) are used to calculate Error value.

Notes:
1. Recommended value for CDF bit of ICCCR.
2. Recommended value for SCGD bit of ICCCR.
3 Recommended value for SMD bit of ICMPR.
4. Recommended value for SCHD bit of ICHPR.
5. Recommended value for SCLD bit of ICLPR.
6. In case of connecting to device, whose $t_{HD;DAT}$ is smaller than 100ns, specifying 0 as CDF is recommended.

16 × Tcyc	B'0_1110	32 × Tcyc	B'1_1110
17 × Tcyc	B'0_1111	33 × Tcyc	B'1_1111

Note: In Normal mode, Tcyc is period of I2Cck.
In Duty variable mode, Tcyc is period of MOD_CLK.

52.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

52.3.1 Data and Clock Filters

These blocks filter out glitches on signals coming from the I2C bus. Glitches up to one internal clock period in width are rejected (for details on the internal clock frequency, see section 52.2.9, Clock Control Register (ICCCR)). This is for the faster I2C bus rate (400 kHz) but does not violate the slower I2C bus rate specification.

These blocks also resynchronize bus signals with the internal clock.

52.3.2 Clock Generator

The clock generator has two functions. Firstly, it generates the SCL (I2C bus clock) according to commands of the master or slave interface. Secondly, it controls the internal clock rate, used by filtering blocks and the master and slave interfaces. This clock functions as a clock enable signal of the registers in these blocks.

52.3.3 Master/Slave Interfaces

These two interfaces run independently and in parallel. The master interface controls the transmission of address and data on the I2C bus. The slave interface monitors the I2C bus and takes part in transmissions if its programmed address is seen on the bus. The interfaces communicate with the control/status registers independently. There is only one interrupt line output from the I2C module. The interrupt source is either the master or the slave.

52.3.4 Software Status Interlocking

To make the software interface with the I2C module as robust and thus simple as possible, various interlocking status mechanisms have been included in the operation of the master and slave interfaces. The status bits involved are:

(1) MDR and SDR

MDR or SDR is set to 1 when data is received. Clear the status after reading the receive data register. If data is received while MDR or SDR is set, the hardware recognizes that unread data remains in the receive data register and automatically holds SCL at the low level to suspend data transmission. In this case, transmission can be resumed by clearing the status after reading the receive data.

Consequently, when receiving data continuously, be sure to clear the status bit (MDR or SDR) after reading the receive data register.

(2) MDE and SDE

If the MDE or SDE status bit is still set when data in the transmit data register is to be transmitted on the I2C bus by the slave or master, the SCL line must be held low until the MDE or SDE status bit is reset. The MDE or SDE status bit being set indicates that the data currently held in the transmit data register has already been transmitted on the I2C bus.

The software must clear this status bit when it writes to the transmit data register after transmission of the next data byte has become possible. This is not required for the first byte of data to be transmitted on the bus.

(3) MAL

When the master loses arbitration, the MAL bit (of the master status register) is set and the master interface is disabled. At this point, master mode is invalid and the I2C bus interface enters the slave mode. When master interface is restored, MAL bit must be cleared before the address re-transmission. [except RZ/G2M V1.3, RZ/G2M V3.0].

(4) SAR

The SAR status bit is set when the slave identifies its address on the I2C bus. At this point the slave interface forces the SCL line low until the SAR status bit is reset.

This is particularly important when a slave transmit is about to take place on the bus, and the slave will transmit the data from the transmit data register. The software responds to the SAR status by writing the required data into the transmit data register and then resetting the SAR status bit. This allows the slave interface to continue the access.

Unless the SAR bit is in use, when the slave is about to receive data, the software might still be reading out data that was loaded in previous access from the receive data register. In this case the valid data still held in the receive data register is overwritten. However, this is avoided using the SAR status bit. After the software has read data in the receive data register, reset the SAR bit (if it is set). Then overwriting the receive data register is avoided.

52.3.5 I2C Bus Data Format

Figure 52.2 shows a timing chart for the I2C bus interface. Table 52.6 describes the meaning of each symbol in Figure 52.2.

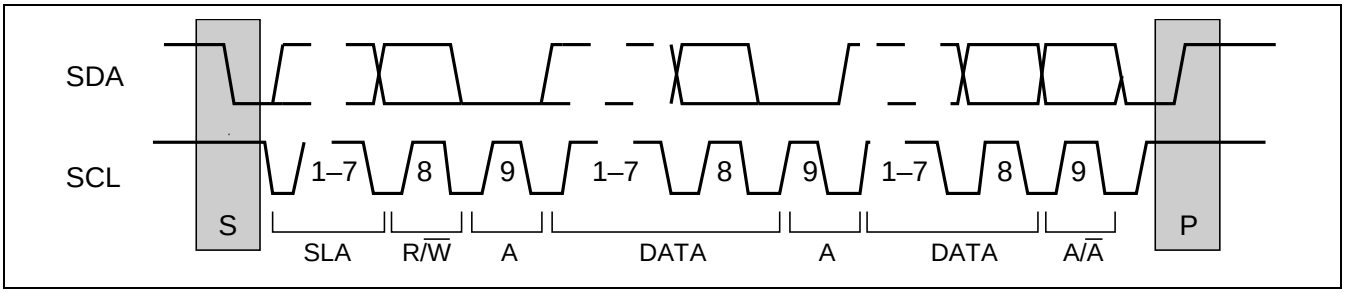

Figure 52.2 I2C Bus Timing

Table 52.6 Description on Symbols of I2C Bus Data Format

Symbol	Description
S	Indicates a start condition. A master device changes SDA from high to low while SCL is high level.
SLA	Indicates a slave address. A slave address is used when a master device selects a slave device.
R/$\overline{W}$	Indicates the direction of data transmission. If the R/$\overline{W}$ bit is 1, the data flows from the slave to the master device. If the bit is 0, the data flows from the master to the slave device.
A	Indicates data acknowledge. Data receiving device makes SDA low level (the slave device returns a data acknowledge signal in master transmission mode, and vice versa).
DATA	Indicates transmit or receive data. The data length is eight bits, which are transferred in the MSB first.
P	Indicates a stop condition. A master device changes SDA from low to high while SCL is high.

52.3.6 7-Bit Address Format

Figure 52.3 shows the format of data transfer from a master to a slave device (master data transmit format). Figure 52.4 shows the data transfer format (master data receive format) when a master device reads the second and the following byte data from a slave device.

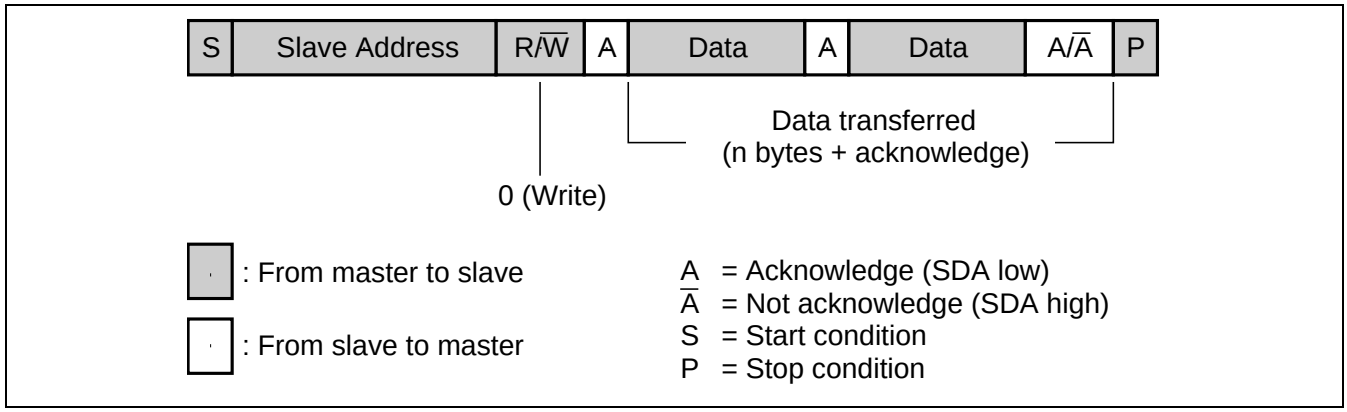

Figure 52.3 Master Data Transmit Format

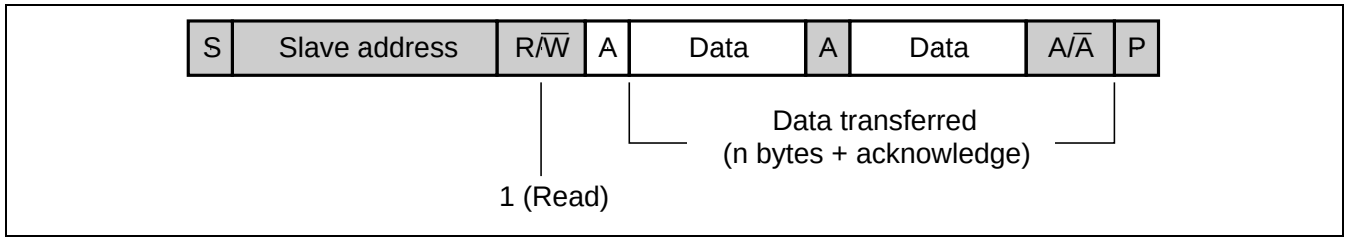

Figure 52.4 Master Data Receive Format

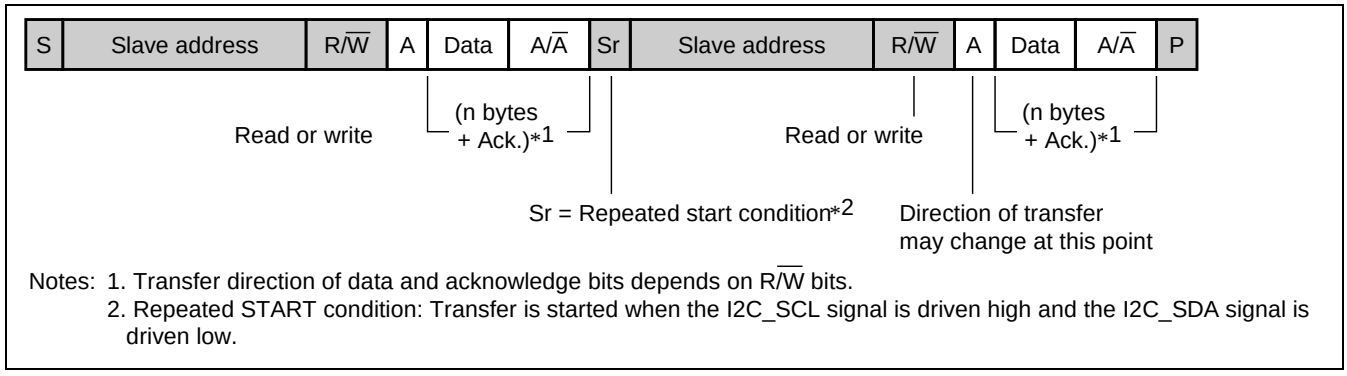
Figure 52.5 shows the combined format when the data transfer direction changes during one transfer. When changing the direction after the first transfer, the repeated START condition (Sr), slave address and R/$\overline{W}$ bits are transmitted. In this case, the R/$\overline{W}$ bit is set to the direction opposite to the first transfer direction. The repeated START condition is issued by the master at the end of a transmit or receive cycle if the enable start generation bit in the master control register has been set.



Notes: 1. Transfer direction of data and acknowledge bits depends on R/$\overline{W}$ bits.
2. Repeated START condition: Transfer is started when the I2C_SCL signal is driven high and the I2C_SDA signal is driven low.

Figure 52.5 Combination Transfer Format of Master Transfer

52.3.7 10-Bit Address Format

Description is given below on the 10-bit address transfer format supported in master mode. This format has three transfer methods as the 7-bit address transfer format.

Figure 52.6 shows the data transmit format. The set value in the master address register is output in one byte following the first START condition (S). The value set in the transmit data register (TXD) is transmitted as a slave address in the second byte. Data on and after the third byte is transferred in the same way as the 7-bit address data.

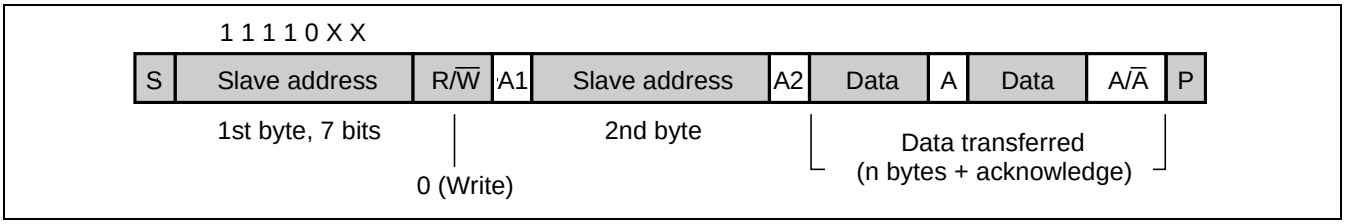


Figure 52.6 10-Bit Address Data Transmit Format

Figure 52.7 shows the data receive format. Two bytes of an address is transmitted in the same way as in the data transmit format. Then, repeated START condition (Sr) is transmitted and the value set in the address register is output. At this time, STM1 must be set to 1 (receive mode). Data is transferred in the same way as in the 7-bit address data receive format.

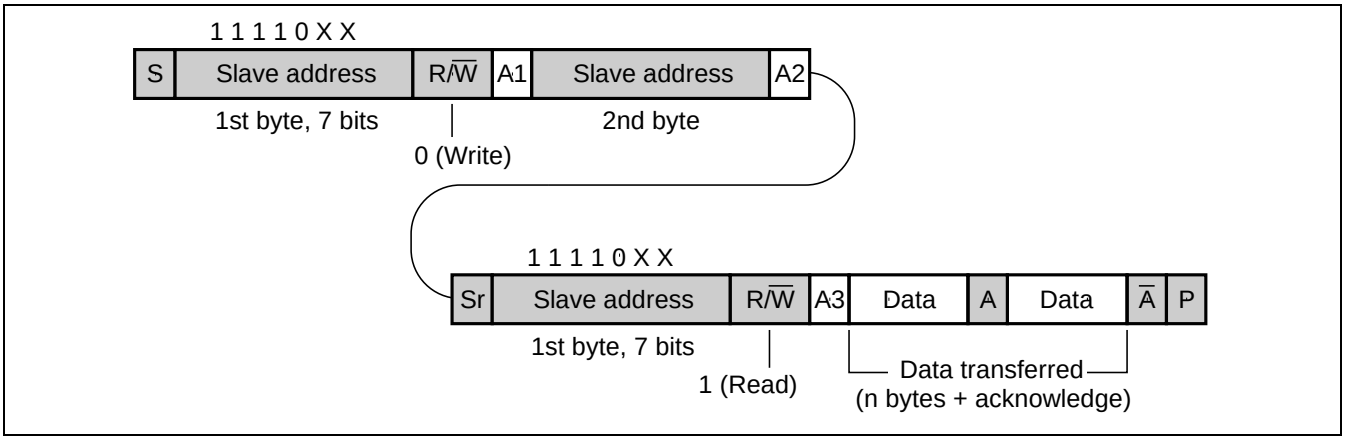

Figure 52.7 10-Bit Address Data Receive Format

Figure 52.8 shows the data transmit/receive combined format.

In the data transmit/receive combined format, data is transmitted after an address is transmitted with the first two bytes. Then, the repeated START condition (Sr) is transmitted instead of STOP condition (P). After Sr is transmitted, the procedure is the same as that in the data receive format.

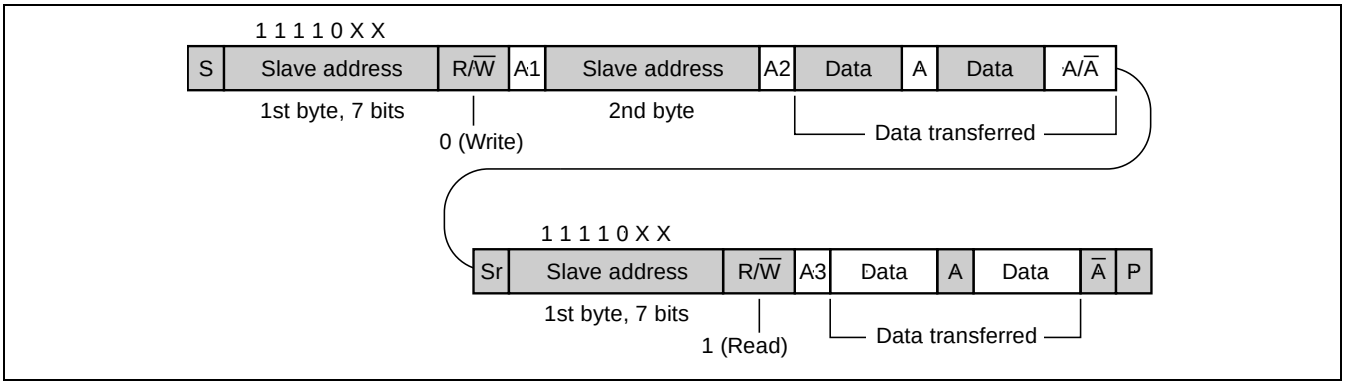

Figure 52.8 10-Bit Address Transmit/Receive Combined Format

52.3.8 Master Transmit Operation

The procedure and operations for transmission in master transmit mode are described below. Figure 52.9 shows the timing chart in master transmit mode. Setting the ICMCR.MDBS bit allows the I2C to operate in single-buffer mode.

1. Set up the initial state by setting the ICMAR, ICTXD, ICCCR, and ICMIER. Note that the setting of the clock control register must be in accord with the rate of transmission.
2. Monitor the ICMCR.FSDA. Confirm that this bit is low, meaning that other I2C devices are not using the bus. After confirmation, set the ICMCR.MIE (bit 3) and ICMCR.ESG (bit 0) bits to 1 to start master transmission.
3. After the transmit START condition, slave address, and data transfer direction bits are transmitted, an interrupt due to the ICMSR.MAT and ICMSR.MDE bits is generated at the timing of (1) in Figure 52.9. At this time, clear the ICMCR.ESG bit to 0. To suspend the data transmission, the master device will hold SCL low until the ICMSR.MDE bit is cleared.
4. Data is transmitted in units of nine bits: 8-bit data and 1-bit ACK. An interrupt of MDE (bit 3) is generated at the ninth clock before data transfer (at the timing of (2) in Figure 52.9). An interrupt of ICMSR.MDT (bit 2) is generated at the eighth clock after 1-byte data transfer (at the timing of (3) in Figure 52.9, Figure 52.10, Figure 52.11). Clear ICMSR.MDE to 0 after setting transmit data.
5. When this I2C receives NACK from the slave device, ICMSR.MNR is set to 1.
   After that, this I2C makes STOP condition and ICMSR.MST is set to 1.
6. To end of transmission, need to set ICMCR.FSB = 1.
   ICMCR.FSB must be set by MDE interruption at final byte data transmission.
   ICMSR.MST (master stop transmitted, at the timing of (4) in Figure 52.9) is checked by interruption or polling.

Signal level changes of (1) to (6) in Figure 52.9 are generated after the falling edge of the clock.

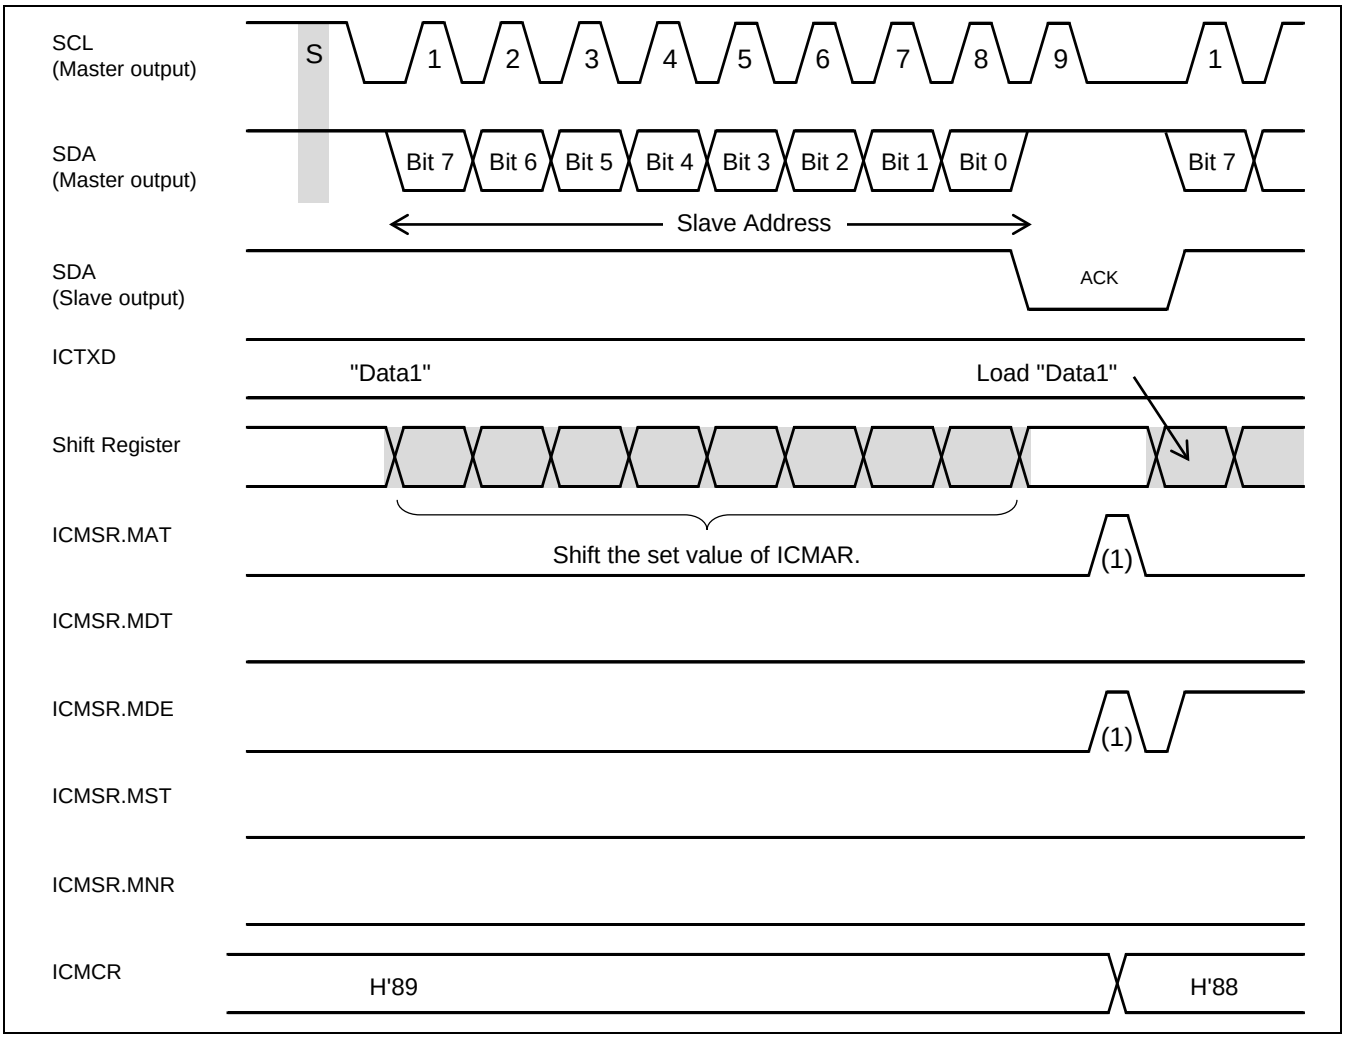

Figure 52.9 Data Transmit Mode Operation Timing

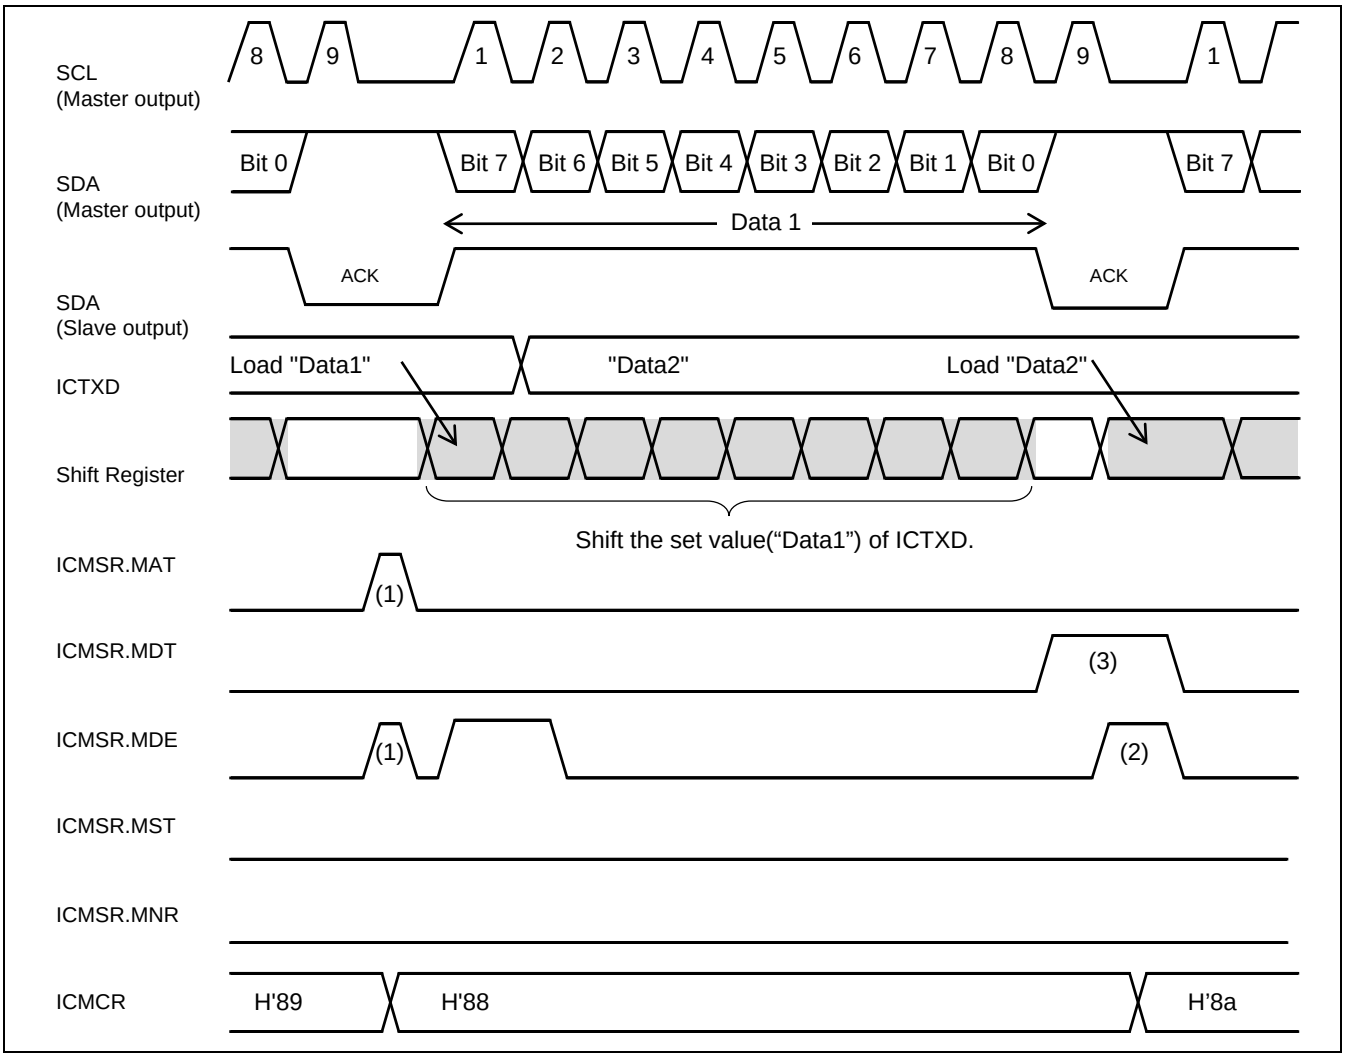

Figure 52.10 Data Transmit Mode Operation Timing

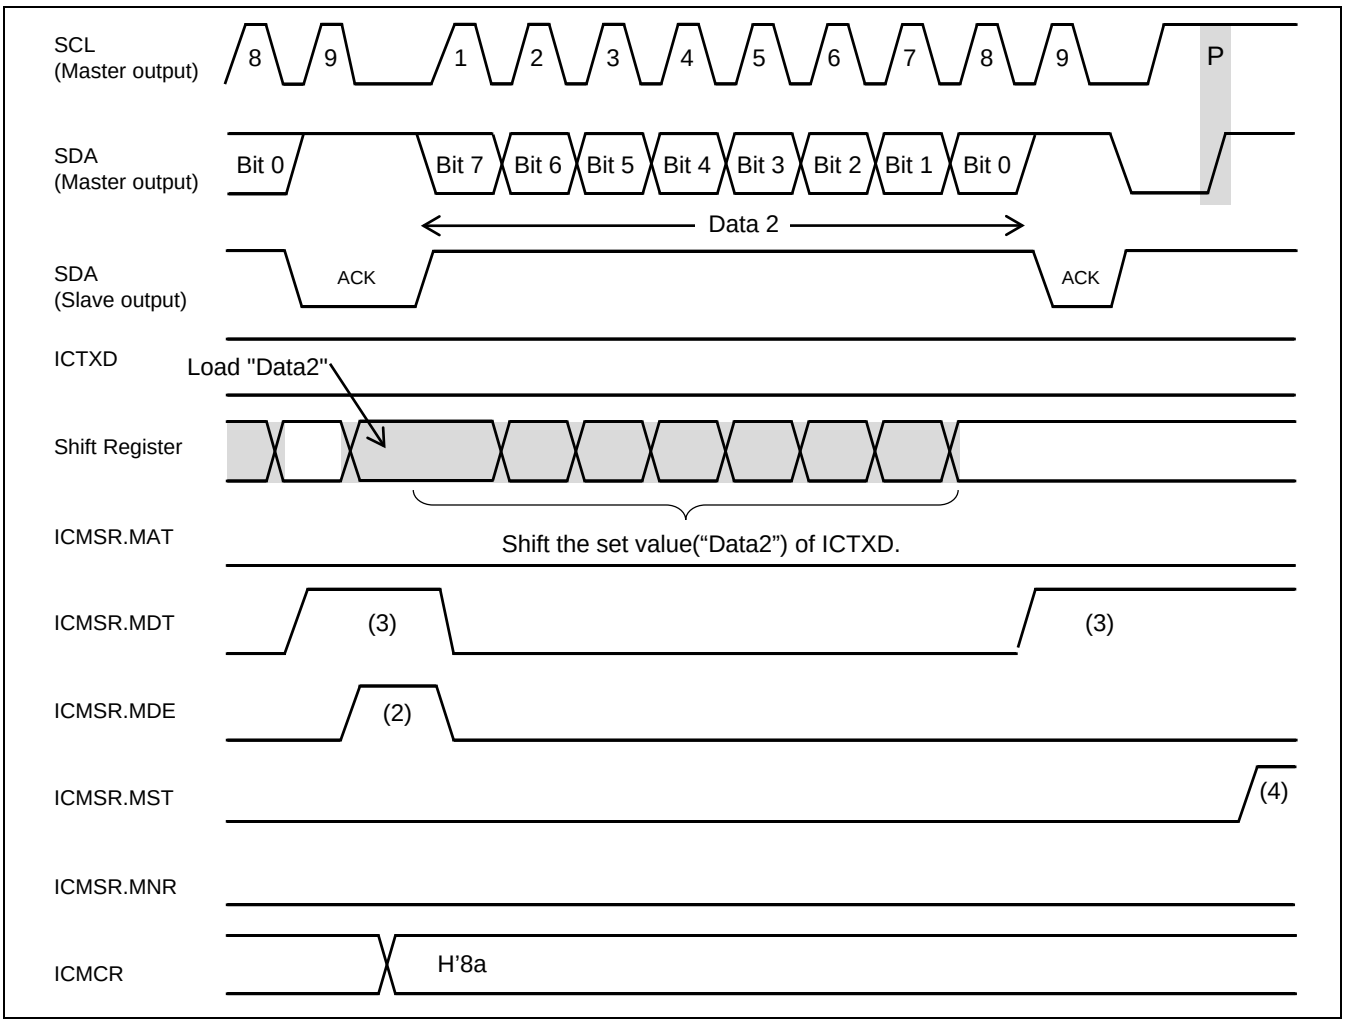

Figure 52.11 Data Transmit Mode Operation Timing

52.3.9 Master Receive Operation

The data receive procedure and operation in master receive mode are described below. Figure 52.12 shows the timing chart in master receive mode. Setting the ICMCR.MDBS bit allows the I2C to operate in single-buffer mode.

1. In master receive mode, as to transmit of a slave address and a 1-bit signal indicating the data transfer direction, operation is the same as that in master transmit mode. At this time, set the data transfer direction to 1 (reception).
2. The slave device automatically enters the data transmit mode according to the signal that indicates the data transfer direction, and transmits 1-byte data in synchronization with the SCL clock output from the master device. The master device generates an interrupt of ICMSR.MDR (bit 1) at the eighth clock (at the timing of (1) in Figure 52.12). Clear the ICMSR.MDR bit after the master device reads ICRXD. If this processing is delayed, the master device extends the SCL period to suspend data transmission (at the timing of (2) in Figure 52.12).
3. To end data transfer, set ICMCR.FSB (bit 1) of the master device and output STOP condition. In order to stop the communication after predetermined number of byte data is transferred, ICMCR.FSB bit needs to be set before the last byte data transfer is started. After confirming reception of the last byte, even when the master receiver has completed the reception transaction.

Signal level changes of (1) to (3) in Figure 52.12 and Figure 52.13 are generated after the falling edge of the clock.

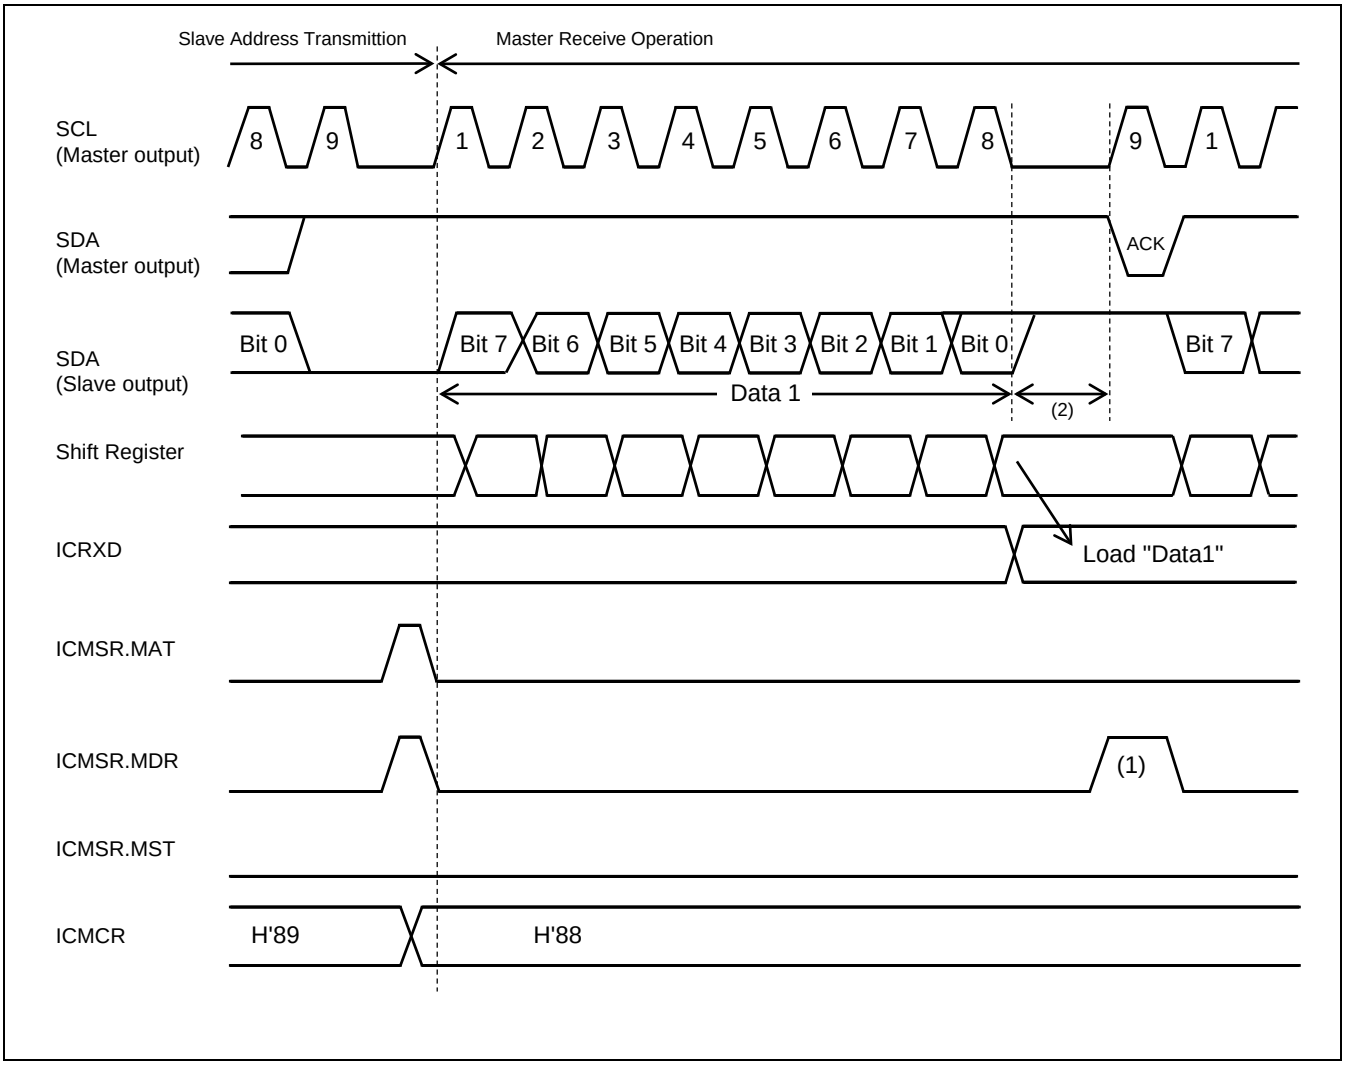

Figure 52.12 Data Receive Mode Operation Timing

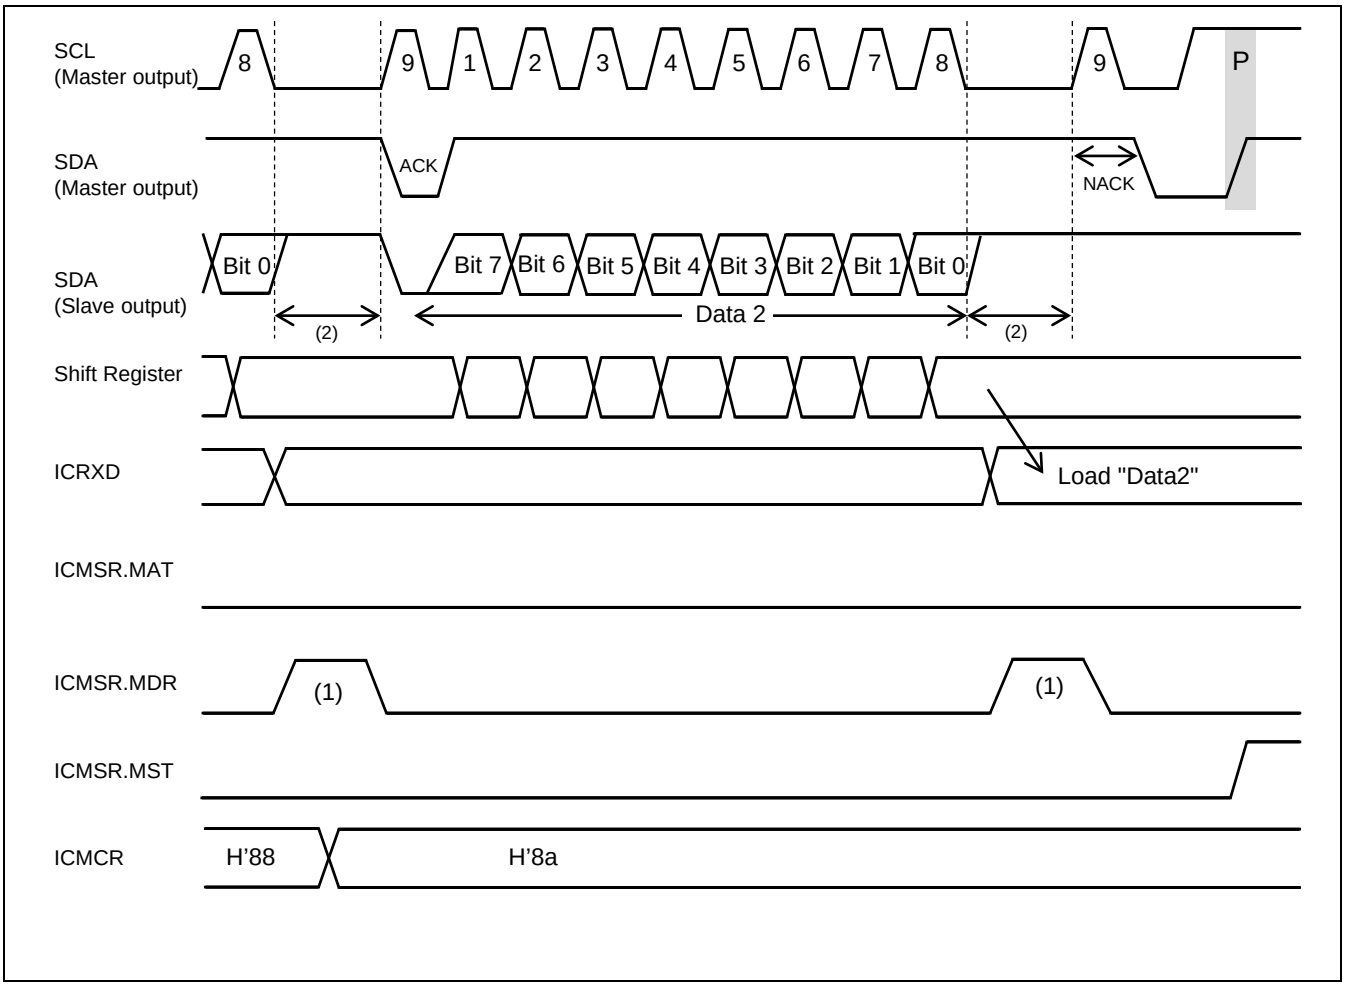

Figure 52.13 Data Receive Mode Operation Timing

52.4 Programming Examples

52.4.1 Master Transmitter

In order to set up the master interface to transmit a data packet on the I2C bus, follow the procedure below (an example for I2C0):

(1) Set value for the clock control register

1. Reset I2C with SRCR and SRSTCLR.
2. Set the Clock Control register 2 (ICCCR2) = H’07 (CDFD = 1, HLSE = 1, SME = 1).
3. Set the Clock Control register (ICCCR) = H’06 (SCGD = 0, CDF = 6, I2C internal clock I2Cck: 19 MHz).
   − Setting ICCCR, ICCCR2 for using Duty ratio fixed or Duty ratio variable. The case for using Variable Duty ratio, have to setting ICCCR2 too. The case for using Fixed Duty ratio, have to setting ICCCR only.
4. Set the SCL Mask Control register (ICMPR) = H’1C (Variable Duty ratio only).
5. Set the SCL High Control register (ICHPR) = H’73 (Variable Duty ratio only).
6. Set the SCL Low Control register (ICLPR) = H’85 (Variable Duty ratio only).
7. Set the First Bit Setup Cycle register (ICFBSCR) = H’0F (1^{st} bit setup cycle = 17 × Tcyc).

(2) Set value for the master control register, first data byte, and address

1. Clear the Master Status register (ICMSR) = H’00 (all 0 clear).
2. Set the Master Interrupt Enable register (ICMIER) = H’09 (MDEE = 1, MATE = 1).
3. Set the Master Address register (ICMAR) = Slave device address + H’00 (Write mode).
4. Set the Transmit Data register (ICTXD) = 1^{st} transmission data.
5. Set the Master Control register (ICMCR) = H’89 (MDBS = 1, MIE = 1, ESG = 1).

(3) Wait for outputting address

1. Wait for master event (an interrupt of the ICMSR.MAT and ICMSR.MDE).
2. Set ICMCR to H'88 (to suspend the data transmission, the master device will hold the SCL low until the MDE bit is cleared).
   — If only one byte of data is transmitted, set the ICMCR to H'8A, meaning that the stop generation is enabled. This generates a stop on the bus as soon as one byte has been transmitted.
3. Clear the ICMSR.MAT & ICMSR.MDE bits.

(4) Monitor transmission of data

1. Wait for master event, ICMSR.MDE.
2. ICTXD = subsequent data.
3. Clear the ICMSR.MDE bit.

   Clear ICMSR.MDE after setting the last byte to be transmitted. After the last byte data is loaded into the shift register, ICMSR.MDE is generated. Before clearing ICMSR.MDE, you must set ICMSR to H'8A (set the force stop control bit).

(5) Wait for end of transmission

1. Wait for the master event, ICMSR.MST.
2. Clear the ICMSR.MST bit.

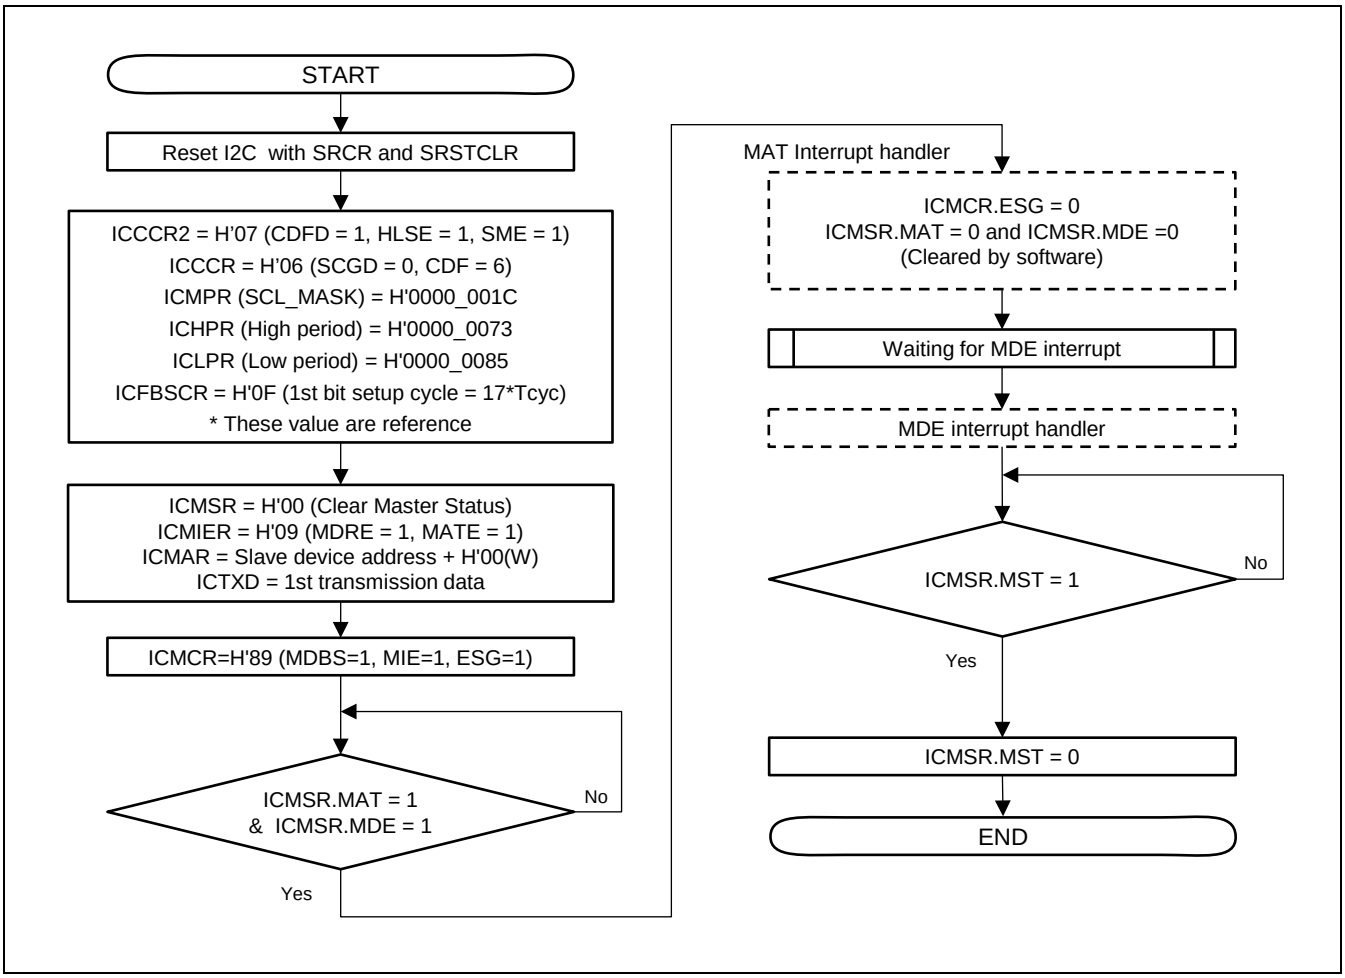

Figure 52.14 Master Transmitter Operation Setting

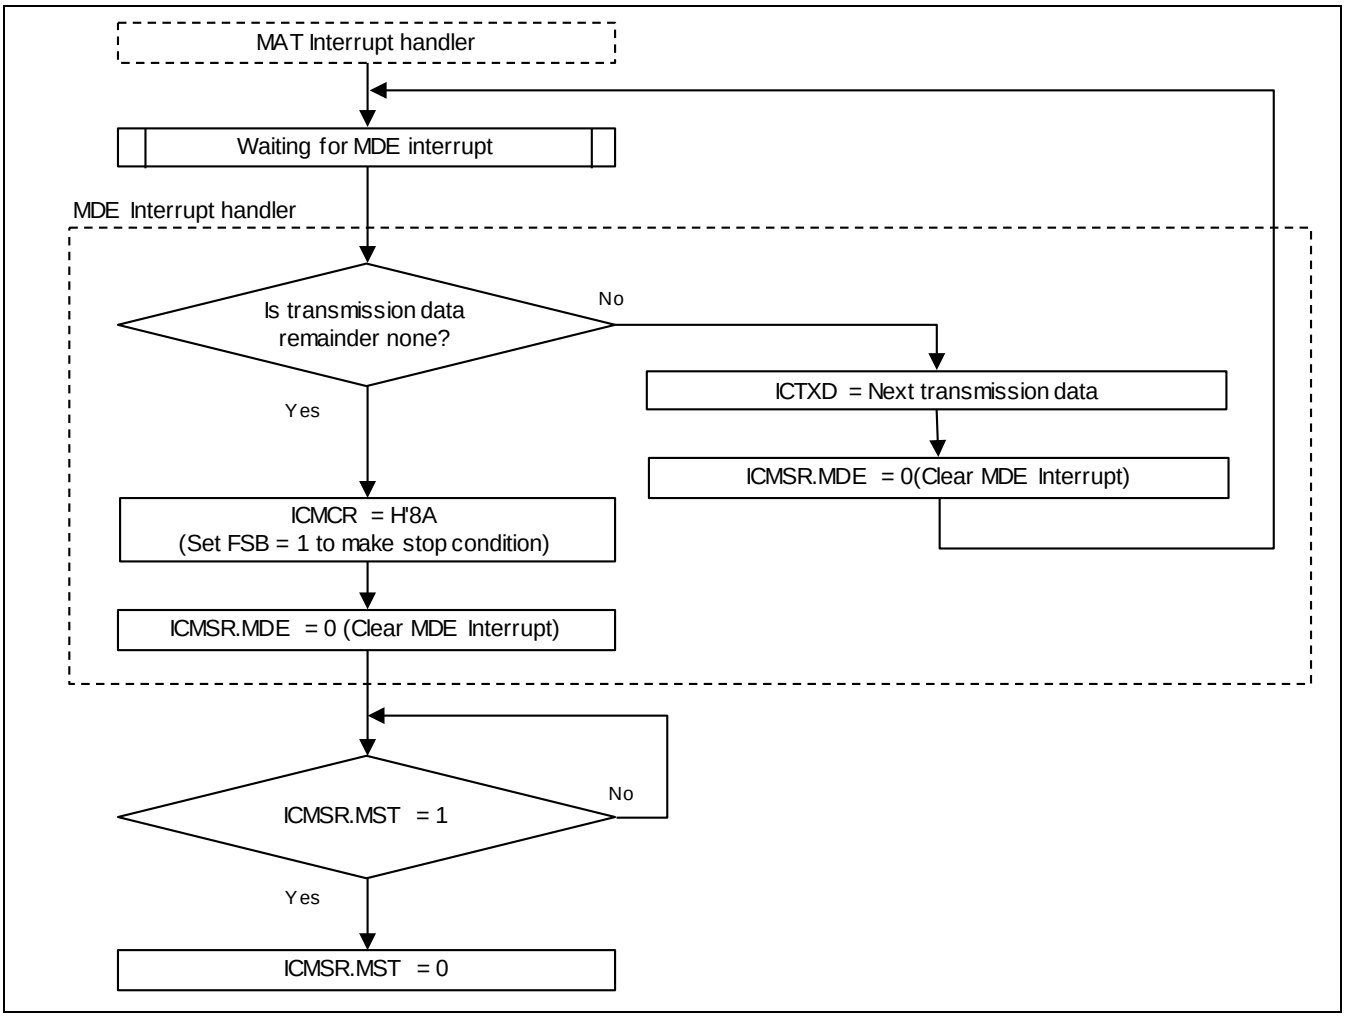

Figure 52.15 MDE Interrupt Handler for Master Transmitter Operation Setting

52.4.2 Master Receiver

In order to set up the master interface to receive a data packet on the I2C bus, follow the procedure below:

(1) Set value for the clock control register

The same procedure as the master transmitter is applied. See the program example for the master transmitter.

(2) Set value for the master control register and address

1. Clear the Master Status register (ICMSR) = H’00 (all 0 clear)
2. Set the Master Interrupt Enable register (ICMIER) = H’03 (MDRE = 1, MATE = 1)
3. Set the Master Address Register (ICMAR) = Slave device address + H’01 (Read mode)
4. Set the Master Control Register (ICMCR) = H'89 (MDBS = 1, MIE = 1, ESG = 1)

(3) Wait for outputting address

1. Wait for master event (an interrupt of the ICMSR.MAT and ICMSR.MDR).
2. Set the ICMCR to H'88 (to suspend the data transmission, the master device will hold the SCL low until the MDR bit is cleared).
   — If only one byte of data is transmitted, set the ICMCR to H'8A, meaning that the stop generation is enabled. This generates a stop on the bus as soon as one byte has been received.
3. Clear the ICMSR.MAT & ICMSR.MDR bits.

(4) Monitor reception of data

1. Wait for master event, ICMSR.MDR.
2. Clear the MDR bit after reading data from the ICRXD.
3. Set the ICMCR to H'8A (set the ICMCR.FSB) before the last byte data transfer is started.

(5) Wait for end of reception

1. Handle the receive interrupt (ICMSR.MDR) in the last byte: that is, read the data and clear the ICMSR.MDR.
2. Wait for master event, ICMSR.MST.
3. Clear the ICMSR.MST bit.

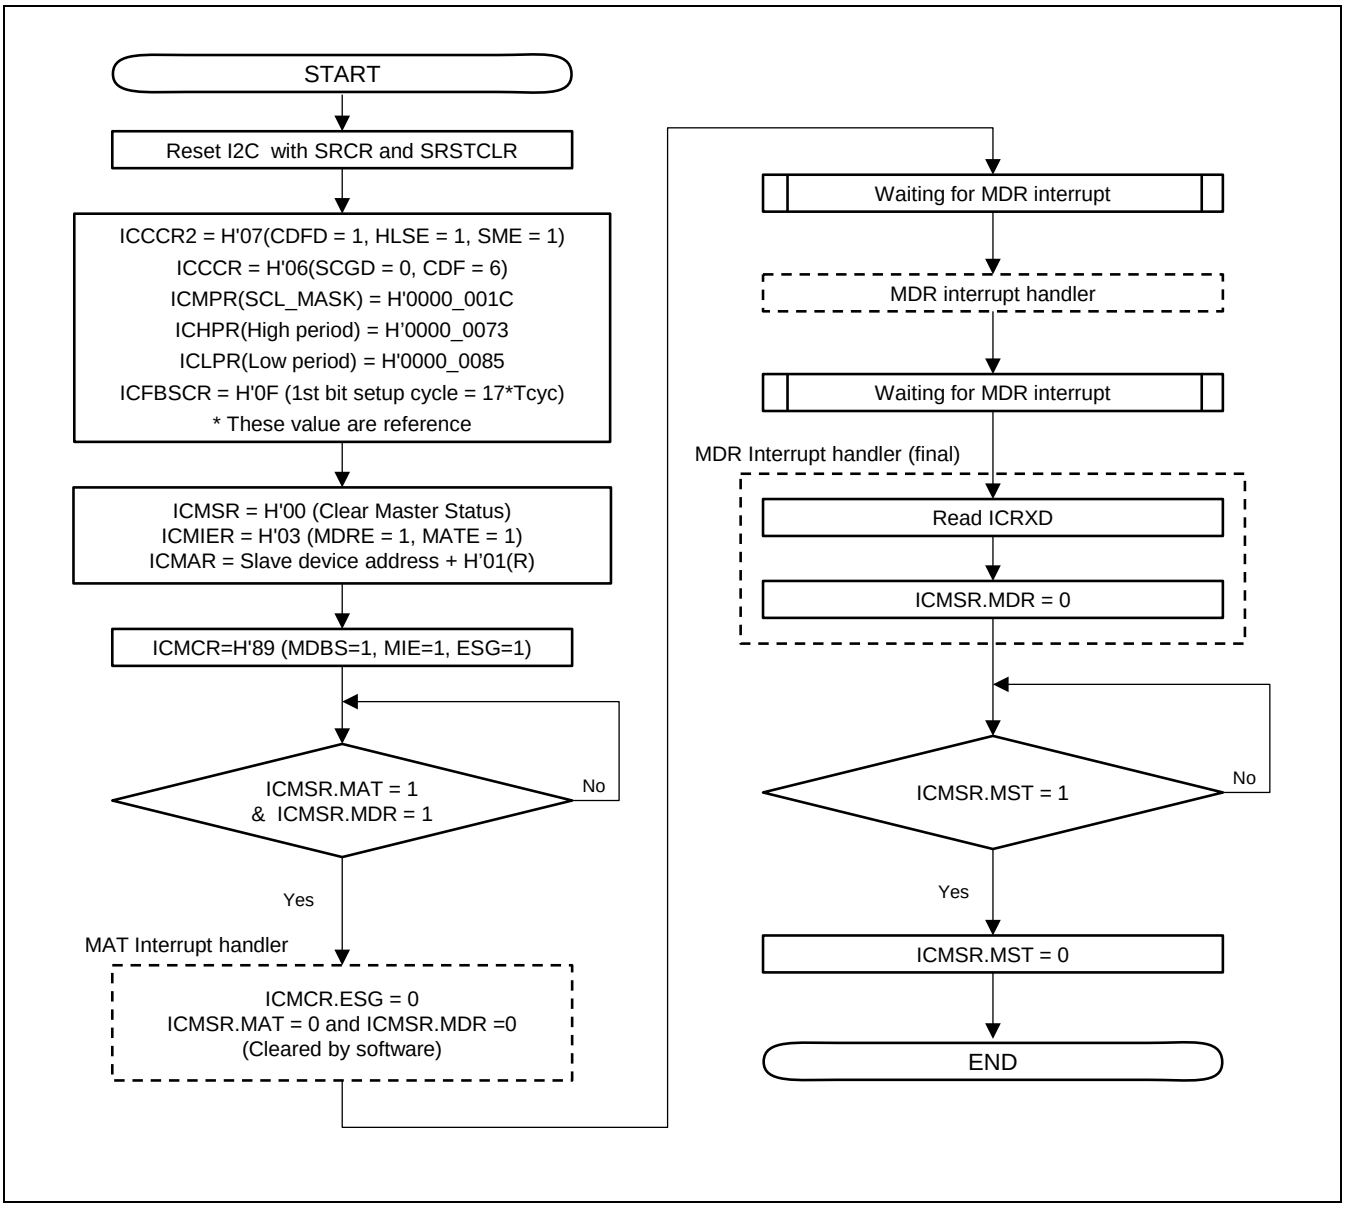

Figure 52.16 Master Receiver Operation Setting

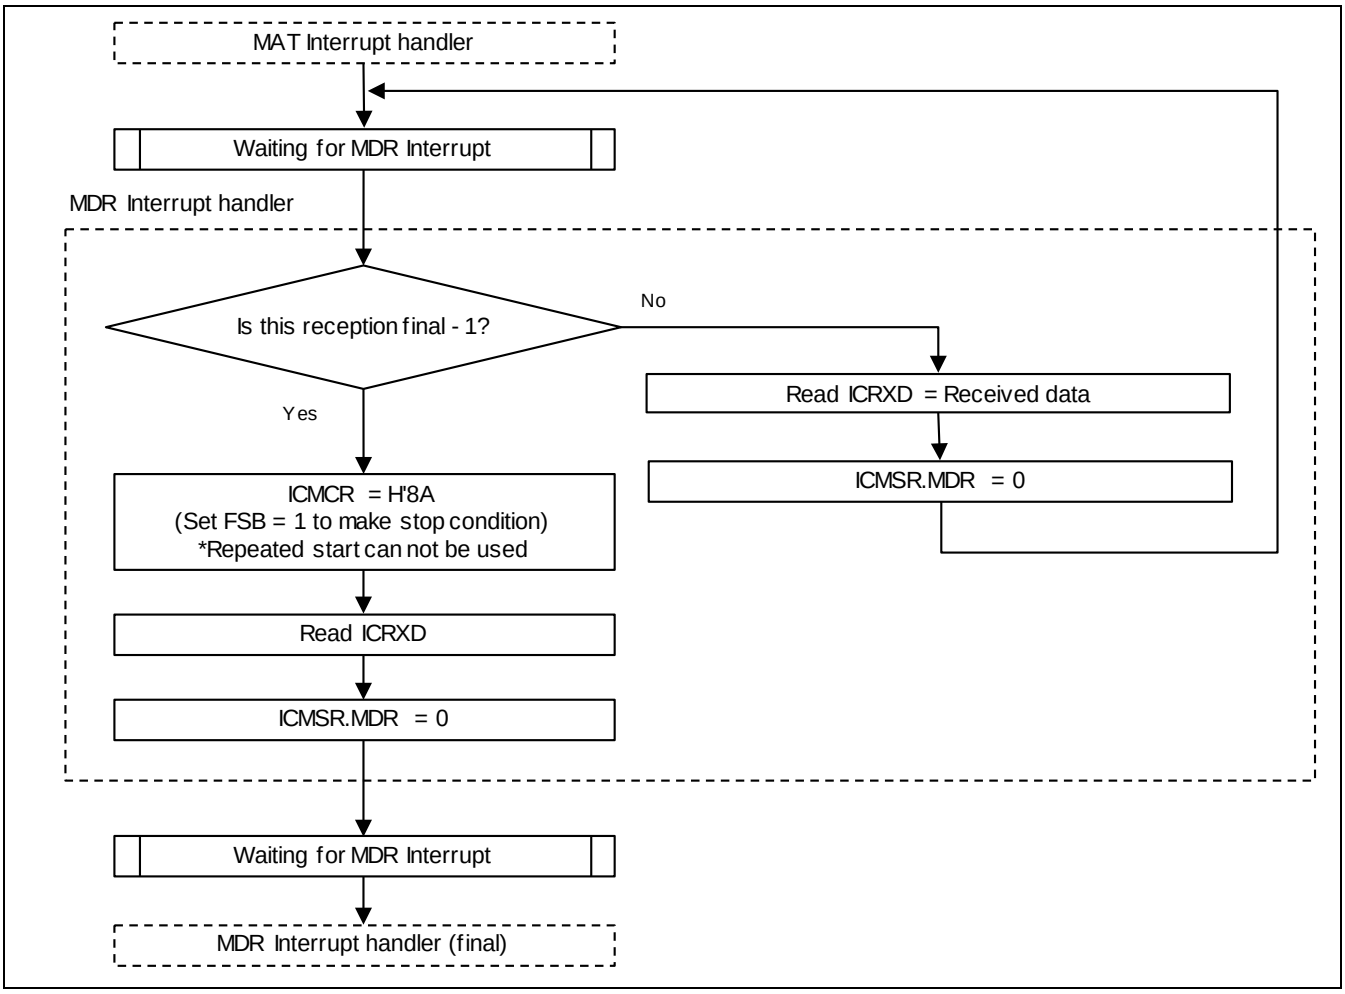

Figure 52.17 MDR Interrupt Handler for Master Receiver Operation Setting

52.4.3 Master Transmitter—Repeated START—Master Receiver

In order to set up the master interface to transmit a data packet on the I2C bus, issue a repeated START condition, then read byte data back from the slave, follow the procedure below:

(1) Set value for the clock control register

The same procedure as the master transmitter is applied. See the program example for the master transmitter.

(2) Set value for the master control register and address

1. Clear the Master Status register (ICMSR) = H’00 (all 0 clear).
2. Set the Master Interrupt Enable register (ICMIER) = H’0B (MDEE = 1, MDRE = 1, MATE = 1).
3. Set the Master Address register (ICMAR) = Slave device address + H’00 (Write mode).
4. Set the Transmit Data register (ICTXD) = 1st transmission data.
5. Set the Master Control register (ICMCR) = H’89 (MDBS = 1, MIE = 1, ESG = 1).

(3) Wait for outputting slave-address for master transmission

1. Wait for master event (an interrupt of the ICMSR.MAT and ICMSR.MDE bits).
2. Clear ICMCR.ESG bit.
3. Clear the ICMSR.MAT and ICMSR.MDE bits.

(4) Monitor transmission of data

1. Wait for master event (an interrupt of the ICMSR.MDE bit).
2. Set ICMAR = Slave device address + H’01 (Read mode).
3. Set ICMCR = H'89 (MDBS = 1, MIE = 1, ESG = 1).
4. Clear the ICMSR.MDE bit.

(5) Wait for outputting slave-address for master reception

1. Wait for master event (an interrupt of ICMSR.MAT and ICMSR.MDR bits).
2. Clear ICMCR ESG bit. (To suspend stop the data transmission, the master device will hold the SCL low until the ICMSR.MDR bit is cleared.)
3. Clear the ICMSR.MAT and ICMSR.MDR bits.

(6) Monitor reception of data

1. Wait for master event (the ICMSR.MDR bit).
2. Clear the ICMSR.MDR bit after reading data from the receive data register.
3. Set ICMCR.FSB to 1 (set the force stop control bit) before the last byte data transfer is started.

(7) Wait for end of reception

1. Handle the receive interrupt (ICMSR.MDR) in the last byte: that is, read the data and clear the ICMSR.MDR.
2. Wait for master event, ICMSR.MST.
3. Clear the ICMSR.MST bit.

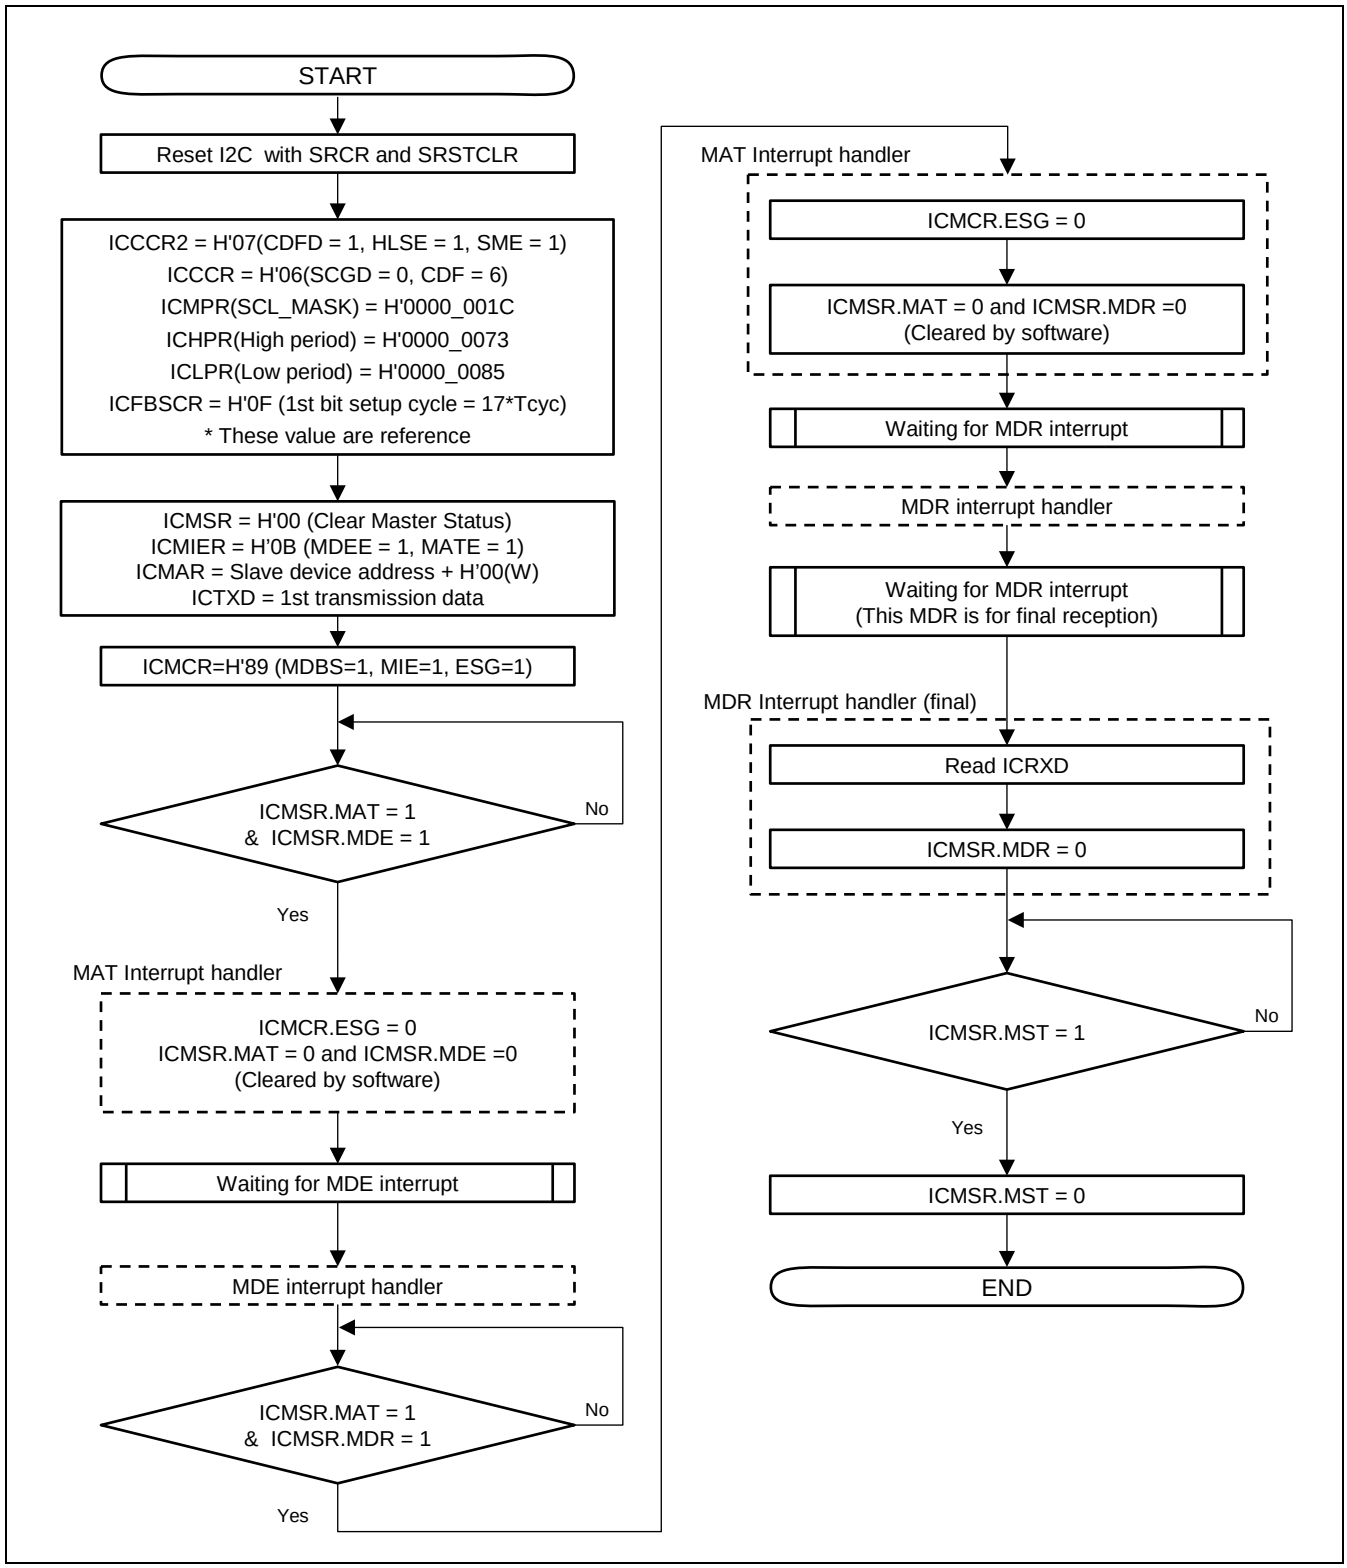

Figure 52.18 Master Transmitter – Repeated START – Receiver Operation Setting

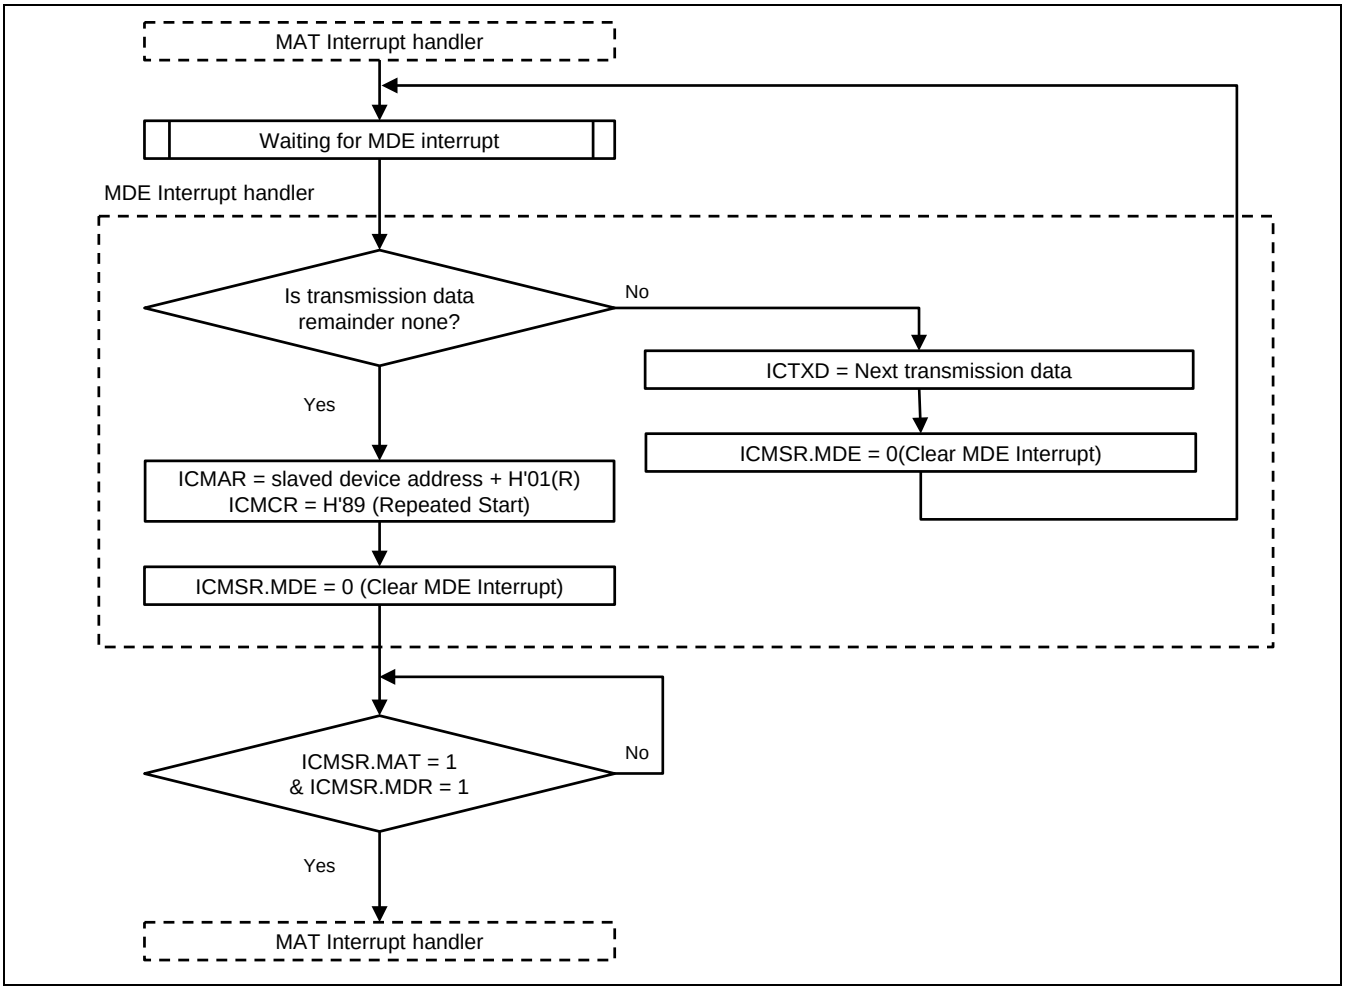

Figure 52.19 MDE Interrupt Handler for Master Transmitter – Repeated START - Receiver Operation Setting

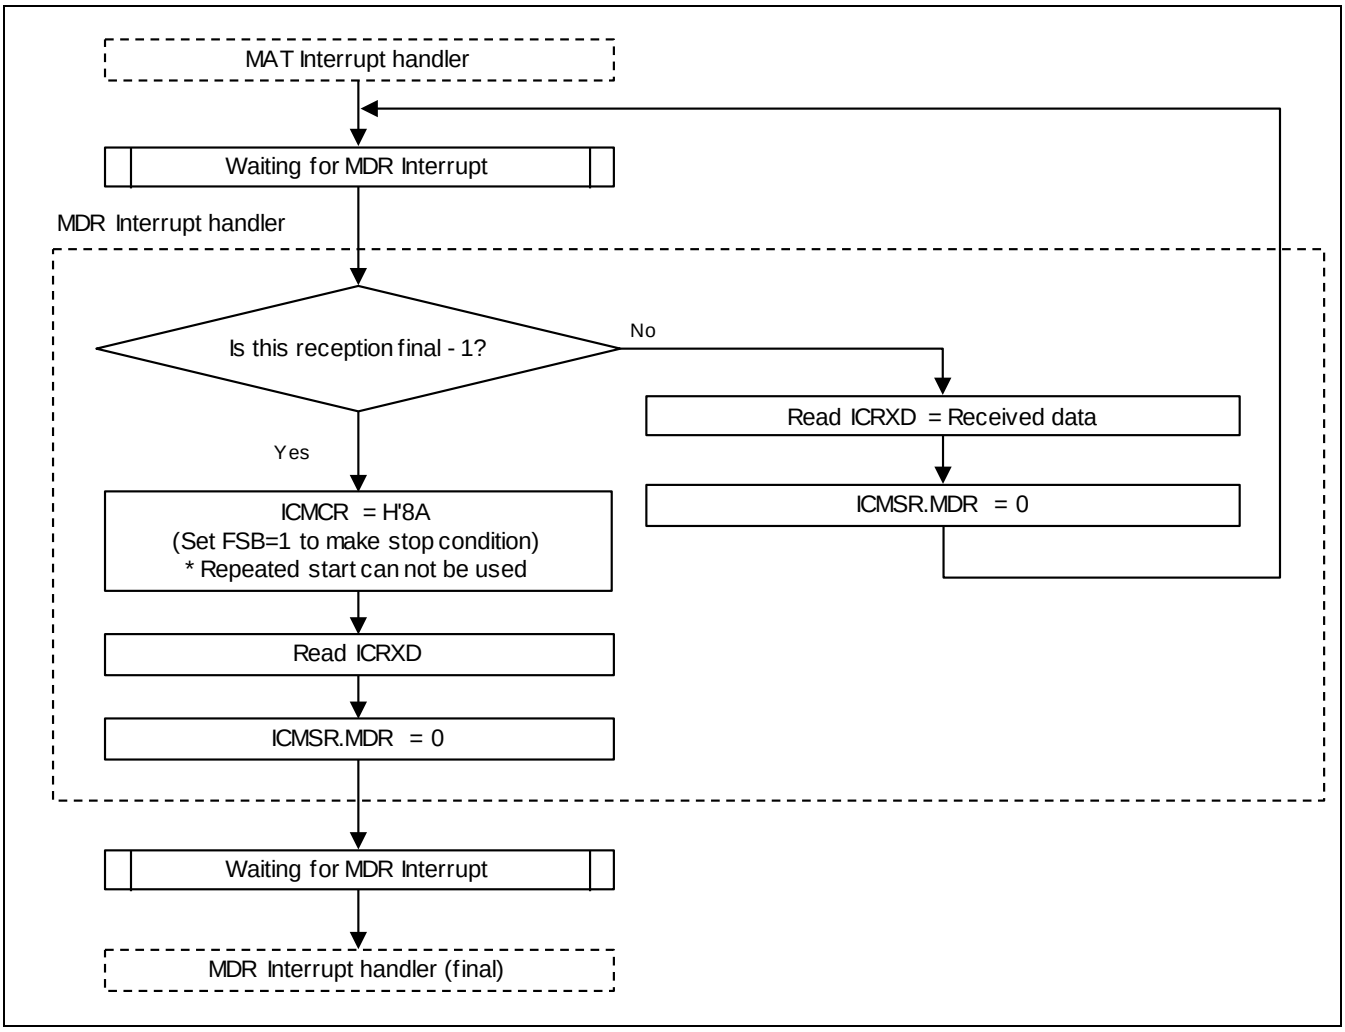

Figure 52.20 MDR Interrupt Handler for Master Transmitter – Repeated START – Receiver Operation Setting

52.4.4 Slave Transmitter

In order to set up the master interface to transmit a data packet on the I2C bus, follow the procedure below (an example for I2C0):

(1) Set value for the slave control register, first data byte and address

1. Reset I2C with SRCR and SRSTCLR.
2. Clear the Slave Status register (ICSSR) = H'00 (all 0 clear).
3. Set the slave Interrupt register (ICSIER) = H'09 (SDEE = 1, SARE = 1).
4. Set Slave Address register (ICSAR) = Slave device address (unique value from other slave devices).
5. Set the Transmit Data register (ICTXD) = 1st transmission data.
6. Set the Slave control register (ICSCR) = H'0E (SDBS = 1, SIE = 1, GCAE = 1).

(2) Wait for receiving address

1. Wait for slave event (an interrupt of the ICSSR.SAR).
2. Clear the ICSSR.SAR bit.

(3) Monitor transmission of data

1. Wait for master event, ICSSR.SDE.
2. ICTXD = subsequent data.
3. Clear the ICSSR.SDE bit.

   Clear ICSSR.SDE after setting the last byte to be transmitted. After the last byte data is loaded into the shift register, ICSSR.SDE is generated. So, skip writing to ICTXD at ICSSR.SDE after last byte data is loaded into the shift register.

(4) Wait for end of transmission

1. Wait for slave event, ICSSR.SSR.
2. Clear the ICSSR.SSR bit.

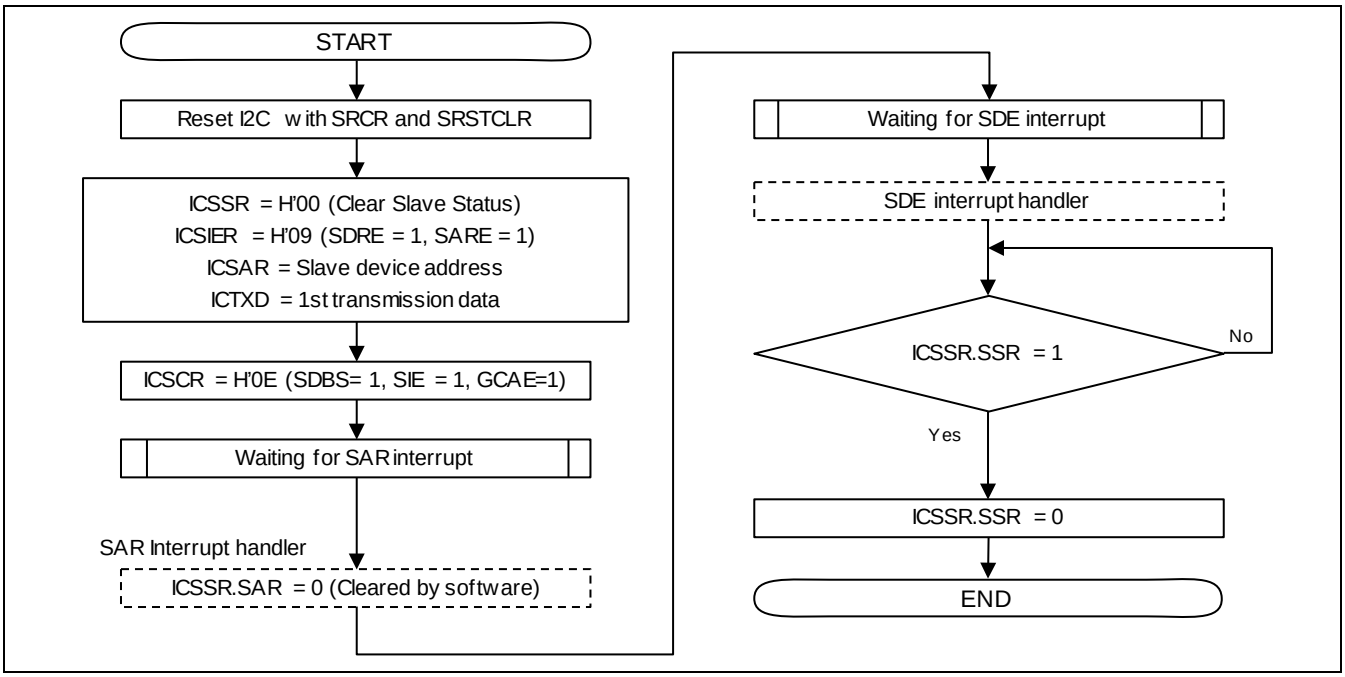

Figure 52.21 Slave Transmitter Operation Setting

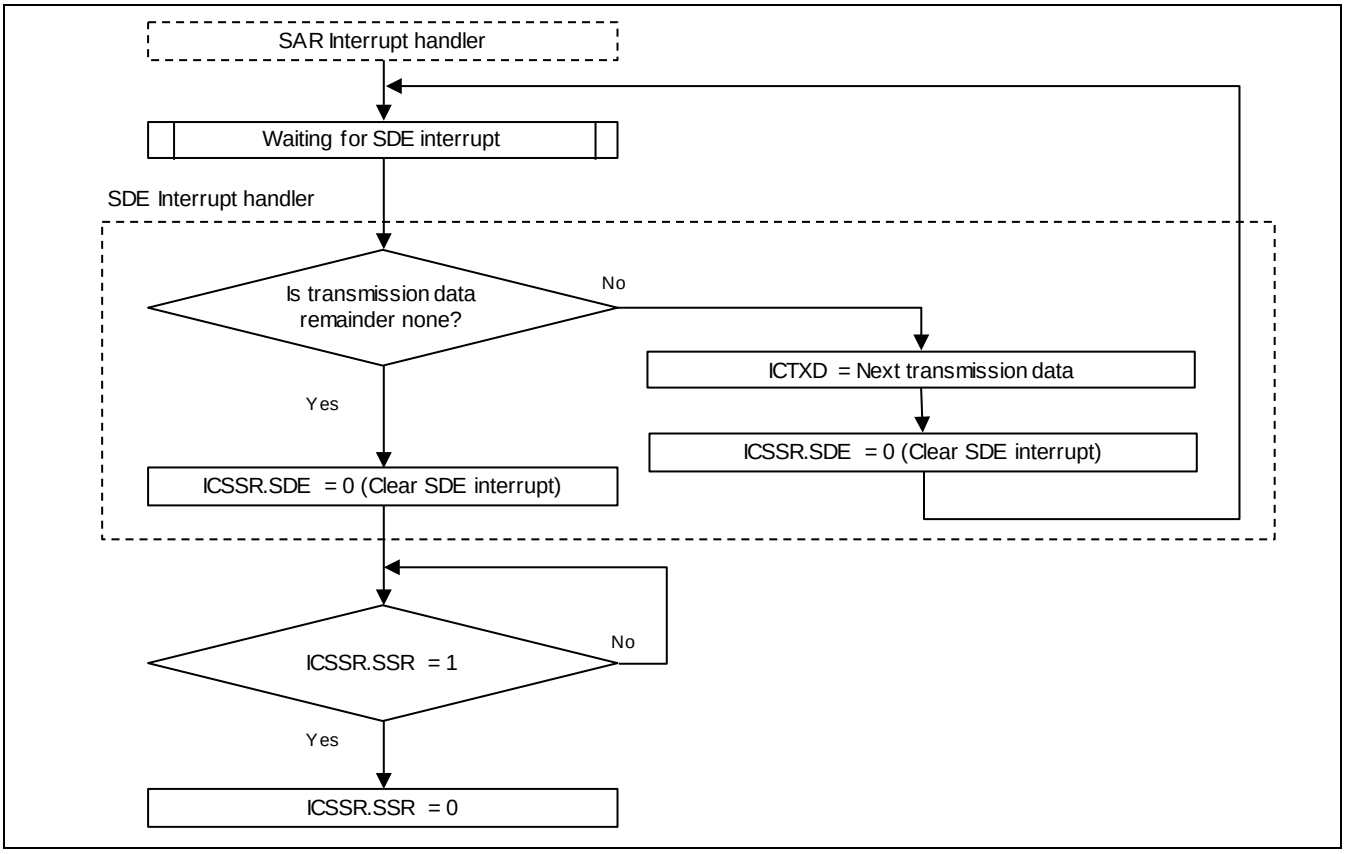

Figure 52.22 SDE Interrupt Handler for Slave transmitter Operation Setting

52.4.5 Slave Receiver

In order to set up the master interface to receive a data packet on the I2C bus, follow the procedure below:

(1) Set value for the master control register and address

1. Reset I2C with SRCR and SRSTCLR.
2. Clear the Slave Status register (ICSSR) = H'00 (all 0 clear).
3. Set the slave Interrupt register (ICSIER) = H'03 (SDRE = 1, SARE = 1).
4. Set Slave Address register (ICSAR) = Slave device address (unique value from other slave devices).
5. Set the Slave control register (ICSCR) = H'0E (SDBS = 1, SIE = 1, GCAE = 1).

(2) Wait for receiving address

1. Wait for slave event (an interrupt of the ICSSR.SAR).
2. Clear the ICSSR.SAR bit.

(3) Monitor reception of data

1. Wait for slave event, ICSSR.SDR bit.
2. Clear the ICSSR.SDR bit after reading data from ICRXD register.

(4) Wait for end of reception

1. Handle the ICSSR.SDR in the last byte: that is, read the data and clear the ICSSR.SDR.
2. Wait for master event, ICSSR.SSR.
3. Clear the ICSSR.SSR bit.

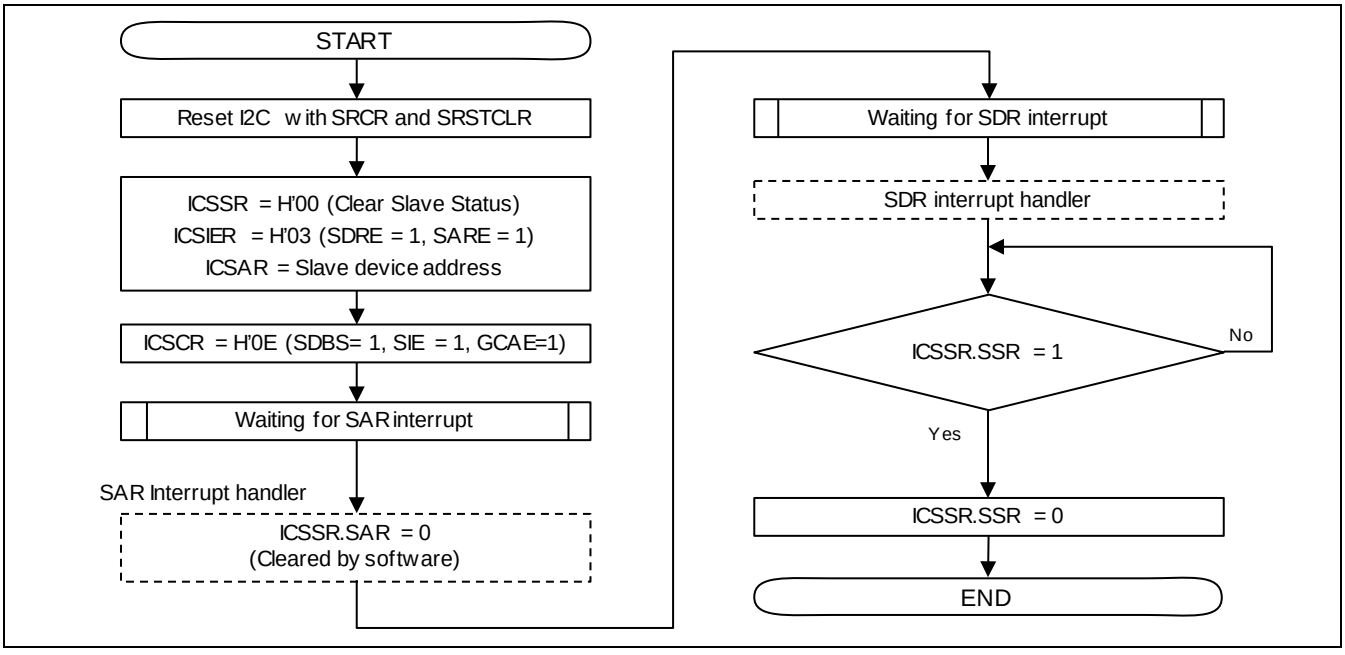

Figure 52.23 Slave Receiver Operation Setting

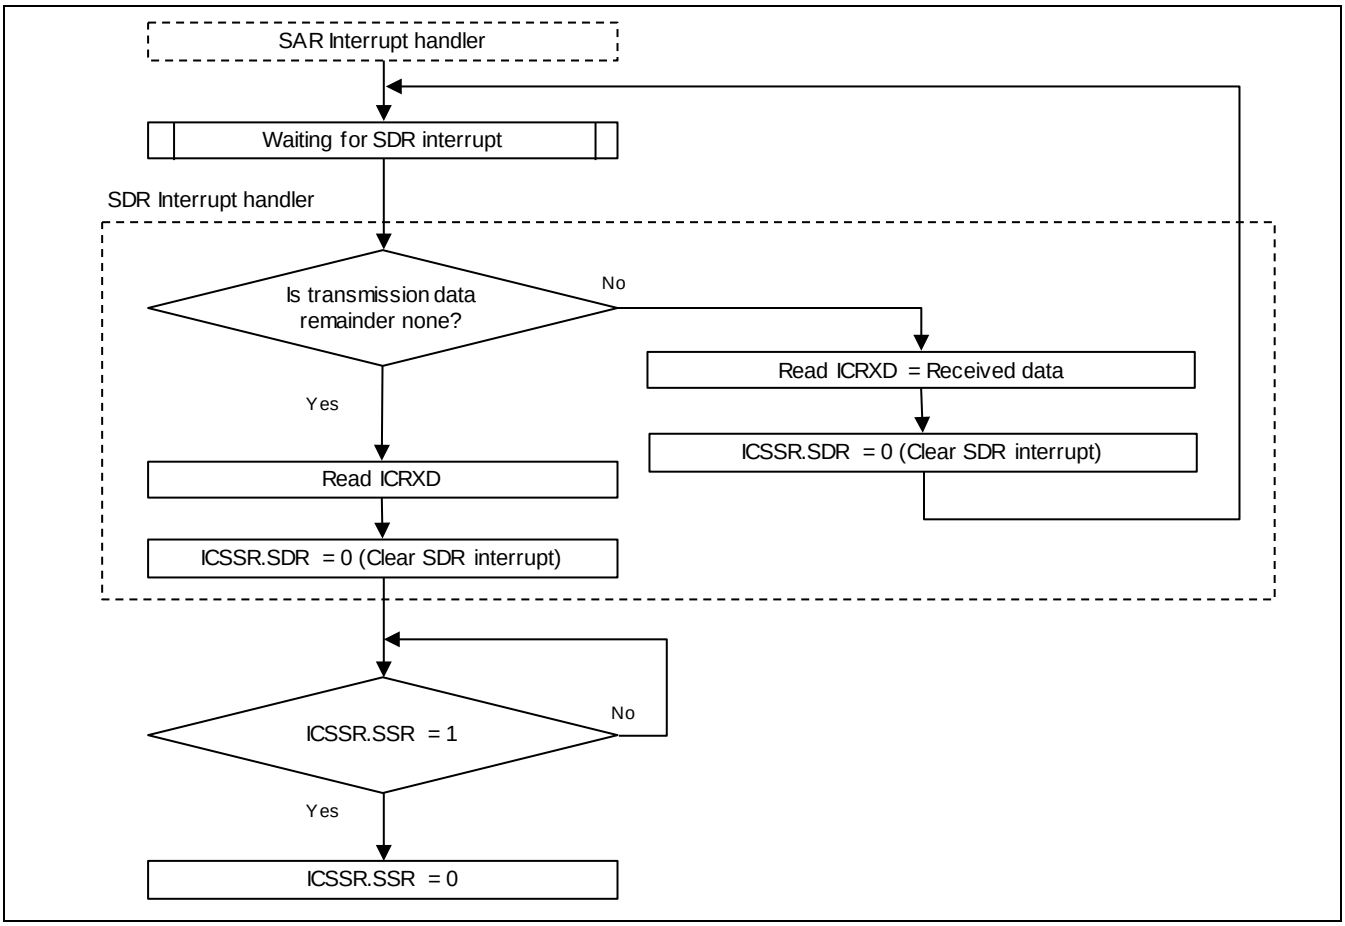

Figure 52.24 SDR Interrupt Handler for Slave Receiver Operation Setting

52.4.6 DMA Mode - Master Transmit Operation

The 1st byte is transferred by PIO, after that enter to DMA mode to start transfer the following bytes.

In DMA transmit mode, I2C module asserts a DMA request to the DMAC. After receiving the request, DMAC write data into I2C data register, and return DMARACK to I2C module. For instance, in order to transfer N0, N1, … , N10 byte. Byte N0 will be transferred by PIO, bytes N1 to N10 will be transferred by using DMAC.

The transmission procedure and operations are described as below:

(1) Set value for the clock control register

1. Reset I2C with SRCR and SRSTCLR.
2. Set the Clock Control register 2 (ICCCR2) = H’07 (CDFD = 1, HLSE = 1, SME = 1).
3. Set the Clock Control register (ICCCR) = H’06 (SCGD = 0, CDF = 6, I2C internal clock I2Cck: 19 MHz).
   — Setting ICCCR, ICCCR2 for using Duty ratio fixed or Duty ratio variable. The case for using Variable Duty ratio, have to setting ICCCR2 too. The case for using Fixed Duty ratio, have to setting ICCCR only.
4. Set the SCL Mask Control register (ICMPR) = H’1C (Variable Duty ratio only).
5. Set the SCL High Control register (ICHPR) = H’73 (Variable Duty ratio only).
6. Set the SCL Low Control register (ICLPR) = H’85 (Variable Duty ratio only).
7. Set the First Bit Setup Cycle register (ICFBSCR) = H’0F (1st bit setup cycle = 17 × Tcyc).

(2) Setting of DMAC

1. Set the number of DMA times (“Total transmit times – 1”).
   - In this phase, DMACHCR.DE = 0.

(3) Set value for the master control register, first data byte, and address

1. Clear the Master Status register (ICMSR) = H’00 (all 0 clear).
2. Set the Master Interrupt Enable register (ICMIER) = H’09 (MDEE = 1, MATE = 1).
3. Set the Master Address register (ICMAR) = Slave device address + H’00 (Write mode).
4. Set the Transmit Data register (ICTXD) = 1st transmission data.
5. Set the Master Control register (ICMCR) = H’89 (MDBS = 1, MIE = 1, ESG = 1).

(4) Wait for outputting address

1. Wait for master event, ICMSR.MAT and ICMSR.MDE.
2. Set ICMCR to H'88 (to suspend the data transmission, the master device will hold the SCL low until the ICMSR.MDE bit is cleared).
   - If only one byte of data is transmitted, set the ICMCR to H'8A, meaning that the stop generation is enabled. This generates a stop on the bus as soon as one byte has been transmitted.
3. Clear the ICMSR.MAT & ICMSR.MDE bits.

(5) Enable DMA

1. Wait for master event, ICMSR.MDE.
2. Set the DMA Enable register (ICDMAER) = H’01 (TMDMAE = 1).
3. Set the DMACHCR.DE = 1 to enable DMA.

(6) DMA interrupt handler

1. Wait for DEI interrupt.
2. Set ICDMAER = H’00 (TMDMAE = 0) to disable DMA transmission.

(7) MDE interrupt handler

1. Wait for MDE interrupt.
2. Set ICMCR = H’8A (FSB = 1) to make stop condition.
3. Clear MDE interrupt (ICMSR.MDE = 0).

(8) Wait for end of transmission

1. Wait for ICMSR.MST = 1.
2. Clear ICMSR.MST = 0.

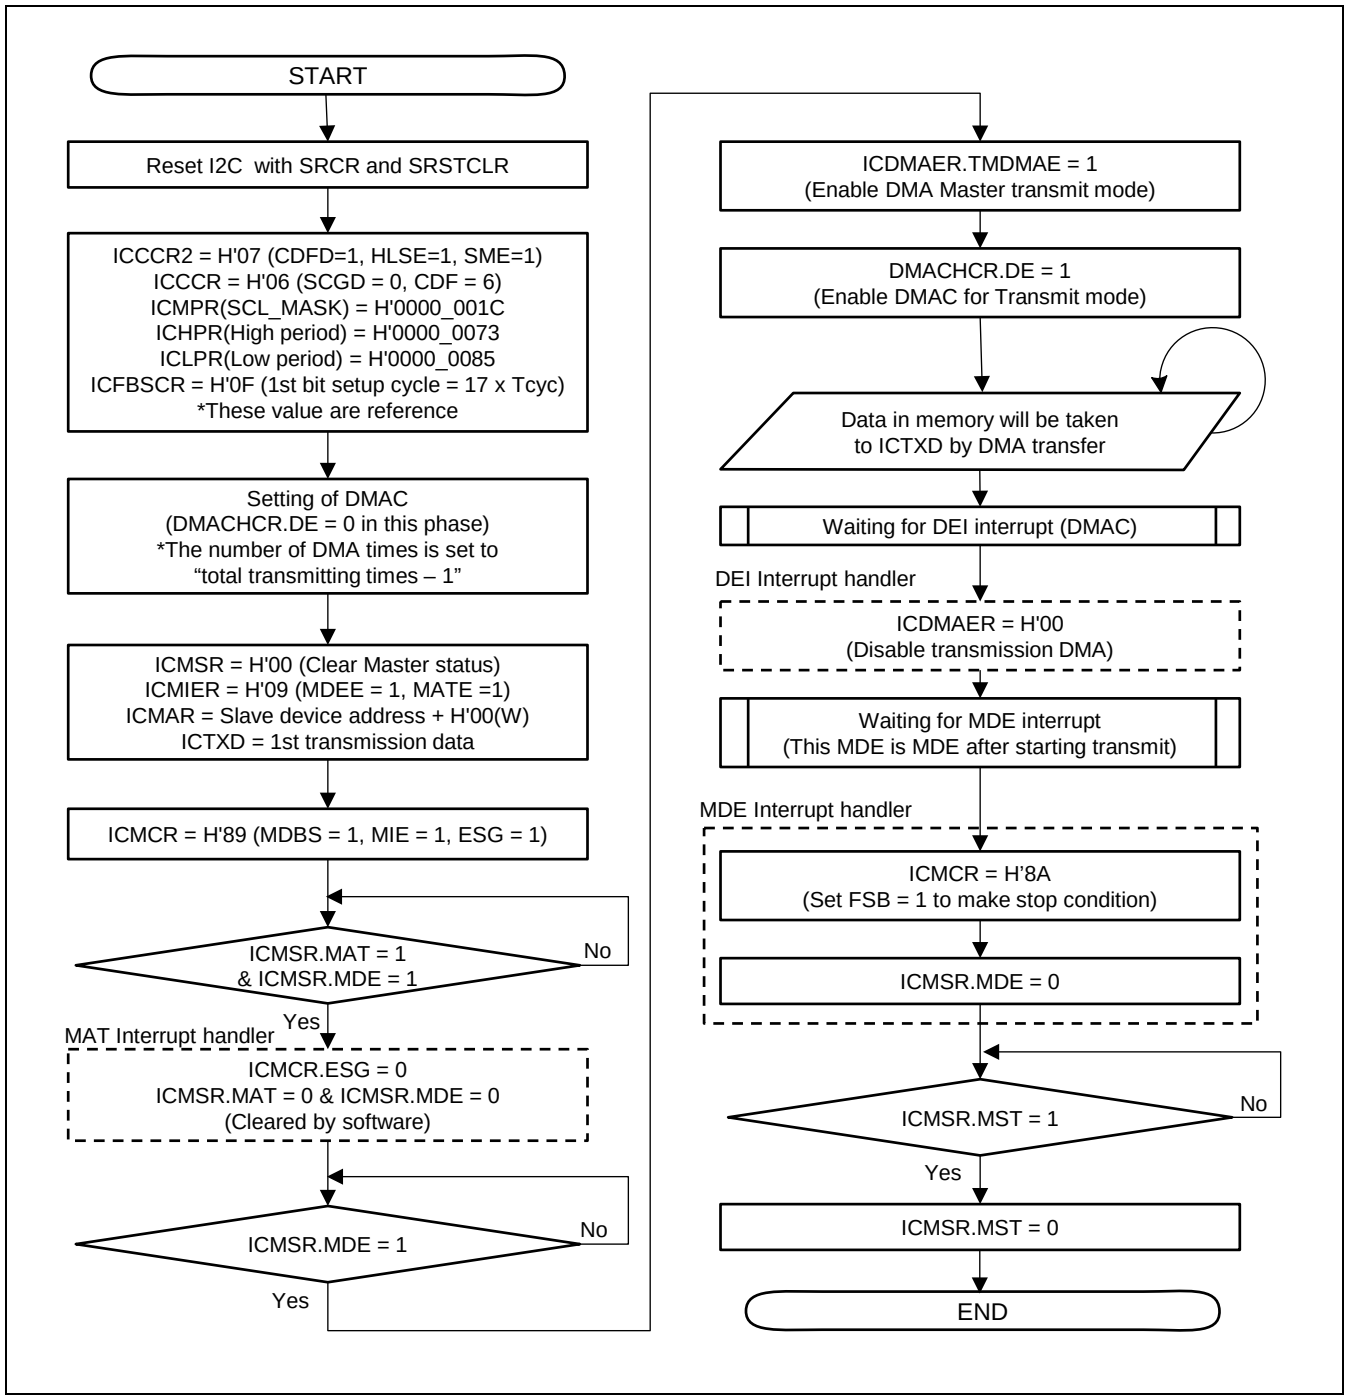

Figure 52.25 Example DMA mode – Master Transmitted Operation Setting

52.4.7 DMA Mode – Master Receive Operation

In DMA receive mode, I2C module asserts a DMA request to the DMAC. After receiving the request, DMAC reads the received data from I2C data register and returns DMARACK to I2C module. All received data bytes will be transferred by using DMAC.

The reception procedure and operations are described as below:

(1) Set value for the clock control register

The same procedure as the master transmitter is applied. See the program example for the master transmitter.

(2) Set value for the master control register, first data byte, and address

1. Clear the Master Status register (ICMSR) = H’00 (all 0 clear).
2. Set the Master Interrupt Enable register (ICMIER) = H’0B (MDEE = 1, MDRE = 1, MATE = 1).
3. Set the Master Address register (ICMAR) = Slave device address + H’00 (Write mode).
4. Set the Transmit Data register (ICTXD) = 1st transmission data.
5. Set the Master Control register (ICMCR) = H’89 (MDBS = 1, MIE = 1, ESG = 1).

(3) Wait for outputting address

1. Wait for master event (an interrupt of the ICMSR.MAT and ICMSR.MDE).
2. Set the ICMCR to H'88 (to suspend the data transmission, the master device will hold the SCL low until the MDE bit is cleared).
   — This generates a stop on the bus as soon as one byte has been transmitted.
3. Clear the ICMSR.MAT & ICMSR.MDE bits.

(4) MDE interrupt handler

1. Wait for master event, ICMSR.MDE.
2. Set the ICMAR = slave device address + H’01(Read mode).
3. Set the ICMCR = H’89 (MDBS = 1, MIE = 1, ESG = 1).
4. Clear the ICMSR.MDE = 0.

(5) Enable DMA of I2C

1. Wait for master event, ICMSR.MAT and ICMSR.MDR.
2. Clear the ICMCR.ESG = 0.
3. Set the DMA Enable register (ICDMAER) = H’02 (RMDMAE = 1).
4. Clear the ICMSR.MAT and ICMSR.MDR bits.

(6) Setting of DMAC

1. Set the number of DMA times (“Total receiving times - 2”).

− In this phase, DMACHCR.DE = 0.

(7) Enable DMA of DMAC

1. Set the DMACHCR.DE = 1 to enable DMA.

(8) DMA interrupt handler

1. Wait for DEI interrupt.
2. Set ICDMAER = H’00 (RMDMAE = 0) to disable DMA transmission.

(9) MDR interrupt handler

1. Wait for master event, ICMSR.MDR.
2. Set the ICMCR = H’8A (MDBS = 1, MIE = 1, FSB = 1).
3. Read ICRXD.
4. Clear the ICMSR.MDR = 0.

(10) Final MDR interrupt handler

1. Wait for master event, ICMSR.MDR.
2. Read ICRXD.
3. Clear the ICMSR.MDR = 0.

(11) Wait for end of transmission

1. Wait for the master event, ICMSR.MST.
2. Clear the ICMSR.MST = 0.

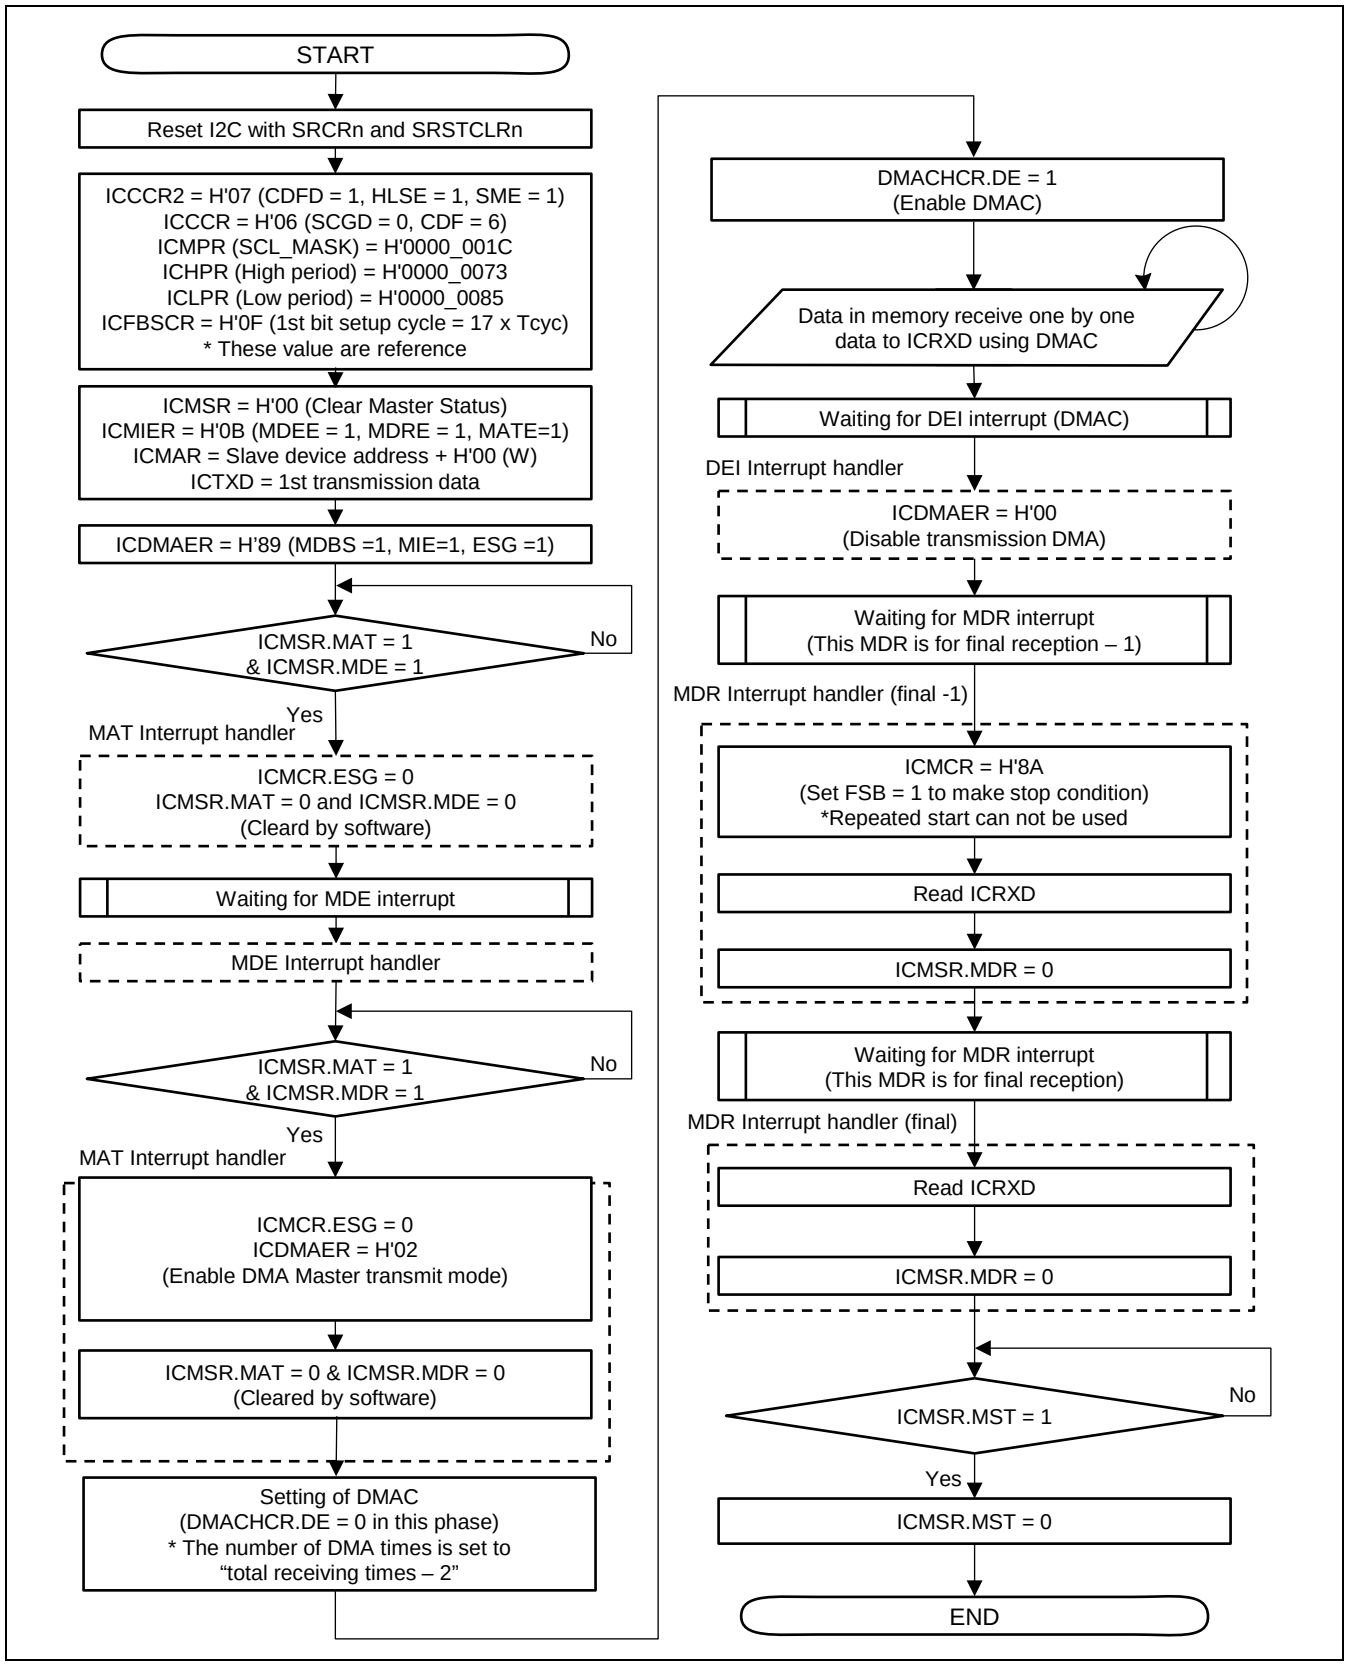

Figure 52.26 Example DMA mode – Master Received Operation Setting

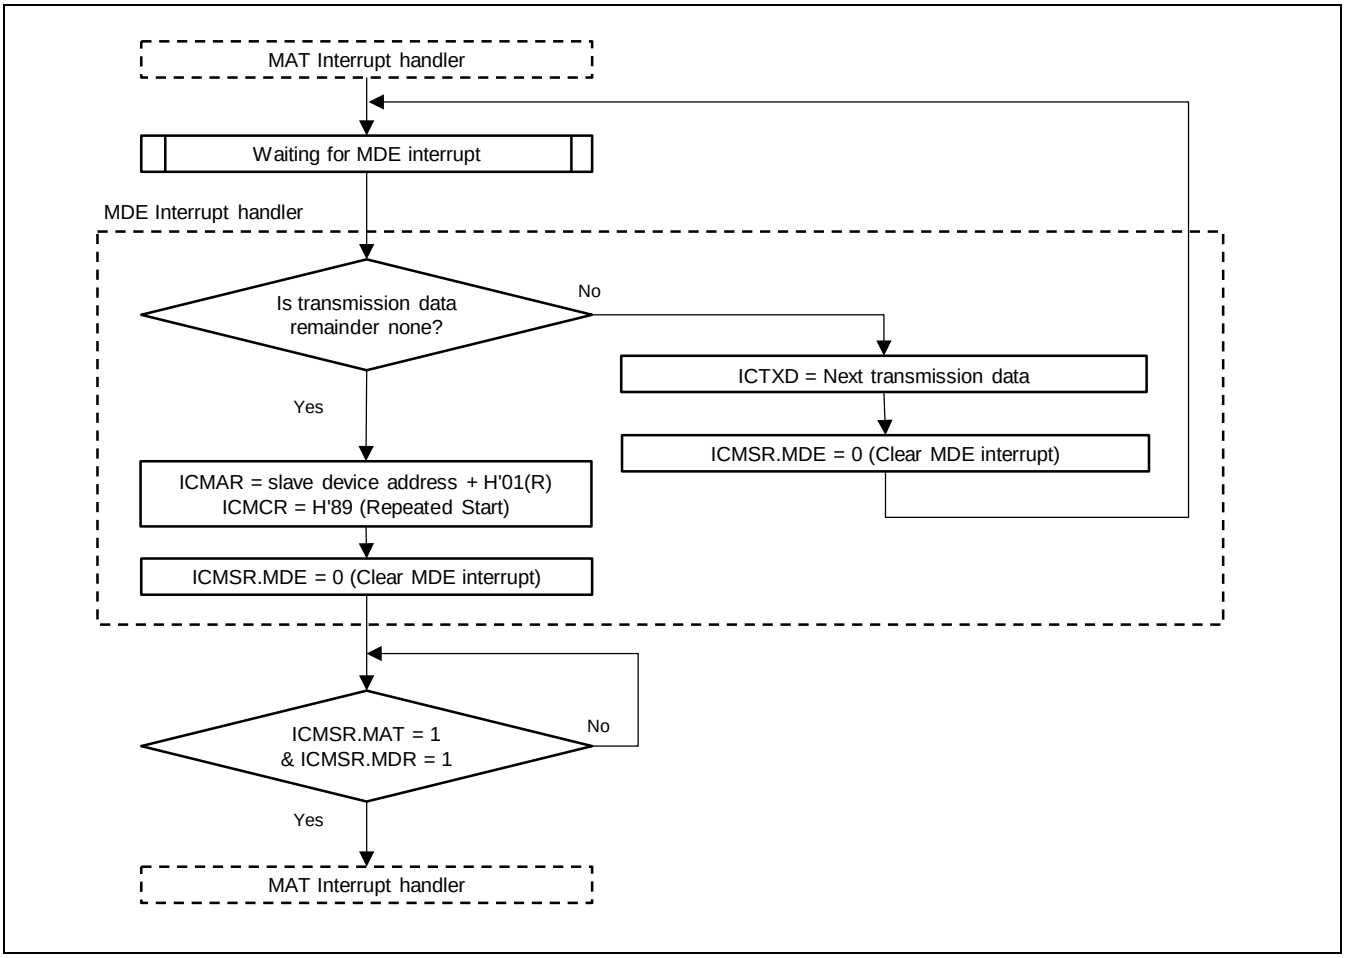

Figure 52.27 MDE Interrupt Handler for Example DMA mode – Master Received Operation Setting

52.4.8 DMA Mode – Slave Transmit Operation

The 1st byte is transferred by PIO, after that enter to DMA mode to start transfer the following bytes.

In DMA transmit mode, I2C module asserts a DMA request to the DMAC. After receiving the request, DMAC write data into I2C data register, and return DMARACK to I2C module. For instance, in order to transfer N0, N1, … , N10 byte. Byte N0 will be transferred by PIO, bytes N1 to N10 will be transferred by using DMAC.

The transmission procedure and operations are described as below:

(1) Setting of DMAC

1. Set the number of DMA times (“Total transmit times – 1”).
   — In this phase, DMACHCR.DE = 0.

(2) Set value for the slave control register, first data byte, and address

1. Reset I2C with SRCR and SRSTCLR.
2. Clear the Slave Status register (ICSSR) = H’00 (all 0 clear).
3. Set the Slave Interrupt Enable register (ICSIER) = H’09 (SDEE = 1, SARE = 1).
4. Set the Slave Address register (ICSAR) = Slave device address.
5. Set the Transmit Data register (ICTXD) = 1st transmission data.
6. Set the DMA Enable register (ICDMAER) = H’04 (TSDMAE = 1).
7. Set the Slave Control register (ICSCR) = H’0E (SDBS = 1, SIE = 1, GCAE = 1).

(3) Wait for receiving address

1. Wait for slave event, ICSSR.SAR.
2. Clear the ICSSR.SAR = 0

(4) Enable DMA

1. Wait for slave event, ICSSR.SDE.
2. Set the DMACHCR.DE = 1 to enable DMA.

(5) DMA interrupt handler

1. Wait for DEI interrupt.
2. Set ICDMAER = H’00 (TSDMAE = 0) to disable DMA transmission.

(6) SDE interrupt handler

1. Wait for slave event, ICSSR.SDE.
2. Clear SDE interrupt (ICSSR.SDE = 0).

(7) Wait for end of transmission

1. Wait for ICSSR.SSR = 1.
2. Set ICSSR.SSR = 0.

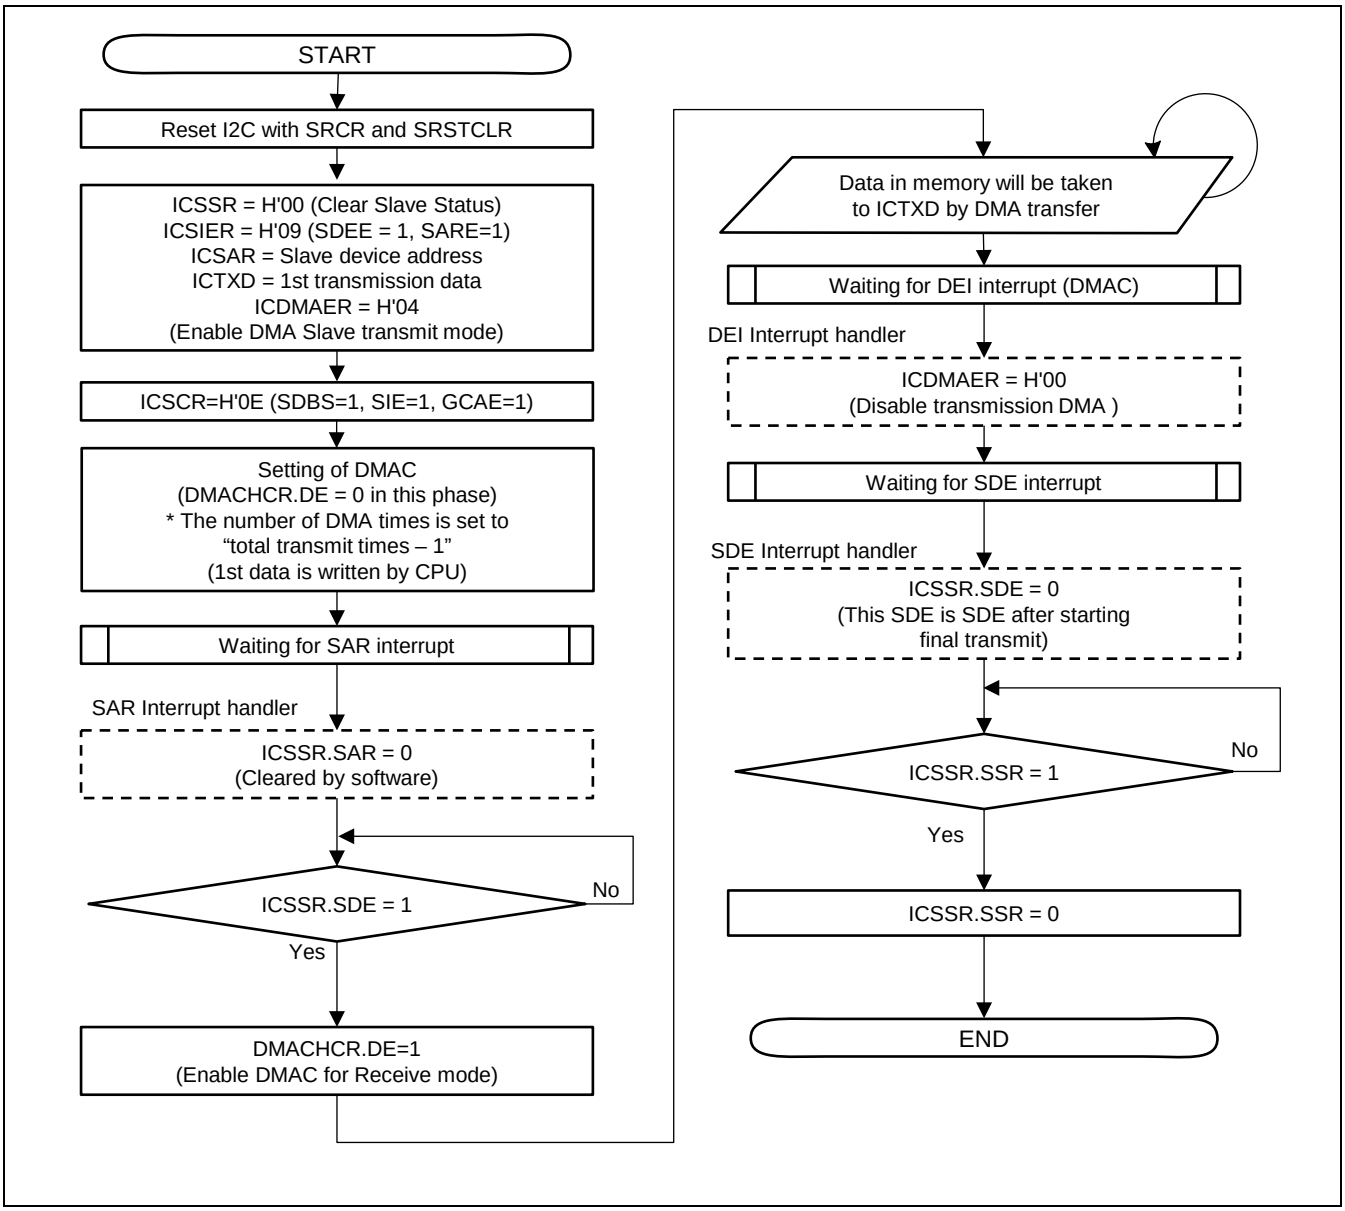

Figure 52.28 Example DMA mode – Slave Transmitted Operation Setting

52.4.9 DMA Mode – Slave Receive Operation

In DMA receive mode, I2C module asserts a DMA request to the DMAC. After receiving the request, DMAC reads the received data from I2C data register and returns DMARACK to I2C module. All received data bytes will be transferred by using DMAC.

The reception procedure and operations are described as below:

(1) Setting of DMAC

1. Set the number of DMA times (“Total receiving times”).
   — In this phase, DMACHCR.DE = 0.

(2) Set value for the slave control register, first data byte, and address

1. Reset I2C with SRCR and SRSTCLR.
2. Clear the Slave Status register (ICSSR) = H’00 (all 0 clear).
3. Set the Slave Interrupt Enable register (ICSIER) = H’03 (SDRE = 1, SARE = 1).
4. Set the Slave Address register (ICSAR) = Slave device address.
5. Set the DMA Enable register (ICDMAER) = H’08 (RSDMAE = 1).
6. Set the Slave Control register (ICSCR) = H’0E (SDBS = 1, SIE = 1, GCAE = 1).

(3) Wait for receiving address

1. Wait for slave event, ICSSR.SAR.
2. Clear the ICSSR.SAR = 0.

(4) Enable DMA

1. Wait for slave event, ICSSR.SDR.
2. Set the DMACHCR.DE = 1 to enable DMA.

(5) DMA interrupt handler

1. Wait for DEI interrupt.
2. Set ICDMAER = H’00 (RSDMAE = 0) to disable DMA transmission.

(6) Wait for end of transmission

1. Wait for ICSSR.SSR= 1.
2. Set ICSSR.SSR = 0.

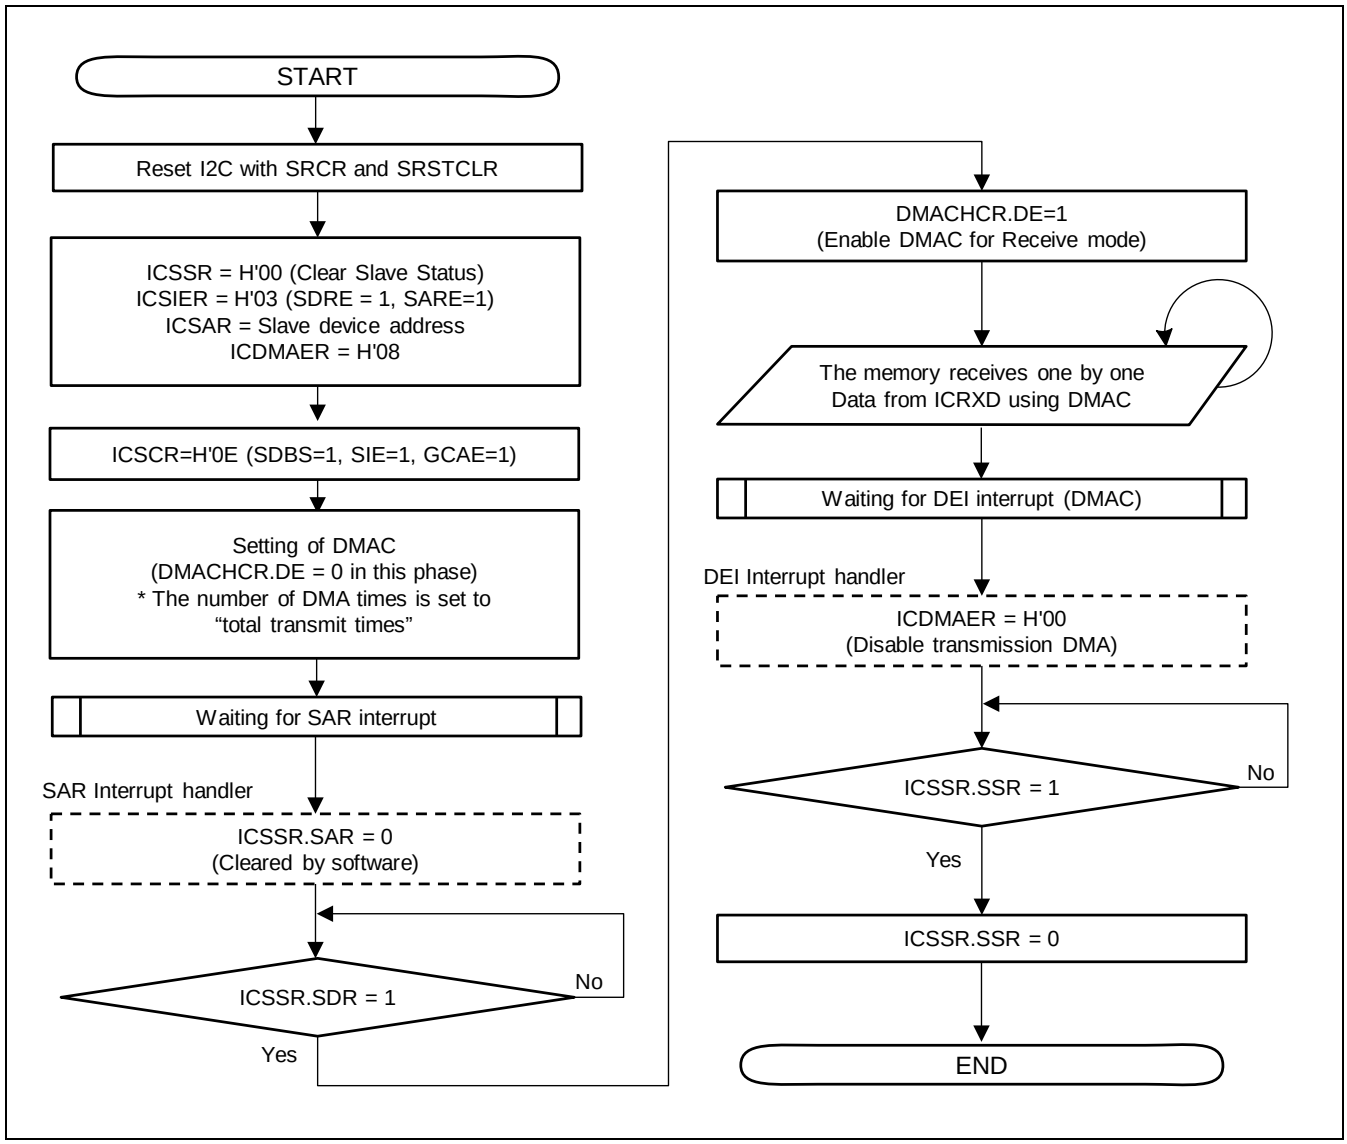

Figure 52.29 Example DMA mode – Slave Received Operation Setting

52.5 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

52.5.1 Usage note for Multi-Master

Do not stop clock distribution to this module, even if this module is not directly used for data transfer, while this module is used in multi-master environment. This module is monitoring SCL and SDA bus line for detecting START and STOP condition for arbitration. If clock is stopped, arbitration problem may occur.

52.5.2 Usage note for SCL frequency calculation equation

In section 52.2.9, Clock Control Register (ICCCR), in the description of SCGD and CDF, following equation is described.

SCLfreq = I2Cck/(20 + SCGD × 8 + F[(tICF + tr + IntDelay) × I2Cck])

I2Cck: I2C internal clock frequency

tICF: I2C SCL falling time (depending on external load)

tr: I2C SCL rising time (depending on external load)

IntDelay: LSI internal delay corresponds to output buffer type.
Open drain buffer: 50 ns (typ.), 110 ns (max.)
LVTTL (low drive only) buffer: 5 ns (typ.), 6 ns (max.).

F[n]: n rounded down to an integer

I2Cck = MOD_CLK/(1 + CDF)

MOD_CLK: module clock frequency

Based on parameter described above, this equation approximately estimates the SCL frequency, but includes some error in the resulting frequency. Before finalizing register setting to be used, measure actual SCL frequency on the board, and confirm that observed frequency satisfy the constraint. The reason why calculated result includes some error is parameters used in this equation varies depending on the characteristics of each sample. For example, tICF and tr depend on logical threshold of IO-cell, and intDelay depends on variation of fabrication process.

For adjustment of SCL frequency, modifying the setting of ICCCR [2:0]. CDF and ICCCR [8:3]. SCGD will be effective. Increasing the value of CDF or SCGD value will make SCL frequency lower. However, how they decrease SCL frequency is different. So, by increasing one register value and decreasing the other, SCL frequency can be adjusted.

52.5.3 Usage note for Pull-up resistance

Do not use internal pull up of PUEN and PUD registers in Pin Function Controller (PFC) section for I2C function. External pull up resistance on board is mandatory for SCL and SDA pins.

52.5.4 Usage note for the transmission and reception procedure

Be sure to reset I2C with Software Reset Register SRCRn (n = 9 or 10*) at the beginning of transmission and reception procedure.
A software reset can be set by controlling the Software Reset Register SRCRn (n = 9 or 10*) and Software Reset Clearing Register SRSTCLRn (n = 9 or 10*) of the “8A. Module Standby, Software Reset”

*: SRCR10 and SRSTCLR10 are only for RZ/G2E

Reset Sequence:

Set the target I2C bit of SRCRn to 1. (**) → Wait 1µsec → Set the target I2C bit of SRSTCLRn to 1. (**) → Wait for the target bit of SRCRn to 0. → End sequence

**: Other bit should be written 0.

52.5.5 Usage note for DMA mode of Receive Operation

If use DMA mode of Receive Operation more than once with repeated START,
issue "STOP condition" and start from beginning of transmission and reception procedure instead of repeated START.

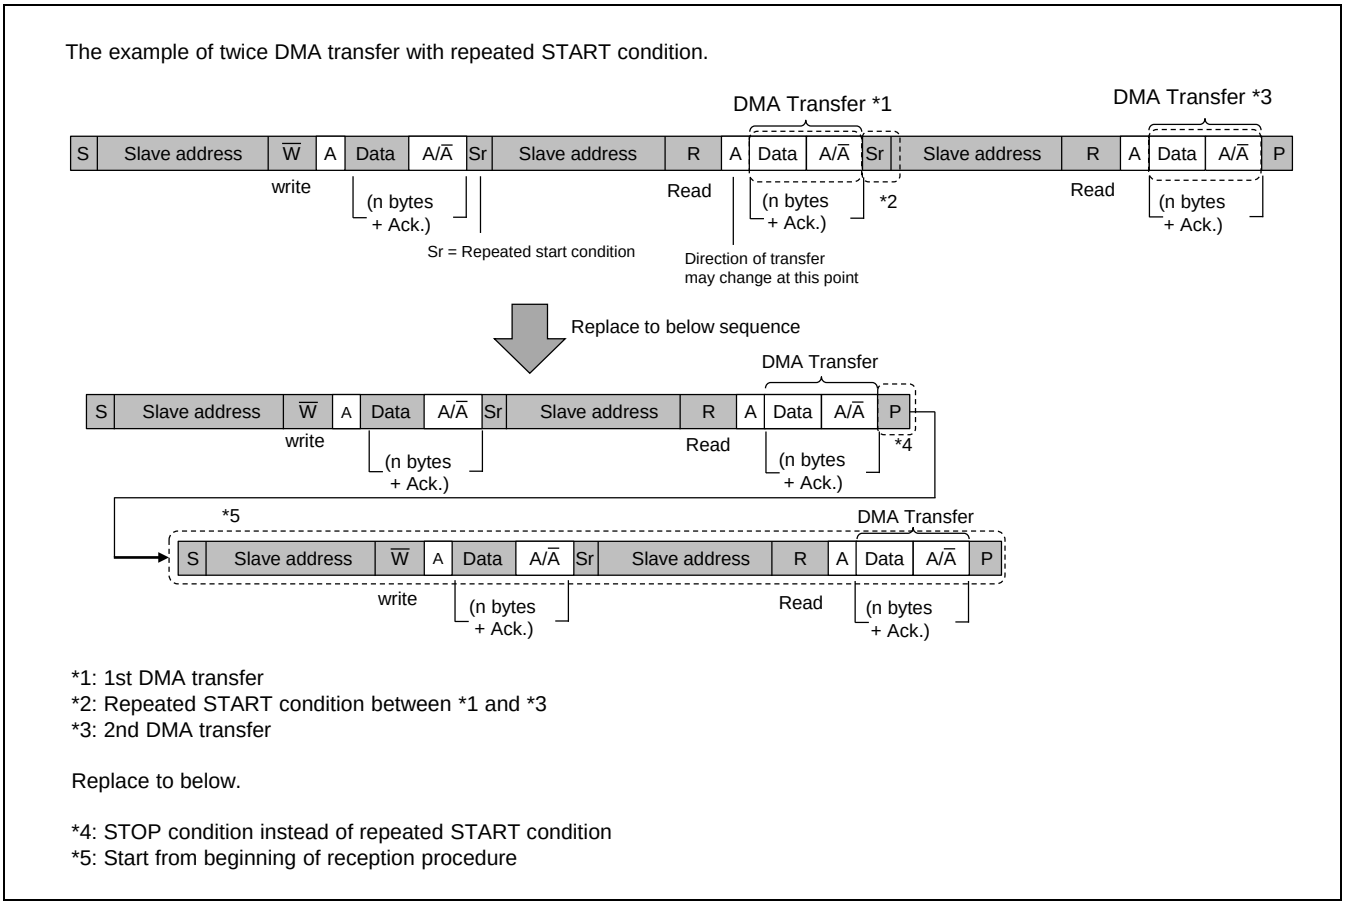

Figure 52.30 Example of Usage Note for DMA mode of Receive Operation

53. IIC Bus Interface for PMIC (IIC for PMIC)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

53.1 Overview

The IIC bus interface uses only one data line (SDA) and one clock line (SCL) to transfer data, saving board and connector space.

Note: "IIC" mentioned in this chapter means the same as “I2C”.

53.1.1 Features

The second generation RZ/G series products have one IIC bus interface module (IIC-PMIC).

The module clock for the IIC-PMIC is CPϕ.

- Data transfer based on I2C bus format from Philips Semiconductor (now NXP Semiconductors)
- Automatic generation of START and STOP conditions
- Control of acknowledge level after receiving data
- Automatic checking of acknowledge bit after transmitting data
- Wait function
  A wait can be inserted by driving the SCL pin low after data transfer, excluding acknowledgement.
  The wait can be canceled by clearing the interrupt flag.
- This module supports only master mode.
  If arbitration is lost, data transfer is stopped and I2C bus is released.
- Four interrupt sources
  — Data transfer enable
  — Wait state
  — Non-acknowledge detection
  — Arbitration lost
- Data transfer speed
  Supports Standard-mode (100 kHz) and Fast-mode (400 kHz)
  — SCL clock frequency can be controlled by register setting.
- Support clock synchronization of SCL line
  A hazard (transient spike) in the SCL high-count period is detected as a loss of arbitration.
- DMA transfer
  Support DMA transfer (transmission and reception).

Figure 53.1 shows a block diagram of the IIC bus interface module.

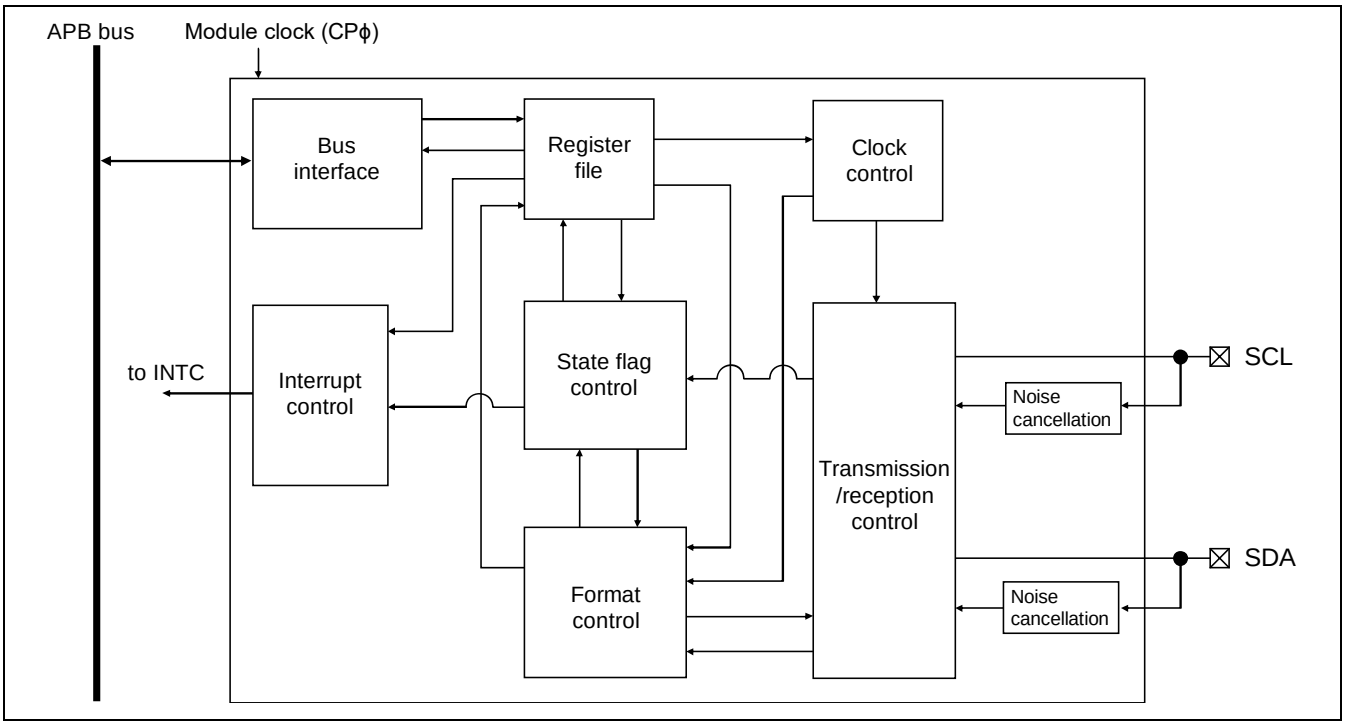

Figure 53.1 Block Diagram of IIC Bus Interface Module

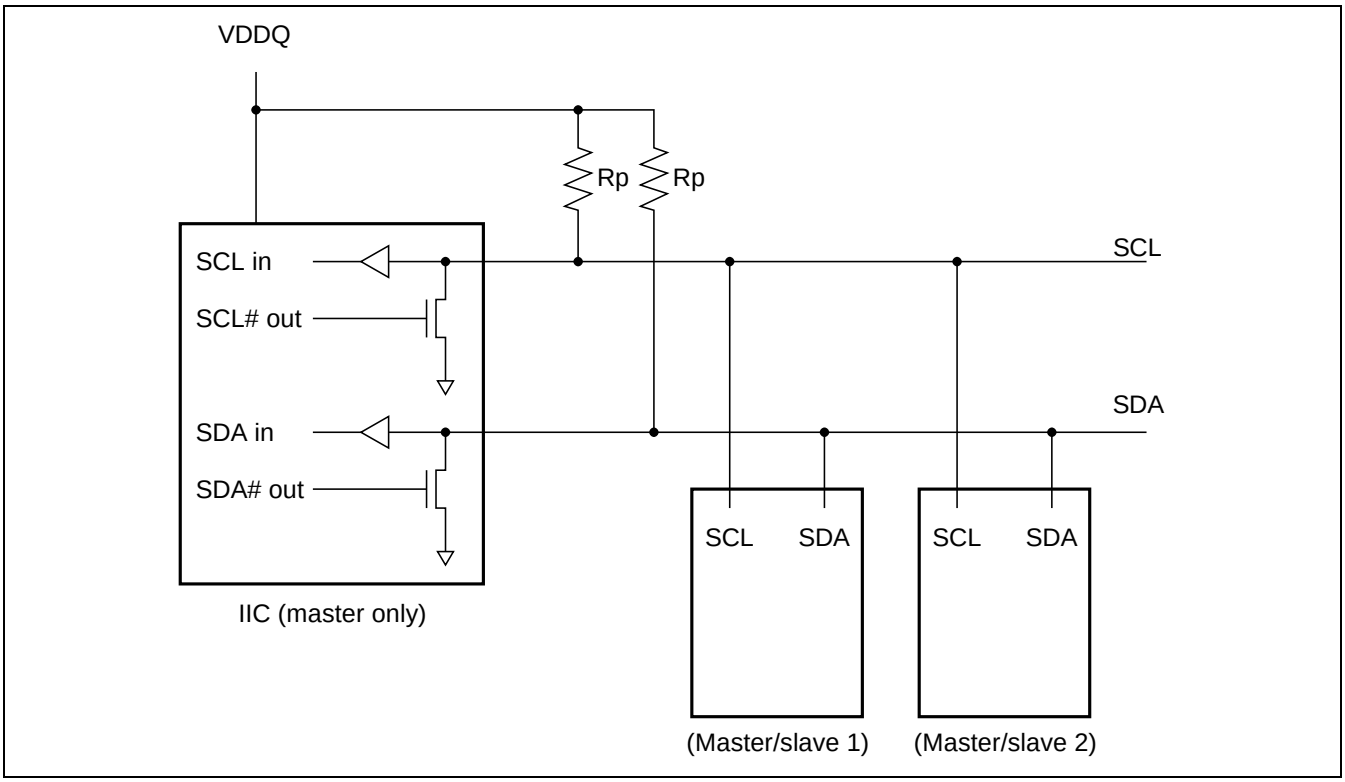

Figure 53.2 Connection Example of IIC Bus Interface Module

53.1.2 External Pins

Table 53.1 summarizes the input/output pins used by the IIC bus interface.

Table 53.1 IIC Bus Interface Pins

Channel Number	Pin Name*1	I/O	Function	Second Generation RZ/G Series Products			
				RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
				Output Buffer Type*2			
0	SCL	I/O	SCL: IIC serial clock input/output pin	OD	OD	OD	OD
	SDA		SDA: IIC serial data input/output pin				

Notes: 1. The actual pin names are SCL_PMIC, SDA_PMIC.
2. Output buffer type: "OD" is open drain buffer. OD assigned channel pins are 1.8 V I/O and input/output 3.3 V tolerant.

The IIC buffer in this LSI is not compliant with the 5V-input. When turning off the I/O power source (3.3 V) of this LSI, turn off the power source of the pull-up resistors connected to the IIC pins.

Note: When using 1.8V IIC pins (OD assigned channel) as 3.3 V tolerant, all the external pull-up voltage power supply to the IIC of this LSI must keep the same power on/off sequence as the VDDQ (3.3 V) of this LSI.

53.1.3 Register Configuration

Table 53.2 shows the register configuration of the IIC bus interface. Table 53.3 shows the register state in each processing mode.

The base address for each channel of the IIC bus interface registers is as follows:

- IIC-PMIC: H'E60B_0000

IIC bus interface module has the registers below.

53.2 Register Description

53.2.1 IIC Bus Data Register (ICDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

ICDR is an 8-bit readable/writable register that is used as a transmit data register when transmitting and a receive data register when receiving.

In transmission mode, write transmit data to this register when the DTE bit in the IIC bus status register (ICSR) is 1.

In receive mode, read receive data from this register when the DTE bit in the IIC bus status register (ICSR) is 1.

Bit:	7	6	5	4	3	2	1	0
	ICDR							
Initial value:	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

53.2.2 IIC Bus Control Register (ICCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

ICCR is an 8-bit readable/writable register that enables or disables the IIC bus interface, specifies the transmission/receive mode, issues START/STOP conditions, and confirms the IIC bus interface bus status.

Table 53.4 ICCR Settings

Operation	Write Data to ICCR (Transmission Mode)	Write Data to ICCR (Receive Mode)
START condition	H'94	—
Repeated START condition	H'94	H'D4 (Change from receive mode to transmission mode)
transmission/receive mode change	H'81 (Change from transmission mode to receive mode)	—
STOP condition	H'90	H'C0

Bit:	7	6	5	4	3	2	1	0
	ICE	RACK	—	TRS	—	BBSY	—	SCP
Initial value:	0	0	0	0	0	0	0	1
R/W:	R/W	R/W	R	R/W	R	R/W	R	(R/W)*

Bit	Bit Name	Initial Value	R/W	Description
7	ICE	B'0	R/W	IIC Bus Interface Enable Enables or disables the IIC bus interface. When this bit is set to 1, transfer operation is enabled. When this bit is cleared to 0 during data transmission, the I2C bus is released and all registers in this module are initialized. (See section 53.4, Usage Notes.) When this bit is cleared to 0 after data transmission, all registers in this module are initialized. When the ICCR is updated while this module is operating, this bit must be set to 1. 0: IIC bus interface module is disabled. (All internal registers are initialized.) 1: IIC bus interface module is enabled.
6	RACK	B'0	R/W	Receive Acknowledge Specifies the acknowledge level in receive mode. In reception, this bit provides the acknowledge level for output on the SDA line after the IIC module receives data. 0: In receive mode, 0 is output to SDA at acknowledge output timing. 1: In receive mode, 1 is output to SDA at acknowledge output timing.
5	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	TRS	B'0	R/W	Transmit/Receive Select Specifies either transmission mode or receive mode. The setting of this bit can be rewritten even during data transfer, but actual operating mode is changed after completion of ongoing transfer including acknowledge bit. 0: Master reception mode. 1: Master transmission mode. When writing 1 to this bit, also set BBSY and SCP bits at the same time.
3	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	BBSY	B'0	R/W	Bus Busy This bit is used to issue START and STOP conditions. To issue a START condition, write 1 to this bit and 0 to the SCP bit. A repeated START condition is issued in the same way. To issue a STOP condition, write 0 to this bit and 0 to the SCP bit. 0: A STOP condition is issued (the SCP bit is also used). 1: A START or repeated START condition is issued (the SCP bit is also used).
1	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	SCP	B'1	(R/W)*	START Condition/STOP Condition Prohibit Controls issuance of START and STOP conditions. To issue a START condition, write 1 to the BBSY bit and 0 to this bit. A repeated START condition is issued in the same way. To issue a STOP condition, write 0 to the BBSY bit and 0 to this bit. This bit is always read as 1. Writing 1 to this bit is ignored. 0: Writing 0 to this bit issues a START or STOP condition, in combination with the BBSY flag. 1: Writing 1 to this bit is ignored.

Note: * For the SCP bit, only writing 0 is valid. Always read as 1.

53.2.3 IIC Bus Status Register (ICSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

ICSR is an 8-bit readable/writable register that performs interrupt request.

Bit:	7	6	5	4	3	2	1	0
	SCLM	SDAM	—	BUSY	AL	TACK	WAIT	DTE
Initial value:	1	1	0	0	0	0	0	0
R/W:	R	R	R	R	R/WC0	R/WC0	R/WC0	R

Bit	Bit Name	Initial Value	R/W	Description
7	SCLM	B’1	R	SCL Monitor Indicates the SCL state sampled by the module clock. 0: Indicates that SCL is 0. 1: Indicates that SCL is 1.
6	SDAM	B’1	R	SDA Monitor Indicates the SDA state sampled by the module clock. 0: Indicates that SDA is 0. 1: Indicates that SDA is 1.
5	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
4	BUSY	B’0	R	IIC Transmit State Bit Indicates the IIC state. After the START condition is generated, the IIC enters the transfer state and this bit is set to 1. After the STOP condition is generated, the IIC enters the non-transfer state and this bit is cleared to 0. When a loss of arbitration is detected, the SDA line is immediately released, but output of the clock signal on SCL continues until frame acknowledgement is completed. This bit is cleared to 0 after end of frame transfer. 0: The IIC module is not busy (transfer by the IIC module is not in progress). 1: The IIC module is busy (transfer by the IIC module is in progress). Setting condition: The IIC module issues the START condition. Clearing condition: The IIC module issues the STOP condition. A loss of arbitration is detected (cleared after SCL clock output is stopped).

Bit	Bit Name	Initial Value	R/W	Description
3	AL	B'0	R/WC0	Arbitration Lost Indicates a loss of arbitration. The IIC bus interface monitors the SDA. If the IIC bus interface detects data different from the data it sent, it sets this bit to 1 to indicate that the bus has been conflicted. This bit is reset by writing 0 to this bit or performing write access to ICDR in transmit mode or read access to ICDR in receive mode when the DTE bit is 1. When a loss of arbitration is detected during data transfer, the SDA line is immediately released. Output of the clock line on SCL continues until frame acknowledgement is completed. This bit does not depend on the ALE bit in ICIC and is always updated. When the ALE bit in ICIC is 0, an arbitration lost interrupt request is not issued to the interrupt controller. When other masters issue the START condition, a loss of arbitration is detected and operation is stopped. 0: Bus arbitration won • When data are written to ICDR (transmit mode) or read from ICDR (receive mode) • When 0 is written to this bit after reading AL = 1 1: Arbitration lost • When the level of the data being received changes during counting of the period at high level for the SCL clock in master receive mode • When the level on the SCL line becomes low during counting of the period at high level for the SCL clock • When a START condition is detected before this module issues its own START condition • When the monitored external SDA and data being output from this module not being equal
2	TACK	B'0	R/WC0	Transmit Acknowledge Bit Indicates the level of the SDA line during acknowledge cycle in transmit mode. This bit is cleared by writing 0. This bit is always 0 when the TACKE bit in ICIC is 0. 0: Indicates that acknowledge (low level on SDA line) have been detected during acknowledge cycle. 1: Indicates that no acknowledge (high level on SDA line) have been detected during acknowledge cycle.
1	WAIT	B'0	R/WC0	Wait Indicates that this module have entered the wait state after data transmission other than the acknowledge bit. When the value of the WAITE bit in ICIC is 1, this module enters the wait state after data transfer (except for acknowledge bit), with driving the SCL to the low level. At this time, this bit is automatically set to 1 and a WAIT interrupt is generated. By writing 0 to this bit, this module recovers from the wait state. This bit is always 0 when WAITE in ICIC is 0. 0: This module is in the normal state. 1: This module is in the wait state.

Bit	Bit Name	Initial Value	R/W	Description
0	DTE	B'0	R	Data Transmit Enable Indicates the transmit state between ICDR and internal transmit/receive buffer. This bit is read only and automatically set or cleared. 0: • When reset is performed • When data is written to ICDR in transmit mode (TRS = 1). • When data is read from ICDR in receive mode (TRS = 0). • When the TRS bit is changed. • When the repeated START condition/STOP conditions are written to the BBSY and SCP bits in ICCR. 1: • When the START/repeated START conditions are generated. • When transmit data is sent to the transmit buffer from ICDR in transmit mode (TRS = 1). • When receive data is sent to ICDR in receive mode (TRS = 0).

53.2.4 IIC Interrupt Control Register (ICIC)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

ICIC is an 8-bit register that enables or disables an interrupt request.

Bit:	7	6	5	4	3	2	1	0
	ICCLB8	ICCHB8	TDMAE	RDMAE	ALE	TACKE	WAITE	DTEE
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	ICCLB8	B'0	R/W	IIC Clock Control Low Bit 8 Sets the low-level period of SCL when the period setting for the module in {ICIC[7], ICCL} is H'100 to H'1FF. Table 53.5 shows transfer rate settings.
6	ICCHB8	B'0	R/W	IIC Clock Control High Bit 8 Sets the high-level period of SCL when the period setting for the module in {ICIC[6], ICCH} is H'100 to H'1FF. Table 53.5 shows transfer rate settings.
5	TDMAE	B'0	R/W	Transmit Data DMA Transfer Request Enable When DTEE is 1, this bit specifies whether data transmit interrupt in transmission mode (TRS = 1) is used as an interrupt to the CPU or a DMA transfer request. When DMA is used for automatic transmission, setup of this bit is unnecessary. 0: Uses TDMAE as an interrupt to the CPU. 1: Uses TDMAE as a DMA transfer request to DMAC.
4	RDMAE	B'0	R/W	Receive Data DMA Transfer Request Enable When the DTEE bit is 1, this bit specifies whether data receive interrupt in receive mode (TRS = 0) is used as an interrupt to the CPU or a DMA transfer request. When DMA is used for automatic transmission, setup of this bit is unnecessary. 0: Uses RDMAE as an interrupt to the CPU. 1: Uses RDMAE as a DMA transfer request to DMAC.
3	ALE	B'0	R/W	Arbitration Lost Interrupt Enable and Function Enable Enables or disables arbitration lost interrupt request. An arbitration lost interrupt is generated if a loss of arbitration occurs when this bit is 1. At this time, the AL bit in ICSR is set to 1. Do not clear this bit to 0 with the AL bit set to 1. 0: Disables an arbitration lost Interrupt. 1: Enables an arbitration lost interrupt.

Bit	Bit Name	Initial Value	R/W	Description
2	TACKE	B'0	R/W	Non-acknowledge Detection Interrupt Enable and Function Enable Enables or disables a non-acknowledge detection interrupt request. A non-acknowledge interrupt is generated if non-acknowledge is received when this bit is 1. At this time, the TACK bit in ICSR is set to 1. Do not clear this bit to 0 with the TACK bit set to 1. 0: Disables non-acknowledge detection Interrupt. 1: Enables non-acknowledge detection interrupt.
1	WAITE	B'0	R/W	Wait Interrupt Enable and Function Enable Enables or disables a wait interrupt request. When WAITE is 1, a wait state in which SCL is driven to the low level follows the transmission of data other than the acknowledge bit. At this time, a WAIT interrupt is generated and the WAIT bit in ICSR is set to 1. Do not clear this bit to 0 with the WAIT bit in ICSR set to 1. 0: Disables an interrupt. 1: A wait interrupt is generated. Note: In Automatic transfer mode, set 1 in a WAITE bit.
0	DTEE	B'0	R/W	Data Transmit Enable Interrupt Enables or disables a data transmit enable interrupt request. An interrupt request is issued if the DTE bit in ICSR is set to 1 when this bit is 1. 0: Disables an interrupt. 1: A data transmit enable interrupt is generated.

53.2.5 IIC Clock Control Register Low (ICCL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

ICCL is an 8-bit readable/writable register that specifies the low-level period of SCL.

ICCL is initialized to H'00 by a reset.

Bit:	7	6	5	4	3	2	1	0
	ICCL							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: Table 53.5 shows transfer rate settings.

53.2.6 IIC Clock Control Register High (ICCH)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

ICCH is an 8-bit readable/writable register that specifies the high-level period of SCL.

ICCH is initialized to H'00 by a reset.

Bit:	7	6	5	4	3	2	1	0
	ICCH							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: Table 53.5 shows transfer rate settings.

53.2.7 IIC Automatic Transmission interrupt Mask Register (ICIMSK)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICIMSK is an 8-bit register that enables or disables the interrupt request output of automatic transmission.

An interrupt is output to AL interrupt event code. The generated interrupt can be checked by ICINT.

Bit:	7	6	5	4	3	2	1	0
	AENDM	TMC2M	TMC1M	TMOUTM	ALM	TACKM	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	AENDM	B'0	R/W	Automatic Transmission End Interrupt Mask 0: Interrupt is not output to INTC- AP at the time of the end of automatic transmission. 1: Interrupt is output to INTC-AP at the time of the end of automatic transmission.
6	TMC2M	B'0	R/W	Timer Count 2 End Interrupt Mask 0: Interrupt is not output to INTC- AP at the time of the end of timer count 2. 1: Interrupt is output to INTC- AP at the time of the end of timer count 2.
5	TMC1M	B'0	R/W	Timer Count 1 End Interrupt Mask 0: Interrupt is not output to INTC- AP at the time of the end of timer count 1. 1: Interrupt is output to INTC- AP at the time of the end of timer count 1.
4	TMOUTM	B'0	R/W	Timeout Error Interrupt Mask 0: Interrupt is not output to INTC- AP at the time of a timeout error. 1: Interrupt is output to INTC- AP at the time of a timeout error.
3	ALM	B'0	R/W	AL Interrupt Mask 0: Interrupt is not output to INTC- AP at the time of the automatic transmission AL. 1: Interrupt is output to INTC- AP at the time of the automatic transmission AL.
2	TACKM	B'0	R/W	TACK Interrupt Mask 0: Interrupt is not output to INTC- AP at the time of the automatic transmission TACK. 1: Interrupt is output to INTC- AP at the time of the automatic transmission TACK.
1, 0	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.

53.2.8 IIC Automatic Transmission Interrupt Flag Register (ICINT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICINT is an 8-bit register that indicates the interrupt state during automatic transmission.

The interrupt bit can be cleared by writing 1 to ICSTART[7] or clearing ICCR[7] to 0 at the start of automatic operation.

Bit:	7	6	5	4	3	2	1	0
	AEND	TMC2	TMC1	TMOUT	AAL	ATACK	AWAIT	ADTE
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	AEND	B'0	R	Automatic Transmission End Flag 0: Under automatic transmission 1: End of automatic transmission
6	TMC2	B'0	R	Timer Count 2 End Flag 0: Timer count 2 is not ended. 1: End of timer count 2
5	TMC1	B'0	R	Timer Count 1 End Flag 0: Timer count 1 is not ended. 1: End of timer count 1
4	TMOUT	B'0	R	Timeout Error Flag 0: No timeout error 1: Timeout error is detected.
3	AAL	B'0	R	Automatic Transmission AL Flag 0: No AL 1: AL is detected.
2	ATACK	B'0	R	Automatic Transmission TACK Flag 0: No TACK 1: TACK is detected. Note: After having finished all the processing appointed in Format, the detection of NACK shows that there was NACK reply during transfer.
1	AWAIT	B'0	R	Automatic Transmission WAIT Flag 0: No WAIT 1: WAIT is detected.
0	ADTE	B'0	R	Automatic Transmission DTE Flag 0: No DTE 1: DTE is detected.

53.2.9 IIC Automatic Transmission Processing Enabling Register (ICACE)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICACE is an 8-bit register that specifies the usage of each function during automatic transmission.

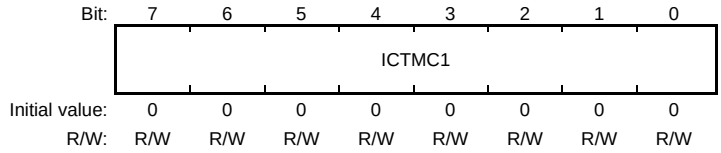
Bit:	7	6	5	4	3	2	1	0
	AENDE	TMC2E	TMC1E	TMOUTE	ALE	TACKE	WAITE	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	AENDE	B’0	R/W	Automatic Transmission End Detection Enable 0: End of automatic transmission is not detected. 1: Detects the end of automatic transmission and outputs it to ICINT.
6	TMC2E	B’0	R/W	Timer Count 1 Enable, Timer Count 2 Enable
5	TMC1E	B’0	R/W	Specify whether wait by TMC1 or TMC2 timer is inserted before assertion of an automatic transmission interrupt and a timeout error detection interrupt. Refer to Figure 53.3 for the wait timing of TMC1 and TMC2. ICACE[6:5] = B’00: TMC1 and TMC2 are not used. ICACE[6:5] = B’01: Interrupt is asserted after counting by TMC1 is finished. ICACE[6:5] = B’11: Interrupt is asserted after counting by TMC1 and TMC2 is finished. ICACE[6:5] = B’10: Setting prohibited
4	TMOUTE	B’0	R/W	Timeout Error Enable When SDA is driven to low even after the STOP condition is generated and counting by TMC1 and TMC2 is finished, a timeout error is detected. 0: Timeout error is not detected. 1: Timeout error is detected and recorded in ICINT.
3	ALE	B’0	R/W	Automatic Transmission AL Error-Handling Enable Specifies whether handling for AL errors detected during automatic transmission is performed or not. 0: No automatic AL error handling (AL is not detected) 1: Automatic AL error handling is performed (to release the SDA bus, continue output of SCL until the time corresponding to 1 byte + ACK, and perform retry or stop processing).
2	TACKE	B’0	R/W	Automatic Transmission ACK Error-Handling Enable Specifies whether handling for ACK error is performed or not (when error handling is selected, either retry or stop processing is performed). 0: No automatic ACK error handling 1: Automatic ACK error handling is performed (retry or stop processing is performed).
1	WAITE	B’0	R/W	WAIT Processing Enable Specifies whether wait processing is inserted during automatic transmission. 0: No automatic WAIT processing. 1: Automatic WAIT processing is performed (waiting for the period specified by the ICTMCW register). Note: In Automatic transfer mode by DMA, set 1 in a WAITE bit.
0	—	B’0	R/W	Reserved The write value should always be 0.

53.2.10 IIC Automatic Transmission Timer Control Register 1 (ICTMC1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICTMC1 is an 8-bit register that specifies the delay time for the timing of detection of automatic transmission being completed and timeout errors.



The delay time is specified by ICTMC1 by following formula.

Delay time = $(ICTMC1)_{10} \times 200 \times t_{Module\ clock}$

(When the frequency of the module clock is 16.66 MHz, the delay time can be specified within the range from 0 µs up to 3060 µs in 12-µs increments.)

53.2.11 IIC Automatic Transmission Timer Control Register 2 (ICTMC2)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICTMC2 is an 8-bit register that specifies the delay time for the timing of detection of automatic transmission being completed and timeout errors.

Bit:	7	6	5	4	3	2	1	0
	ICTMC2							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

The delay time is specified by ICTMC2 by the following formula.

Delay time = (ICTMC2) $_{10} \times 200 \times t_{\text{Module clock}}$

(When the frequency of the module clock is 16.66 MHz, the delay time can be specified within the range from 0 µs up to 3060 µs in 12-µs increments.)

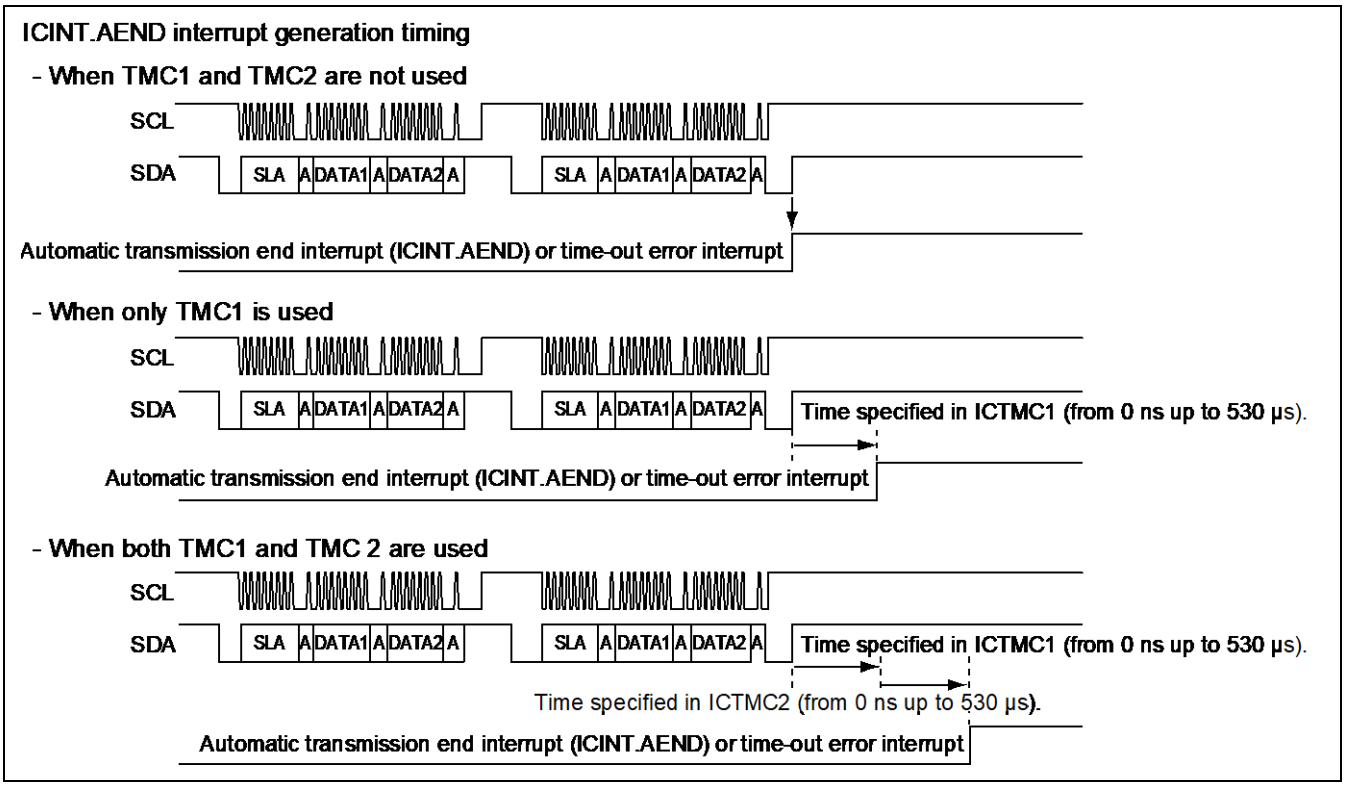


Figure 53.3 Wait Timing Chart of TMC1 and TMC2

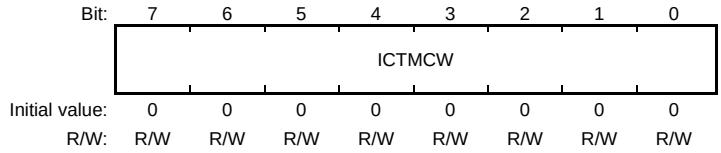
53.2.12 IIC Automatic Transmission Wait Control Register (ICTMCW)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICTMCW is an 8-bit register that specifies the wait time during automatic transmission. When ICACE.WAITE is set to 1 for activating the wait processing function, set a value other than H'00 to this register.



The wait time is specified by ICTMCW by following formula.

Delay time = $(\text{ICTMCW})_{10} \times 20 \times t_{\text{Module clock}}$ by ICTMCW

(When the frequency of the module clock is 16.66 MHz, the delay time can be specified within the range from 0 µs up to 306 µs in 1.2-µs increments.)

Although a wait time can be specified by this register, the period of waiting may be different from the specified value because a transition of the actual SCL bus may be delayed by a clock cycle. Also, in the case of automatic transmission, 1 cycle of waiting is always inserted automatically before the acknowledge cycle.

53.2.13 IIC Automatic Transmission Transmit Start Register (ICSTART)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICSTART is an 8-bit register that specifies start, reset, and abort of automatic transmission.

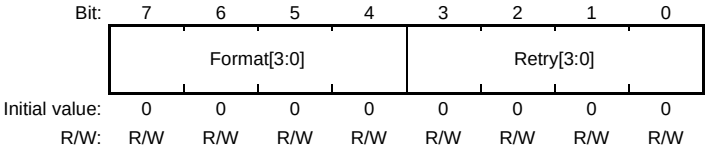
Bit:	7	6	5	4	3	2	1	0
	Auto Start	AutoTrans Reset	Auto Stop	—	—	—	ATDMA	ARDMA
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	AutoStart	B'0	R/W	Automatic Transmission Start Automatic transmission starts by writing 1 to this bit. Do not clear this bit to 0 during automatic transmission.
6	AutoTransReset	B'0	R/W	Automatic Transmission Reset The internal state of automatic transmission is reset by writing 1 to this bit. After reset, write 0 to this bit. Writing 1 to this bit does not initialize automatic transmission-related registers. For register initialization, use reset function by writing 0 to ICCR.ICE.
5	AutoStop	B'0	R/W	Automatic Transmission Stop By writing 1 to this bit, the STOP condition is generated at the boundary of a 1byte + ACK-cycle unit and automatic transmission stops. Writing 1 to this bit may result in stopping transmission such that the transfer format is not as expected. 0: Normal operation 1: STOP condition is generated and automatic transmission stops.
4 to 2	—	All 0	R/W	Reserved The write value should always be 0.
1	ATDMA	B'0	R/W	Automatic Transmission DMA Enable 0: DMA is not used for data transmission by automatic transmission. 1: DMA is used for all data transmission by automatic transmission.
0	ARDMA	B'0	R/W	Automatic Reception DMA Enable 0: DMA is not used for data reception by automatic transmission. 1: DMA is used for all data reception by automatic transmission.

53.2.14 IIC Automatic Transmission Transmit Control Register (ICATFR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICATFR is an 8-bit register that specifies an automatic transmission format and the number of retry processing.



Bit	Bit Name	Initial Value	R/W	Description
7 to 4	Format[3:0]	H'0	R/W	IIC Automatic Transmission Format Selection Specify the format of automatic transmission. Refer to Figure 53.5 for a communication format. S = START condition, Sr = Repeated START condition, P = STOP condition H'0: S → Transmission 1 → P H'1: S → Transmission 1 → Reception 1 → P H'2: S → Transmission 1 → Sr → Transmission 2 → P H'3: S → Transmission 1 → Sr → Transmission 2 → Receive 1 → P H'4: S → Transmission 1 → Reception 1 → Sr → Transmission 2 → P H'5: S → Transmission 1 → Reception 1 → Sr → Transmission 2 → Reception 2 → P Others: Setting prohibited
3 to 0	Retry[3:0]	H'0	R/W	Retry Number for Automatic Transmission * Specify the maximum number of retry when an AL error or non-acknowledge error occurs. When either of errors has reached the specified number, AL or TACK error is reported. H'0: No retry H'1: Retry once. H'2: Retry up to twice. - H'E: Retry up to 14 times. H'F: Setting prohibited.

Note: * After having finished all the processing appointed in Format, the error is reflected.
When there is an error during transfer, IIC transfers it again from a beginning of Format.
Because DMAC does not support this re-try, the RETRY processing using DMAC is not possible.

53.2.15 IIC Automatic Transmission Transmit Time Register 1 (ICATSET1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICATSET1 is an 8-bit register that specifies the number of data of the transmission 1 in the format specified by ICATFR[7:4].

The maximum value which can be specified in this register is 10 when using the ICATD00 to ICATD09 registers, and 256 when using a DMA transfer.

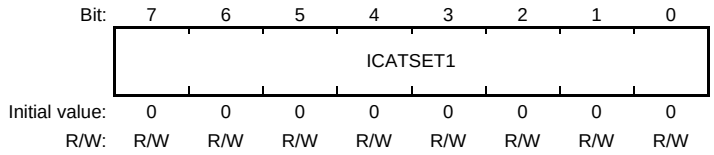
A slave address is also contained in the transmission data.

Specify the values as follows when ICATD00 to ICATD09 are in use.

1-byte transmission ICATSET1[7:0] = H'00
2-byte transmission ICATSET1[7:0] = H'01
10-byte transmission ICATSET1[7:0] = H'09

Specify the size of transmission for a DMA transfer. In the case of DMA, transfer the data to only ICATD00.

256-byte transmission ICATSET1[7:0] = H'FF (maximum)



53.2.16 IIC Automatic Transmission Transmit Time Register 2 (ICATSET2)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICATSET2 is an 8-bit register that specifies the number of data of the transmission 2 in the format specified by ICATFR[7:4].

The maximum number which can be specified in this register is 10 when using the ICATD10 to ICATD19 registers, and 256 when using a DMA transfer.

A slave address is also contained in the transmission data.

Specify the values as follows when ICATD10 to ICATD19 are in use.

1-byte transmission ICATSET2[7:0] = H'00
2-byte transmission ICATSET2[7:0] = H'01
10-byte transmission ICATSET2[7:0] = H'09

Specify the size of transmission for a DMA transfer. In the case of DMA, transfer the data to only ICATD10.

256-byte transmission ICATSET2[7:0] = H'FF (maximum)

Bit:	7	6	5	4	3	2	1	0
	ICATSET2							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

53.2.17 IIC Automatic Transmission Receive Time Register 1 (ICARSET1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICARSET1 is an 8-bit register that specifies the number of data of the reception 1 in the format specified by ICATFR[7:4].

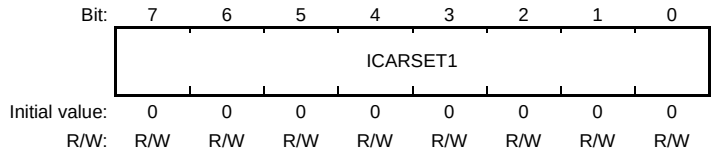
The maximum number which can be specified in this register is 10 when using the ICARD00 to ICARD09 registers, and 256 when using a DMA transfer.

Specify the values as follows when ICARD00 to ICARD09 are in use.

1-byte transmission ICARSET1[7:0] = H'00
2-byte transmission ICARSET1[7:0] = H'01
10-byte transmission ICARSET1[7:0] = H'09

Specify the size of transmission for a DMA transfer. In the case of DMA, read the data only from ICARD00.

256-byte transmission ICARSET1[7:0] = H'FF (maximum)



53.2.18 IIC Automatic Transmission Receive Time Register 2 (ICARSET2)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICARSET2 is an 8-bit register that specifies the number of data of the reception 1 in the format specified by ICATFR[7:4].

The maximum number which can be specified in this register is 10 when using the ICARD10 to ICARTD19 registers, and 256 when using a DMA transfer.

Specify the values as follows when ICARD10 to ICARD19 are in use.

1-byte transmission ICARSET2[7:0] = H'00
2-byte transmission ICARSET2[7:0] = H'01
10-byte transmission ICARSET2[7:0] = H'09

Specify the size of transmission for a DMA transfer. In the case of DMA, read the data only from ICARD10.

256-byte transmission ICARSET2[7:0] = H'FF (maximum)

Bit:	7	6	5	4	3	2	1	0
	ICARSET2							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

53.2.19 IIC Automatic Transmission Transmit Data 00 to 09 (ICATD00 to ICATD09)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICATD00 to ICATD09 are 8-bit registers that are used to store the transmit data of transmission 1.

Bit:	7	6	5	4	3	2	1	0
	ICATD00 to ICATD09							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

53.2.20 IIC Automatic Transmission Transmit Data 10 to 19 (ICATD10 to ICATD19)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICATD10 to ICATD19 are 8-bit registers that are used to store the transmit data of transmission 2.

Bit:	7	6	5	4	3	2	1	0
	ICATD10 to ICATD19							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

53.2.21 IIC Automatic Transmission Receipt Data 00 to 09 (ICARD00 to ICARD09)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICARD00 to ICARD09 are 8-bit registers that are used to store the received data of reception 1.

Bit:	7	6	5	4	3	2	1	0
	ICARD00 to ICARD09							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

53.2.22 IIC Automatic Transmission Receipt Data 10 to 19 (ICARD10 to ICARD19)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

ICARD10 to ICARD19 are 8-bit registers that are used to store the received data of reception 2.

Bit:	7	6	5	4	3	2	1	0
	ICARD10 to ICARD19							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

53.2.23 Transfer Rate

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The IIC transfer rate can be specified by the settings in ICCL and ICCH is based on the module clock.

Table 53.5 lists transfer rate settings, and Figure 53.4 shows SCL waveforms.

Table 53.5 Transfer Rate Maximum Settings Example

	Module clock	ICIC[7] + ICCL	ICIC[6] + ICCH	Transfer Rate*
Standard	8.33 MHz	H'017	H'010	99.21 kHz
	10 MHz	H'01B	H'014	100.00 kHz
	12.5 MHz	H'022	H'01A	99.21 kHz
	16.66 MHz	H'02E	H’023	99.21 kHz
Fast-mode	8.33 MHz	H'005	H'003	378.79 kHz
	10 MHz	H'006	H'004	384.62 kHz
	12.5 MHz	H'008	H'005	390.63 kHz
	16.66 MHz	H'00B	H'007	396.83 kHz

Note: * The transfer rates in above settings are theoretical values. The actual transfer rates are generally smaller than those theoretical values due to the pull-up resistor (Rp) and the capacitance (Cp). However, there is no harm in communication because the actual transfer rates satisfy the I2C bus specifications. (Smaller ICCL and ICCH can increase the actual transfer rates. In this case, though, set ICCL and ICCH to ensure that t_{LOW} and t_{HIGH} are within the specifications.)

Calculation example of ICCL and ICCH:

- Conditions
  Module clock: 16.66 MHz
  IIC transfer rate: 100 kHz
  L/H sample ratio in SCL: L/H = 5/4

- Result
  ICIC[7] + ICCL = ((Module clock/IIC transfer rate) × (L/(L + H)) – 1)/2
  = (((16.66 × 10^6)/(100 × 10^3)) × (5/(5 + 4)) – 1)/2 = 45 = H'2D
  ICIC[6] + ICCH = ((Module clock / IIC transfer rate) × (H / (L + H)) – 5)/2
  = (((16.66 × 10^6)/(100 × 10^3)) × (4/(5 + 4)) – 5)/2 = 34 = H'22

53.3.1 I2C Bus Data Format

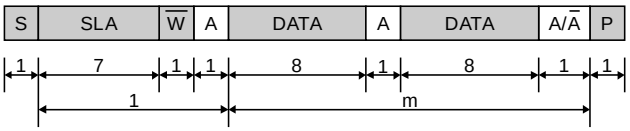
The I2C bus is based on protocol, which contains the slave address, data, and an acknowledge bit. These are shown in Figure 53.5. The first frame following a START condition always consists of 8 bits.

The symbols used in Figure 53.5 are explained in Table 53.6.

Table 53.6 I2C Bus Data Format Symbols

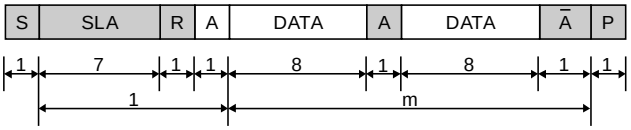
Symbol	Description
S	START condition. The master device drives SDA from high to low while SCL is high.
Sr	Repeated START condition. The master device drives SDA from high to low while SCL is high.
SLA	Slave address. The master device selects a slave device.
R/$\overline{W}$	Indicates the direction of data transfer: from the slave device to the master device when R/$\overline{W}$ is 1, or from the master device to the slave device when R/$\overline{W}$ is 0.
A	Acknowledge. The receiving device (the slave device in master transmit mode, or the master device in master receive mode) drives SDA low to acknowledge a transfer.
DATA	Transmitted or received data. The bit length is 8 bits.
P	STOP condition. The master device drives SDA from low to high while SCL is high.

(a) Master transmission mode (7-bit address format)



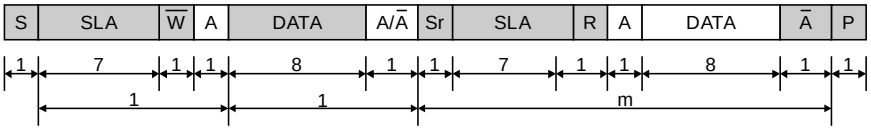
Number of transmission frames (m = 1~)

(b) Master reception mode (7-bit address format)



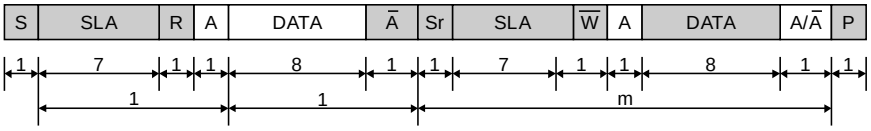
Number of transmission frames (m = 1~)

(c) The direction is converted from transmission to reception in master mode (7-bit address compound format)



Number of transmission frames (m = 1~)

(d) The direction is converted from reception to transmission in master mode (7-bit address compound format)



Number of transmission frames (m = 1~)

S: START condition
P: STOP condition
Sr: Repeated START condition
R/W: Direction of data transfer
A: Receipt acknowledgement
A: Data non-receipt acknowledgement

Master to slave

Slave to master

Figure 53.5 I2C Bus Data Formats (7-Bit Address Format)

53.3.2 Master Transmit Operation (Using WAIT Function)

In master transmit mode, the master device outputs the transmission clock and transmission data, and receives the acknowledge signal after receiving data. The transmission procedure and operations are described below.

1. Write ICCR.ICE to 0 to reset the IIC module. (Write ICCR = H'01)
2. Set ICCR.ICE to activate the IIC module. (Write H'81 to ICCR)
3. Set ICIC[7]+ICCL, ICIC[6]+ICCH, and ICIC[3:0], according to the operating mode.
4. Write H'94 to ICCR to issue the START condition. The DTE bit in ICSR is then set to 1.
5. Wait for a DTE interrupt or until ICSR.DTE becomes 1.
6. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1.
   And write transmission data (slave address and write bit) to ICDR. The ICSR.DTE bit is then automatically cleared. Data transmission starts after data is sent to the internal transmit buffer.
7. Wait for a WAIT interrupt or until ICSR.WAIT becomes 1.
8. If more transmission data remains, write transmission data (ex. register address or data) to ICDR. And clear ICSR.WAIT to exit from the WAIT status. After exiting from the WAIT state, go back to step 7.
9. If no more transmission data remains, write H'90 to ICCR to issue the STOP condition.
   And clear ICSR.WAIT to exit from the WAIT status. After exiting, go to step 10.
10. Wait until ICSR.BUSY is cleared.
11. Clear ICCR.ICE to 0 to reset the IIC module. (Write ICIC = H'01)

Figure 53.6 shows the flowchart of the master transmission procedure.

By repeating steps 7 and 8, data can be transmitted consequently.

A non-acknowledge interrupt occurs if the received acknowledge signal is 1 (TACK = 1). If the received acknowledge bit is 1, it is recommended to STOP transmission after the STOP condition is generated. Refer to section 53.3.11, Non-Acknowledge Operation, for the stop method.

To change the transmission mode to the receive mode, write H'81 to ICCR, instead of generating the STOP condition in step 9.

To generate a repeated START condition, write H'94 to ICCR, instead of generating the STOP condition in step 9.

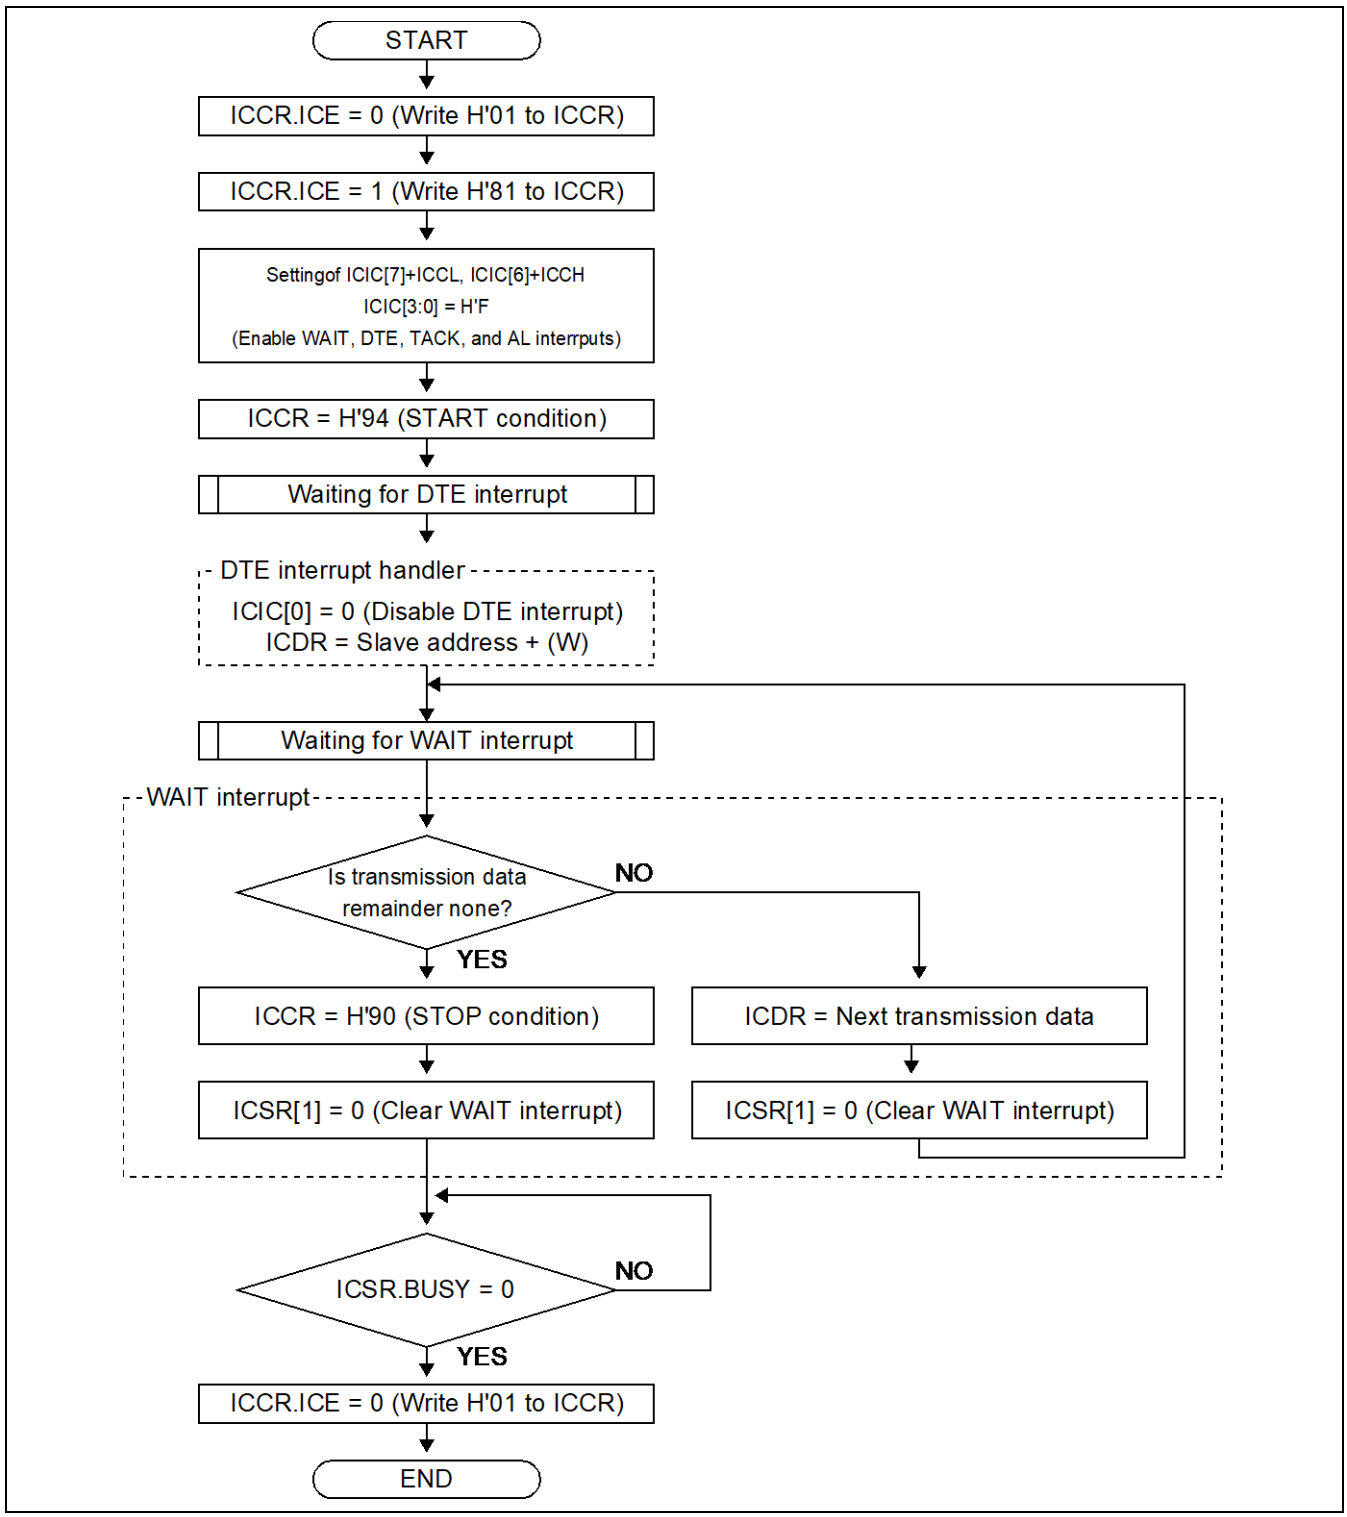


Figure 53.6 Example Flow for Transmission (a) Master Transmission Mode (Using WAIT Function)

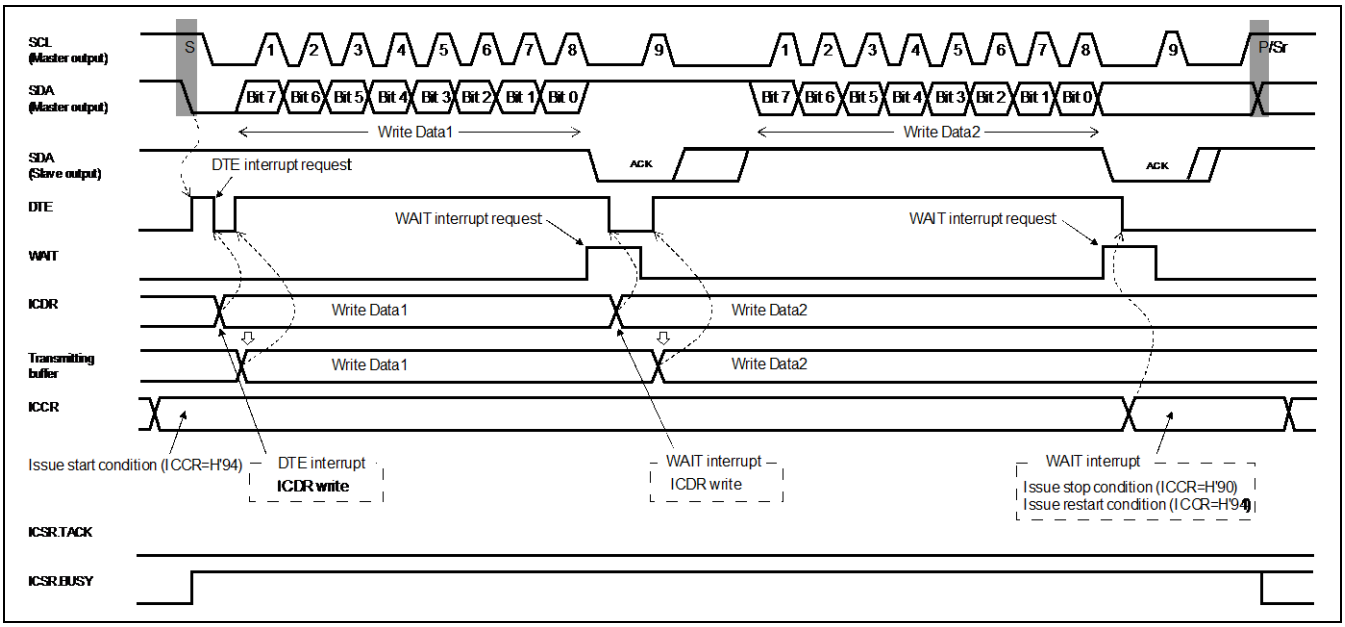

Figure 53.7 Example for Transmission (a) Master Transmission Mode (Using WAIT Function)

53.3.3 Master Receive Operation (Using WAIT Function)

In master receive mode, the master device outputs the receive clock, and returns an acknowledge signal after the slave device transmits data. The reception procedure and operations in master receive mode are described below.

(1) When two or more bytes of data are received continuously

1. Write ICCR.ICE to 0 to reset the IIC module. (Write ICCR = H'01)
2. Set ICCR.ICE to activate the IIC module. (Write H'81 to ICCR)
3. Set ICIC[7]+ICCL, ICIC[6]+ICCH, and ICIC[3:0], according to the operating mode.
4. Write H'94 to ICCR to issue the START condition. The DTE bit in ICSR is then set to 1.
5. Wait for a DTE interrupt.
6. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1.
   And write transmission data (slave address and write bit) to ICDR. The ICSR.DTE bit is then automatically cleared. Data transmission starts after data is sent to the internal transmit buffer.
7. Wait for a WAIT interrupt.
8. If more transmission data remains, write transmission data (ex. register address) to ICDR. And clear ICSR.WAIT to exit from the WAIT status. After exiting from the WAIT status, go back to step 7.
9. If no more transmission data remains, clear ICSR.WAIT to exit from the WAIT status. After exiting, go to step 10.
10. Write H'94 to ICCR to issue the repeated START condition, and set ICIC.DTEE to enable a DTE interrupt.
11. Wait for a DTE interrupt.
12. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1. And write transmission data (slave address and read bit) to ICDR. The ICSR.DTE bit is then automatically cleared. Data transmission starts after data is sent to the internal transmit buffer.
13. Wait for a WAIT interrupt.
14. Write H'81 to ICCR to changing the transmission mode to the receive mode. And clear ICSR.WAIT to exit from the WAIT status.
15. Wait for a WAIT interrupt.
16. If this interrupt is not final reception data for I2C bus, execute below action.
    - Read ICDR to get reception data, then ICSR.DTE is cleared. *1
    - Clear ICSR.WAIT to exit from the WAIT status.

    *1 This reading result is previous receiving result. So, if this WAIT interruption is 1st time WAIT of reading phase,skip this ICDR reading.
17. If this interrupt is final reception data for I2C bus, execute below action.
    - Read ICDR to get reception data, then ICSR.DTE is cleared. *2
    - Set H'C0 to ICCR to make STOP condition.
    - Set ICIC.DTEE to enable a DTE interrupt.
    - Clear ICSR.WAIT to exit from the WAIT status.

    *2 This read result is previous one from final reception data.
18. Wait for a DTE interrupt.
19. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1.
    Read data from ICDR. The ICSR.DTE bit is then automatically cleared. *3

    *3 This reading result is final reception data
20. Wait until ICSR.BUSY is cleared.
21. Clear ICCR.ICE to 0 to reset the IIC module. (Write ICCR = H'01)

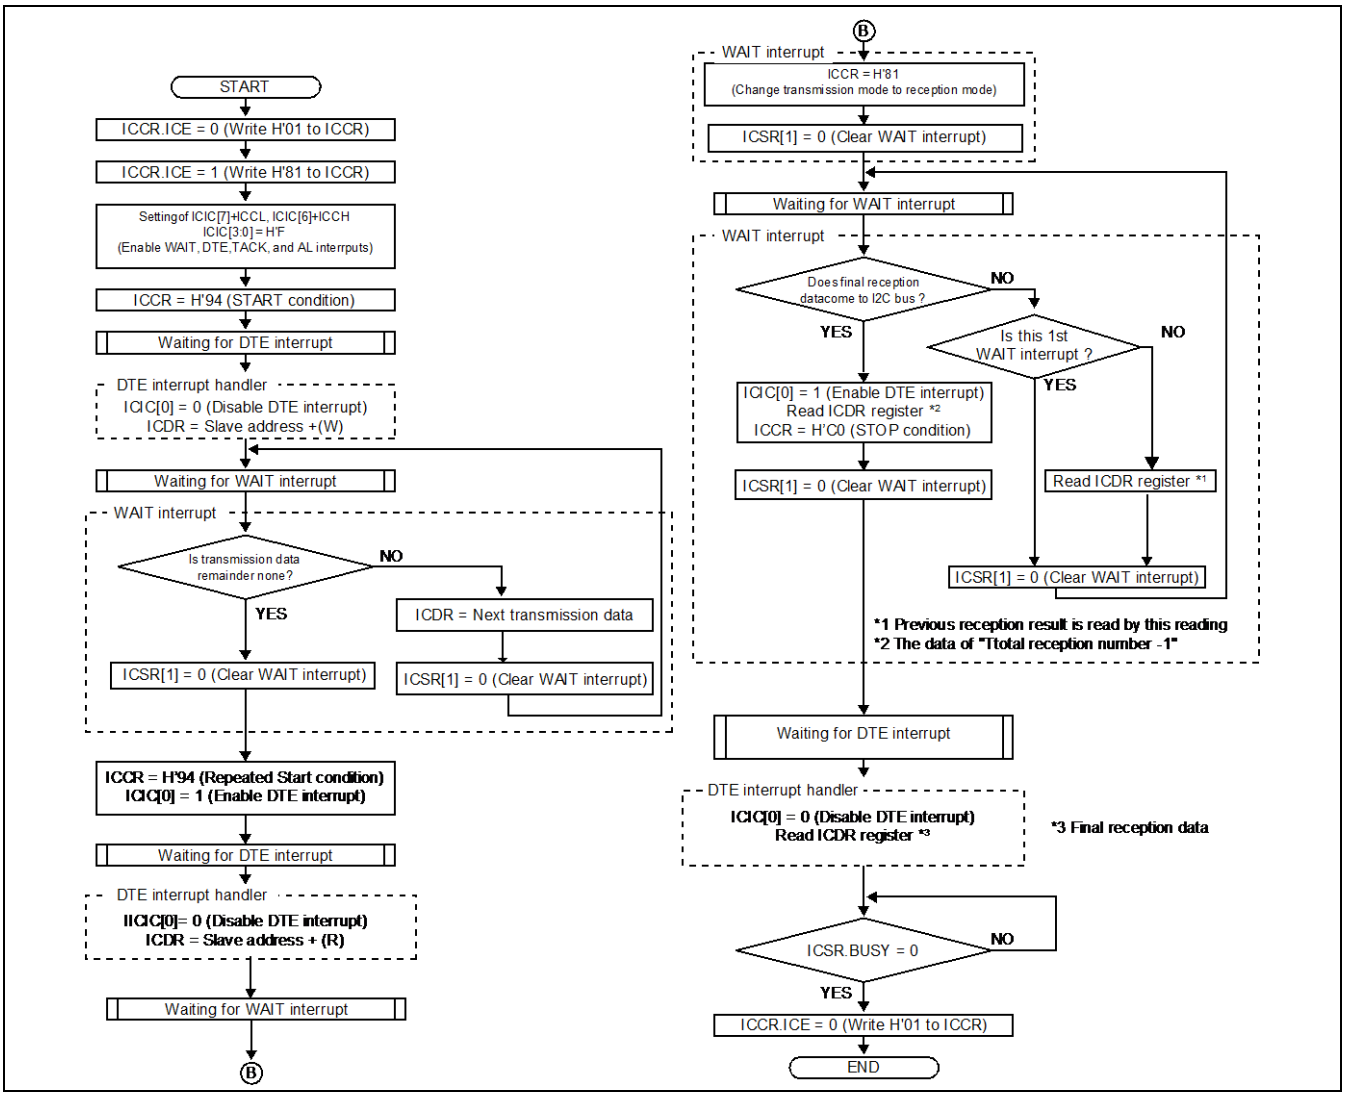

Figure 53.8 Example Flow for n-Byte Write/n-Byte Read (c) The Direction is Converted from Transmission to Reception (Using WAIT Function)

Figure 53.8 is the flow of this.

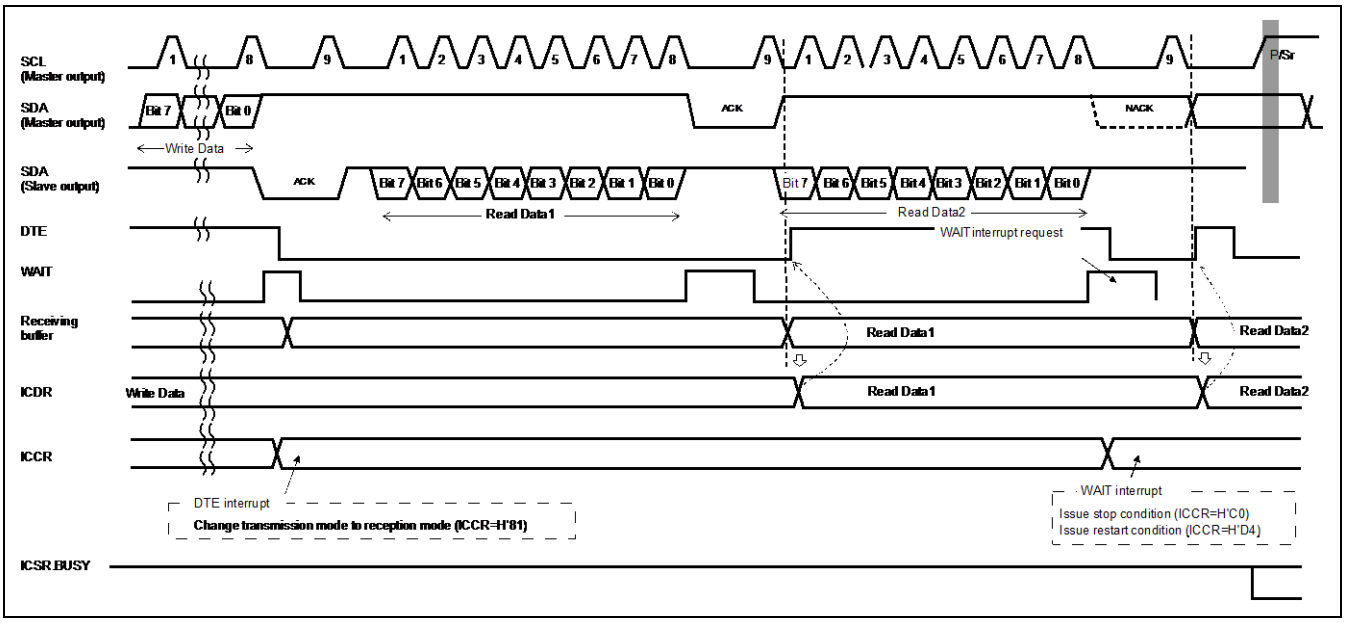

Figure 53.9 Example for Read (c) Master Reception Mode (Using WAIT Function)

(2) When only one byte of data is received

When only one byte data is received, use a WAIT interrupt to issue the STOP or repeated START condition by writing to ICCR.

1. Write ICCR.ICE to 0 to reset the IIC module. (Write ICCR = H'01)
2. Set ICCR.ICE to activate the IIC module. (Write H'81 to ICCR)
3. Set ICIC[7]+ICCL, ICIC[6]+ICCH, and ICIC[3:0], according to the operating mode.
4. Write H'94 to ICCR to issue the START condition. The DTE bit in ICSR is then set to 1.
5. Wait for a DTE interrupt.
6. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1.
   And write transmission data (slave address and write bit) to ICDR. The ICSR.DTE bit is then automatically cleared. Data transmission starts after data is sent to the internal transmit buffer.
7. Wait for a WAIT interrupt.
8. Write H'81 to ICCR for changing the transmission mode to the receive mode. And clear ICSR.WAIT to exit from the WAIT status.
9. Wait for a WAIT interrupt.
10. Set ICCR to H'C0 for the STOP condition. Set ICIC.DTEE to enable a DTE interrupt, then clear ICSR.WAIT to exit from the WAIT status.
11. Wait for a DTE interrupt.
12. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1. Read data from ICDR. The ICSR.DTE bit is then automatically cleared.
13. Wait until ICSR.BUSY is cleared.
14. Clear ICCR.ICE to 0 to reset the IIC module. (Write ICIC = H'01)

Figure 53.10 shows the flowchart of 1-byte reception.

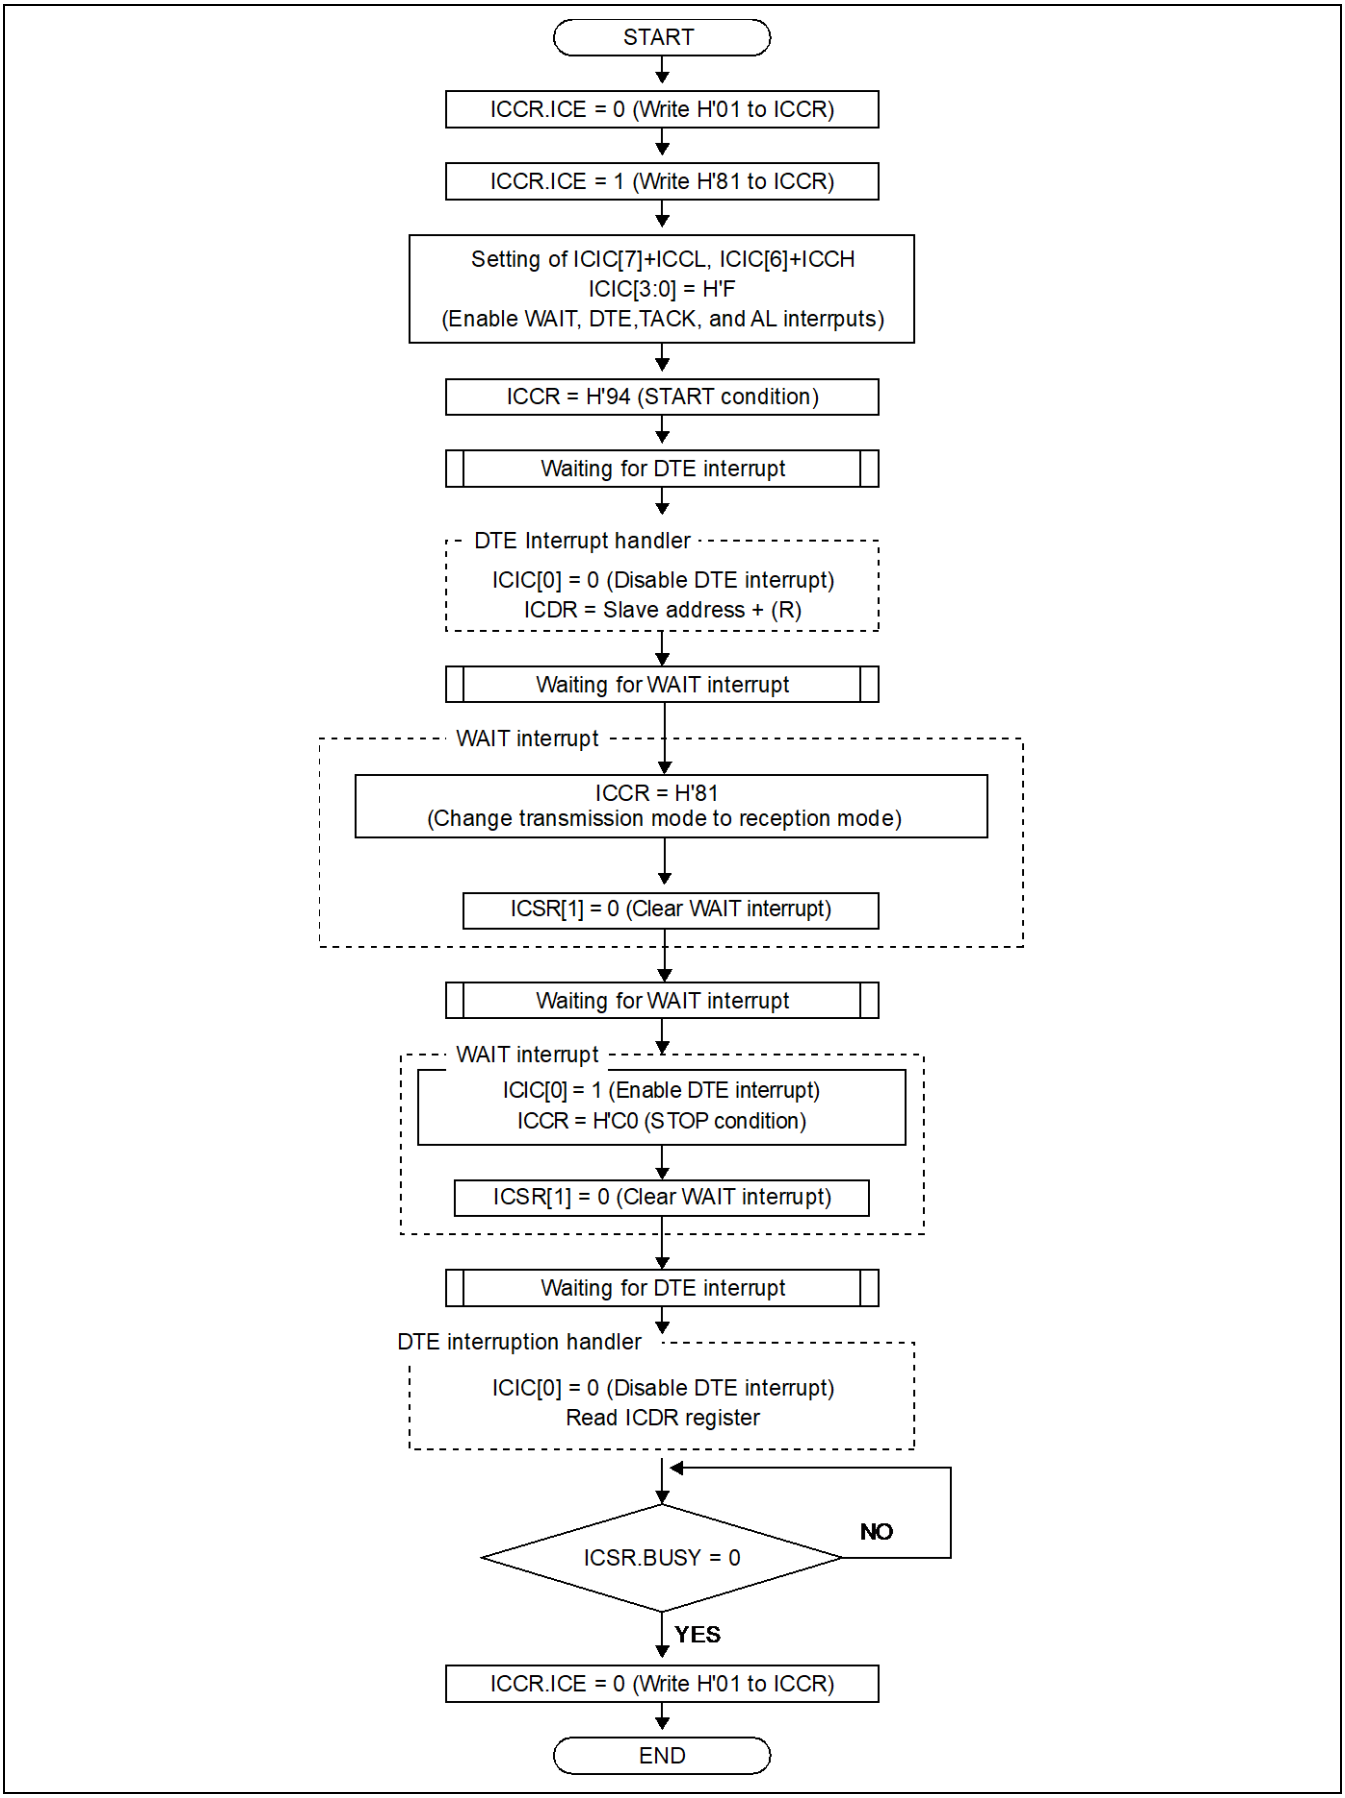

Figure 53.10 Example of Software Flow for 1-Byte Write/1-Byte Read (Using WAIT Function)

53.3.4 IIC Continuous Transmission by DMA

In DMA transmit mode, the IIC module asserts a DMA request to the DMAC. The received DMAC writes data to ICDR, and returns DMARACK to the IIC module. The transmission procedure and operations are described below.

1. Write ICCR.ICE to 0 to reset the IIC module. (Write ICCR = H'01)
2. Set ICCR.ICE to activate the IIC module. (Write H'81 to ICCR)
3. Set ICIC[7]+ICCL, ICIC[6]+ICCH, and ICIC[3:0], and ICIC[5], according to the operating mode.
4. Set DMAC including number of transmission data.
5. Write H'94 to ICCR to issue the START condition.
6. DMAC writes the transmit data to ICDR from the memory space specified by DMAC register until transmission finishes.
7. Wait for a transfer end interrupt from DMAC.
8. Clear ICIC.TDMA to disable DMA transmission after a transfer end interrupt is asserted.
9. Wait for a WAIT interrupt.
10. Clear ICSR.WAIT to exit from the WAIT status. After the acknowledge clock, the STOP condition is generated and operation is stopped.
11. Wait until ICSR.BUSY is cleared.
12. Clear ICCR.ICE to 0 to reset the IIC module. (Write ICIC = H'01)

Figure 53.11 shows the flow of data transmission with DMA.

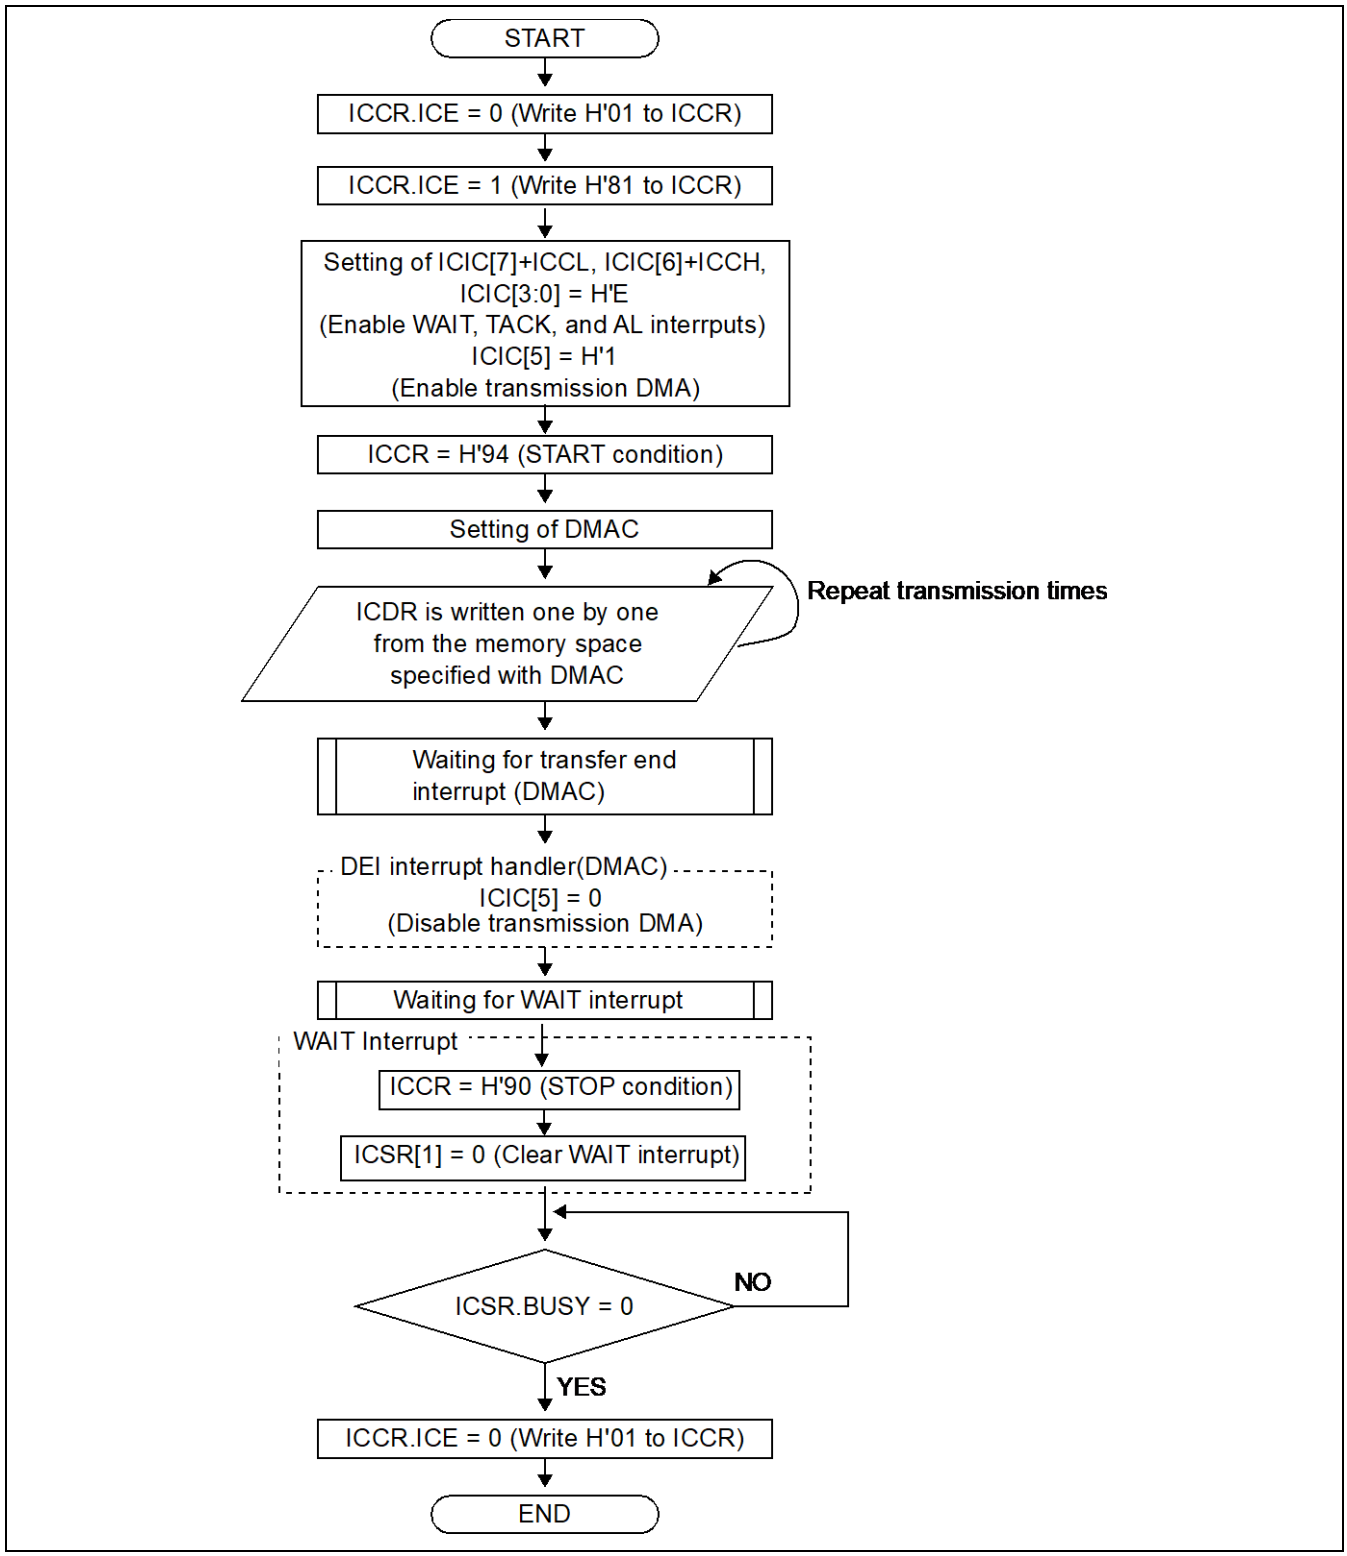

Figure 53.11 Example Flow for Transmission (a) Master Transmission Mode (Using WAIT and DMA Function)

53.3.5 IIC Continuous Receive by DMA

In DMA receive mode, the master device asserts DMA request to DMAC. The DMAC that received the request reads the received data from ICDR, and returns DMARACK to the IIC module. In case of receiving data continuously by DMA, 4 bytes or more receive data is required. The reception procedure and operations are described below.

1. Write ICCR.ICE to 0 to reset the IIC module. (Write ICCR = H'01)
2. Set ICCR.ICE to activate the IIC module. (Write H'81 to ICCR)
3. Set ICIC[7] + ICCL, ICIC[6]+ICCH, and ICIC[3:0], according to the operating mode.
4. Write H'94 to ICCR to issue the START condition. The DTE bit in ICSR is then set to 1.
5. Wait for a DTE interrupt.
6. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE becomes 1.
   And write transmission data (slave address and write bit) to ICDR. The ICSR.DTE bit is then automatically cleared. Data transmission starts after data is sent to the internal transmit buffer.
7. Wait for a WAIT interrupt.
8. If one or more transmission data remains, write transmission data (ex. register address) to ICDR. And clear ICSR.WAIT to exit from the WAIT status. After exiting from the WAIT state, go back to step 7.
9. If no more transmission data remains, clear ICSR.WAIT to exit from the WAIT status. After exiting, go to step 10.
10. Write H'94 to ICCR to issue the repeated START condition, and set ICIC.DTEE to enable a DTE interrupt,
11. Wait for a DTE interrupt.
12. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1. And write transmission data (slave address and read bit) to ICDR. The ICSR.DTE is then automatically cleared. Data transmission starts after data is sent to the internal transmit buffer.
13. Wait for a WAIT interrupt.
12. Write H'81 to ICCR for changing the transmission mode to the receive mode. And clear ICSR.WAIT to exit from the WAIT status.
14. DMAC reads the received data from ICDR, and stores them into the destination area until receiving data is finished.
15. Wait for a transfer end interrupt of DMAC.
16. Clear ICIC.RDMA to disable the received DMA.
17. Wait for a WAIT interrupt.
20. Read data from ICDR. And ICCR = H'C0 for the STOP condition.
21. Set ICIC.DTEE to enable a DTE interrupt. And clear ICSR.WAIT to exit from the WAIT status.
22. Wait for a DTE interrupt.
23. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1. Read data from ICDR. The ICSR.DTE bit is then automatically cleared.
24. Wait until CSR.BUSY is cleared.
25. Clear ICCR.ICE to 0 to reset the IIC module. (Write ICCR = H'01)

Notice: DMA reception is allowed that reception total times is 3 or more.

Figure 53.12 is the flow of this.

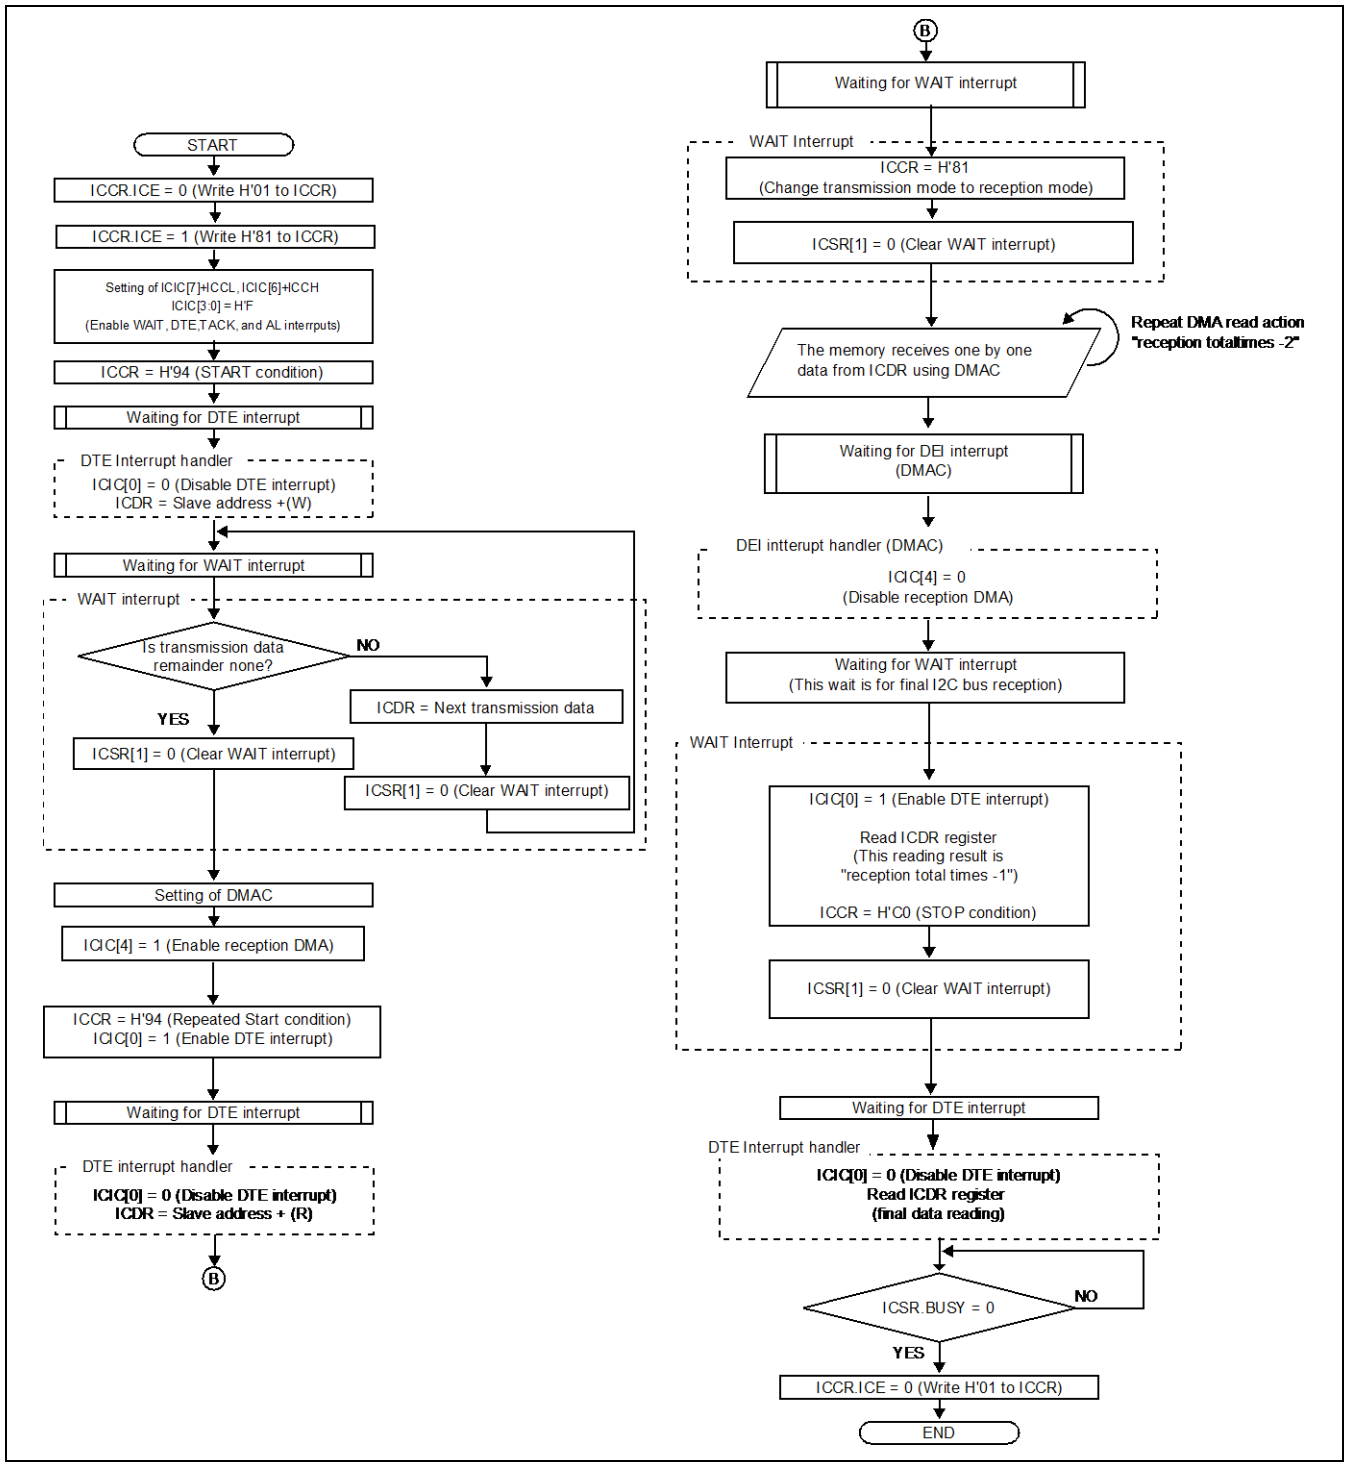

Figure 53.12 Example Flow for n-Byte Write/n-Byte Read (c) The Direction is Converted From Transmission to Reception (Using WAIT and DMA Function)

53.3.6 Automatic transfer mode

An automatic transfer mode can automatically carry out transfer of IIC by appointing ICATFR.Format.

1. Write ICCR.ICE to 0 to reset the IIC module. (Write ICCR = H'01)
2. Set ICCR.ICE to activate the IIC module. (Write H'81 to ICCR)
3. Set ICIC[7] + ICCL, ICIC[6] + ICCH, ICIC[1] = 1, ICACE, and ICIMSK.
4. Set transfer format to ICATFR.Format. And set the number of the transfer and data like Table 53.7.
5. Write H’80 in the ICSTART to start IIC transfer.
6. Wait for a AEND interrupt.
7. Clear ICINT.AEND to disable a AEND interrupt.
8. Because data are stored away at the time of reception by ICARD**, begin to read data. (** = 00 to 09, 10 to 19)
9. Clear ICCR.ICE to 0 to reset the IIC module. (Write ICCR = H'01)

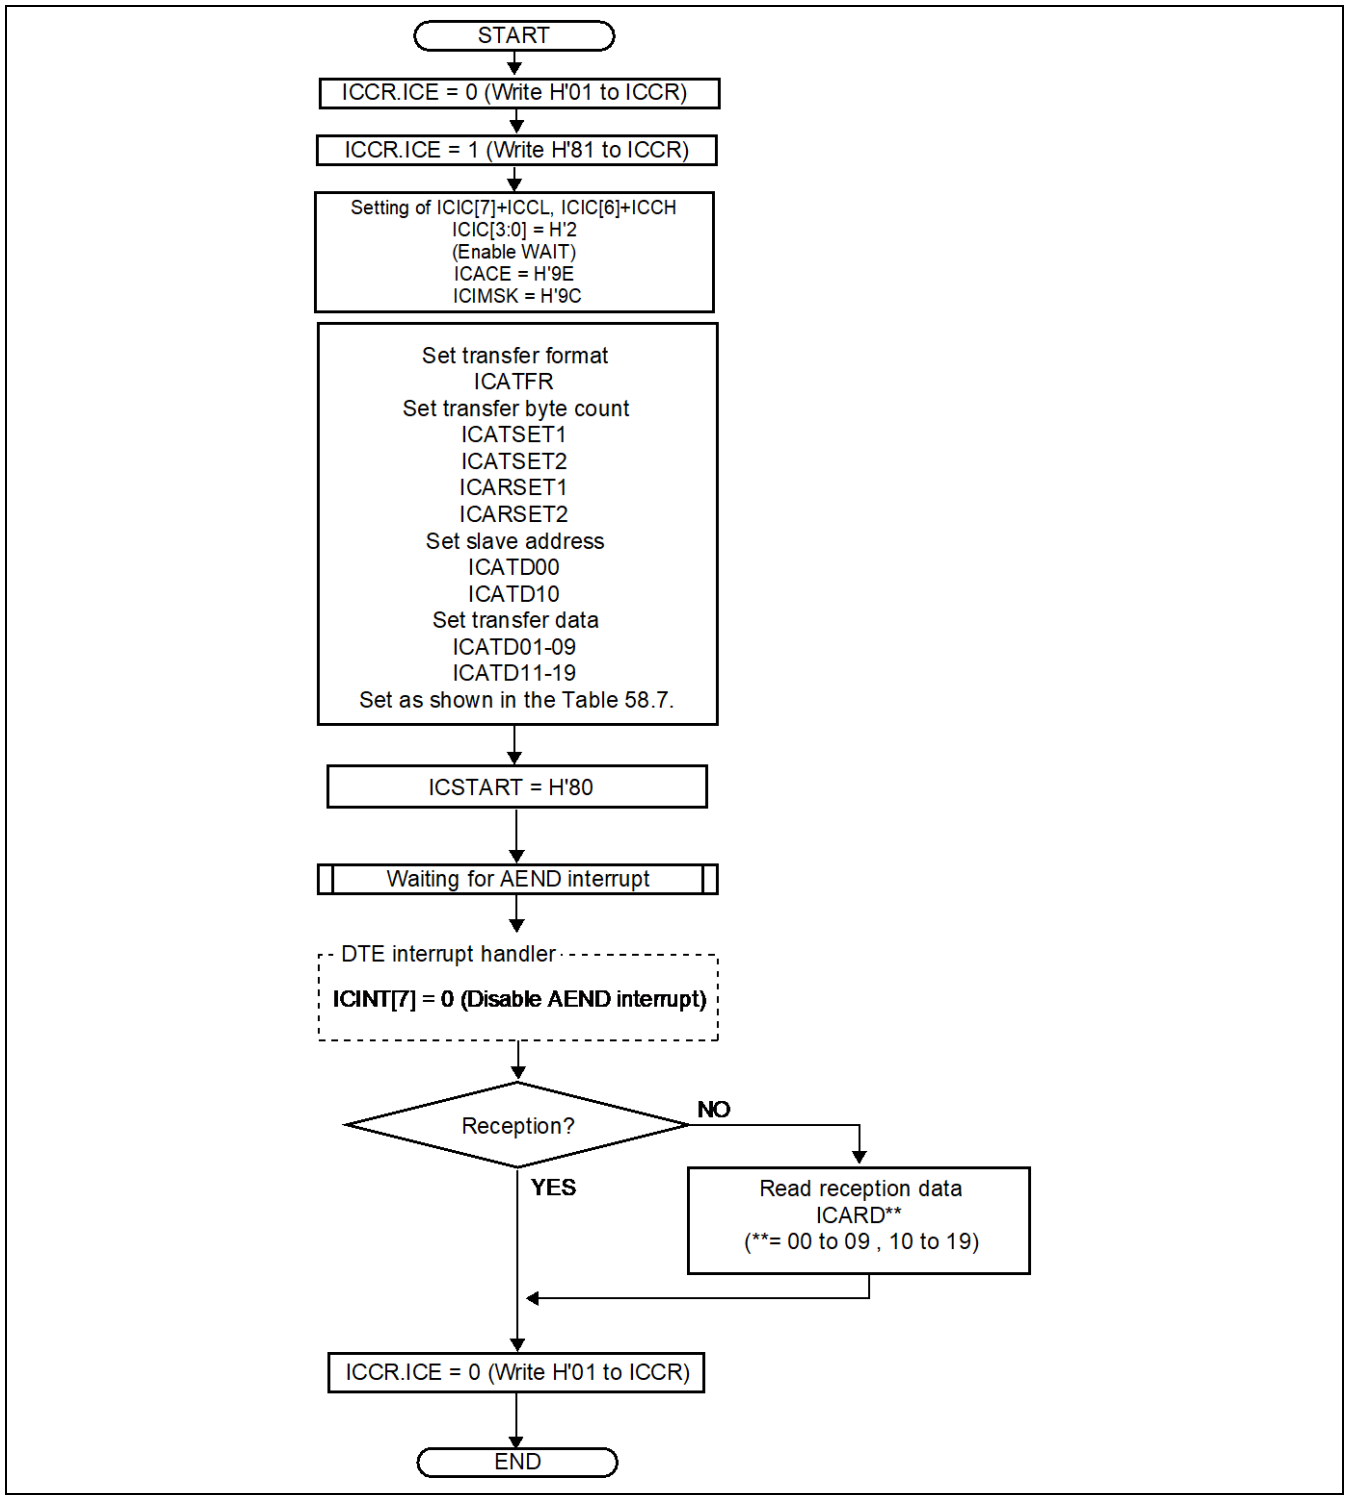

Figure 53.13 Example Flow for n-Byte Write/n-Byte Read (c) The Direction is Converted From Transmission to Reception (Using WAIT and DMA Function)

Table 53.7 Register setting list according to Format (without DMA)

Format	0000	0001	0010	0011	0100	0101

53.3.7 Automatic transfer mode by DMA

An automatic transfer mode by DMA can automatically carry out transfer of IIC by appointing ICATFR.Format.

1. Write ICCR.ICE to 0 to reset the IIC module. (Write ICCR = H'01)
2. Set ICCR.ICE to activate the IIC module. (Write H'81 to ICCR)
3. Set ICIC[7] + ICCL, ICIC[6] + ICCH, ICIC[1] = 1, ICACE, and ICIMSK.
4. Set transfer format to ICATFR.Format. And set the number of the transfer and data like Table 53.8.
5. Write H’81 or H’82 or H’83 in the ICSTART to start IIC transfer.
6. When transmitting, ICATD00 is written one by one from the memory space specified by DMAC. When receiving, the memory receives one by one from ICARD00 using DMAC.
6. Wait for a AEND interrupt.
7. Clear ICINT.AEND to disable a AEND interrupt.
8. Clear ICCR.ICE to 0 to reset the IIC module. (Write ICCR = H'01)

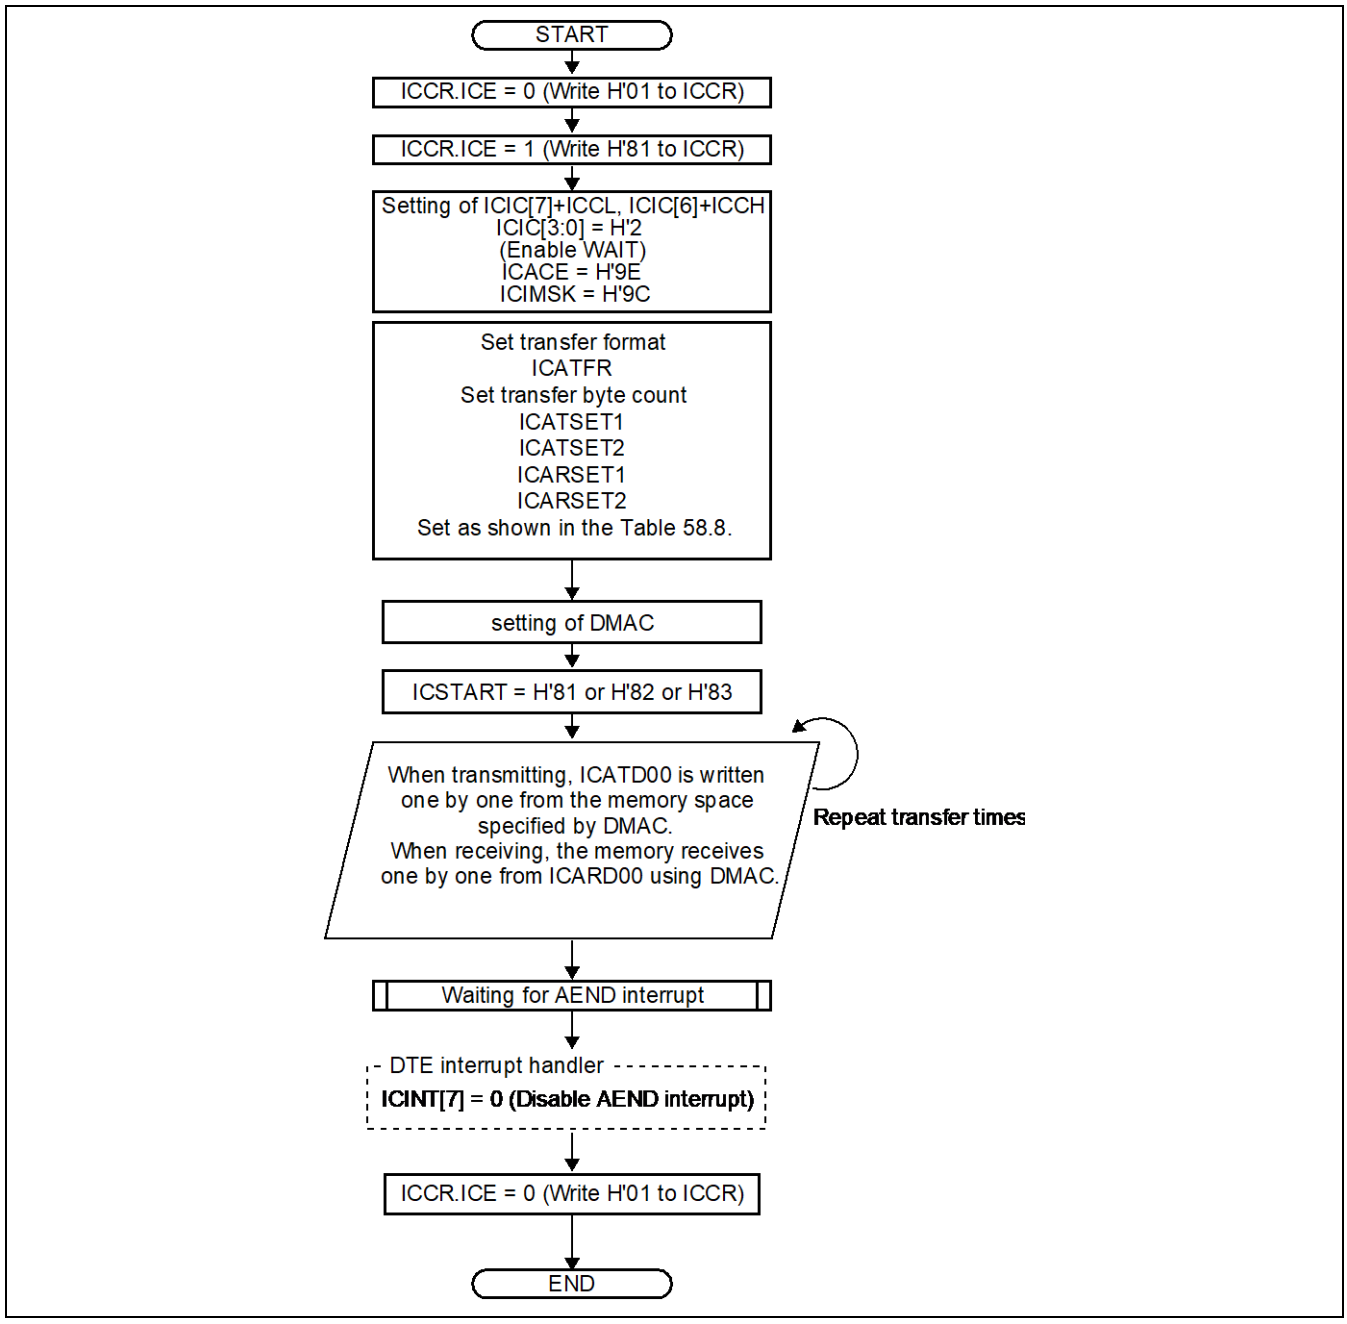

Figure 53.14 Example Flow for n-Byte Write/n-Byte Read (c) The Direction is Converted From Transmission to Reception (Using WAIT and DMA Function)

53.3.8 Synchronizing SCL Line

When the SCL line state is changed from high to low, connected devices may start counting in the low period. When the clock of a device becomes low, the device holds the SCL line low until its clock becomes high (see Figure 53.15). However, even if the clock of the device is changed from low to high, the SCL line state does not change when clocks of other devices are in the low period. Therefore, the low period of the SCL line is determined by the device with the longest low period. At this time, a device with the short low period waits in the high state.

When all devices complete the low period, the clock line is open and in the high state. Therefore, the device clock and SCL line are in the same state, and start counting both of pulses in high level period. The SCL line enters the low state again by the device that has first completed the high period.

The low period is determined by the device with the longest low period, and the high period is determined by the device with the shortest high period. The SCL line is then synchronized.

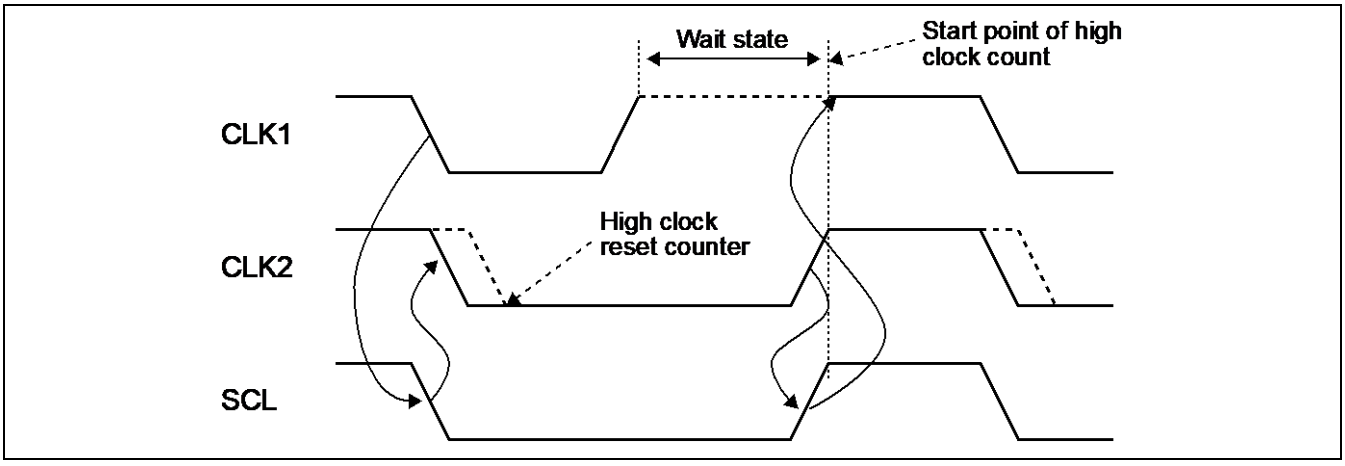

Figure 53.15 Synchronizing SCL Line

53.3.9 Noise Canceller

For removing spike noise on the SCL and SDA line, the noise canceller circuit is implemented. Figure 53.16 shows a block diagram of the noise canceller circuit.

The noise canceller consists of two cascaded FFs and a match detector. The SCL/SDA signal is sampled by FFs with module clock, and recognize that SCL/SDA signals are toggled if both of two FF's outputs have toggled. If only one output of FFs have toggled, previously latched value is output to the internal logic.

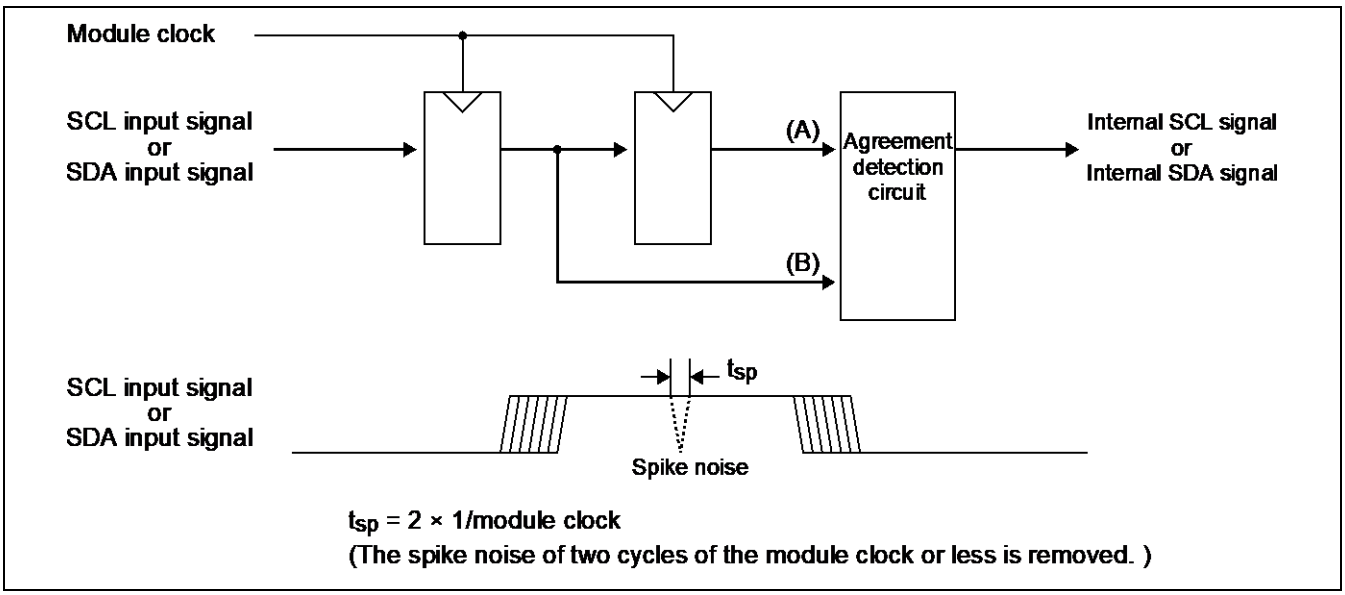

Figure 53.16 Block Diagram of Noise Canceller

53.3.10 Arbitration Lost Operation

This module can assert an arbitration lost interrupt request when bus conflict is detected.

Interrupt assert conditions are described below.

(1) When the level of the data being received changes during counting of the period at high level for the SCL clock.
(2) When the level on the SCL line becomes low, while the SCL clock is controlled by this module, and not driven by this module.
(3) When this module detects the START condition before issuing the START condition.
(This AL case does not detect it in Automatic Mode.)
(4) When the SDA data driven by this module and monitored SDA signals are not equal.

In case of conditions above, the AL bit in ICSR is set to 1 and an arbitration lost interrupt is asserted.

When a loss of arbitration is detected in transmission mode, the SDA line is released right now. For SCL clock line, clocks kept be output until the end of the frame including acknowledge cycle and released. Figure 53.17 shows an example of arbitration lost interrupt operation timing.

In case of conditions below, the AL bit in ICSR is set to 0.

- When data is written to ICDR (in transmission mode), or data is read (in receive mode) while DTE = 1.
- When 0 is written to the AL bit in ICSR.

When arbitration is lost by the acknowledge bit, hold SCL and SDA at a low level.

ICE reset must be performed by the software to release the bus.

Do not clear the ALE bit to 0 while the AL bit is 1. It is recommended to set ALE bit only before the start of communication.

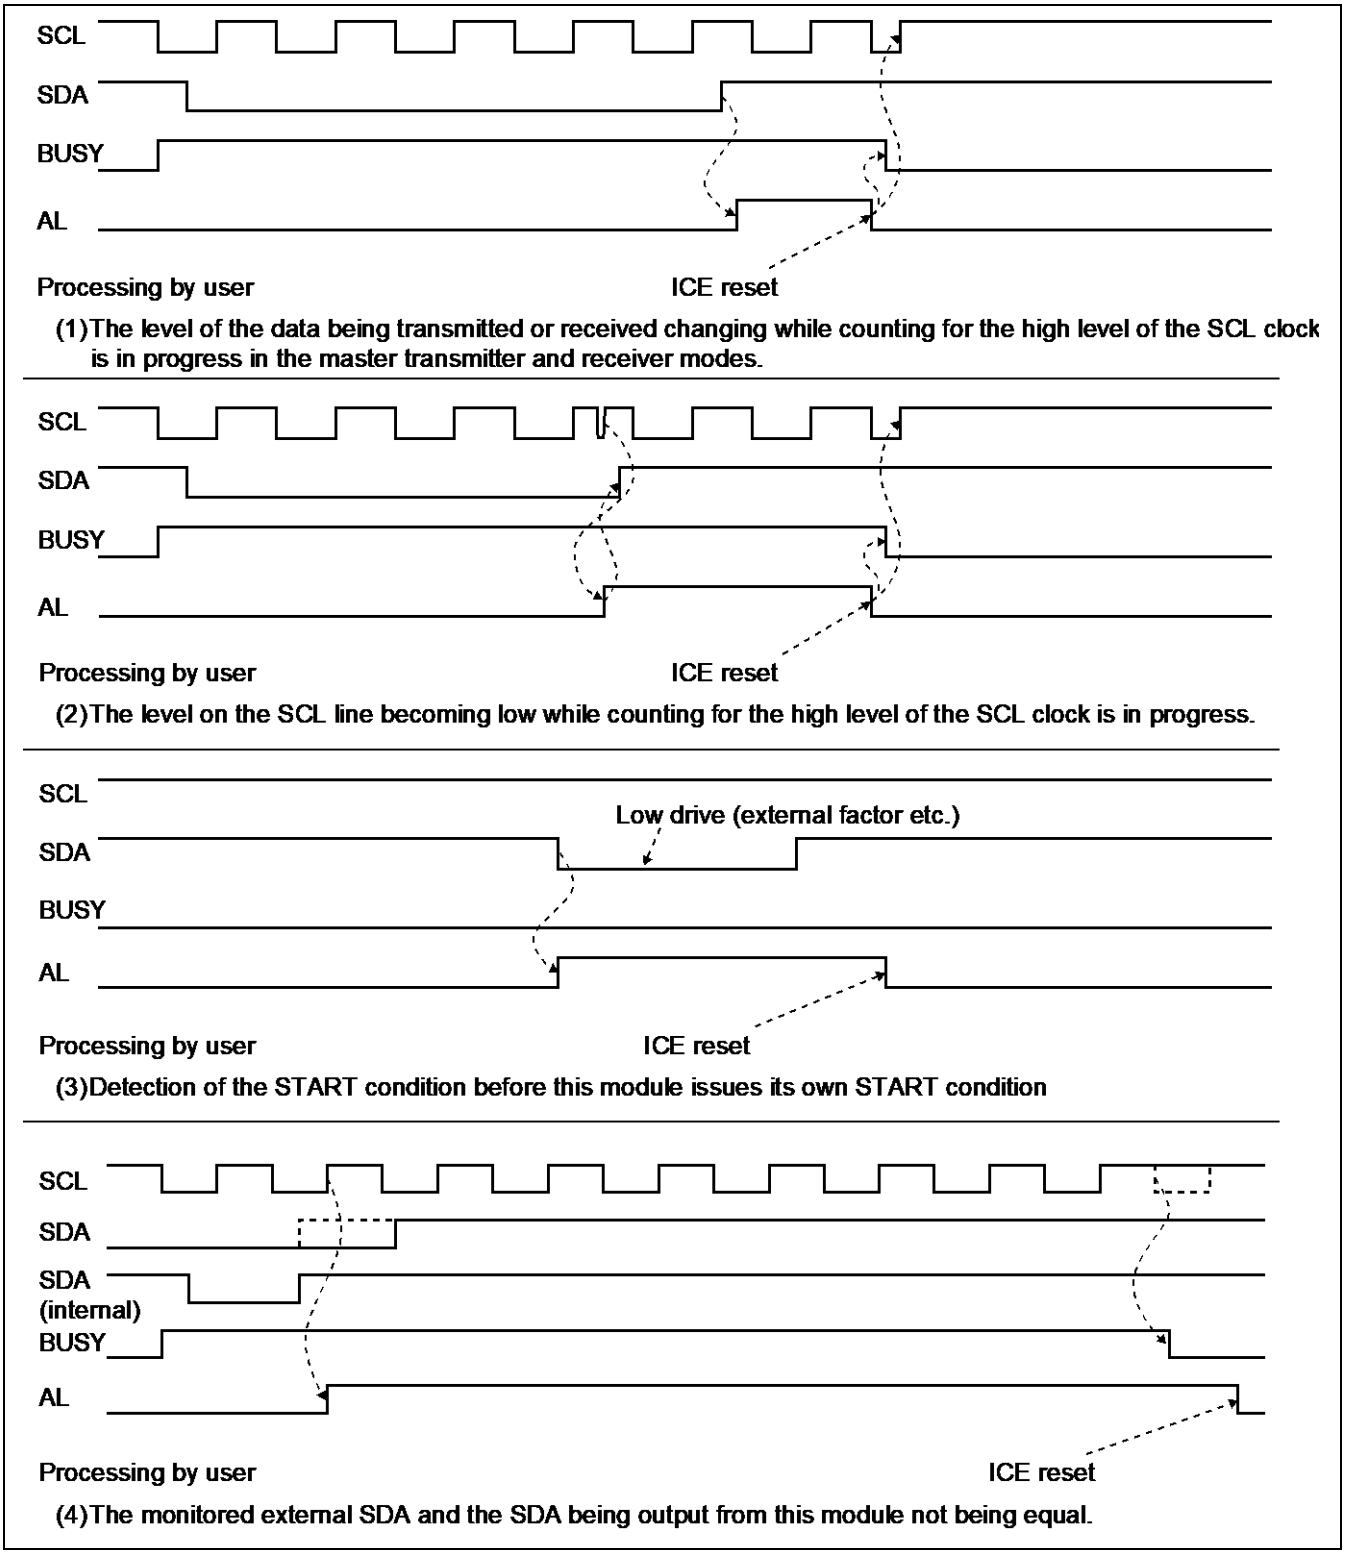

Figure 53.17 Example of Arbitration Lost Interrupt Operation Timing

53.3.11 Non-Acknowledge Operation

This module can assert a non-acknowledge interrupt when there is no acknowledge from the receiving device in transmission.

An acknowledge bit from the receiving device is stored in the TACK bit in ICSR. A non-acknowledge interrupt is asserted if the TACK bit is set to 1 when TACKE in ICIC is 1.

Generating a STOP condition after a non-acknowledge interrupt is recommended. The STOP condition should be generated even if the ICCR is already set for further processing (for example, generating the repeated START condition). Figure 53.19 shows an example processing of generating the STOP condition when non-acknowledge interrupt is asserted.

Do not set the TACKE bit in ICIC if processing for non-acknowledgement is not required.

Do not clear TACKE bit to 0 while TACK bit is 1. It is recommended to set TACKE bit only before start of communication.

Figure 53.18 shows an example of non-acknowledge operation timing.

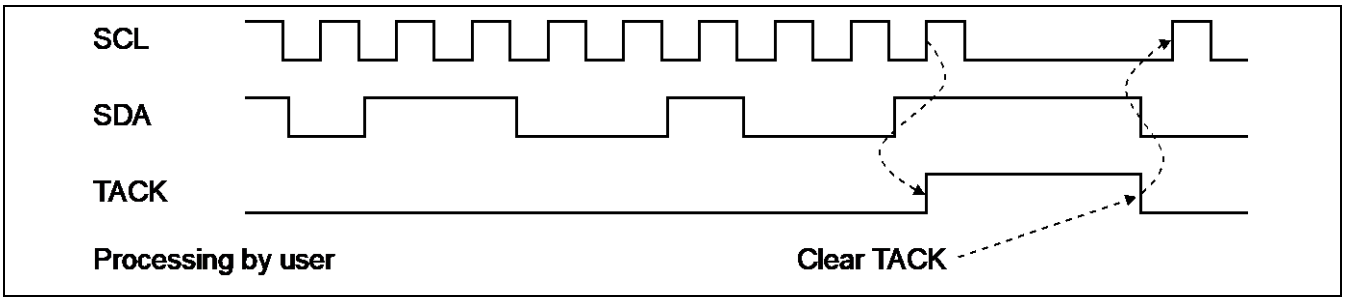

Figure 53.18 Example of Non-Acknowledge Operation Timing

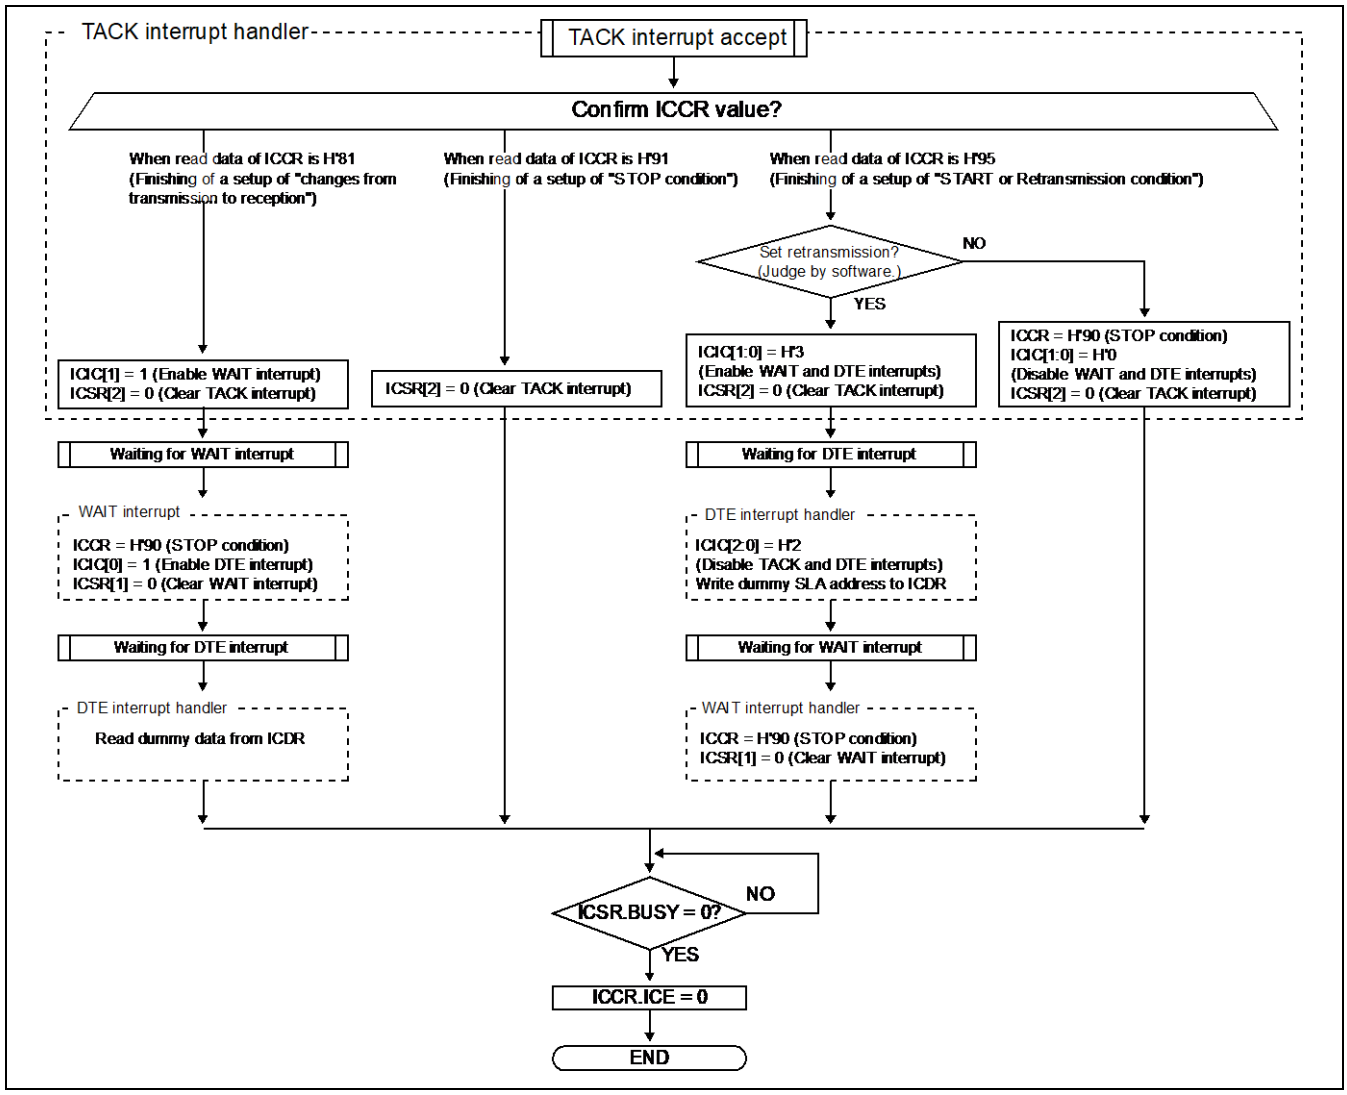

Figure 53.19 Generating a STOP Condition When Non-Acknowledge Interrupt Asserted

53.3.12 Wait Operation

This module can go into the wait state by assert of WAIT bit in ICSR. WAIT is set to 1 at the falling edge of the eighth transmit clock while this module is operating in master mode.

After that, the transmit clock is fixed to low until the WAIT bit is cleared to 0.

When the WAIT bit is cleared to 0, the ninth transmit clock is generated and the state is recovered from the wait state.

In case of using WAIT interrupt, data transfer by the I2C bus is suspended from the time WAIT is asserted by the hardware until the time WAIT is cleared by software.

It is recommended to set the WAITE bit only before the start of communication.

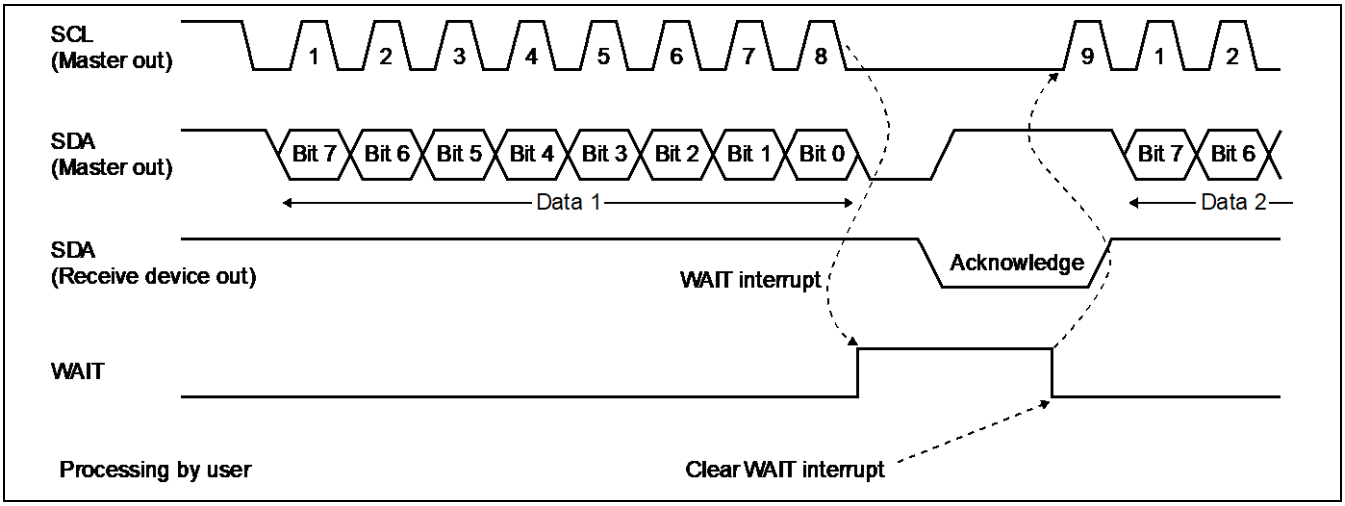

Figure 53.20 Example of Wait Operation Timing

53.4 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

(1) Arbitration lost

When a loss of arbitration is detected, the I2C bus may not be released soon depending on the status of slave devices. Reset the IIC module by the ICE bit in ICCR register when re-starting data transfer after a loss of arbitration is detected.

(2) ICE reset

When asserting ICE reset during data transfer, SCL clock is stopped immediately and the bus may not be released depending on the status of the slave device.

(3) Processing for stop condition generation

When data is transmitted or received after a STOP condition is generated, it may not be possible to generate a STOP condition hereafter. Initialize all registers in the IIC module by clearing the ICE bit in ICCR to 0, after a STOP condition has been generated or before making settings to trigger data transmission or reception after a STOP condition has been generated.

(4) Handling of IIC when not in use

Set the ICE bit in ICCR to 0 to disable the unused channels while the IIC bus interface is not used.

(5) Abort of data transfer in the middle of IIC communication

Aborting data transfer may violate the I2C protocol. Make sure that the external device accepts such violations when you need to abort transfer in progress.

54. Clock-Synchronized Serial Interface with FIFO (MSIOF)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

54.1 Overview

This LSI includes clock-synchronized serial I/O module with FIFO (MSIOF). In this module, MSOϕ is used as a module clock.

54.1.1 Features

- Number of channels: Four channels
- FIFO capacity: 32 bits × 64 stages for transmission and 32 bits × 256 stages for reception
  - For reception FIFO, receiving 1 FRAME with 2 group with 64 words requires at most 128 FIFO stages.
- MSB first or LSB first selectable for data transmission and reception
- Synchronization by level [RZ/G2H]
- Synchronization by frame synchronization pulse, level, or left/right channel switch [Except for RZ/G2H]
- Supports master and slave modes
- Interrupts: One interrupt line, with 12 internal factors per module.
- Serial clock
- DMA transfer
- Serial format

  Supports serial formats: SPI (master and slave modes). [RZ/G2H].
  Supports serial formats: IIS, SPI (master and slave modes). [Except for RZ/G2H]
- CLK/SYNC (SPI) in common transmit/receive mode

54.1.2 Block diagram

Figure 54.1 shows a block diagram of the MSIOF.

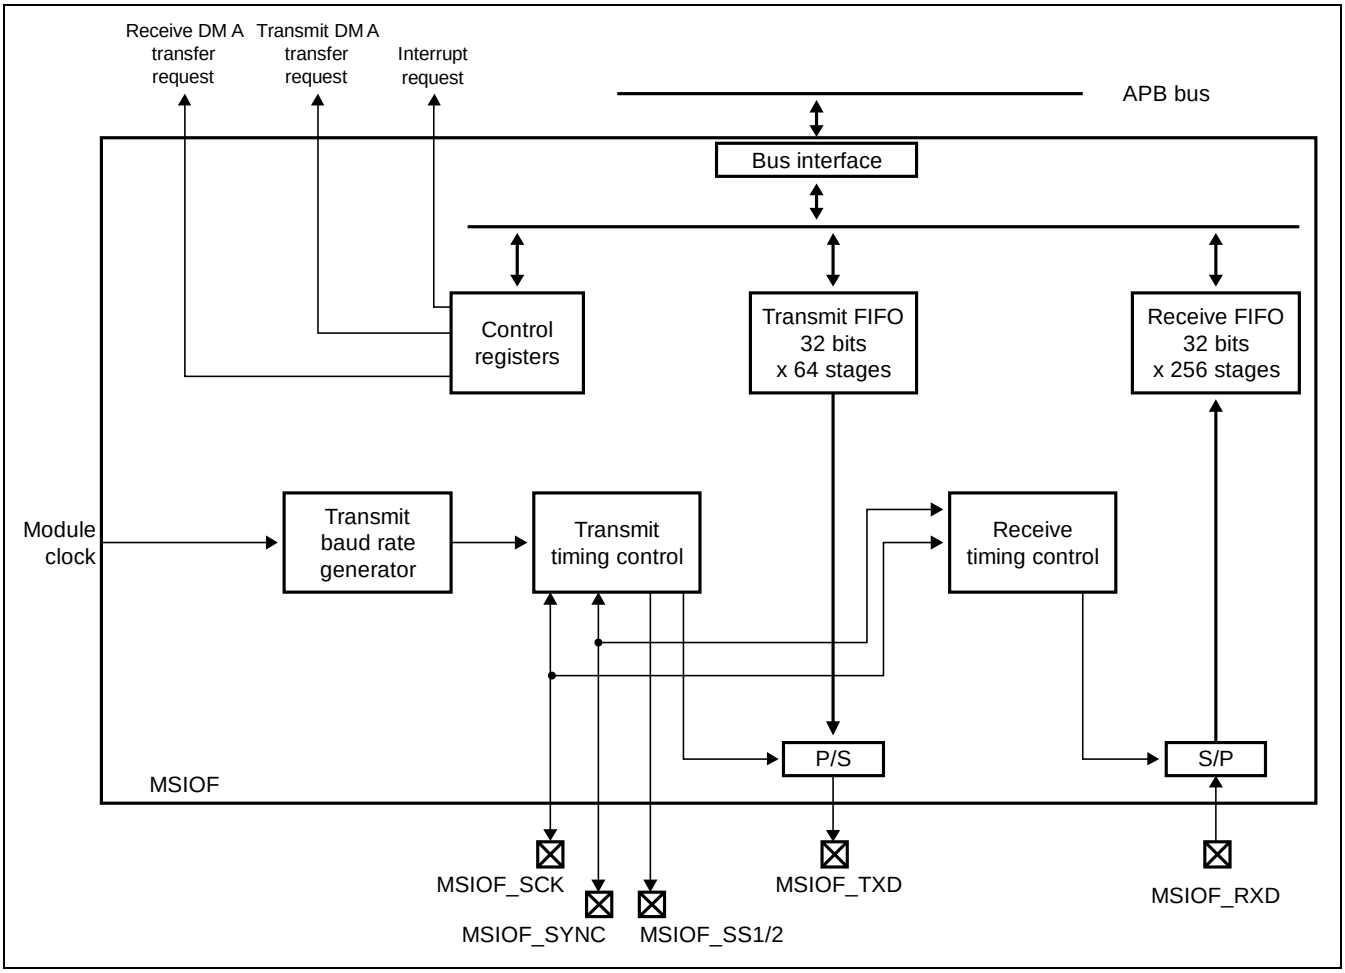

Figure 54.1 Block Diagram of MSIOF

54.1.3 External Pins

Table 54.6 Connected modules

Module name	Connected module name	Function of connected module
MSIOF	AP-System Core	Access the Register
	CPG	Output Clocks
	PFC	Select External pins
	Module Standby	Control to stop clocks
	Software Reset	Execute software reset
	INTC-AP	Control to interrupt
	SYS-DMAC	Control Direct Memory Access

54.2 Register Description

[Legend for Register Descriptions]

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC1: Readable/writable. Writing 1 initializes the bit, and writing 0 is ignored.

R: Read-only. The write value should always be initial value.

—/WB: Write-only. The read value is undefined.

54.2.1 MSIOF Transmit Mode Register 1 (SITMDR1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SITMDR1 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.
The settings of this register should be not changed when SICTR.RXE or SICTR.TXE are B'1. Otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TRMD	PCON	SYNCMD[1:0]		SYNCCH[1:0]		SYNCAC	BITLSB	—	DTDL[2:0]			—	SYNCDL[2:0]		
Initial value:	1	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	FLD[1:0]		—	TXSTP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	B'1	R/W	Transfer Mode Selects the transfer mode. 0: Slave mode 1: Master mode
30	PCON	B'0	R/W	Transfer Signal Connection 0: Setting prohibited 1: MSIOF_SCK and MSIOF_SYNC are used as common signals for transmission and reception (MSIOF_SCK and MSIOF_SYNC).
29, 28	SYNCMD[1:0]	B'00	R/W	SYNC Mode These bits specify the mode for the MSIOF_SYNC signal. [RZ/G2H] B'10: Level mode/SPI Other than above: Setting prohibited [Except for RZ/G2H] B'00: Frame start synchronization pulse B'01: Reserved B'10: Level mode/SPI B'11: L/R mode
27, 26	SYNCCH[1:0]	B'00	R/W	Synchronization Signal Channel Select These bits are valid only in master mode. B'00: The frame synchronization signal output at MSIOF_SYNC. B'01: The frame synchronization signal output at MSIOF_SS1. B'10: The frame synchronization signal output at MSIOF_SS2. B'11: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Descriptions
25	SYNCAC	B’0	R/W	MSIOF_SYNC Polarity 0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode 1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode
24	BITLSB	B’0	R/W	MSB/LSB First 0: MSB first 1: LSB first
23	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
22 to 20	DTDL[2:0]	B’001	R/W	Data Pin Bit Delay for MSIOF_SYNC Pin The value specified with TXDIZ in SICTR is output during transmission. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDL and SYNCDL becomes an integer value. [RZ/G2H] B’010: 2-clock-cycle delay Other than above: Setting prohibited [Except for RZ/G2H] B’000: No bit delay B’001: 1-clock-cycle delay B’010: 2-clock-cycle delay B’101: 0.5-clock-cycle delay B’110: 1.5-clock-cycle delay Other than above: Setting prohibited
19	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	SYNCDL[2:0]	B’000	R/W	Frame Synchronization Signal Timing Delay These bits extend the transmit frame synchronization signal. The value specified with TXDIZ in SICTR is output during transmission. These bits are invalid when SYNCMD [1:0] = B'01. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDL and SYNCDL becomes an integer value. In L/R mode, these bits should always be set to B’000. B’000: No bit delay B’001: 1-clock-cycle delay B’010: 2-clock-cycle delay B’011: 3-clock-cycle delay B’101: 0.5-clock-cycle delay B’110: 1.5-clock-cycle delay Other than above: Setting prohibited
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
3, 2	FLD [1:0]	B’00	R/W	Frame Synchronization Signal Interval Specify the minimum idle time between frames in the number of serial clock cycles. This setting is valid only in master mode. In L/R mode, these bits should always be set to B’00. In SPI mode, these bits shall not be set to B’00. B’00: 0-clock-cycle delay B’01: 1-clock-cycle delay B’10: 2-clock-cycle delay B’11: 3-clock-cycle delay
1	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	TXSTP	B’1	R/W	Transmission Stop 0: Setting prohibited 1: Stop a frame from starting to transmit until either the number of FIFO stages equals the frame size or the FIFO is full and simultaneously a frame started cannot be interrupted in between.

54.2.2 MSIOF Transmit Mode Register 2 (SITMDR2)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SITMDR2 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.
The settings of this register should be not changed when SICTR.RXE or SICTR.TXE are B’1. Otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	GRP	—	BITLEN1[4:0]					—	—	WDLEN1[5:0]					
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	GRP	B’0	R/W	Group Count 0: Group count 1 1: Group count 2
29	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
28 to 24	BITLEN1[4:0]	B’0_1111	R/W	Data Size (8 to 32 bits) The word size (bits) of Group 1 is set to the value specified in these bits + 1. Either 8, 16, 24, or 32 bits can be specified as word size.
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 16	WDLEN1[5:0]	H'00	R/W	Word Count (1 to 64 words) The word count of Group 1 is set to WDLEN1 + 1.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

54.2.3 MSIOF Transmit Mode Register 3 (SITMDR3)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SITMDR3 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.
The settings of this register should be not changed when SICTR.RXE or SICTR.TXE are B'1. Otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	BITLEN2[4:0]					—	—	WDLEN2[5:0]					
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2[4:0]	B'0_1111	R/W	Word Size (8 to 32 bits) The word size (bits) of Group 2 is set to the value specified in these bits + 1. Either 8, 16, 24, or 32 bits can be specified as word size. When setting SITMDR1.BITLSB = B'1 and SITMDR2.GRP = 1, set the same value as SITMDR2.BITLEN1.
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 16	WDLEN2[5:0]	H'00	R/W	Word Count (1 to 64 words) The word count of Group 2 is set to WDLEN2 + 1.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

54.2.4 MSIOF Receive Mode Register 1 (SIRMDR1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SIRMDR1 is a 32-bit readable/writable register that specifies the MSIOF receive mode.
The settings of this register should be not changed when SICTR.RXE or SICTR.TXE are B'1. Otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TRMD	—	SYNCMD[1:0]		—	—	SYNCAC	BITLSB	—	DTDL[2:0]			—	SYNCDL[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R/W	R	R/W	R/W	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	B'0	R/W	Transfer Mode Selects the transfer mode. This bit should be set to 0.
30	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
29, 28	SYNCMD [1:0]	B'00	R/W	SYNC Mode The mode setting in these bits should be the same as that in SITMDR1.SYNCMD. [RZ/G2H] B'10: Level mode/SPI Other than above: Setting prohibited [except for RZ/G2H] B'00: Frame start synchronization pulse B'01: Reserved B'10: Level mode/SPI B'11: L/R mode
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	SYNCAC	B'0	R/W	SYNC Polarity B'0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode B'1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode This bit must have the same setting as the SYNCAC bit of SITMDR1.
24	BITLSB	B'0	R/W	MSB/LSB First B'0: MSB first B'1: LSB first

Bit	Bit Name	Initial Value	R/W	Descriptions
23	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
22 to 20	DTDL[2:0]	B’001	R/W	Data Pin Bit Delay for MSIOF_SYNC Pin B’000: No bit delay B’001: 1-clock-cycle delay B’010: 2-clock-cycle delay Other than above: Setting prohibited In case of SPI mode, only B’000 is allowed to set to this field.
19	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	SYNCDL [2:0]	B’000	R/W	MSIOF_SYNC Timing Delay These bits should always be set to B’000.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

54.2.5 MSIOF Receive Mode Register 2 (SIRMDR2)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SIRMDR2 is a 32-bit readable/writable register that specifies the MSIOF receive mode.
The settings of this register should be not changed when SICTR.RXE or SICTR.TXE are B'1. Otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	GRP	—	BITLEN1[4:0]					—	—	WDLEN1[5:0]					
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2[4:0]	B'0_1111	R/W	Word Size (8 to 32 bits) The word size (bits) of Group 2 is set to the value specified in these bits + 1. Either 8, 16, 24, or 32 bits can be specified as word size. When using reception in master mode, set the same value as the value specified by the BITLEN2 bits in SITMDR3.
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 16	WDLEN2[5:0]	H'00	R/W	Word Count (1 to 64 words) The word count of Group 2 is set to WDLEN2 + 1. When using reception in master mode, set the same value as the value specified by the WDLEN2 bits in SITMDR3.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

54.2.7 MSIOF Control Register (SICTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SICTR is a 32-bit readable/writable register that specifies the MSIOF operating state.

The values written to the TXE, RXE, TFSE, RFSE, TSCKE, and RSCKE bits become valid (can be read from the bits) several cycles after writing. These bits should not be modified at the same time. Modify one bit at a time, and check that the new value can be read from the bit, and then modify another bit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSCKIZ[1:0]		RSCKIZ[1:0]		TEDG	REDG	—	—	TXDIZ[1:0]		—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSCKE	TFSE	RSCKE	RFSE	—	—	TXE	RXE	—	—	—	—	—	—	TXRST	RXRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	TSCKIZ[1:0]	B’00	R/W	Transmit Clock Input/output Polarity Select in SPI Mode When Transmission is Disabled When SPI mode is not used, these bits must always be set to B’00. These bits must always be set B’10 or B’11 when SPI mode. [Master mode] B’00: Outputs MSIOF_SCK when transmission is disabled. B’01: Setting prohibited B’10: Outputs 0. B’11: Outputs 1. [Slave mode] B’00: Inputs MSIOF_SCK when transmission is disabled. B’01: Setting prohibited B’10: Inputs 0 through MSIOF_SCK when transmission is disabled. B’11: Inputs 1 through MSIOF_SCK when transmission is disabled.
29, 28	RSCKIZ[1:0]	B’00	R/W	Receive Clock Polarity Select in SPI Mode Set the same value as the value specified by the TSCKIZ bits. Other setting is prohibited.
27	TEDG	B’0	R/W	Transmit Timing 0: Outputs transmit data at the rising edge of the clock. 1: Outputs transmit data at the falling edge of the clock.
26	REDG	B’0	R/W	Receive Timing 0: Samples receive data at the falling edge of the clock. 1: Samples receive data at the rising edge of the clock.
25, 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
23, 22	TXDIZ[1:0]	B'00	R/W	Pin Output When Transmission is Disabled These bits specify the MSIOF_TXD pin output state when transmission is disabled. B'00: Outputs 0. B'01: Outputs 1. B'10: Setting prohibited B'11: Setting prohibited
21 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	TSCKE	B'0	R/W	Transmit Serial Clock Output Enable This bit is valid in master mode. When this bit is set to 1, the MSIOF initializes the baud rate generator and initiates the operation. At the same time, the MSIOF outputs the clock generated by the baud rate generator to the MSIOF_SCK pin. After the clock is output, 1 can be read. When transmitting data, set this bit to 1 before setting the TFSE and TXE bits. After data transmission, clear the TFSE and TXE bits and then clear this bit to 0. [Write data] 0: Disables the MSIOF_SCK output. (Outputs the value specified with TSCKIZ.) 1: Enables the MSIOF_SCK output. [Read data] 0: Does not output MSIOF_SCK. (Outputs the value specified with TSCKIZ.) 1: Outputs MSIOF_SCK.
14	TFSE	B'0	R/W	Transmit Frame Synchronization Signal Output Enable This bit is valid in master mode. When this bit is set to 1, the MSIOF initializes the frame counter and initiates the operation. After the transmit frame synchronization signal is output, 1 can be read. When 0 is written to this bit, 0 is set after transmission of the frame. [Write data] 0: Disables the MSIOF_SYNC output. (Outputs the value specified with SYNCAC.) 1: Enables the MSIOF_SYNC output. [Read data] 0: Does not output MSIOF_SYNC. (Outputs the value specified with SYNCAC.) 1: Outputs MSIOF_SYNC.
13	RSCKE	B'0	R/W	Receive Serial Clock Output Enable The write value should always be 0.
12	RFSE	B'0	R/W	Receive Frame Synchronization Signal Output Enable The write value should always be 0.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
9	TXE	B'0	R/W	Transmit Enable When this bit is set to 1, the MSIOF starts data transmission from the beginning of the next frame (at the rising edge of the frame synchronization signal). After the valid data is output, 1 can be read. When value 1 set to this bit becomes valid, the MSIOF issues a transmit data transfer request according to the setting of the TFWM bits in SIFCTR. When transmit data is stored in the transmit FIFO, transmission of data from the MSIOF_TXD pin begins. When 0 is written to this bit, 0 is set after transmission of the frame. This bit is initialized upon a transmit reset. [Write data] 0: Disables the MSIOF_TXD output. (Outputs the value specified with TXDIZ.) 1: Enables the MSIOF_TXD output. [Read data] 0: Does not output MSIOF_TXD. (Outputs the value specified with TXDIZ.) 1: Outputs MSIOF_TXD.
8	RXE	B'0	R/W	Receive Enable When this bit is set to 1, the MSIOF starts data reception from the beginning of the next frame (at the rising edge of the frame synchronization signal). When value 1 set to this bit becomes valid, the MSIOF starts receiving data through the MSIOF_RXD pin. When receive data is stored in the receive FIFO, the MSIOF issues a receive data transfer request according to the setting of the RFWM bits in SIFCTR. This bit is initialized upon a receive reset. [Write data] 0: Disables data reception through MSIOF_RXD. 1: Enables data reception through MSIOF_RXD. [Read data] 0: Data is not received through MSIOF_RXD. 1: Data can be received through MSIOF_RXD.
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
1	TXRST	B'0	R/W	Transmit Reset When value 1 set to this bit becomes valid, the MSIOF immediately sets transmit data through the MSIOF_TXD pin to 0, and initializes the transmit data registers and transmit-related status. When value 1 set to this bit becomes valid when PCON = 1, the RXRST bit is also becomes valid. The following registers and bits are initialized. SITFDR (Transmit FIFO write pointer) TDREQ bit in SISTR TXE bit This bit is read as 1 until the reset operation is completed for about 20 cycles of module clock. No data should be written to SICTR or the transmit FIFO during this time period. [Write data] 0: Does not reset transmit operation. 1: Resets transmit operation. [Read data] 0: Transmit operation reset is completed. 1: Transmit operation is being reset.
0	RXRST	B'0	R/W	Receive Reset When value 1 set to this bit becomes valid, the MSIOF immediately disables reception through the MSIOF_RXD pin, and initializes the receive data registers and receive-related status. The following registers and bits are initialized. SIRFDR (Receive FIFO read pointer) RDREQ bit in SISTR RXE bit This bit is read as 1 until the reset operation is completed for about 20 cycles of module clock. No data should be written to SICTR or read the receive FIFO during this time period. [Write data] 0: Does not reset receive operation. 1: Resets receive operation. [Read data] 0: Receive operation reset is completed. 1: Receive operation is being reset.

54.2.8 MSIOF Transmit Clock Select Register (SITSCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SITSCR is a 16-bit readable/writable register that specifies the conditions for generating transmit serial clock in master mode. SITSCR can be specified when the TRMD bit in SITMDR1 is set to B'1.
The settings of this register should be not changed when SICTR.TSCKE is B’1. Otherwise, the operation cannot be guaranteed.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSSEL[1:0]		MSIMM	BRPS[4:0]					—	—	—	—	—	BRDV[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	MSSEL[1:0]	B’00	R/W	Master Clock Source Select The master clock is the clock input to the baud rate generator. B‘00: Selects module clock as the source of master clock. Others: Setting prohibited
13	MSIMM	B’0	R/W	Master Clock Direct Select B’0: Selects the clock output from the baud rate generator as the serial clock. B’1: Setting prohibited
12 to 8	BRPS[4:0]	B’0_0000	R/W	Prescaler Setting These bits specify the master clock (MSOϕ) division ratio in the count value of the prescaler in the baud rate generator. The specifiable value is from B’0_0000 (× 1/1) to B’1_1111 (× 1/32).
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	BRDV[2:0]	B’000	R/W	Baud Rate Generator's Division Ratio These bits specify the frequency division ratio for the output stage of the baud rate generator. The final frequency division ratio of the baud rate generator is determined as BRPS × BRDV (1/1024 max.). B’000: Prescaler output × 1/2 B’001: Prescaler output × 1/4 B’010: Prescaler output × 1/8 B’011: Prescaler output × 1/16 B’100: Prescaler output × 1/32 B’101: Setting prohibited B’110: Setting prohibited B’111: Prescaler output × 1/1 Note: - B'111 is valid only when the BRPS [4:0] bits are set to B'0_0001. - BRPS × BRDV = 1/1 is invalid（BRPS × BRDV = 1/2 min).

54.2.9 MSIOF Transmit FIFO Data Register (SITFDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SITFDR is a 32-bit write-only register that specifies the transmit FIFO data of the MSIOF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SITFD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SITFD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SITFD1[15:0]	H'0000	—/WB	These bits specify the upper 16 bits of the FIFO data to be output through MSIOF_TXD.
15 to 0	SITFD2[15:0]	H'0000	—/WB	These bits specify the lower 16 bits of the FIFO data to be output through MSIOF_TXD.

54.2.10 MSIOF Receive FIFO Data Register (SIRFDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SIRFDR is a 32-bit read-only register that stores the receive FIFO data of the MSIOF.

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SIRFD1[15:0]	Undefined	R	Store the upper 16 bits of the FIFO data received through MSIOF_RXD.
15 to 0	SIRFD2[15:0]	Undefined	R	Store the lower 16 bits of the FIFO data received through MSIOF_RXD.

54.2.11 MSIOF Status Register (SISTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Each bit in SISTR becomes an MSIOF interrupt source when the corresponding bit in SIIER is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	TFEMP	TDREQ	—	—	—	—	TEOF	—	TFS ERR	TFOVF	TFUDF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/WC1	R	R	R	R	R	R/WC1	R	R/WC1	R/WC1	R/WC1	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	RFFUL	RDREQ	—	—	—	—	REOF	—	RFS ERR	RFUDF	RFOVF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/WC1	R	R	R	R	R	R/WC1	R	R/WC1	R/WC1	R/WC1	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29	TFEMP	B'0	R/WC1	Transmit FIFO Empty This bit is set to 1, when the TXE bit in SICTR is 1, and transmit FIFO is empty. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: Transmit FIFO is not empty. 1: Transmit FIFO is empty.
28	TDREQ	B'0	R	Transmit Data Transfer Request This bit is set, when the empty space in the transmit FIFO exceeds the size specified by the TFWM bits in SIFCTR. When transferring transmit data through the DMAC, this bit is always cleared after one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the MSIOF again sets this bit to 1. This bit is valid when the TXE bit in SICTR is 1. This bit indicates a state; if the size of empty space in the transmit FIFO becomes less than the size specified by the TFWM bits in SIFCTR, the MSIOF clears this bit. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. However, when the TDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of empty space in the transmit FIFO has not exceeded the size specified by the TFWM bits in SIFCTR. 1: The size of empty space in the transmit FIFO has exceeded the size specified by the TFWM bits in SIFCTR.
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
23	TEOF	B'0	R/WC1	Frame Transmission End This bit is set, when one-frame data transmission is completed. This bit is valid when the TXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: One-frame transmission end is not detected. 1: One-frame transmission end is detected.
22	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	TFSERR	B'0	R/WC1	Transmit Frame Synchronization Error This bit is set, when the next transmit frame synchronization timing arrives before the previous data transmission has been completed. If a transmit frame synchronization error occurs, the MSIOF performs transmission only for the slots that can be transferred. This bit is valid when the TXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No transmit frame synchronization error has occurred. 1: A transmit frame synchronization error has occurred.
20	TFOVF	B'0	R/WC1	Transmit FIFO Overflow A transmit FIFO overflow means that there has been an attempt to write to SITFDR when the transmit FIFO is full. If a transmit FIFO overflow occurs, the MSIOF ignores the write operation causing the overflow. This bit is valid when the TXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No transmit FIFO overflow has occurred. 1: A transmit FIFO overflow has occurred.
19	TFUDF	B'0	R/WC1	Transmit FIFO Underflow A transmit FIFO underflow means that loading for transmission has occurred when the transmit FIFO is empty. Output data is unknown when under flow is occurred. This bit is valid when the TXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No transmit FIFO underflow has occurred. 1: A transmit FIFO underflow has occurred. Note: If transmission size is larger than 64-words per frame, do not use this bit. See 54.4.5 for details.

Bit	Bit Name	Initial Value	R/W	Descriptions
18 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	RFFUL	B'0	R/WC1	Receive FIFO Full This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: Receive FIFO is not full. 1: Receive FIFO is full.
12	RDREQ	B'0	R	Receive Data Transfer Request This bit is set, when the valid data space in the receive FIFO exceeds the size specified by the RFWM bits in SIFCTR. When transferring receive data through the DMAC, this bit is always cleared by one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the MSIOF again sets this bit to 1. This bit is valid when the RXE bit in SICTR is 1. This bit indicates a state; if the size of valid data space in the receive FIFO becomes less than the size specified by the RFWM bits in SIFCTR, the MSIOF clears this bit. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. However, when the RDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of valid data space in the receive FIFO has not exceeded the size specified by the RFWM bits in SIFCTR. 1: The size of valid data space in the receive FIFO has exceeded the size specified by the RFWM bits in SIFCTR.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	REOF	B'0	R/WC1	Frame Reception End The MSIOF issues the frame reception end flag upon completion of one-frame data reception. This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: One-frame reception end is not detected. 1: One-frame reception end is detected.
6	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
5	RFSERR	B'0	R/WC1	Receive Frame Synchronization Error A receive frame synchronization error occurs when the next receive frame synchronization timing arrives before the previous data reception has been completed. If a receive frame synchronization error occurs, the MSIOF performs reception only for the slots that can be transferred. This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit will clear this bit. Writing 0 to this bit will be ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No receive frame synchronization error has occurred 1: A receive frame synchronization error has occurred
4	RFUDF	B'0	R/WC1	Receive FIFO Underflow A receive FIFO underflow means that reading of SIRFDR has occurred when the receive FIFO is empty. If a receive FIFO underflow occurs, the value read from SIRFDR is not guaranteed. This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No receive FIFO underflow has occurred. 1: A receive FIFO underflow has occurred.
3	RFOVF	B'0	R/WC1	Receive FIFO Overflow A receive FIFO overflow means that writing has been caused by receiving operation when the receive FIFO is full. If a receive FIFO overflow occurs, the receive data causing the overflow is lost. This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No receive FIFO overflow has occurred. 1: A receive FIFO overflow has occurred.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

54.2.12 MSIOF Interrupt Enable Register (SIIER)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SIIER is a 32-bit readable/writable register that enables the issuance of MSIOF interrupts. When each bit in this register is set to 1 and the corresponding bit in SISTR is set to 1, the MSIOF issues an interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TDMAE	—	TFEMPE	TDREQE	—	—	—	—	TEOFE	—	TFSERRE	TFOVFE	TFUDFE	—	—	—

R/W:	R/W	R	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TDMAE	B'0	R/W	Transmit Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The TDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.
30	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
29	TFEMPE	B'0	R/W	Transmit FIFO Empty Enable 0: Disables interrupts due to transmit FIFO empty. 1: Enables interrupts due to transmit FIFO empty.
28	TDREQE	B'0	R/W	Transmit Data Transfer Request Enable 0: Disables interrupts due to transmit data transfer requests. 1: Enables interrupts due to transmit data transfer requests.
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23	TEOFE	B'0	R/W	Frame Transmission End Enable 0: Disables a frame transmission end interrupt. 1: Enables a frame transmission end interrupt.
22	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	TFSERRE	B'0	R/W	Transmit Frame Synchronization Error Enable 0: Disables interrupts due to transmit frame synchronization errors. 1: Enables interrupts due to transmit frame synchronization errors.
20	TFOVFE	B'0	R/W	Transmit FIFO Overflow Enable 0: Disables interrupts due to transmit FIFO overflow. 1: Enables interrupts due to transmit FIFO overflow.

Bit	Bit Name	Initial Value	R/W	Descriptions
19	TFUDFE	B'0	R/W	Transmit FIFO Underflow Enable 0: Disables interrupts due to transmit FIFO underflow. 1: Enables interrupts due to transmit FIFO underflow.
18 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	RDMAE	B'0	R/W	Receive Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The RDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.
14	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
13	RFFULE	B'0	R/W	Receive FIFO Full Enable 0: Disables interrupts due to receive FIFO full. 1: Enables interrupts due to receive FIFO full.
12	RDREQE	B'0	R/W	Receive Data Transfer Request Enable 0: Disables interrupts due to receive data transfer requests. 1: Enables interrupts due to receive data transfer requests.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	REOFE	B'0	R/W	Frame Reception End Enable 0: Disables a frame reception end interrupt. 1: Enables a frame reception end interrupt.
6	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	RFSERRE	B'0	R/W	Receive Frame Synchronization Error Enable 0: Disables interrupts due to receive frame synchronization errors. 1: Enables interrupts due to receive frame synchronization errors.
4	RFUDFE	B'0	R/W	Receive FIFO Underflow Enable 0: Disables interrupts due to receive FIFO underflow. 1: Enables interrupts due to receive FIFO underflow.
3	RFOVFE	B'0	R/W	Receive FIFO Overflow Enable 0: Disables interrupts due to receive FIFO overflow. 1: Enables interrupts due to receive FIFO overflow.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

54.2.13 MSIOF FIFO Control Register (SIFCTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SIFCTR is a 32-bit readable/writable register that indicates the area available for the transmit/receive FIFO transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TFWM[2:0]			—	—	TFUA[6:0]							—	—	—	—

R/W:	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFWM[2:0]			RFUA[8:0]									—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	TFWM[2:0]	B’000	R/W	Transmit FIFO Watermark A transfer request of the transmit FIFO is issued by the TDREQE bit in SIIER. The transmit FIFO always operates as a 64-stage FIFO regardless of the setting of these bits. B’000: Issues a transfer request when 64 stages of the transmit FIFO are empty. B’001: Issues a transfer request when 32 or more stages of the transmit FIFO are empty. B’010: Issues a transfer request when 24 or more stages of the transmit FIFO are empty. B’011: Issues a transfer request when 16 or more stages of the transmit FIFO are empty. B’100: Issues a transfer request when 12 or more stages of the transmit FIFO are empty. B’101: Issues a transfer request when 8 or more stages of the transmit FIFO are empty. B’110: Issues a transfer request when 4 or more stages of the transmit FIFO are empty. B’111: Issues a transfer request when 1 or more stages of transmit FIFO are empty.
28, 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 20	TFUA[6:0]	H'40	R	Transmit FIFO Usable Area Indicate the number of words that can be transferred by the CPU or DMAC as B'000_0000 (full) to B'100_0000 (empty).
19 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 13	RFWM[2:0]	B’000	R/W	Receive FIFO Watermark A transfer request of the receive FIFO is issued by the RDREQE bit in SIIER. The receive FIFO always operates as a 256-stage FIFO regardless of the setting of these bits. B’000: Issues a transfer request when 1 stage or more of the receive FIFO are valid. B’001: Issues a transfer request when 4 or more stages of the receive FIFO are valid. B’010: Issues a transfer request when 8 or more stages of the receive FIFO are valid. B’011: Issues a transfer request when 16 or more stages of the receive FIFO are valid. B’100: Issues a transfer request when 32 or more stages of the receive FIFO are valid. B’101: Issues a transfer request when 64 or more stages of the receive FIFO are valid. B’110: Issues a transfer request when 128 or more stages of the receive FIFO are valid. B’111: Issues a transfer request when 256 stages of the receive FIFO are valid.
12 to 4	RFUA[8:0]	All 0	R	Receive FIFO Usable Area Indicate the number of words that can be transferred by the CPU or DMAC as B'0_0000_0000 (empty) to B'1_0000_0000 (full).
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

54.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

54.3.1 Operating Mode

(1) Common transmit/receive mode

Common clock and frame synchronization signals are used for transmission and reception.

Master mode: MSIOF_SCK and MSIOF_SYNC are output.
Slave mode: MSIOF_SCK and MSIOF_SYNC are input.

54.3.2 Serial Clocks

(1) Clock output in master mode

In master mode, the baud rate generator is used to generate the serial clock. The division ratio is from 1/2 to 1/1024.

(2) Clock input in slave mode

In slave mode, the clock input for transmission and reception is used as the serial clock.

(3) Multiple channel function

This module provides the multiple channel function as shown in Figure 54.2.

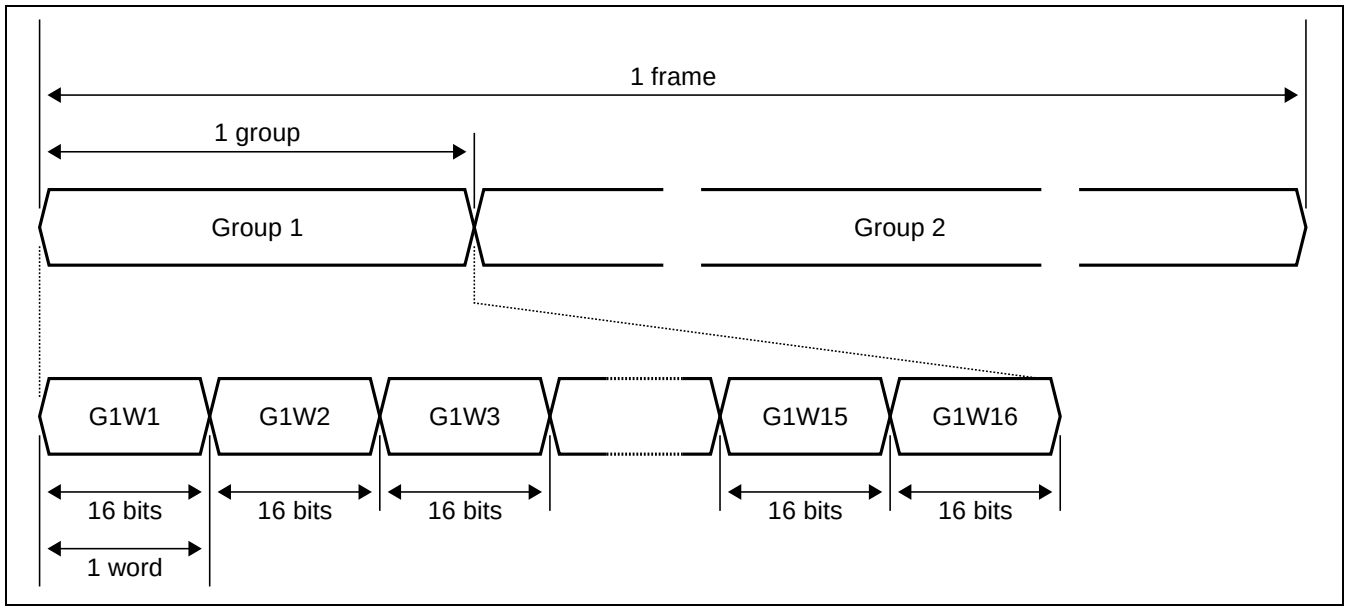

Figure 54.2 Multiple Channel Structure

The following conditions can be specified for the multiple channel function.

- Up to 2 groups in one frame
- Up to 64 words in one group
- 8, 16, 24, or 32 bits in one word

54.3.3 Serial Timing

(1) MSIOF_SYNC

The MSIOF_SYNC is a frame synchronization signal. The following three modes are available.

[RZ/G2H]
- Level/SPI: Level signal asserted during frame transmission

[Except for RZ/G2H]
- Frame start synchronization pulse: 1-bit-width pulse indicating the start of a frame
- Level/SPI: Level signal asserted during frame transmission
- L/R: 1/2-frame-width pulse indicating the first-half groups in a high level and the last-half groups in a low level

Figure 54.3 to Figure 54.5 show the synchronization timing in these modes using the MSIOF_SYNC signal.

(a) Frame start synchronization pulse

The rising edge of the synchronization pulse indicates the start of a frame.

The delay between the rising edge of the synchronization signal and the start of data transmission or reception can be specified with the DTDL bits. The width of the synchronization pulse can be extended through the SYNCDL bit setting.

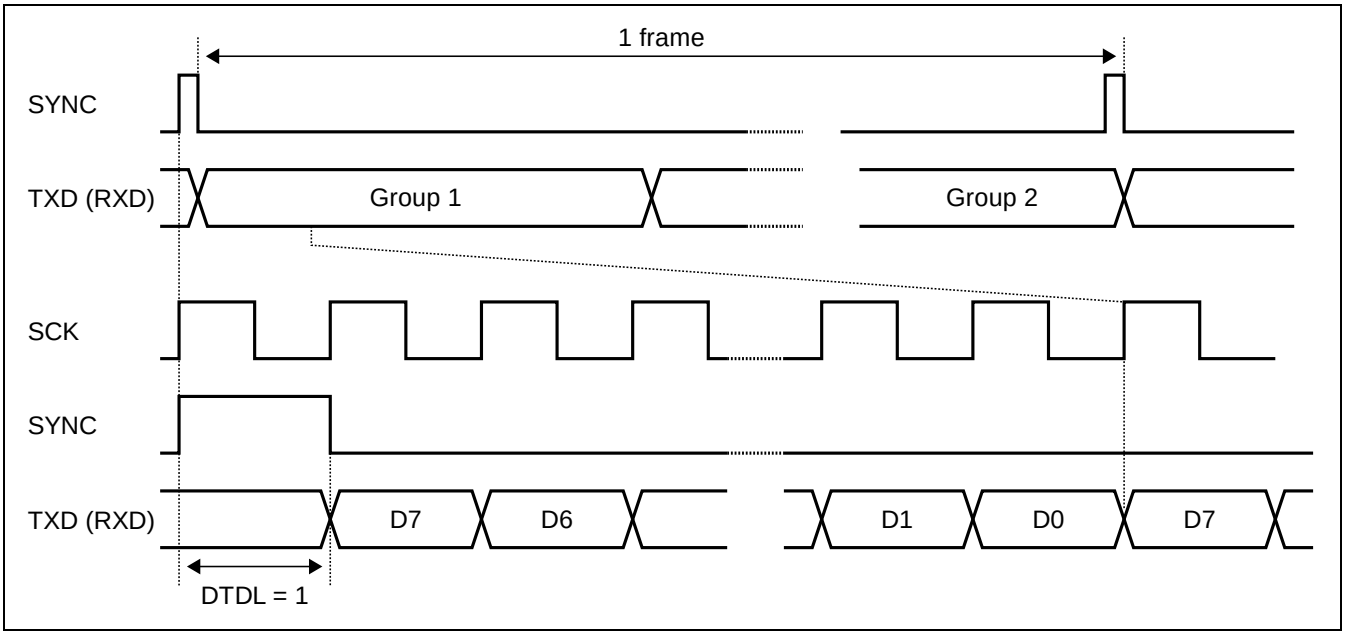

Figure 54.3 Synchronization Timing in Start Frame Synchronization Pulse Mode

(b) Level synchronization

The synchronization signal is driven high for the frame length.

The delay between the rising edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits and the delay between the end of transmission or reception and the falling edge of the synchronization signal can be specified with the SYNCDL bits (DTDL = 0 to 2(RZ/G2H is only 2) and SYNCDL = 0 to 3). These settings are valid only in master mode. This mode is available for the SPI master or slave operation.

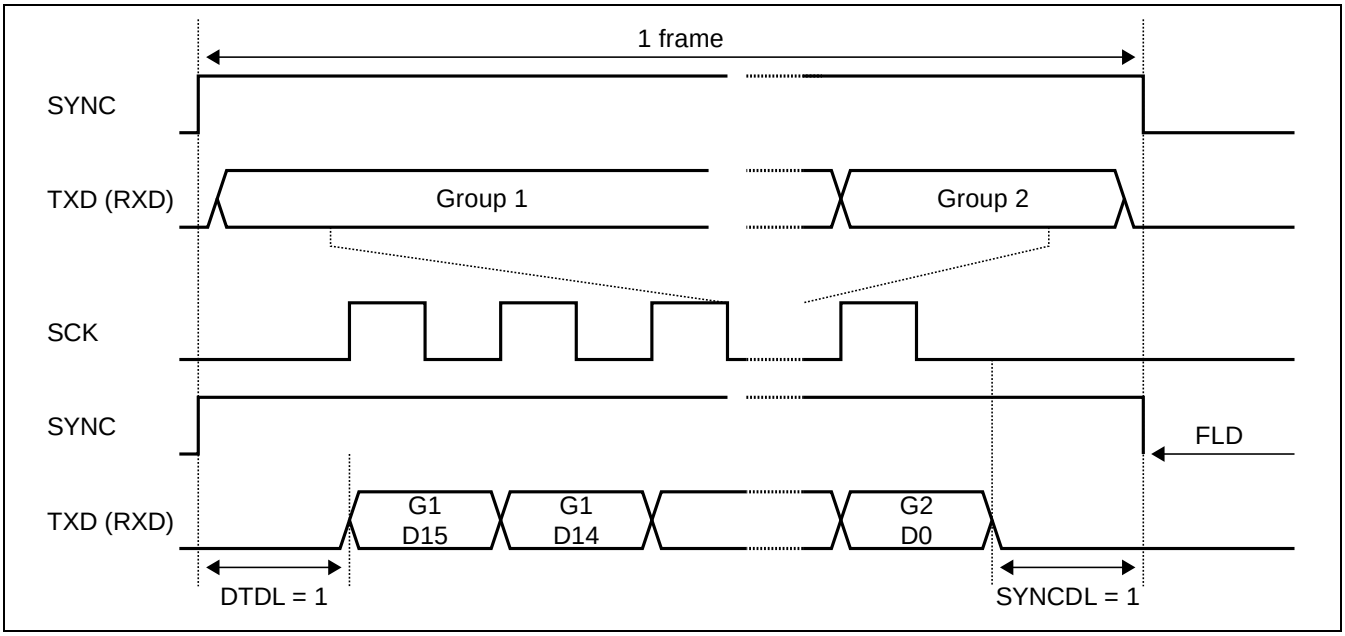

Figure 54.4 Synchronization Timing in Level Synchronization Mode

(c) L/R synchronization

A high level in the synchronization signal indicates the first-half groups and a low level indicates the last-half groups.

The delay between the rising or falling edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits.

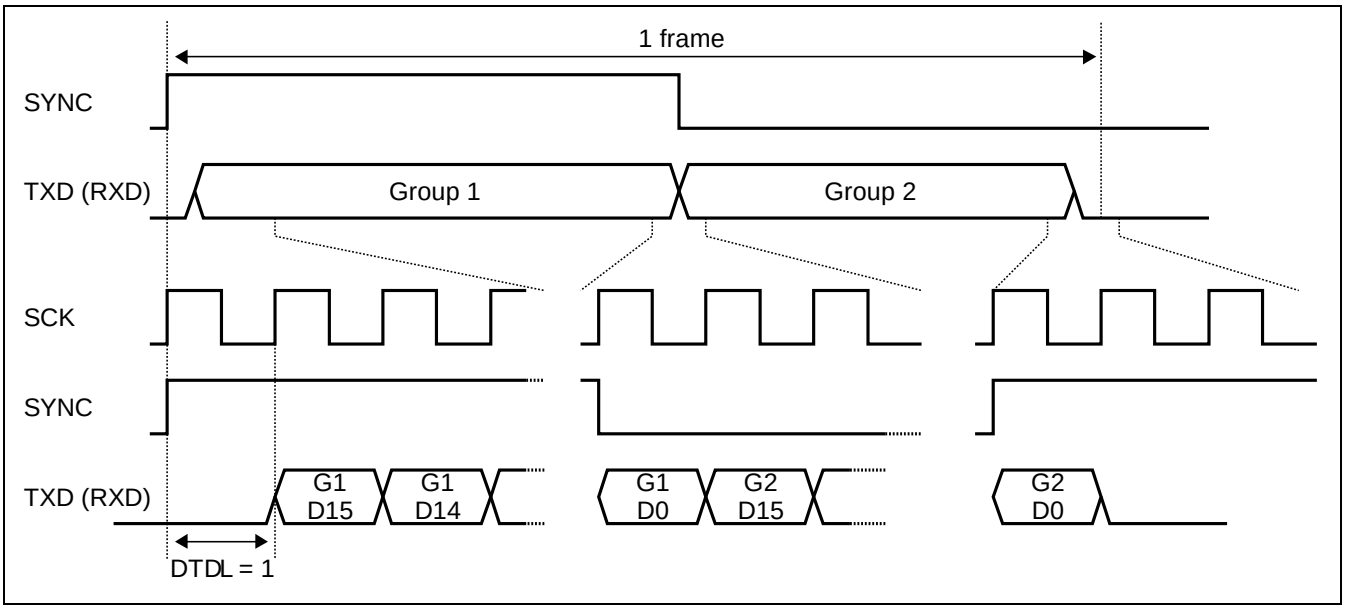

Figure 54.5 Synchronization Timing in L/R Synchronization Mode

(2) Transmit/receive timing

The timing of MSIOF_TXD transmission relative to MSIOF_SCK and of MSIOF_RXD can be specified as sampling on either edge, as listed below. The respective settings are made in TEDG and REDG bits of SICTR.

- Falling-edge sampling
- Rising-edge sampling

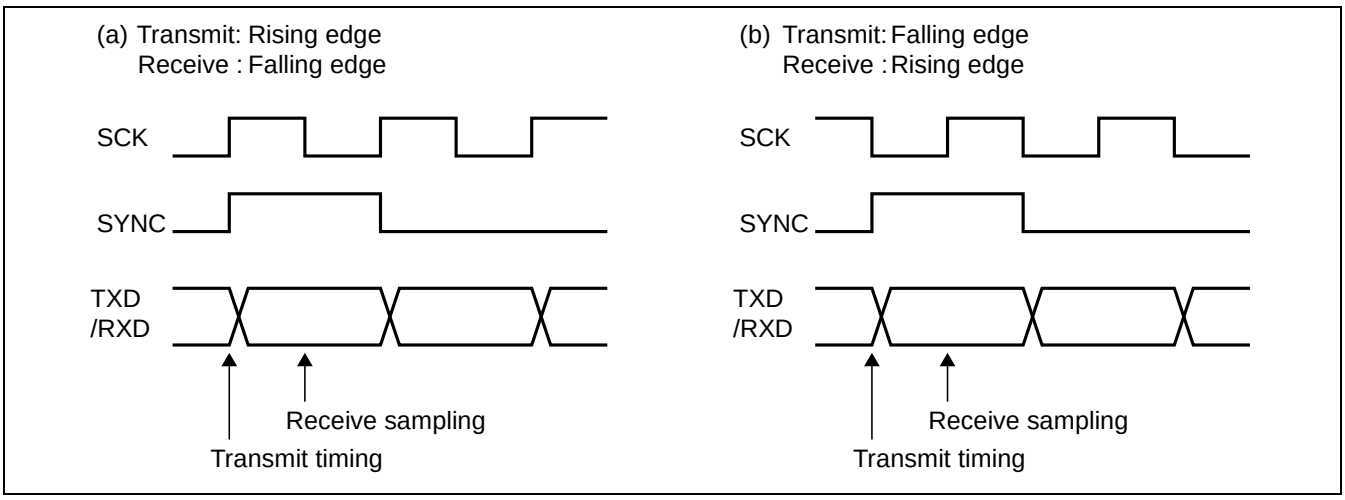

Figure 54.6 Transmit/Receive Timing.

54.3.4 Transfer Data Allocation to Registers

(1) Transmit/receive data

Transmit/receive data (FIFO data) should be written to or read from the following registers.

- Transmit FIFO data writing: SITFDR (32-bit access)
- Receive FIFO data reading: SIRFDR (32-bit access)

Figure 54.7 shows the bit alignment of these registers.

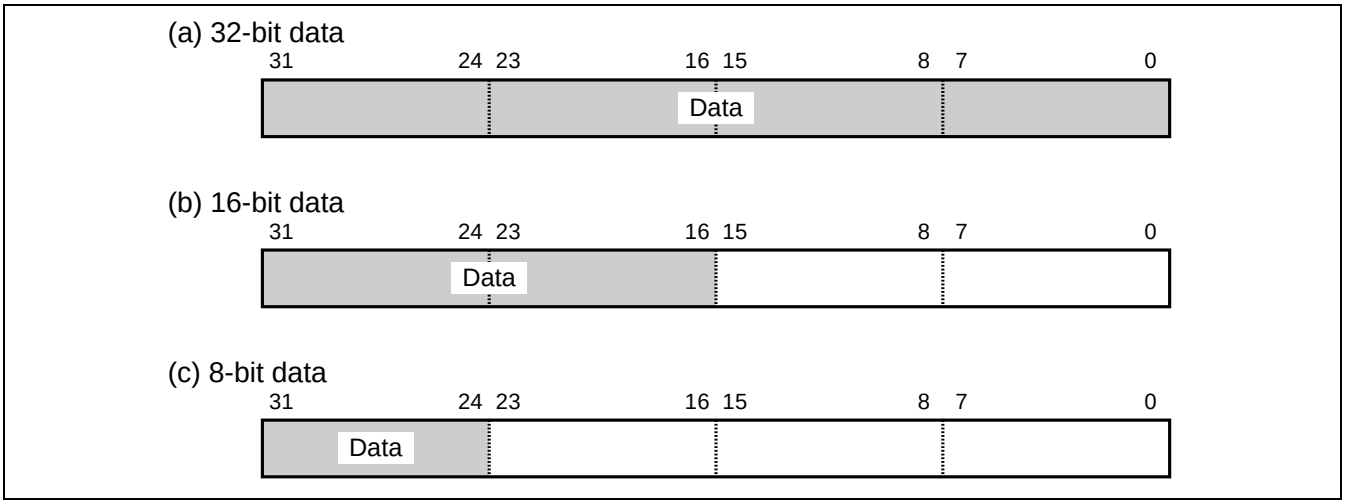

Figure 54.7 Transmit/Receive Data Bit Alignment

54.3.5 FIFO

(1) Overview

The transmission and receive FIFOs of the MSIOF have the following features.

- 32 bits × 64 stages for transmission and 32 bits × 256 stages for reception
- The FIFO pointer is updated in one read or write cycle regardless of the access size of the CPU or DMAC. (One access cannot be divided into multiple accesses.)

(2) Transfer request

A request for FIFO data transfer can be issued to the CPU or DMAC as the following interrupt sources.

- FIFO transmit request: TDREQ (interrupt source for transmission)
- FIFO receive request: RDREQ (interrupt source for reception)

The conditions for requesting FIFO data transfer can be specified separately for transmission and reception. The conditions for the transmit FIFO and receive FIFO are specified in the TFWM[2:0] bits and RFWM[2:0] bits in SIFCTR, respectively.

Table 54.7 Condition for Issuing Transmit Request

TFWM[2:0]	Number of Requested Stages	Condition for Transmit Request	Areas Used
B'000	1	64 stages of empty area	Smallest
B'001	32	32 or more stages of empty area	
B'010	40	24 or more stages of empty area	
B'011	48	16 or more stages of empty area	
B'100	52	12 or more stages of empty area	
B'101	56	8 or more stages of empty area	
B'110	60	4 or more stages of empty area	
B'111	64	1 or more stages of empty area	Largest

Table 54.8 Condition for Issuing Receive Request

RFWM[2:0]	Number of Requested Stages	Condition for Receive Request	Areas Used
B'000	1	1 or more stages of valid data	Smallest
B'001	4	4 or more stages of valid data	
B'010	8	8 or more stages of valid data	
B'011	16	16 or more stages of valid data	
B'100	32	32 or more stages of valid data	
B'101	64	64 or more stages of valid data	
B'110	128	128 or more stages of valid data	
B'111	256	256 stages of valid data	Largest

The maximum FIFO stages are always available even if the data area or empty area exceeds the size specified for the transfer condition. Accordingly, an overflow error or an underflow error occurs if the data area or empty area exceeds the maximum number of FIFO stages.

The FIFO transfer request is canceled when the specified condition is not satisfied even if the FIFO does not become empty or full.

(3) Number of FIFOs

The number of transmit and receive FIFO stages used are indicated by the following registers.

- Transmit FIFO: The number of empty FIFO stages is indicated by the TFUA [6:0] bits in SIFCTR.
- Receive FIFO: The number of valid data stages is indicated by the RFUA [8:0] bits in SIFCTR.

These registers show the number of data stages that can be transferred by the CPU. DMA transfer should be set the following setting.

SIFCTR.TFWM[2:0] = B’111
SIFCTR.RFWM[2:0] = B’000

54.3.6 Transmit and Receive Procedures

(1) Transmission in master mode

Figure 54.8 and Figure 54.9 shows an example of settings and operation for transmission in master mode.

No.	Operating flow	Description	Operation
1	SITMDR1/2/3 SITSCR SIFCTR SIIER setting	Operating mode Clock setting FIFO water mark Setting interrupt/DMA enable	
2	SICTR Set SICTR.TSCKE to 1	Transmission rate setting Baud rate generator starting	Output serial clock

8			
9	Set SICTR.RXE to 0	Reception disable	
10		Read SICTR.RXE = 0	

Figure 54.15 Example of Receive Procedure in Slave Mode

(5) Reset

After a power-on reset is applied, module stop state is canceled, or a reset signal is asserted through the TXRST or RXRST setting in SICTR, it takes about 20 cycles of module clock to complete the internal reset of the module. During a period from the beginning of reset until the TXRST or RXRST value is read as 0, do not modify the control register or access the FIFOs.

The MSIOF can reset the transmit and receive units by setting the following bits to 1.

- Transmit reset: TXRST bit in SICTR
- Receive reset: RXRST bit in SICTR

Table 54.9 Transmit and Receive Reset

Type	Objects Initialized
Transmit reset	SITFDR (Transmit FIFO write pointer) TDREQ bit in SISTR TXE bit in SICTR (When SITMDR1.PCON = 1, Receive reset is also asserted.)
Receive reset	SIRFDR (Receive FIFO read pointer) RDREQ bit in SISTR RXE bit in SICTR

(6) Initial operating mode

After a power-on reset, both transmit and receive units are initialized to master mode (0 is output through MSIOF_SCK and MSIOF_SYNC). When using slave mode, keep the connected device outputting 0 until the operating mode setting is completed.

54.3.7 Interrupts

The MSIOF has one type of interrupt.

(1) Interrupt sources

Interrupts can be generated by several sources. Each source is shown as an MSIOF status in SISTR. Table 54.10 lists the MSIOF interrupt sources.

Table 54.10 MSIOF Interrupt Sources

No.	Classification	Bit Name	Function Name	Description
1	Transmission	TDREQ	Transmit FIFO transfer request	The transmit FIFO has empty space of specified size or more.
2		TFEMP	Transmit FIFO empty	The transmit FIFO is empty.
3		TEOF	Frame transmission end	Transmission of data with a length of one frame is completed.
4	Reception	RDREQ	Receive FIFO transfer request	The receive FIFO stores data of specified size or more.
5		RFFUL	Receive FIFO full	The receive FIFO is full.
6		REOF	Frame reception end	Reception of data with a length of one frame is completed.
7	Error	TFUDF	Transmit FIFO underflow	Serial data transmit timing has arrived while the transmit FIFO is empty.
8		TFOVF	Transmit FIFO overflow	The transmit FIFO is written to while it is full.
9		RFOVF	Receive FIFO overflow	Serial data is received while the receive FIFO is full.
10		RFUDF	Receive FIFO underflow	The receive FIFO is read while the receive FIFO is empty.
11		TFSERR	Transmit FS error	A transmit frame synchronization signal is input before the specified number of bits has been reached (in slave mode).
12		RFSERR	Receive FS error	A receive frame synchronization signal is input before the specified number of bits has been reached (in slave mode).

Whether an interrupt is issued from an interrupt source is determined by the SIIER settings. If an interrupt source bit is set to 1 and the corresponding bit in SIIER is set to 1, an MSIOF interrupt is issued.

(2) TDREQ and RDREQ

The transmit FIFO transfer request (TDREQ) and receive FIFO transfer request (RDREQ) are signals indicating the state. If the state changes after TDREQ or RDREQ is set, it is automatically cleared by the MSIOF.

When the DMA transfer is used, a DMA transfer request signal is pulled low for one cycle at the end of DMA transfer.

(3) Processing when errors occur

- Transmit FIFO underflow (TFUDF)
  An undefined value is output.
- Transmit FIFO overflow (TFOVF)
  The contents of the transmit FIFO are protected, and the write operation causing the overflow is ignored.
- Receive FIFO overflow (RFOVF)
  Data causing the overflow is discarded and lost.
- Receive FIFO underflow (RFUDF)
  An undefined value is output on the bus.
- Transmit FS error (TFSERR)
  The internal counter is reset according to the synchronization signal in which an error occurs.
- Receive FS error (RFSERR)
  The internal counter is reset according to the synchronization signal in which an error occurs.

54.3.8 Transmit and Receive Timing

Examples of the MSIOF serial transmission and reception are shown in Figure 54.16 and Figure 54.17.

(1) 16-bit synchronization pulse

Synchronization pulse method, one group, one word, 16 bits in a word, no bit delay

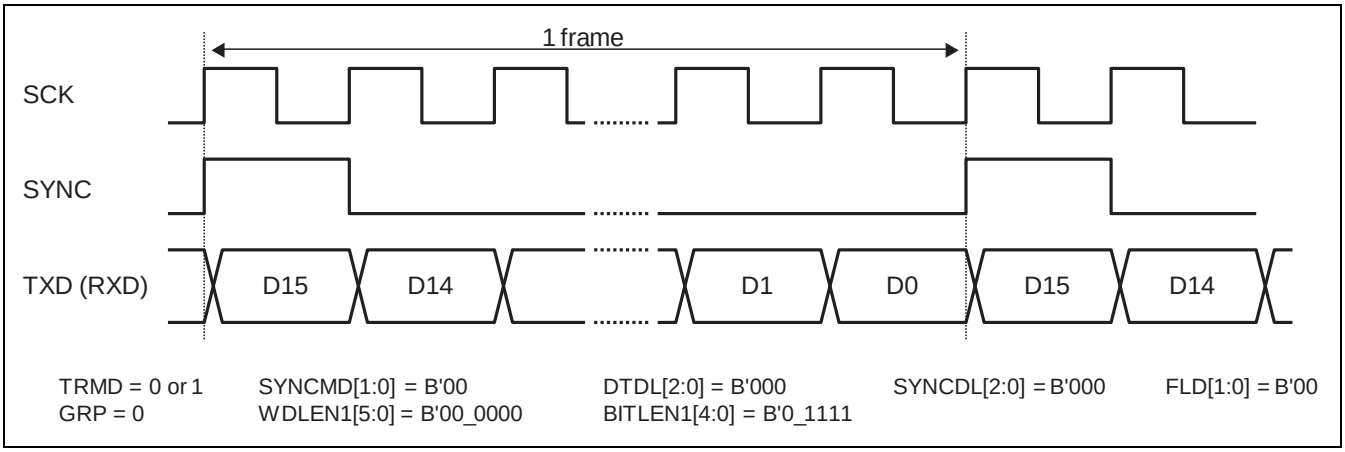

Figure 54.16 Transmit and Receive Timing (16 Bits)

(2) 32-bit synchronization pulse

Synchronization pulse method, one group, 32 words, 32 bits in a word, 1-bit delay

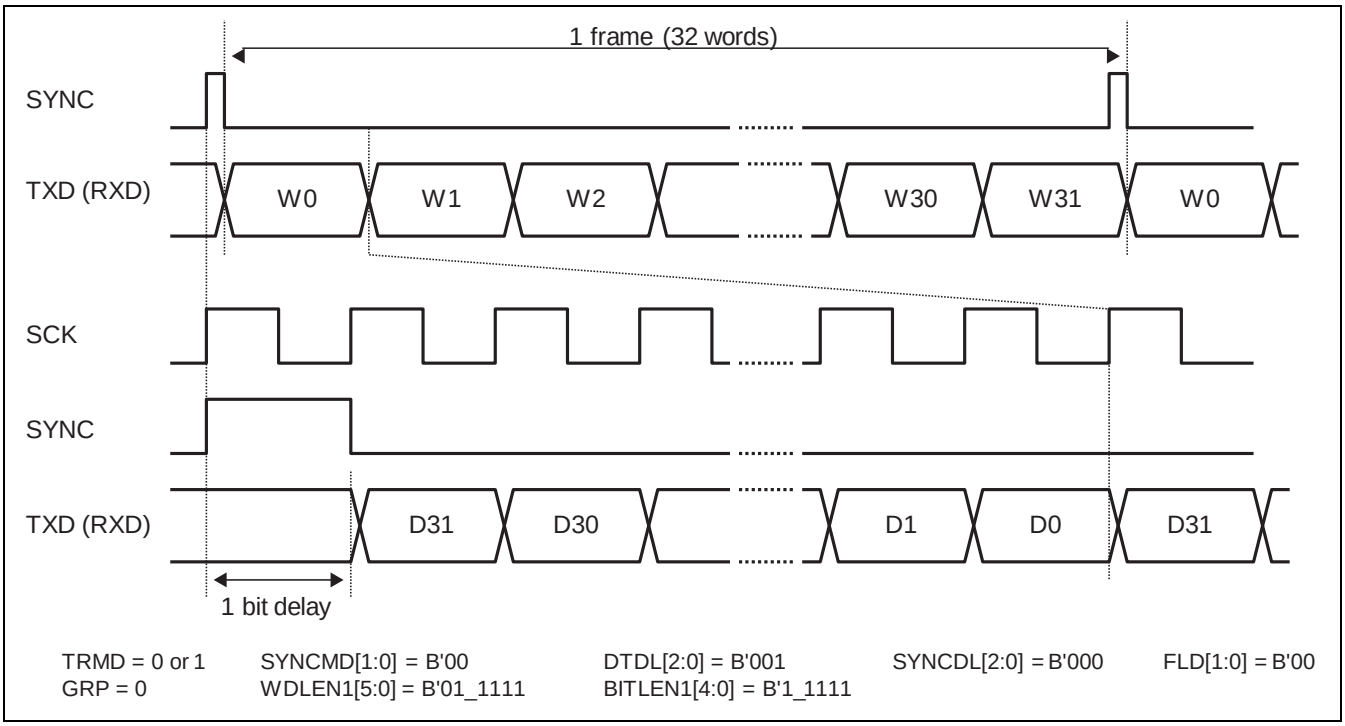

Figure 54.17 Transmit and Receive Timing (32 Bits)

(3) 32-bit IIS transmission

L/R mode, 2 groups, 1 word for each group, 32-bit word for each group, 1-bit delay

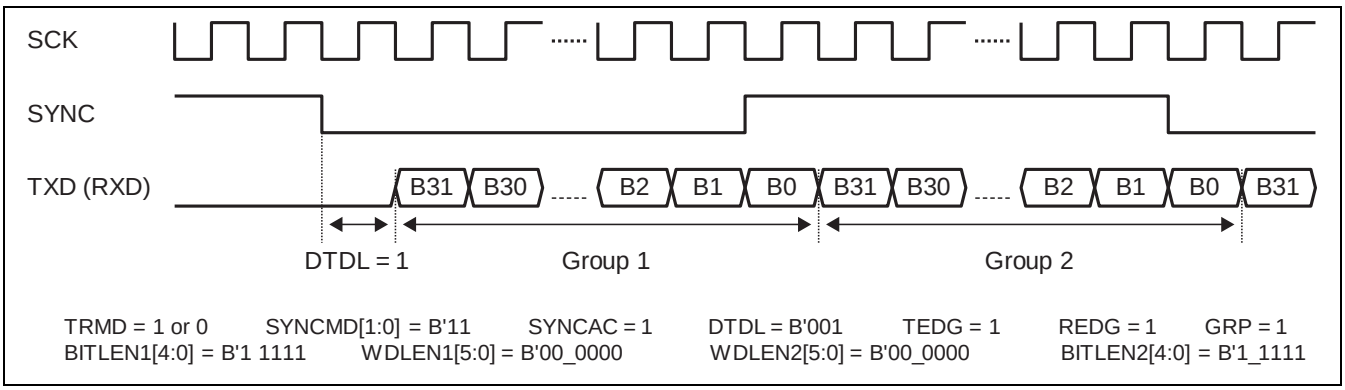

Figure 54.18 Transmit Timing (24-Bit IIS)

54.3.9 SPI

With the appropriate register settings, the MSIOF can be used as an SPI device.

(1) Example of SPI device connection

Figure 54.19 shows an example of connection with an SPI device.

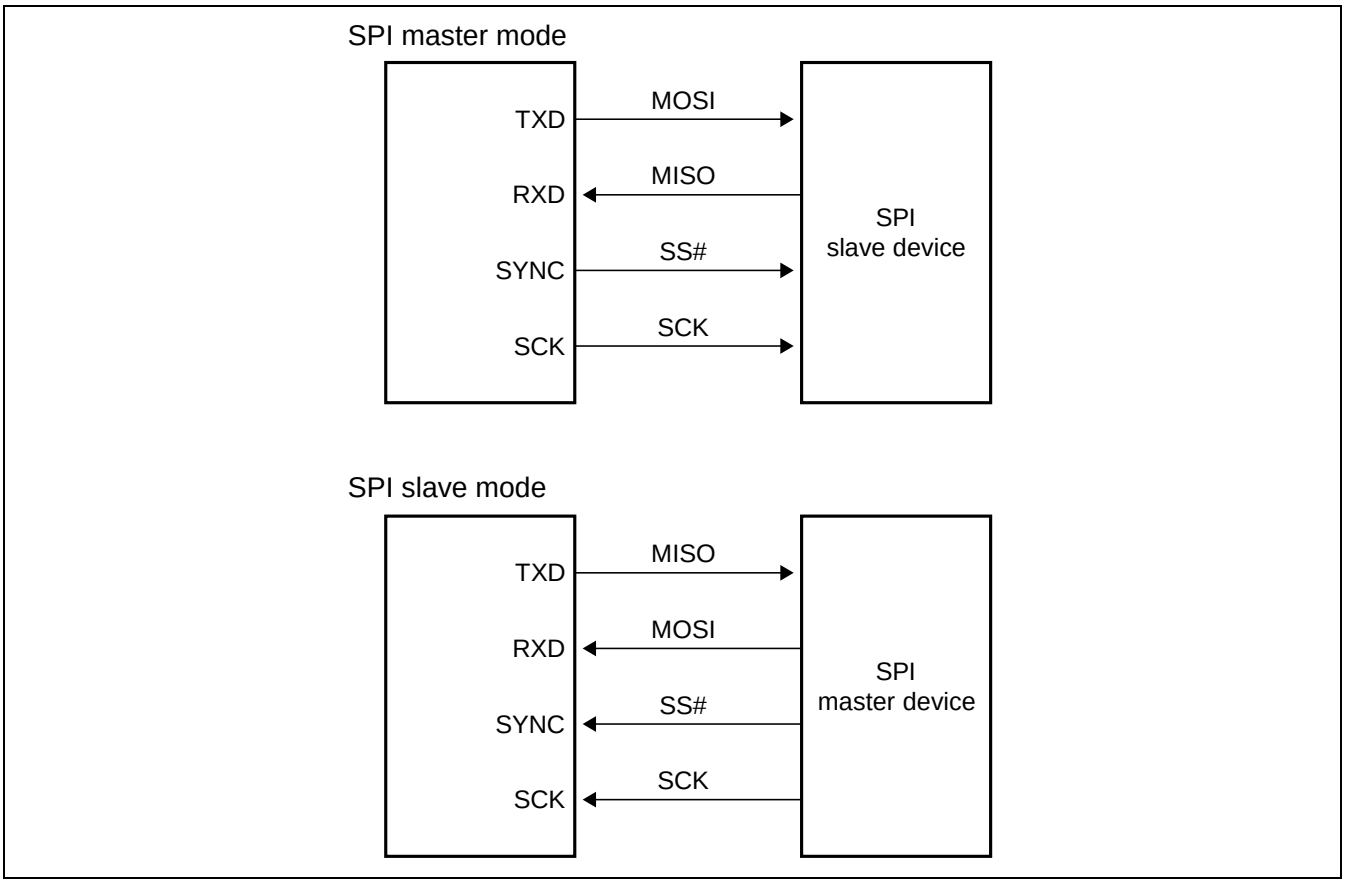

Figure 54.19 Example of SPI Device Connection

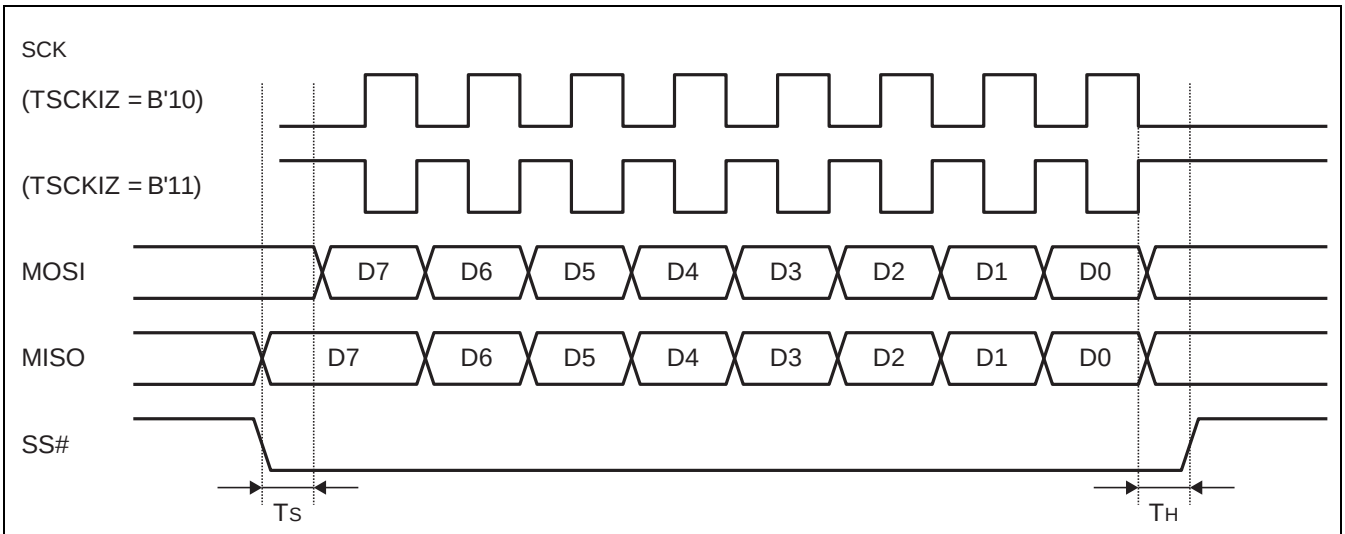
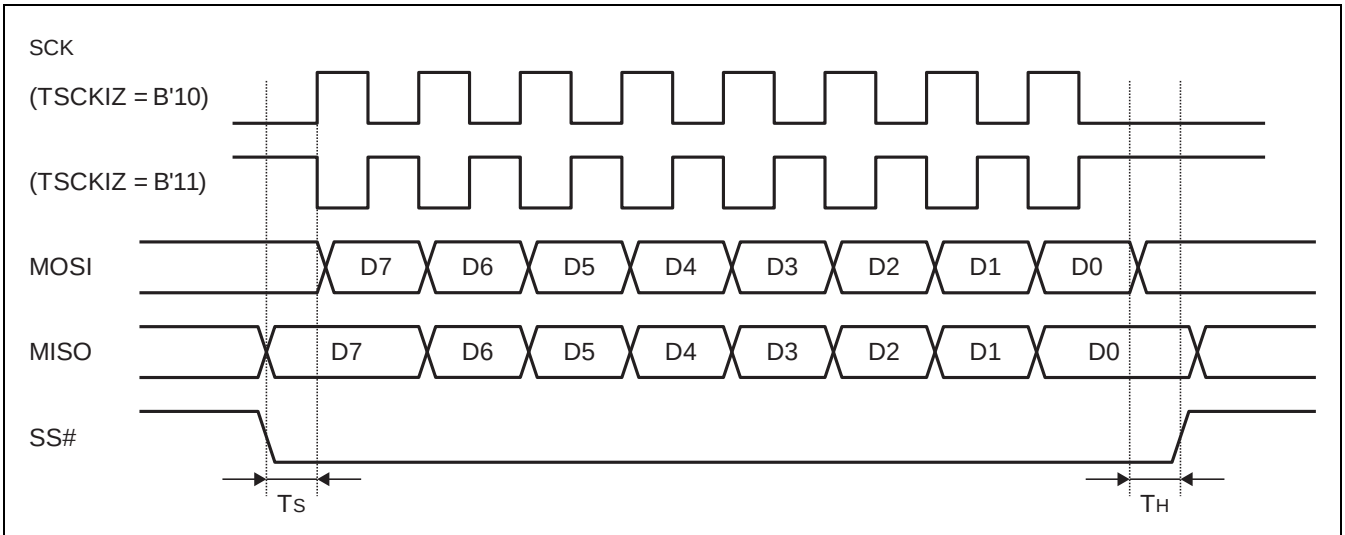
(2) SPI serial clock timing

Figure 54.20 and Figure 54.21 show the data and clock timing in SPI mode. As shown in the figures, four types of serial transfer formats can be used.



Transmit: TRMD = 1 (master) or 0 (slave) PCON = 1 SYNCMD[1:0] = B'10 SYNCAC = 1
GRP = 0 BITLEN1[4:0] = B'0_0111 WDLEN1[5:0] = B'00_0000
Receive: TRMD = 0 SYNCMD[1:0] = B'10 SYNCAC = 1
GRP = 0 BITLEN1[4:0] = B'0_0111 WDLEN1[5:0] = B'00_0000
Set DTDL to satisfy TS (0 to 2 can be specified in 0.5-clock-cycle units) Set SYNCDL to satisfy TH (0 to 2 can be specified in 0.5-clock-cycle units)
The sum of DTDL and SYNCDL settings should be an integer.
SICTR: (Upper) TSCKIZ[1:0] = B'10, RSCKIZ[1:0] = B'10, TEDG = 1, REDG = 1
(Lower) TSCKIZ[1:0] = B'11, RSCKIZ[1:0] = B'11, TEDG = 0, REDG = 0

Figure 54.20 SPI Clock and Data Timing 1



Transmit: TRMD = 1 (master) or 0 (slave) PCON = 1 SYNCMD[1:0] = B'10 SYNCAC = 1
GRP = 0 BITLEN1[4:0] = B'0_0111 WDLEN1[5:0] = B'00_0000
Receive: TRMD = 0 SYNCMD[1:0] = B'10 SYNCAC = 1
GRP = 0 BITLEN1[4:0] = B'0_0111 WDLEN1[5:0] = B'00_0000
Set DTDL to satisfy TS (0 to 2 can be specified in 0.5-clock-cycle units) Set SYNCDL to satisfy TH (0 to 2 can be specified in 0.5-clock-cycle units)
The sum of DTDL and SYNCDL settings should be an integer.
SICTR: (Upper) TSCKIZ[1:0] = B'10, RSCKIZ[1:0] = B'10, TEDG = 0, REDG = 0
(Lower) TSCKIZ[1:0] = B'11, RSCKIZ[1:0] = B'11, TEDG = 1, REDG = 1

Figure 54.21 SPI Clock and Data Timing 2

54.3.10 IIS

This module can support IIS format with following setting which is shown in Figure 54.22 and Figure 54.23. BITLEN1 and BITLEN2 bits will change by usage.

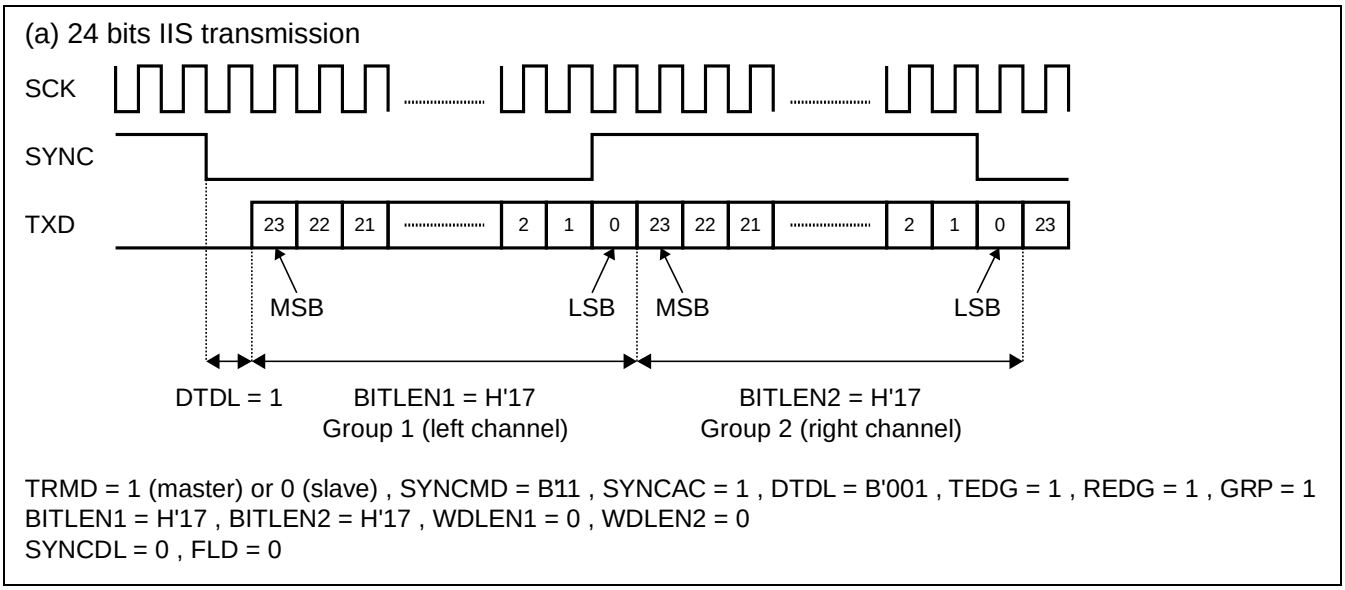


Figure 54.22 24 Bits IIS Transmission

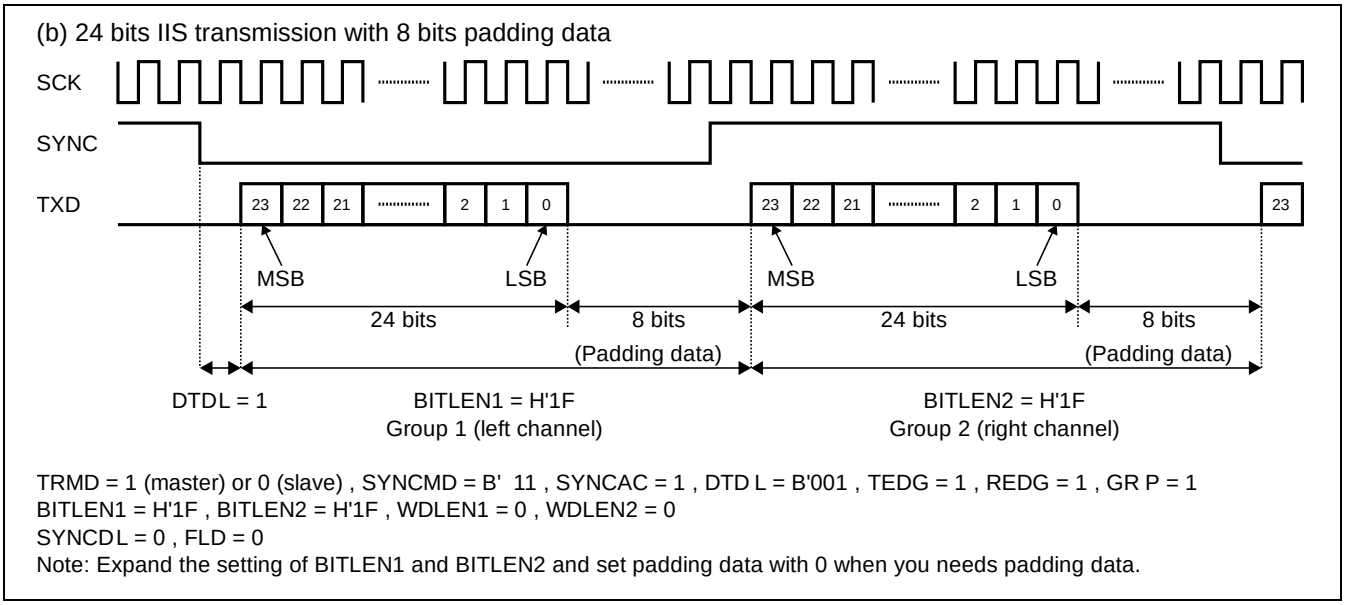

Figure 54.23 24 Bits IIS Transmission with 8 Bits Padding Data

54.4 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

54.4.1 Notes for Using SPI Mode

- For SPI master mode operation, set the FLD bits in SITMDR1 for at least 3 cycles of module clock.
- For SPI slave mode operation, set the frame synchronization signal interval to at least 4 cycles of module clock.
- For SPI slave mode operation, the setting for data delay should be always set to 0.
- For SPI slave mode operation, TXDIZ bits work on SS signal invalid state.

54.4.2 Notes for Using SPI slave Mode

1. In case of SPI slave mode, this module can't receive any data from external device, before SICTR [8]. RXE is set to 1. Prepare scheme to guarantee data will arrive only after SICTR [8]. RXE is set to 1, by higher level arbitration.

2. In case of SPI slave mode, this module needs to receive assert of SYNC signal to start receiving data. For this purpose, SYNC signal from master device must be connected to SYNC port, even in the environment, in which only two devices (master and slave) exist. Also, SYNC signal must be asserted after SICTR [8]. RXE bit is set. SYNC signal assertion while SICTR [8]. RXE is 0, received data can't guarantee.

3. When the MSIOF operates with all the following condition 1 to 3, the MSIOF in SPI slave mode cannot start the next transmission. The MSIOF cannot support SPI mode under following condition.

- Condition

1) MSIOF is in SPI slave mode (SITMDR1.TRMD = 0, SITMDR1.SYNCMD[1:0] = 10)
2) SYNC (CS) signal is being asserted from master
3) TXE or RXE in SICTR is set to 1 during SYNC (CS) is asserted

This limitation means the MSIOF cannot respond to the SYNC (CS).
It is necessary to control the MSIOF enabling timing by the master and system.

[Workaround]
Use master mode for SPI.
If use slave mode for SPI, consider following alternative.

[Alternative]
If the master device can support handshaking, use the handshaking transmission.
For the MSIOF in SPI slave mode, use with the GPIO output for SPI handshaking; the system operation must be tested and evaluated thoroughly by user.

4. In case of SPI slave mode, this module must not set SICTR[1].TXRST or SICTR[0].RXRST during SYNC signal asserted.

54.4.3 Notes for Transmitting Audio data via MSIOF

If you want to transmit audio data via MSIOF, don't set the master clock (MSOϕ) to SSCG.

54.4.4 Notes on Fixed Value related to MSIOF registers

It is necessary to change from the initial value to the specific fixed value for these bits in the MSIOF registers. Setting other value is prohibited.

Table 54.11 Fixed Value for the MSIOF Registers without any condition

Section		Bit Number	Fixed Value
54.2.1	MSIOF Transmit Mode Register 1 (SITMDR1)	30	B'1

54.4.5 Notes for Transmit FIFO Underflow (SISTR.TFUDF)

If transmission size is less than or equal to 64-words per frame, transmit FIFO Underflow (SISTR.TFUDF) needs to be ignored. If transmission size is larger than 64-words per frame, use Transmit FIFO Empty (SISTR.TFEMP) instead of this bit. To skip Empty (SISTR.TFEMP) state after the transmission completion, write 1-word dummy data to the transmit FIFO and perform reset after the transferring. If the next transfer data can be prepared, it can be possible to store next data instead of dummy data. In that case, the reset process can be skipped. If Empty is detected during transfer, reset after the stop processing of each module completed, and redo initialization.

The following is an example flow when Transmit FIFO Empty (SISTR.TFEMP) interrupt is detected.

1. SISTR.TFEMP interrupt detection
2. Clear interrupt enable of MSIOF
3. Wait for SISTR.TEOF/REOF=1 state of MSIOF
4. Stop processing of DMAC (After DMACHCR.DE=0 at DMAC, wait for DMACHCR.DE=0)
5. DMAC channel reset (DMACHCLR.CLR[m]=1 at DMAC, m=usage channel)
6. Change PFC setting (MSIOF_SCK, MSIOF_SYNC) to GPIO(In) side
7. Assert SW reset for activating MSIOF channels in use (SRCR2.MSIOF)
8. De-assert SW reset for using MSIOF channels in use (SRSTCLR2.MSIOF) (Regarding procedure of SW reset, please refer to the sec 8A. Module Standby, Software Reset)
9. Reconfigure MSIOF and DMAC When using PIO access, the No4 and No5 and the reconfiguration of DMAC in No9 are unnecessary. (The reconfiguration of MSIOF in No9 is necessary.)

Note: DMAC is SYS-DMAC

55. PWM

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

55.1 Overview

This LSI incorporates seven channels for , RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N, RZ/G2E;

Internal bus clock:

— RZ/G2H: S0D12ϕ
— RZ/G2M V1.3: S0D12ϕ
— RZ/G2M V3.0: S0D12ϕ
— RZ/G2N: S0D12ϕ
— RZ/G2E: S3D4Cϕ

55.1.1 Features

- PWM output cycle settable (10 bits)
- PWM output cycle settable within the range from 2 cycles to $2^{24} \times 1023$ cycles of internal bus clock (i.e. from 30 ns to 257.5 seconds when internal bus clock = 66.66 MHz)
- High-level width of the PWM output signal settable (10 bits)
- Continuous pulse output or single pulse output selectable

55.1.2 Block Diagram

Figure 55.1 shows a block diagram of the PWM timer.

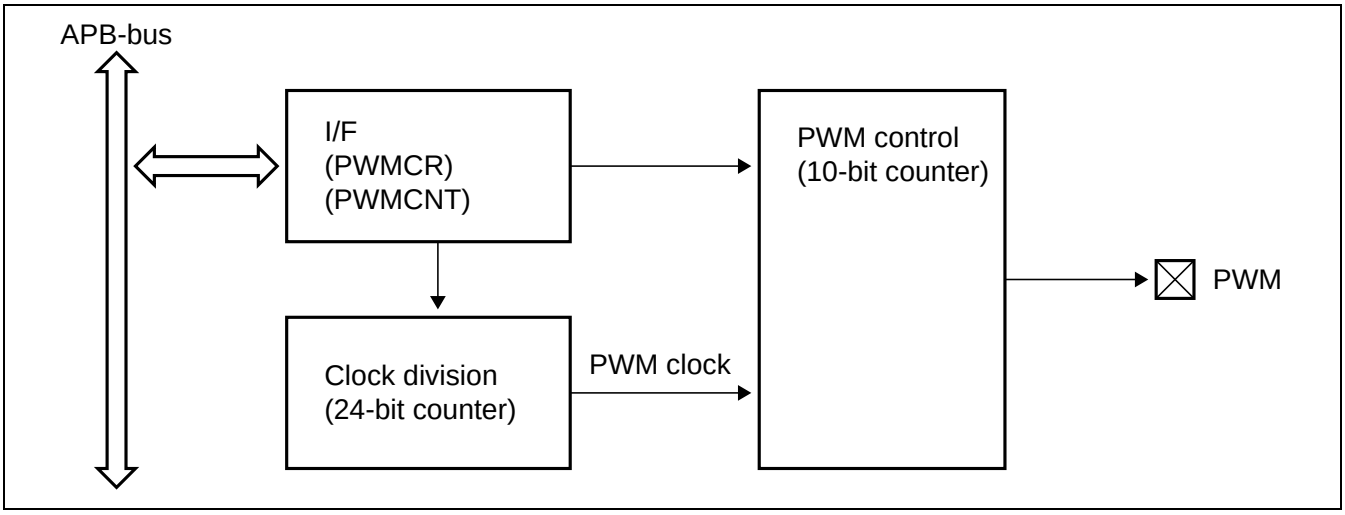

Figure 55.1 Block Diagram of PWM Timer

55.1.3 External Pins

Table 55.1 shows the pin configuration of the PWM timer.

Table 55.1 Pin Configuration

			Second Generation RZ/G Series Products			
Pin Name	**I/O**	**Function**	**RZ/G2H**	**RZ/G2M V1.3 RZ/G2M V3.0**	**RZ/G2N**	**RZ/G2E**
PWM0	Output	PWM0 timer pulse output	√	√	√	√
PWM1	Output	PWM1 timer pulse output	√	√	√	√

	PWM count register	PWMCNT	R/W	H'E6E3_6004	32	√	√	√	√

Note: Do not access addresses other than those listed above. If access is attempted, a malfunction may occur.

Table 55.3 Register States in Each Operating Mode

Name	Abbreviation	Power-on Reset/Software Reset	Module Standby
PWM control register	PWMCR	H'0000_0000	Retained
PWM count register	PWMCNT	H'0000_0000	Retained

The registers of the PWM timer are mapped into the internal bus address space.

55.2 Register Description

Registers in the PWM timer are allocated to and arranged in the address space of the internal bus.

Legend for Register Description

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

R: Read-only. When the bit is reserved, the write value should always be 0. Writing 1 to these bits can cause a malfunction of PWM.

—/W: Write-only. The read value is undefined.

55.2.1 PWM Control Register (PWMCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	CC0			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CCMD	—	—	—	SYNC	—	—	—	—	—	—	SS0	—	—	—	EN0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
19 to 16	CC0	B'0000	R/W	Clock Control The clock frequency of the PWM counter is obtained by dividing the frequency of the clock signal of internal bus clock. When the internal bus clock frequency is f MHz, the following PWM clock frequencies are obtained. B'0000: f MHz B'0001: f MHz/2^2 B'0010: f MHz/2^4 B'0011: f MHz/2^6 B'0100: f MHz/2^8 B'0101: f MHz/2^{10} B'0110: f MHz/2^{12} B'0111: f MHz/2^{14} B'1000: f MHz/2^{16} B'1001: f MHz/2^{18} B'1010: f MHz/2^{20} B'1011: f MHz/2^{22} B'1100: f MHz/2^{24} When B'1101, B'1110, or B'1111 is set, the PWM clock frequency is f MHz/2^{24}.

Bit	Bit Name	Initial Value	R/W	Description
15	CCMD	B'0	R/W	CC0 Frequency Division Mode Changes the PWM clock frequency set by the clock control (CC0) bits. 0: The PWM clock frequency set by CC0 is used. 1: The PWM clock frequency set by CC0 is changed as follows: 1 - B'0000: f MHz/2 1 - B'0001: f MHz/2^3 1 - B'0010: f MHz/2^5 1 - B'0011: f MHz/2^7 1 - B'0100: f MHz/2^9 1 - B'0101: f MHz/2^{11} 1 - B'0110: f MHz/2^{13} 1 - B'0111: f MHz/2^{15} 1 - B'1000: f MHz/2^{17} 1 - B'1001: f MHz/2^{19} 1 - B'1010: f MHz/2^{21} 1 - B'1011: f MHz/2^{23} If B'1100, B'1101, B'1110, or B'1111 is set for CC0, the PWM clock frequency is f MHz/2^{24} irrespective of the CCMD value.
14 to 12	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
11	SYNC	B'0	R/W	Specifies whether to allow the set values in the PWM count register (PWMCNT) to be reflected in the timer operation synchronously with setting the PWM control register (PWMCR). 0: Allows the PWMCNT set values to be reflected in the timer operation irrespective of PWMCR setting. 1: Allows the PWMCNT set values to be reflected in the timer operation synchronously with PWMCR setting. For details, refer to section 55.3 Operation.
10 to 7	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
6, 5	—	All 0	R/W	Reserved The read value is always 0. The write value should always be 0.
4	SS0	B'0	R/W	Single Pulse Output 0: The timer operates in continuous pulse output mode. 1: The timer operates only for a single cycle and then stops.
3	—	B'0	R/W	Reserved The read value is always 0. The write value should always be 0.
2, 1	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
0	EN0	B'0	R/W	Channel Enable 0: The channel is held in the idle state, and outputs a high level. 1: The channel outputs high and low levels in a predetermined cycle. This bit is automatically cleared in single pulse output mode.

55.2.2 PWM Count Register (PWMCNT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	CYC0									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PH0									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
25 to 16	CYC0	H'000	R/W	PWM Cycle Sets the PWM output cycle. The cycle set by these bits is the sum of the high-level and low-level periods. Setting H'000 is prohibited.
15 to 10	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
9 to 0	PH0	H'000	R/W	PWM High-Level Period Sets the period for which the PWM timer outputs a high-level signal. Setting H'000 is prohibited.

Note: For the CYC0 and PH0 bits, set the number of cycles to be counted of the PWM clock signal whose frequency has been set by the CC0 and CCMD bits in the PWM control register.

55.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

The duty ratio of a PWM output pulse can be obtained by setting a high-level period and a cycle. The timer channel counts the PWM clock signal pulses using a 10-bit counter to generate the PWM output pulse having the specified period and cycle. When the channel function is enabled (EN0 = 1), the timer outputs a high level until the counter value reaches the value set in the PH0 bits of the PWM count register (PWMCNT). The output goes low when the PH0 value is reached, and is held low until the counter value reaches the value set in the CYC0 bits of PWMCNT. When the CYC0 value is reached, the output goes high and the counter is reset.

Unless the channel function is enabled, the output is held high, and the counter is held in the reset state.

Figure 55.2 shows the PWM state transition during the operation described above.

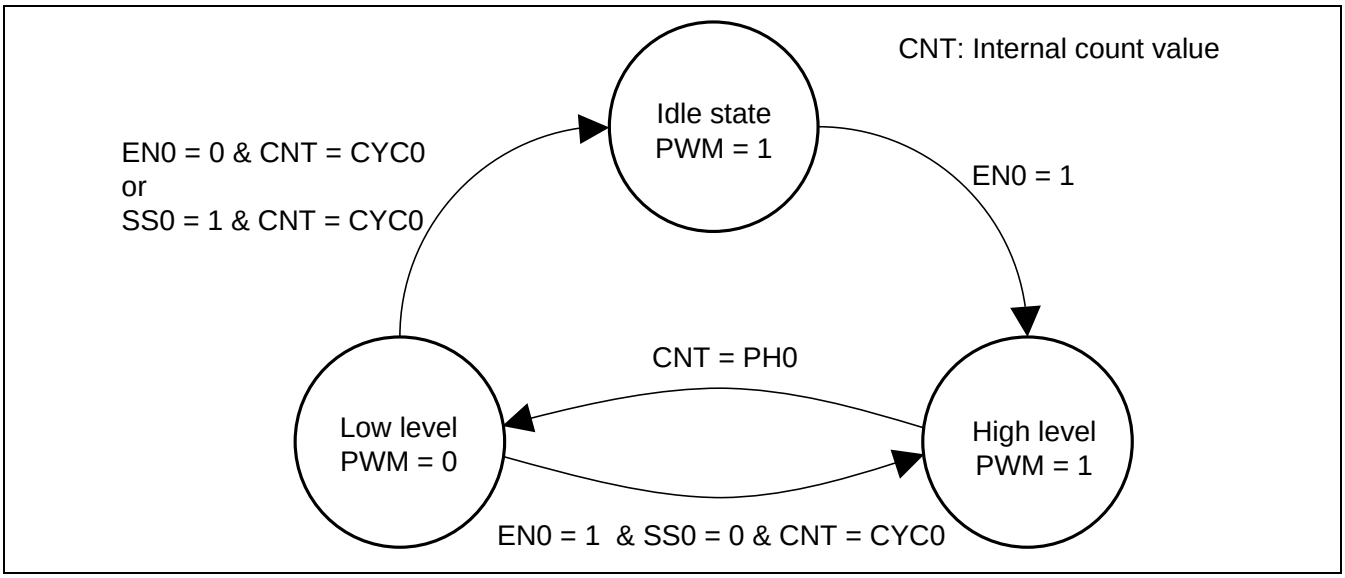

Figure 55.2 PWM Timer State Transition

Note that after a channel has been enabled by writing 1 to EN0, the number of clock pulses before output of the first falling edge from a channel is greater than the value set in the PWM control register and PWM count register by up to four cycles of the internal bus clock. After that, the PWM output rises and falls according to a set timing. Figure 55.3 schematically shows this output timing. This figure shows an internal operation.

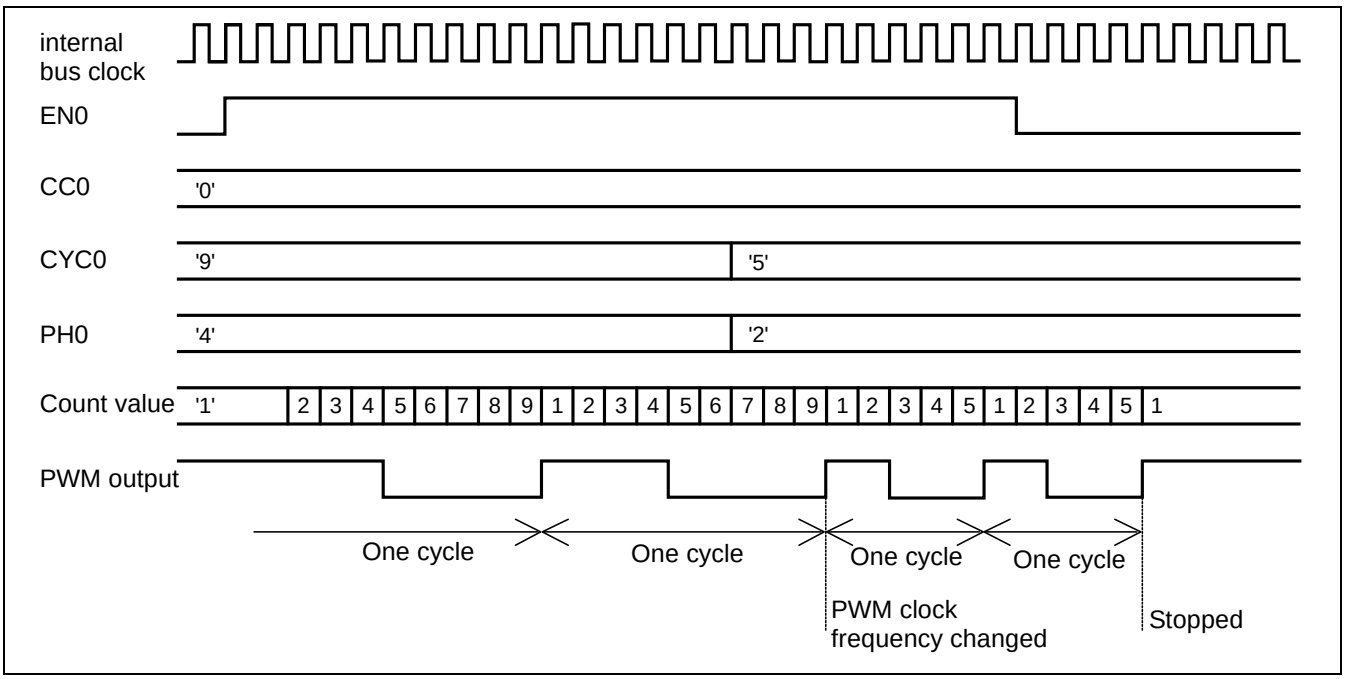

Figure 55.3 PWM Output Timing

1. The period from enabling the channel to the first falling edge output from the channel is the sum of a set value and up to four cycles of the internal bus clock.
2. After that, the PWM high and low widths are the same as the set values.
3. When the PWM count register is changed during operation (EN0 = 1), timing of the output will be in accord with the new settings after output of the current cycle has been completed.
4. When the CC0 and CCMD bit values in the PWM control register are changed during operation (EN0 = 1), timing of the output will be in accord with the new settings after output of the current cycle has been completed.
5. To stop the timer operation, write 0 to the EN0 bit. The timer stops operation after completing the output of the current cycle. Note that, however, if 1 is written to EN0 again before completing the output of the current cycle, the timer does not stop but continues to operate.
6. For the PWM timer output, continuous pulse output mode and single pulse output mode are supported. In continuous pulse output mode, the timer outputs pulses continuously while EN0 is 1. In single pulse output mode, the timer outputs a single pulse. In this mode, EN0 is automatically cleared.
7. To change the values of the clock control bits (CC0) and the CC0 frequency division mode bit (CCMD) in the PWMCR register and of the PWM cycle bits (CYC0) and the PWM high-level period bits (PH0) in the PWMCNT register at the same time during the PWM operation, the following procedure should be followed:
   1. Write 1 to the SYNC bit. (Write the original set values to the other bits in PWMCR.)
   2. Change the PWMCNT value.
   3. Change the CC0 and CCMD values in PWMCR. (Write the original set values to the other bits in PWMCR. The SYNC bit should be held at 1.)

   By following the above procedure, the new PWMCNT value is reflected in the timer operation synchronously with PWMCR setting.
   When changing only the PWMCNT value while SYNC = 1, writing to PWMCR is required after changing the PWMCNT value. In this case, write the same values as the original set values to the PWMCR bits. On the other hand, when changing only the PWMCR value, writing to PWMCNT is not required.
   If PWMCNT and PWMCR values are changed while SYNC = 0, the change to the values might not be completed within a single PWM output cycle but actually take two or more cycles. This may disturb the period or duty cycle of the PWM output.
   Note that, when the PWCNT value is changed while SYNC = 1, the new values are read from PWMCNT even before PWMCR is set.

55.4 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

When using the PWM timer, note the following points.

When the CYC0 value is equal to or smaller than PH0 value in the PWM count register, the PWM output is held high. In this case, to start pulse output, clear EN0 to 0, set CYC0 to the value greater than the PH0 value, and then set EN0 to 1.

Note that, a maximum period equivalent to CYC0 = H'3FF at the set PWM clock frequency may be required before pulse output is started.

56. SPI Multi I/O Bus Controller (RPC-IF)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

56.1 Overview

The SPI multi I/O bus controller enables direct connection of the serial flash memory, HyperFlash, or Octal-SPI Flash memory to this LSI.

56.1.1 Features

This module allows the serial flash memory or HyperFlash memory connected to this LSI to be accessed by the external address space read mode or manual mode.

The external address space read mode is able to read from Flash memory only. The manual mode is able to write to and read from Flash memory.

(1) Serial Flash Memory Interface

- Up to two serial flash memory devices can be connected. Note that two serial flash memory devices are operated in parallel interface and each 1xQSPI operation is not supported.
- When 1xQSPI configuration, QSPI0 pins in this LSI are connected to the serial flash memory.
- A data bus size of 1 bit or 4 bits can be selected for a serial flash memory device.
- Support single data rate (SDR) and Double data rate (DDR) transfer
- Only the master operation is supported (the slave operation is not supported).
- Support Octal-SPI flash interface by using 2ch mode with 4bit bus size

Note: “Octal-SPI flash” indicates 8-bit SPI flash with one ChipSelect, one Clock source and one DataStrobe configuration. Serial flash memory specification without “8-bit” description specifies general SPI flash interface (including SPI compatible mode) in this manual.

Note: The RZ/G2M V1.3 (not RZ/G2M V3.0) does not support DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit).
Note that the RZ/G2M V1.3 (not RZ/G2M V3.0) supports the Hyperflash and Octal-SPI memory devices even though it requires DDR operation.

(2) HyperFlash Interface

- One HyperFlash can be connected.
- The data bus size is fixed to 8 bits.
- Wrapped Burst is not supported.

(3) External Address Space Read Mode

- A read access from the bus master to the SPI multi I/O bus space is automatically converted into a read command to the device and the read data are returned to the bus master.
- Normal read and burst read operation
- Efficient data reception is possible by utilizing the on-chip read cache memory (64-bit line × 32 entries) during burst read operation.

(4) Manual Mode

- Desired command, read, and write accesses to the serial flash memory or HyperFlash memory are possible.
- Efficient data writing is possible by using write buffer.
- Not support the on-chip read cache memory during read operation.

56.1.2 Block Diagram

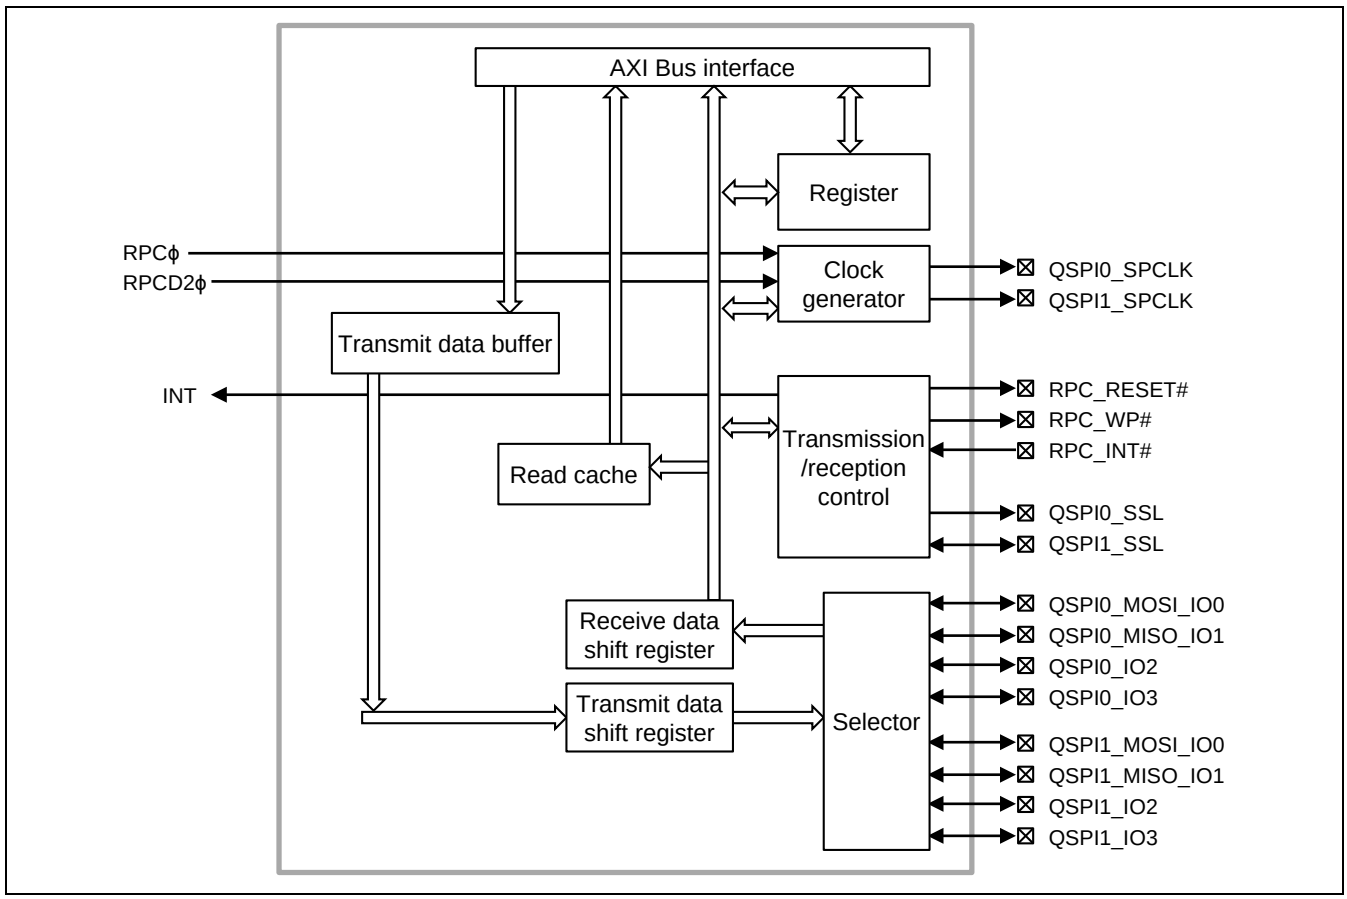

Figure 56.1 RPC-IF Block Diagram

56.1.3 External Pins

Table 56.1 shows the pin configuration of the RPC-IF.

Table 56.1 Pin Name

			Function		Second Generation RZ/G Series Products			
Pin Name	**Symbol**	**I/O**	**When serial flash is selected.**	**When HyperFlash is selected.**	**RZ/G2H**	**RZ/G2M V1.3 RZ/G2M V3.0**	**RZ/G2N**	**RZ/G2E**
Channel 0 clock pin*2	QSPI0_SPCLK	Output	Clock output	Differential clock output +	√	√	√	√
Channel 0 master transmit data/data 0	QSPI0_MOSI_IO0	I/O	Master transmit data/data 0	Data 0	√	√	√	√

Channel 0 data 2 pin	QSPI0_IO2	I/O	Data 2	Data 2	√	√	√	√
Channel 0 data 3 pin	QSPI0_IO3	I/O	Data 3	Data 3	√	√	√	√
Channel 0 slave select pin	QSPI0_SSL	Output	Slave selection	Chip selection	√	√	√	√
Channel 1 clock pin*1,*2,*4	QSPI1_SPCLK	Output	Clock output	Differential clock output -	√	√	√	√
Channel 1 master transmit data/data 0 pin	QSPI1_MOSI_IO0	I/O	Master transmit data/data 0	Data 4	√	√	√	√
Channel 1 slave transmit data/data 1 pin	QSPI1_MISO_IO1	I/O	Slave transmit data/data 1	Data 5	√	√	√	√
Channel 1 data 2 pin	QSPI1_IO2	I/O	Data 2	Data 6	√	√	√	√
Channel 1 data 3 pin	QSPI1_IO3	I/O	Data 3	Data 7	√	√	√	√
Channel 1 slave select pin*1,*4	QSPI1_SSL	I/O	Slave selection or Data strobe	Read data strobe (RDS)	√	√	√	√
Flash-RESET pin*1,*3	RPC_RESET#	Output	Reset signal output	Reset signal output	√	√	√	√
Write protect pin*1	RPC_WP#	Output	Write protect (WP)	Write protect (WP)	√	√	√	—
INT pin*1	RPC_INT#	Input	Interrupt input	Interrupt input	√	√	√	√

Notes: When a serial flash memory is to be connected with BSZ[1:0] being set to 00, the serial flash device should be connected to the QSPI0_* pins.

In the text, the channel number is omitted (e.g. QSPIn_SSL).

These pins are 1.8V operation only [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N]

These pins are 1.8/3.3V operation selectable [RZ/G2E]

1. These pins should be connected depending on the serial flash specification.
2. The frequency of QSPIn_SPCLK is same as RPCD2ϕ.
3. RPC_RESET# cannot be used with Serial Flash boot. Instead, connect PRESETOUT# to the Serial Flash RESET# terminal. Also, when using 1.8V serial flash, step down voltage from 3.3V to 1.8V. (3.3V serial flash is unnecessary.) [RZ/G2E]
4. When MD[4:1]=B'0010/B'0011(dma HyperFlash), B'1010/B'1011(xip HyperFlash),
   - During RPC_RESET# is low level, QSPI1_SPCLK is low output and QSPI1_SSL is high output.
   - During RPC_RESET# is high level, QSPI_SPCLK is high output and QSPI1_SSL is Hi-Z.

56.1.4 Register Configuration

Table 56.2 shows the register configuration of the RPC-IF.

Table 56.2 Register Configuration

56.2 Register Description

The registers of the RPC-IF are assigned to and located in the address space of the internal bus.

[Legend for Register Descriptions]

Initial value: Register value after a reset.

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

R: Read-only. The write value should always be initial value. For details of initial value, refer to Table 56.3.

—/WB: Write-only. The read value is undefined.

56.2.1 Common Control Register (CMNCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMNCR is a 32-bit register that controls the SPI multi I/O bus controller. The settings of this register are reflected both in external address space read mode and manual operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MD	—	—	—	—	—	—	—	MOIIO3		MOIIO2		MOIIO1		MOIIO0	
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	IO0FV		—	—	—	—	—	—	BSZ	
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

Bit	Bit Name	Initial Value	R/W	Description
31	MD	—	R/W	Operating Mode Switch Switches the operating modes. 0: External address space read mode 1: Manual mode
30 to 25	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.

Bit	Bit Name	Initial Value	R/W	Description
24	—	—	R	Reserved This bit is always read as initial value. The write value should always be initial value.
23, 22	MOIIO3[1:0]	—	R/W	QSPIn_SSL Output Idle Value Fix QSPIn_IO3 Fixes output value of QSPIn_IO3 in QSPIn_SSL negation period. B’00: 0 B’01: 1 B’10: The value in the last bit of the previous transfer (Hi-Z, if Hi-Z was the value in the last bit of the previous transfer). B’11: Hi-Z Notes: 1. This bit should be specified to one when Octal-SPI flash is connected 2. When connecting to HyperFlash, this function is always "10: Output value is the last bit value of the previous transfer (Hi-Z, if Hi-Z was the last bit value of the previous transfer)"
21, 20	MOIIO2[1:0]	—	R/W	QSPIn_SSL Output Idle Value Fix QSPIn_IO2 Fixes output value of QSPIn_IO2 in QSPIn_SSL negation period. B’00: Output value 0 B’01: Output value 1 B’10: Output value is the last bit value of the previous transfer (Hi-Z, if Hi-Z was the last bit value of the previous transfer). B’11: Output value Hi-Z Notes: 1. This bit should be specified to one when Octal-SPI flash is connected 2. When connecting to HyperFlash, this function is always "10: Output value is the last bit value of the previous transfer (Hi-Z, if Hi-Z was the last bit value of the previous transfer)"
19, 18	MOIIO1[1:0]	—	R/W	QSPIn_SSL Output Idle Value Fix QSPIn_IO1 Fixes output value of QSPIn_IO1 in QSPIn_SSL negation period. B’00: Output value 0 B’01: Output value 1 B’10: Output value is the last bit value of the previous transfer (Hi-Z, if Hi-Z was the last bit value of the previous transfer). B’11: Output value Hi-Z Notes: 1. This bit should be specified to one when Octal-SPI flash is connected 2. When connecting to HyperFlash, this function is always "10: Output value is the last bit value of the previous transfer (Hi-Z, if Hi-Z was the last bit value of the previous transfer)"

Bit	Bit Name	Initial Value	R/W	Description
17, 16	MOIIO0[1:0]	—	R/W	QSPIn_SSL Output Idle Value Fix QSPIn_IO0 Fixes output value of QSPIn_IO0 in QSPIn_SSL negation period. B’00: Output value 0 B’01: Output value 1 B’10: Output value is the last bit value of the previous transfer (Hi-Z, if Hi-Z was the last bit value of the previous transfer). B’11: Output value Hi-Z Notes: 1. This bit should be specified to one when Octal-SPI flash is connected 2. When connecting to HyperFlash, this function is always "B’10: Output value is the last bit value of the previous transfer (Hi-Z, if Hi-Z was the last bit value of the previous transfer)"
15 to 10	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
9, 8	IO0FV[1:0]	—	R/W	QSPIn_IO0 Fixed Value for 1-bit Size Input Fixes the output value of QSPIn_IO0 pin for 1-bit size input. B’00: Output value 0 B’01: Output value 1 B’10: Output value is the last bit value of the previous transfer (Hi-Z, if Hi-Z was the last bit value of the previous transfer). B’11: Output value Hi-Z
7 to 2	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
1, 0	BSZ[1:0]	—	R/W	Data Bus Size Specifies the number of serial flash memory devices to be connected. When HyperFlash is connected, these bits should always be set to 01. B’00: Serial flash memory x 1 B’01: Serial flash memory x 2 or HyperFlash x 1 or Octal-SPI flash memory x 1 B’1X: Setting prohibited Note: After changing the value of this bit field, all the entries in the read cache must be cleared by setting the RCF bit in DRCR to B’1.

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

56.2.2 SSL Delay Register (SSLDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SSLDR is a 32-bit register that adjusts the timing between the QSPIn_SSL signal and the QSPIn_SPCLK signal.

The settings of this register are reflected both in external address space read mode and manual operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	SPNDL		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SLNDL			—	—	—	—	—	SCKDL		
Initial value:	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18 to 16	SPNDL[2:0]	B’000	R/W	Next Access Delay Sets the period from transfer end to next transfer start (next access). B’000: 1 cycle of QSPIn_SPCLK B’001: 2 cycles of QSPIn_SPCLK B’010: 3 cycles of QSPIn_SPCLK B’011: 4 cycles of QSPIn_SPCLK B’100: 5 cycles of QSPIn_SPCLK B’101: 6 cycles of QSPIn_SPCLK B’110: 7 cycles of QSPIn_SPCLK B’111: 8 cycles of QSPIn_SPCLK
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	SLNDL[2:0]	B’100	R/W	QSPIn_SSL Negation Delay Sets the period from the time the last QSPIn_SPCLK edge is sent of a transfer to QSPIn_SSL pin negation (QSPIn_SSL negation delay). B’100: 5.5 cycles of QSPIn_SPCLK B’101: 6.5 cycles of QSPIn_SPCLK B’110: 7.5 cycles of QSPIn_SPCLK B’111: 8.5 cycles of QSPIn_SPCLK Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	SCKDL[2:0]	B’000	R/W	Clock Delay Sets the period from QSPIn_SSL pin assertion to QSPIn_SPCLK oscillation (clock delay). B’000: 1 cycle of QSPIn_SPCLK B’001: 2 cycles of QSPIn_SPCLK B’010: 3 cycles of QSPIn_SPCLK B’011: 4 cycles of QSPIn_SPCLK B’100: 5 cycles of QSPIn_SPCLK B’101: 6 cycles of QSPIn_SPCLK B’110: 7 cycles of QSPIn_SPCLK B’111: 8 cycles of QSPIn_SPCLK

56.2.3 Data Read Control Register (DRCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

DRCR is a 32-bit register that sets the operation in the external address space read mode.

For other than SSLN bit, the settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	SSLN	—	—	—	RBURST				
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	—/WB	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	RCF	RBE	—	—	—	—	—	—	—	SSLE
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	—/WB	R/W	R	R	R	R	R	R	R	R/W

Notes: 1. Initial value varies depending on boot mode. (Refer to Table 56.3.)
2. This function is available for write operation only. In read case, use external address space mode to read more than 32bit (1xQSPI) or 64bit (2xQSPI) data.

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
24	SSLN	—	—/WB	QSPIn_SSL Negation Asserted QSPIn_SSL can be negated by writing 1 to this bit when both the RBE and SSLE bits are 1. This bit is always read as 0. To start next access after QSPIn_SSL negation using this bit, read SSLF in CMNSR = 0 to confirm that the QSPIn_SSL has been negated. Note: This setting is only valid while serial flash memory is connected.
23 to 21	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
20 to 16	RBURST[4:0]	—	R/W	Read Data Burst Length Sets the burst length (data unit count) when reading. This bit field is enabled when the RBE bit is set to 1. B'0_0000: 1 data unit B'0_0001: 2 continuous data units : B'1_1110: 31 continuous data units B'1_1111: 32 continuous data units One data unit is 64 bits long.
15 to 10	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.

Bit	Bit Name	Initial Value	R/W	Description
9	RCF	—	—/WB	Read Cache Flush When 1 is written to this bit, all the entries in the read cache are cleared. This bit is always read as 0. After flushing the read cache by writing 1 to the RCF bit, read the DRCR before proceeding to read from the external address space. After operating by manual mode or using cache area as Write Buffer, this cache area must be cleared by writing 1 to the RCF bit.
8	RBE	—	R/W	Read Burst Enables or disables burst read. 0: Normal read Data is read according to the access size. 1: Burst read As many data units as the burst count specified in RBURST[4:0] bits are read. Read cache is enabled. Note: If an access spreads over the last address of the flash while a cache is enabled, the access address does not agree with the internal address of the flash. Manage the access so that the read address and the data size of the access does not spread over the last address.
7 to 1	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
0	SSLE	—	R/W	QSPIn_SSL Negation Setting Sets the conditions for QSPIn_SSL negation during read burst. QSPIn_SSL is negated for each access during normal read. 0: QSPIn_SSL is negated after transfer of data set in burst length. 1: QSPIn_SSL is negated when the accessed address is not continuous with the previously transferred address. Note: This setting is only valid while serial flash memory is connected.

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

56.2.4 Data Read Command Setting Register (DRCMR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

DRCMR is a 32-bit register that sets the commands issued in external address space read mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	CMD							
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	OCMD							
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
23 to 16	CMD[7:0]	—	R/W	Command Sets the command.
15 to 8	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
7 to 0	OCMD[7:0]	—	R/W	Optional Command Sets the optional command.

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

56.2.5 Data Read Extended Address Setting Register (DREAR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

DREAR is a 32-bit register that sets the address when the serial flash address is output in 32-bit mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed. This register is valid while the serial flash is connected.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	EAV							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	EAC		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

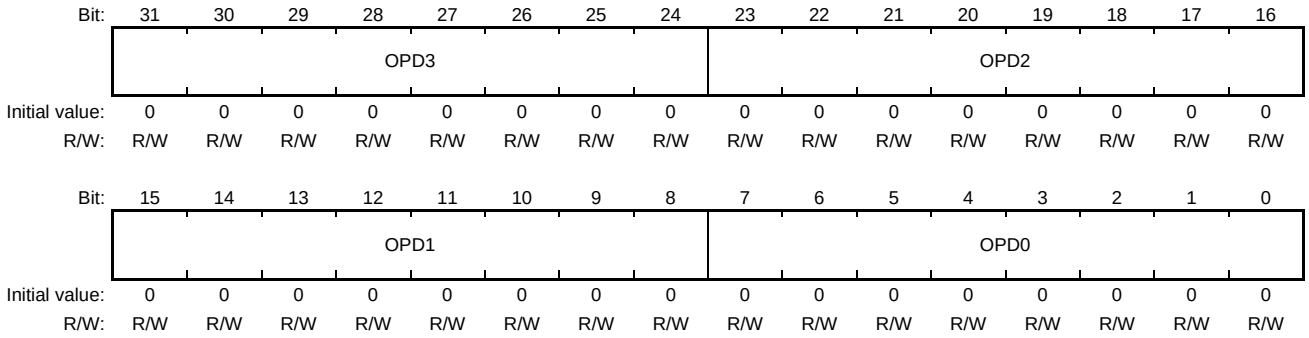
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	EAV[7:0]	H'00	R/W	32-Bit Extended Upper Address Fixed Value Sets the upper address bit values of the external address specified by the EAC[2:0] bits when the serial flash address is output in 32-bit mode. Bit 0 corresponds to the serial flash address bit [25], and bit 7 corresponds to the bit [32]. This setting is valid when the ADE[3] bit in DRENR is 1. When EAC[2:0] are 000, serial flash address [32:25] fixed values should set to EAV[7:0]. When EAC[2:0] are 001, serial flash address [32:26] fixed values should set to EAV[7:1]. (1) BSZ[1:0] bits in CMNCR = 00 (one serial flash memory connected) (2) BSZ[1:0] bits in CMNCR = 01 (two serial flash memory devices connected) Serial flash addresses [32:1] are used for accessing.
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	EAC[2:0]	B’000	R/W	32-Bit Extended External Address Valid Range Sets the range of the external address to be used as serial flash address when the serial flash address is output in 32-bit mode. This setting is valid when the ADE[3] bit in DRENR is 1. B’000: External address bits [24:0] enabled B’001: External address bits [25:0] enabled Other than above: Setting prohibited

56.2.6 Data Read Option Setting Register (DROPR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

DROPR is a 32-bit register that sets the option data in external address space read mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	OPD3[7:0]	H'00	R/W	Option Data 3 Sets the option data 3.
23 to 16	OPD2[7:0]	H'00	R/W	Option Data 2 Sets the option data 2.
15 to 8	OPD1[7:0]	H'00	R/W	Option Data 1 Sets the option data 1.
7 to 0	OPD0[7:0]	H'00	R/W	Option Data 0 Sets the option data 0.

Note: OPD3, OPD2, OPD1, and OPD0 are output in this order.

56.2.7 Data Read Enable Setting Register (DRENR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

DRENR is a 32-bit register that sets the bit size of the command, optional command, address, option data, and read data in external address space read mode and enables output of data other than read data. When connecting to HyperFlash, refer to Table 56.7 (Enable Registers (HyperFlash)).

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

Bit	Bit Name	Initial Value	R/W	Description
31, 30	CDB[1:0]	—	R/W	Command Bit Size Sets the command size in bit units. B’00: 1 bit B’10: 4 bits Other than above: Setting prohibited
29, 28	OCDB[1:0]	—	R/W	Optional Command Bit Size Sets the optional command size in bit units. B’00: 1 bit B’10: 4 bits Other than above: Setting prohibited
27, 26	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
25, 24	ADB[1:0]	—	R/W	Address Bit Size Sets the address size in bit units. B’00: 1 bit B’10: 4 bits Other than above: Setting prohibited
23, 22	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
21, 20	OPDB[1:0]	—	R/W	Option Data Bit Size Sets the option data size in bit units. B’00: 1 bit B’10: 4 bits Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
19, 18	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
17, 16	DRDB[1:0]	—	R/W	Data Read Size in Bit Units Sets the data read size in bit units. B’00: 1 bit B’10: 4 bits Other than above: Setting prohibited
15	DME	—	R/W	Dummy Cycle Enable Enables or disables insertion of a dummy cycle. The dummy cycle is inserted before the read data. Setting of a transfer starting with a dummy cycle is prohibited. 0: Insertion of a dummy cycle is disabled. 1: Insertion of a dummy cycle is enabled.
14	CDE	—	R/W	Command Enable Enables or disables output of commands. 0: Output disabled 1: Output enabled
13	—	—	R	Reserved This bit is always read as initial value. The write value should always be initial value.
12	OCDE	—	R/W	Optional Command Enable Enables or Disables output of Optional commands. 0: Output disabled 1: Optional command output enabled
11 to 8	ADE[3:0]	—	R/W	Address Enable Sets the address to be output. Be sure to use the following setting. Otherwise, the operation is not guaranteed. (1) BSZ[1:0] in CMNCR = 00 (one serial flash memory connected) B’0000: Output disabled B’0111: Data in address[23:0] is output. B’1111: Data in address[31:0] is output. Other than above: Setting prohibited (2) BSZ[1:0] in CMNCR = 01 (two serial flash memory devices connected) B’0000: Output disabled B’0111: Address[24:1] is output. B’1111: Address[32:1] is output. Other than above: Setting prohibited (3) PHYMEM in PHYCNT = 11 (HyperFlash connected) B’0100: HyperFlash protocol is output. Other than above: Setting prohibited Refer to Table 56.7 for the detail setting. (4) OCT in PHYCNT = 1 (Octal-SPI connected) with 8-8-8 protocol B’1100: Octal-SPI with 8-8-8 protocol is output. Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	OPDE[3:0]	—	R/W	Option Data Enable Sets the option data to be output. Be sure to use the following setting. Otherwise, the operation is not guaranteed. B’0000: Output disabled B’1000: OPD3 is output. B’1100: OPD3 and OPD2 are output. B’1110: OPD3, OPD2, and OPD1 are output. B’1111: OPD3, OPD2, OPD1, and OPD0 are output. Other than above: Setting prohibited
3 to 0	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

56.2.8 Manual Mode Control Register (SMCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SMCR is a 32-bit register that sets the operation in manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SSLKP	—	—	—	—	—	SPIRE	SPIWE	SPIE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R/W	R/W	—/WB

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	SSLKP	B’0	R/W	QSPIn_SSL Signal Level Determines the QSPIn_SSL status after the end of transfer. 0: QSPIn_SSL signal is negated at the end of transfer. 1: QSPIn_SSL signal level is maintained from the end of transfer to the start of next access. Note: This function is available for write operation only. In read case, use external address space mode to read more than 32bit (1xQSPI) or 64bit (2xQSPI) data.
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	SPIRE	B’0	R/W	Data Read Enable Enables reading in manual mode. 0: Data reading disabled 1: Data reading enabled When the transfer data bit size is set to 4 bits with the SPIDB[1:0] bits, the SPIRE and SPIWE bits should not be set to 1 at the same time.
1	SPIWE	B’0	R/W	Data Write Enable Enables writing in manual mode. 0: Data writing disabled 1: Data writing enabled When the transfer data bit size is set to 4 bits with the SPIDB[1:0] bits, the SPIRE and SPIWE bits should not be set to 1 at the same time.

Bit	Bit Name	Initial Value	R/W	Description
0	SPIE	B'0	—/WB	SPI Data Transfer Enable Data is transferred by setting this bit to B'1. This bit is enabled only when the TEND bit in CMNSR is set to B'1. The operation cannot be guaranteed when this bit is set to 1 with the TEND bit set to B'0. This bit is always read as B'0. Note: When the QSPIn_SSL pin is negated, the command, optional command, address, and option data that are output enabled are output even if the SPIRE and SPIWE bits are set to B'0. When the QSPIn_SSL pin is asserted, follow the notes described in section 56.4.3, "Notes on Starting Transfer from the QSPIn_SSL Retained State in Manual Mode".

56.2.9 Manual Mode Command Setting Register (SMCMR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SMCMR is a 32-bit register that sets the commands issued in manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	CMD							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	OCMD							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

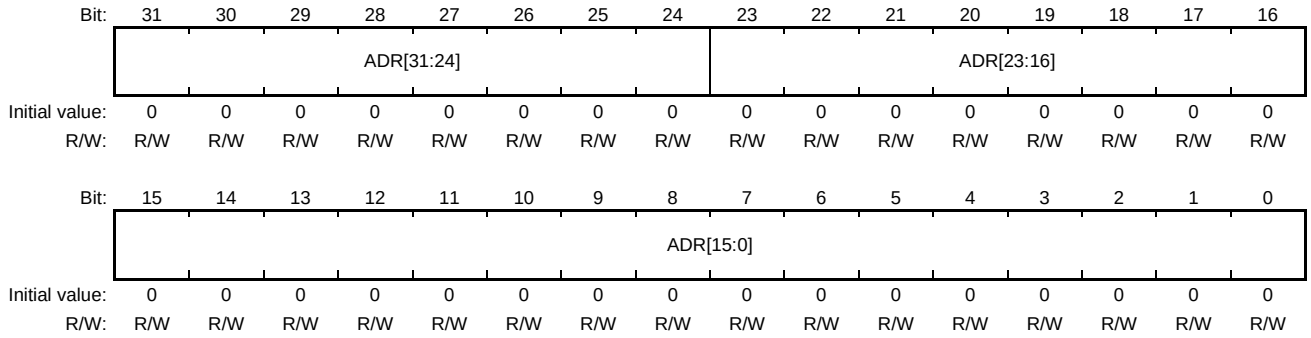
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	CMD[7:0]	H'00	R/W	Command Sets the command.
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	OCMD[7:0]	H'00	R/W	Optional Command Sets the optional command.

56.2.10 Manual Mode Address Setting Register (SMADR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SMADR is a 32-bit register that sets the addresses in manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.



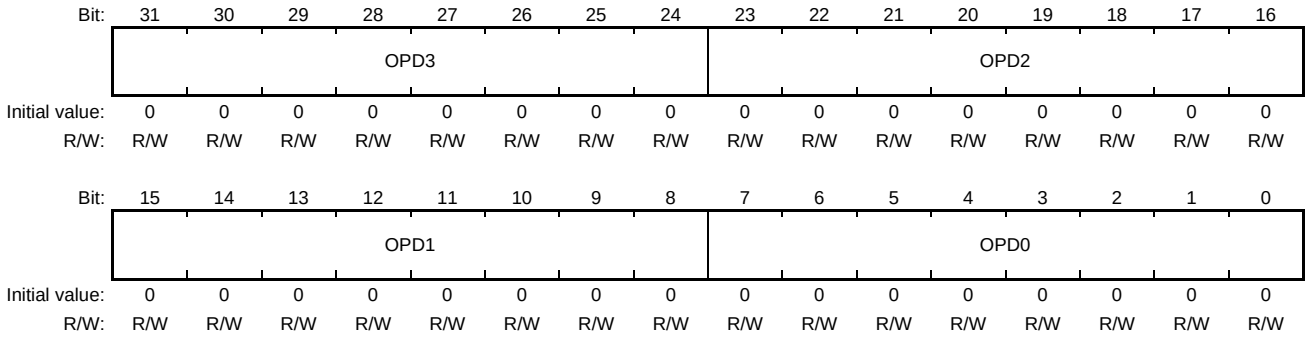
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	ADR[31:24]	H'00	R/W	Address Sets the value of bits 31 to 24 when the serial flash address is output in 32-bit units. This setting is valid when ADE[3] in SMENR is 1.
23 to 0	ADR[23:0]	H'00_0000	R/W	Address Sets the address.

56.2.11 Manual Mode Option Setting Register (SMOPR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SMOPR is a 32-bit register that sets the option data in manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	OPD3[7:0]	H'00	R/W	Option Data 3 Sets the option data 3.
23 to 16	OPD2[7:0]	H'00	R/W	Option Data 2 Sets the option data 2.
15 to 8	OPD1[7:0]	H'00	R/W	Option Data 1 Sets the option data 1.
7 to 0	OPD0[7:0]	H'00	R/W	Option Data 0 Sets the option data 0.

Note: OPD3, OPD2, OPD1, and OPD0 are output in this order.

56.2.12 Manual Mode Enable Setting Register (SMENR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SMENR is a 32-bit register that sets the bit size of the command, optional command, address, option data, and transfer data in manual mode and enables their output. SMENR also enables dummy cycle insertion. Disabling all of the command, optional command, address, option data, dummy cycle, and transfer data is prohibited. At least one of them except dummy cycle must be enabled. When connecting to HyperFlash, refer to Table 56.7 (Enable Registers (HyperFlash)).

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31, 30	CDB[1:0]	B’00	R/W	Command Bit Size Sets the command size in bit units. B’00: 1 bit B’10: 4 bits Other than above: Setting prohibited
29, 28	OCDB[1:0]	B’00	R/W	Optional Command Bit Size Sets the optional command size in bit units. B’00: 1 bit B’10: 4 bits Other than above: Setting prohibited
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25, 24	ADB[1:0]	B’00	R/W	Address Bit Size Sets the address size in bit units. B’00: 1 bit B’10: 4 bits Other than above: Setting prohibited
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
21, 20	OPDB[1:0]	B’00	R/W	Option Data Bit Size Sets the option data size in bit units. B’00: 1 bit B’10: 4 bits Other than above: Setting prohibited
19, 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17, 16	SPIDB[1:0]	B’00	R/W	Transfer Data Bit Size Sets the transfer data size in bit units. B’00: 1 bit B’10: 4 bits Other than above: Setting prohibited
15	DME	B’0	R/W	Dummy Cycle Enable Enables or disables insertion of the dummy cycle before the read data. Note: Dummy cycle insertion is prohibited for write in manual mode including the case in which a transfer ends with a dummy cycle. A setting is prohibited for a transfer starting with a dummy cycle. 0: Dummy cycle insertion disabled 1: Dummy cycle insertion enabled
14	CDE	B’1	R/W	Command Enable Sets the command to be output. 0: Output disabled 1: Output enabled Note: Specify this bit to 0 in external address space read mode with Octal-SPI flash.
13	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
12	OCDE	B’0	R/W	Optional Command Enable Sets the optional command to be output. 0: Optional command output disabled 1: Optional command output enabled

Bit	Bit Name	Initial Value	R/W	Description
11 to 8	ADE[3:0]	B’0000	R/W	Address Enable Sets the address to be output. The following settings must be used. Otherwise, the operation cannot be guaranteed. (1) serial flash memory, or Octal-SPI without 8-8-8 protocol connected 0000: Output disabled B’0100: ADR[23:16] is output B’0110: ADR[23:8] is output B’0111: ADR[23:0] is output B’1111: ADR[31:0] is output Other than above: Setting prohibited Note: These bits should be specified B’0111 or B’1111 with Write Buffer function. Refer to Figure 56.18. (2) Octal-SPI with 8-8-8 protocol connected B’1100: Octal-SPI with 8-8-8 protocol is output. Other than above: Setting prohibited (3) HyperFlash connected B’0100: HyperFlash protocol is output. Other than above: Setting prohibited Refer to Table 56.7 for the detail setting.
7 to 4	OPDE[3:0]	B’0000	R/W	Option Data Enable Sets the option data to be output. The following settings must be used. Otherwise, the operation cannot be guaranteed. B’0000: Output disabled B’1000: OPD3 is output. B’1100: OPD3 and OPD2 are output. B’1110: OPD3, OPD2, and OPD1 are output. B’1111: OPD3, OPD2, OPD1, and OPD0 are output. Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	SPIDE[3:0]	B’0000	R/W	Transfer Data Enable Sets valid transfer data. Valid data differs depending on the BSZ[1:0] bit setting in CMNCR. The following settings must be used. Otherwise, the operation cannot be guaranteed. (1) BSZ[1:0] in CMNCR = 00 (one serial flash memory connected) B’0000: Not transferred B’1000: 8 bits transferred (enables data at address 0 of the manual mode read/write data registers 0) B’1100: 16 bits transferred (enables data at addresses 0 to 1 of the manual mode read/write data registers 0) B’1111: 32 bits transferred (enables data at addresses 0 to 3 of the manual mode read/write data registers 0) Other than above: Setting prohibited (2) BSZ[1:0] in CMNCR = 01 (two serial flash memory devices connected) B’0000: Not transferred B’1000: 16 bits transferred (enables data at addresses 0 to 1 of the manual mode read/write data registers 0) B’1100: 32 bits transferred (enables data at addresses 0 to 3 of the manual mode read/write data registers 0) B’1111: 64 bits transferred (enables data at addresses 0 to 3 of the manual mode read/write data registers 0 and data at addresses 0 to 3 of the manual mode read/write data registers 1) Other than above: Setting prohibited

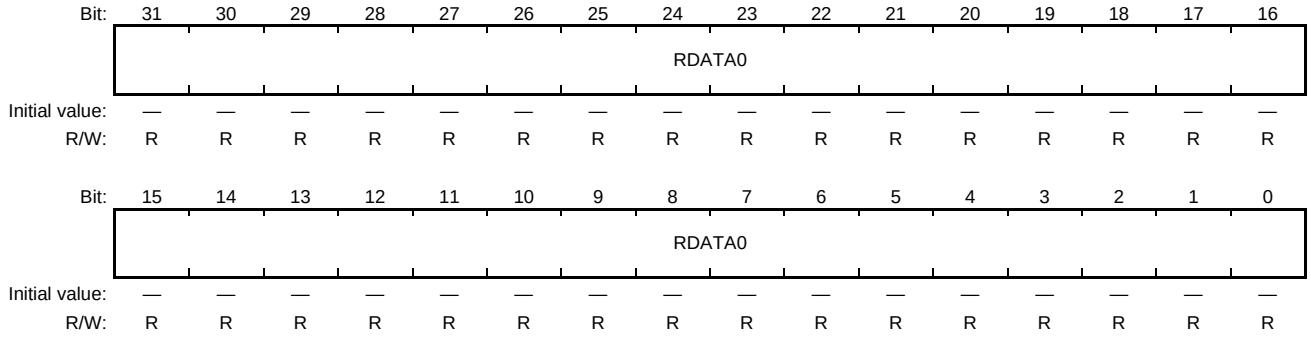
56.2.13 Manual Mode Read Data Register 0 (SMRDR0)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SMRDR0 is a 32-bit register that holds the read data in manual mode.

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the manual mode enable setting register (SMENR). Be sure to access from LSB.

The data should be read when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDATA0 [31:0]	Undefined	R	Read Data Holds the data read in manual mode. Data bits differ depending on the BSZ[1:0] bit setting in CMNCR. BSZ[1:0] = B'00: Read data[31:0] BSZ[1:0] = B'01: Read data[63:32]

Note: The contents of this register and SMRDR1 are modified upon completion of reception in manual mode. Be sure to read data when reception in manual mode is completed.

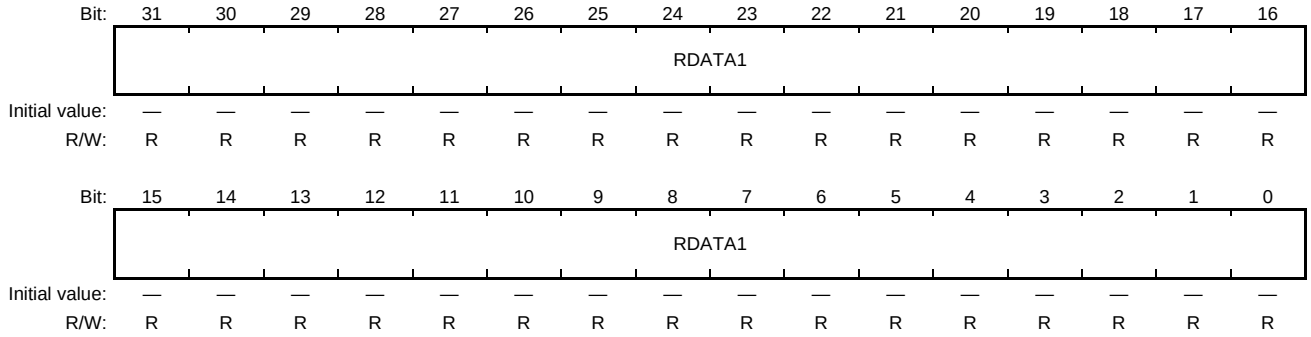
56.2.14 Manual Mode Read Data Register 1 (SMRDR1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SMRDR1 is a 32-bit register that holds the read data in manual mode.

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the manual mode enable setting register (SMENR). Be sure to access from LSB.

The data should be read when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDATA1 [31:0]	Undefined	R	Read Data Holds the data read in manual mode. Data bits differ depending on the BSZ[1:0] bit setting in CMNCR. BSZ[1:0] = B'00: Bits in this register are disabled. BSZ[1:0] = B'01: Read data[31:0]

56.2.15 Manual Mode Write Data Register 0 (SMWDR0)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SMWDR0 is a 32-bit register that sets the write data in manual mode.

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the manual mode enable setting register (SMENR). Be sure to access from address 0.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	WDATA0 [31:0]	H'0000_0000	R/W	Write Data Holds the data to be written in manual mode. Data bits differ depending on the BSZ[1:0] bit setting in CMNCR. BSZ[1:0] = B'00: Write data[31:0]. BSZ[1:0] = B'01: Write data[63:32].

56.2.16 Manual Mode Write Data Register 1 (SMWDR1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SMWDR1 is a 32-bit register that sets the write data in manual mode.

This register is enabled when the BSZ[1:0] bits in CMNCR are set to 01 (two serial flash memory devices or HyperFlash connected) and disabled when BSZ[1:0] in CMNCR are set to 00 (one serial flash memory connected).

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the manual mode enable setting register (SMENR). Be sure to access from address 0.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	WDATA1 [31:0]	H'0000_0000	R/W	Write Data Holds the data to be written in manual mode. Data bits differ depending on the BSZ[1:0] bit setting in CMNCR. BSZ[1:0] = B'00: Bits in this register are disabled. BSZ[1:0] = B'01: Write data[31:0].

56.2.17 Common Status Register (CMNSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMNSR is a 32-bit register that holds flags indicating the operating state.

The settings of this register are reflected both in external address space read mode and manual operating mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	SSLF	B’0	R	QSPIn_SSL Pin State Monitor B’0: QSPIn_SSL pin is negated. B’1: QSPIn_SSL pin is asserted.
0	TEND	B’1	R	Transfer End Flag Indicates whether the data transfer has ended. 0: Indicates that data transfer is in progress. 1: Indicates that data transfer has ended.

56.2.18 Data Read Dummy Cycle Setting Register (DRDMCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

DRDMCR is a 32-bit register that sets the size and number of dummy cycles to be inserted in external address space read mode.

The settings of this register are enabled when the DME bit in the data read enable setting register (DRENR) is 1.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	DMCYC				
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
4 to 0	DMCYC[4:0]	—	R/W	Number of Dummy Cycles Setting Sets the number of dummy cycles to be inserted when the DME bit in the data read enable setting register (DRENR) is 1. B'0_0000: 1 cycle B'0_0001: 2 cycles B'0_0010: 3 cycles .... B'1_0010: 19 cycles B'1_0011: 20 cycles Other than above: Setting prohibited

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

56.2.19 Data Read DDR Enable Register (DRDRENR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

DRDRENR is a 32-bit register that specifies the SDR or DDR transfer of the address, option data, and read data in external address space read mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	HYPE			—	—	—	ADDRE	—	—	—	OPDRE	—	—	—	DRDRE
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R/W	R/W	R/W	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
14 to 12	HYPE	—	R/W	HyperFlash or Octal-SPI flash in DDR mode Enable B'101*: HyperFlash or Octal-SPI flash in DDR mode B'100*: Octal-SPI flash to issue only command in DDR mode B'000: SPI flash mode Other than above: Setting prohibited Setting prohibited when using DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit) (RZ/G2M V1.3 Ver.1.2) (not RZ/G2M V3.0)
11 to 9	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
8	ADDRE	—	R/W	Address DDR Enable Specifies the SDR or DDR transfer of the address. 0: SDR transfer 1*: DDR transfer Note: When HyperFlash is connected, specify 1 in this bit. Setting prohibited when using DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit) (RZ/G2M V1.3 Ver.1.2) (not RZ/G2M V3.0)
7 to 5	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.

Bit	Bit Name	Initial Value	R/W	Description
4	OPDRE	—	R/W	Option Data DDR Enable Specifies the SDR or DDR transfer of the option data. 0: SDR transfer 1*: DDR transfer Setting prohibited when using DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit) (RZ/G2M V1.3 Ver.1.2) (not RZ/G2M V3.0)
3 to 1	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
0	DRDRE	—	R/W	Data Read DDR Enable Specifies the SDR or DDR transfer of the data read. 0: SDR transfer 1*: DDR transfer Note: When Hyperflash is connected, specify 1 in this bit. Setting prohibited when using DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit) (RZ/G2M V1.3 Ver.1.2) (not RZ/G2M V3.0)

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

56.2.20 Manual Mode Dummy Cycle Setting Register (SMDMCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SMDMCR is a 32-bit register that sets the size and number of dummy cycles to be inserted in manual mode.

The settings of this register are enabled when the DME bit in the manual mode enable setting register (SMENR) is 1.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	DMCYC				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	DMCYC[4:0]	B’0_0000	R/W	Number of Dummy Cycles Setting Sets the number of dummy cycles to be inserted when the DME bit in the manual mode enable setting register (SMENR) is 1. B’0_0000: 1 cycle B’0_0001: 2 cycles B’0_0010: 3 cycles .... B’1_0010: 19 cycles B’1_0011: 20 cycles Other than above: Setting prohibited

56.2.21 Manual Mode DDR Enable Register (SMDRENR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SMDRENR is a 32-bit register that specifies the SDR or DDR transfer of the address, option data, and data for transfer in manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	HYPE			—	—	—	ADDRE	—	—	—	OPDRE	—	—	—	SPIDRE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 12	HYPE	B'000	R/W	HyperFlash or Octal-SPI flash in DDR mode Enable B'101*: HyperFlash or Octal-SPI flash in DDR mode B'100*: Octal-SPI flash to issue only command in DDR mode 000: SPI flash mode Other than above: Setting prohibited Setting prohibited when using DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit) (RZ/G2M V1.3) (not RZ/G2M V3.0)
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	ADDRE	B'0	R/W	Address DDR Enable Specifies the SDR or DDR transfer of the address. 0: SDR transfer 1*: DDR transfer Note: When HyperFlash is connected, specify 1 in this bit. Setting prohibited when using DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit) (RZ/G2M V1.3) (not RZ/G2M V3.0)
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	OPDRE	B'0	R/W	Option Data DDR Enable Specifies the SDR or DDR transfer of the option data. 0: SDR transfer 1*: DDR transfer Setting prohibited when using DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit) (RZ/G2M V1.3) (not RZ/G2M V3.0)

Bit	Bit Name	Initial Value	R/W	Description
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SPIDRE	B'0	R/W	Transfer Data DDR Enable Specifies the SDR or DDR transfer of the data for transfer. 0: SDR transfer 1*: DDR transfer Note: When HyperFlash is connected, specify 1 in this bit. Setting prohibited when using DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit) (RZ/G2M V1.3) (not RZ/G2M V3.0)

56.2.22 PHY Control Register (PHYCNT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

PHYCNT is a 32-bit register that sets the PHY operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CAL	—	—	—	—	—	—	—	OCTA		EXDS	OCT	DDRCAL	HS	STRTIM	
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	—/WB	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	STRTIM	—	—	—	—	—	—	—	—	—	—	WBUF2	—	WBUF	PHYMEM	
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W	R/W

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

Bit	Bit Name	Initial Value	R/W	Description
31	CAL	—	—/WB	PHY Calibration Executes calibration of the PHY. 1: Calibration is executed. 0: Calibration is not executed. Note: When set this bit to 1, STRTIM[2:0] should be set to B'110 (RZ/G2M V1.3, RZ/G2M V3.0) or B'111. (Other products).
30 to 24	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
23, 22	OCTA	—	R/W	Octal-SPI flash alignment Specify data alignment with Octal-SPI flash memory. Refer to 56.3.14 for detail. These bits should be set to 00 when HyperFlash or serial flash memory is connected. B'00: HyperFlash or serial flash memory x 1ch or 2ch is connected B'10: Support sequential alignment B'01: Support alternate alignment B'11: Support alternate alignment Note: Alternate alignment with OCTA[1:0] = 01 is available in manual mode only.
21	EXDS	—	R/W	External Data Strobe Uses external Data Strobe signal with serial flash memory when connecting to serial flash with Data Strobe. When Octal-SPI flash memory is connected, specify this bit to 1. Note: Set this bit to 0 when HyperFlash is connected. 1: Use external Data Strobe signal 0: Not use external Data Strobe signal
20	OCT	—	R/W	Octal-SPI flash protocol mode 1: Use Octal-SPI DDR/SDR protocol mode 0: Specify 0 in the other than above mode

Bit	Bit Name	Initial Value	R/W	Description
19	DDRCAL	—	R/W	This bit is specified to 1 in SW calibration for DDR transfer of serial flash operation. Keep 1 in DDR transfer of serial flash operation after SW calibration. When SW calibration for DDR transfer of serial flash is not executed, this bit should be specified to 0. Note: Specify 0 to this bit. (RZ/G2M V1.3 Ver.1.2) (not RZ/G2M V3.0)
18	HS	—	R/W	High Speed response mode Specify high speed response mode. 1: The read data is output to bus master in parallel of device access when DRCR.RBE = 1. 0: The read data is output to bus master after the number of data which is specified in DRCR.RBURST is read. Notes: 1. This bit should be specified to 1 when using DMA transfer. DRCR.RBURST should be set to B'1_1111. 2. Accessing to register area during DMA transfer is prohibited. 3.When this bit set to 1, access address alignment from RPC to flash memory should be 256Byte align.
17 to 15	STRTIM[2:0]	—	R/W	Strobe Timing Adjustment bit These bits specify the internal strobe delay which is used for the flash device without external strobe, like serial flash memory. When connecting to HyperFlash or any other flash device which has strobe, set these bits to B’110 (RZ/G2M V1.3) or B’111 (Other products). B’111: The delay is smallest. B’110: The delay is 2nd smallest. : B’001: The delay is 2nd biggest. B’000: The delay is biggest. Note: Only STRTIM[2:1] is available in RZ/G M3W (not RZ/G2M V3.0). STRTIM[0] should always be 0.
14 to 5	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
4	WBUF2	—	R/W	Write Buffer Enable2 The write buffer is used when the flash memory is written to. Refer to 56.3.13 for usage of the write buffer. 1: The write buffer is used to write data to the flash memory. 0: The write buffer is not used.
3	—	—	R	Reserved This bit is always read as initial value. The write value should always be initial value.
2	WBUF	—	R/W	Write Buffer Enable The write buffer is used when the flash memory is written to. Refer to 56.3.13 for usage of the write buffer. 1: The write buffer is used to write data to the flash memory. 0: The write buffer is not used.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PHYMEM	—	R/W	Device Selection Selects a device to connect. B’00: Serial flash in SDR mode B’01*: Serial flash in DDR mode B’11: HyperFlash Other than above: Setting prohibited Setting prohibited when using DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit) (RZ/G2M V1.3 Ver.1.2) (not RZ/G2M V3.0)

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

56.2.23 PHY Timing Offset Register 1 (PHYOFFSET1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

PHYOFFSET1 is a 32-bit register that sets the timing adjustment in DDR operation.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	DDRTMG		—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
29, 28	DDRTMG	—	R/W	DDR Operation Timing Register Specify the timing adjustment in DDR read operation. B’10: When SMDRENR.SPIDRE or DRDRENR.DRDRE = 1 in read operation. B’11: When SMDRENR.SPIDRE or DRDRENR.DRDRE = 0 in read operation Other than above: Setting prohibited Setting prohibited when using DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit) (RZ/G2M V1.3) (not RZ/G2M V3.0)
27 to 0	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.

56.2.24 Timing Offset Register 2 (PHYOFFSET2)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

PHYOFFSET2 is a 32-bit register that sets the timing adjustment in DDR operation.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	OCTTMG			—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	1	0	0	0	0	1	1	0	0	0	1
R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	OCTTMG	B’100	R/W	Octal-SPI flash Operation Timing Specifies the timing adjustment when write to Octal-SPI flash B’000: Write Buffer Operation of serial flash with 1-1-4 or 1-4-4 of Table 56.14 B’100: serial flash or Hyperflash B’011: Octal-SPI flash operation Other than above: Setting prohibited Note: Specify B’100 when serial flash compatible mode of Octal-SPI flash.
7 to 0	—	B’0011_0001	R	Reserved These bits are always read as 0. The write value should always be initial value.

56.2.25 PHY Interrupt Register (PHYINT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

PHYINT is a 32-bit register that sets the interrupt signal and the pins.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	INTIE	—	—	—	—	—	RSTEN	WPEN (*)	INTEN
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R/W	(*)	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	RSTVAL	WPVAL (*)	INT
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	(*)	R

Notes: Initial value varies depending on boot mode. (Refer to Table 56.3.)

* RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, and RZ/G2N support these bits as WPEN and WPVAL. These bits are assigned R/W.

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
24	INTIE	—	R/W	RPC_INT# Pin Input Enable Input Enables or disables the RPC_INT# pin. 0: The RPC_INT# pin input is disabled. 1: The RPC_INT# pin input is enabled. Note: This bit and PHYINT.INTEN bit should be 1 when using interrupt from external device.
23 to 19	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
18	RSTEN	—	R/W	RPC_RESET# Pin Enable Enables or disables the RPC_RESET# pin. 0: The RPC_RESET# pin is disabled. 1: The RPC_RESET# pin is enabled, and the value on RSTVAL is reflected.

Bit	Bit Name	Initial Value	R/W	Description
17	WPEN	—	R/W	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, and RZ/G2N] RPC_WP# Pin Enable Enables or disables the RPC_WP# pin. 0: The RPC_WP# pin is disabled. 1: The RPC_WP# pin is enabled, and the settings of WPVAL are reflected
	—	—	R	[RZ/G2E] Reserved This bit is always read as initial value. The write value should always be initial value.
16	INTEN	—	R/W	RPC_INT# Pin Enable Enables or disables the RPC_INT# pin. 0: The RPC_INT# pin is disabled. 1: The RPC_INT# pin is enabled, and the interrupt signal from HyperFlash is enabled.
15 to 3	—	—	R	Reserved These bits are always read as initial value. The write value should always be initial value.
2	RSTVAL	—	R/W	RPC_RESET# Pin Output Value Specifies the value output from the RPC_RESET# pin. This setting is enabled when RSTEN = 1. 0: RPC_RESET# = H 1: RPC_RESET# = L
1	WPVAL	—	R/W	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, and RZ/G2N] RPC_WP# Pin Output Value Specifies the value output from the RPC_WP# pin. This setting is enabled when WPEN = 1. 0: RPC_WP# = H 1: RPC_WP# = L
	—	—	R	[RZ/G2E] Reserved This bit is always read as initial value. The write value should always be initial value.
0	INT	—	R	Interrupt Status When RPC _INT# is set to L, this bit becomes H to notice interrupt occurs in the connected device.

Note: Initial value varies depending on boot mode. (Refer to Table 56.3.)

56.2.26 Address Division Register 1 (ADD_DIV1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	—	—

ADD_DIV1 is a 32-bit register that specifies the address which divides the RPC-IF area for security domain.

Only Secure CPU can access to this register.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	SECEN	B’1	R/W	Secure function enable bit Enables secure function command restriction. 0: secure 1: non-secure The others: reserved Refer to 56.3.18 for the usage.
7, 6	AREA3[1:0]	All 0	R/W	Area Attribution 3 Specifies the attribution of Area3 which is specified by ADD_DIVn register in RPC-IF area. B’00: secure B’01: non-secure The others: reserved Refer to 56.3.18 for the usage.
5, 4	AREA2[1:0]	All 0	R/W	Area Attribution 2 Specifies the attribution of Area2 which is specified by ADD_DIVn register in RPC-IF area. B’00: secure B’01: non-secure The others: reserved Refer to 56.3.18 for the usage.

Bit	Bit Name	Initial Value	R/W	Description
3, 2	AREA1[1:0]	All 0	R/W	Area Attribution 1 Specifies the attribution of Area1 which is specified by ADD_DIVn register in RPC-IF area. B’00: secure B’01: non-secure The others: reserved Refer to 56.3.18 for the usage.
1, 0	AREA0[1:0]	All 0	R/W	Area Attribution 0 Specifies the attribution of Area0 which is specified by ADD_DIVn register in RPC-IF area. B’00: secure B’01: non-secure The others: reserved Refer to 56.3.18 for the usage.

56.2.30 Access Right Register (ARIGHT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	—	—

ARIGHT is a 32-bit register that specifies the semaphore function which limits the access to the register of this controller.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	RIGHT_NONS	—	RIGHT_SEC	RIGHT_EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	RIGHT_NONS	B'0	R	Right Bit For Non-Secure Specifies the right bit for Non-Secure CPU. This bit is set to 1 when Non-Secure CPU writes 1 on RIGHT_EN bit. 1: Non-Secure CPU has a right to access 0: Non-Secure CPU doesn't have a right to access Note this bit can be cleared by both Secure and Non-Secure CPU.
2	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
1	RIGHT_SEC	B'0	R	Right Bit For Secure Specifies the right bit for Secure CPU. This bit is set to 1 when Secure CPU writes 1 on RIGHT_EN bit. 1: Secure CPU has a right to access 0: Secure CPU doesn't have a right to access
0	RIGHT_EN	B'0	R/W	Access Right Enable Specifies the access right function to enable. When accessing to this register with RIGHT_EN = 1, the right is reflected in each bit 3 and 1 according to the attribution of each master. To cancel the access right, the same attribution master should access to this register with RIGHT_EN = 0. The access is ignored when the attribution of access is different. 0: Not use access right function 1: Use access right function Note: Secure attribution can overwrite Non-Secure right.

56.2.31 Secure Command Register (SEC_CMDn (n = 0 to 15))

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	—	—

SEC_CMDn (n = 0 to 15) is a 32-bit register that specifies the command which is prohibited for Secure CPU.

Only Secure CPU can access to this register.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	WCMDEN1	B'0	R/W	Write Command 1 Enable Enables to limit the Write command which is specified In WCMD1. 0: Disable to limit the Write command which is specified In WCMD1. 1: Enable to limit the Write command which is specified In WCMD1.
30 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	WCMD1	All 0	R/W	Write Command 1 Specifies the Write command to limit.
15	WCMDEN2	B'0	R/W	Write Command 2 Enable Enables to limit the Write command which is specified In WCMD2. 0: Disable to limit the Write command which is specified In WCMD2. 1: Enable to limit the Write command which is specified In WCMD2.
14 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	WCMD2	All 0	R/W	Write Command 2 Specifies the Write command to limit.

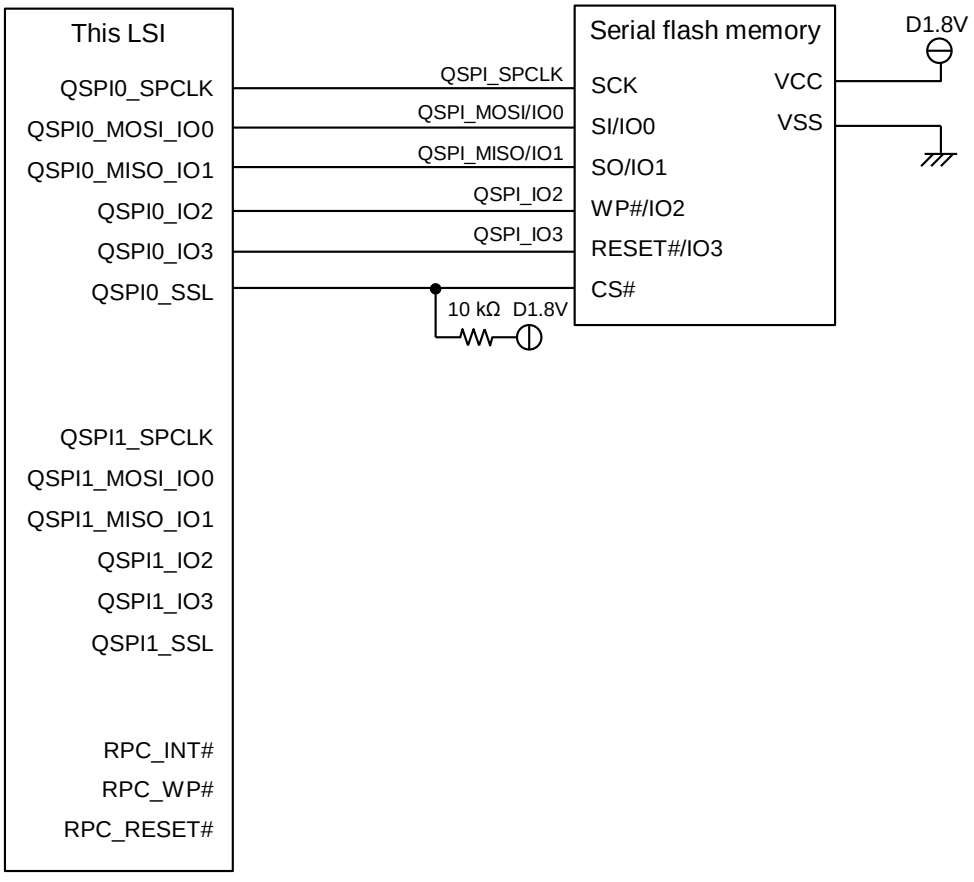
56.3 Operation

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

56.3.1 System Configuration

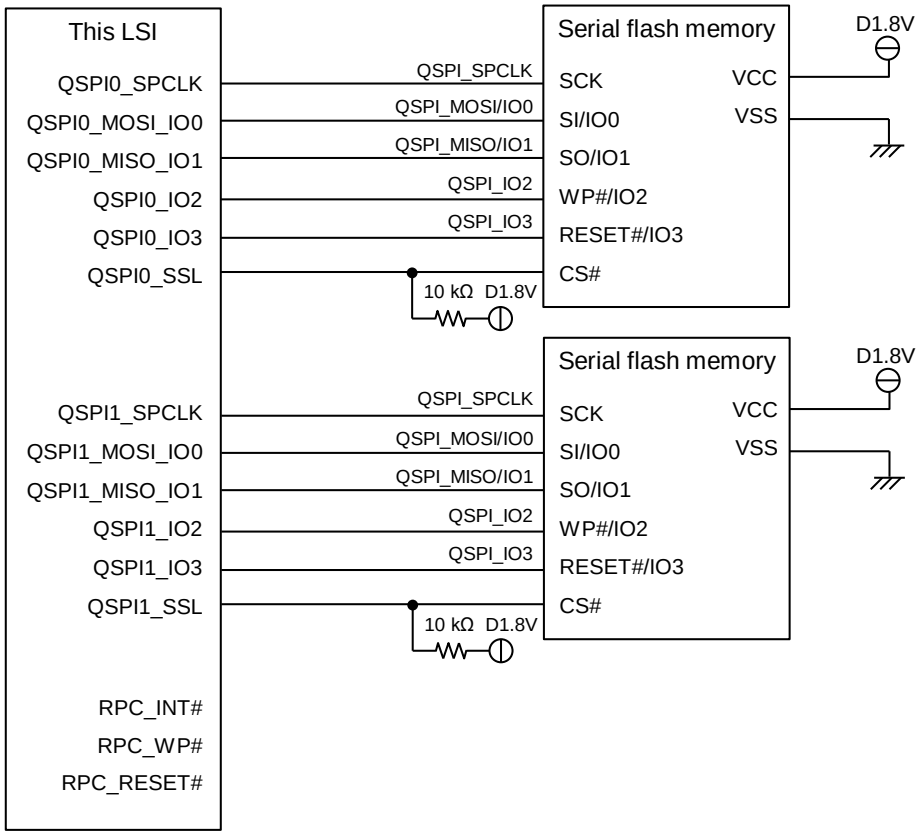
With this module, one or two serial flash memory devices (data size of 1, 2, and 4 bits) or one HyperFlash (data size of 8 bits) can be connected. The connected devices can be selected using the BSZ[1:0] bits in CMNCR.

Examples of system configuration are shown in Figure 56.2, 56.3, 56.4 and 56.5.



Note: 1. When this LSI connects to 1 x serial flash memory, please use ch0 pins.
ch1 pins are not available in this configuration.
2. RPC_RESET# cannot be used with serial flash boot. Instead, connect PRESETOUT# to the serial flash RESET# terminal. Also, when using 1.8V serial flash, step down voltage from 3.3V to 1.8V. (3.3V serial flash is unnecessary.) [RZ/G2E]

Figure 56.2 Example of System Configuration with One 4-Bit Serial Flash Memory Device Connected



Note: [RZ/G2E]
RPC_RESET# cannot be used with serial flash boot. Instead, connect PRESETOUT# to the serial flash RESET# terminal. Also, when using 1.8 V serial flash, step down voltage from 3.3 V to 1.8 V. (3.3 V serial flash is unnecessary.)

Figure 56.3 Example of System Configuration with Two 4-Bit Serial Flash Memory Devices Connected (BSZ[1:0] Bits in CMNCR = 01)

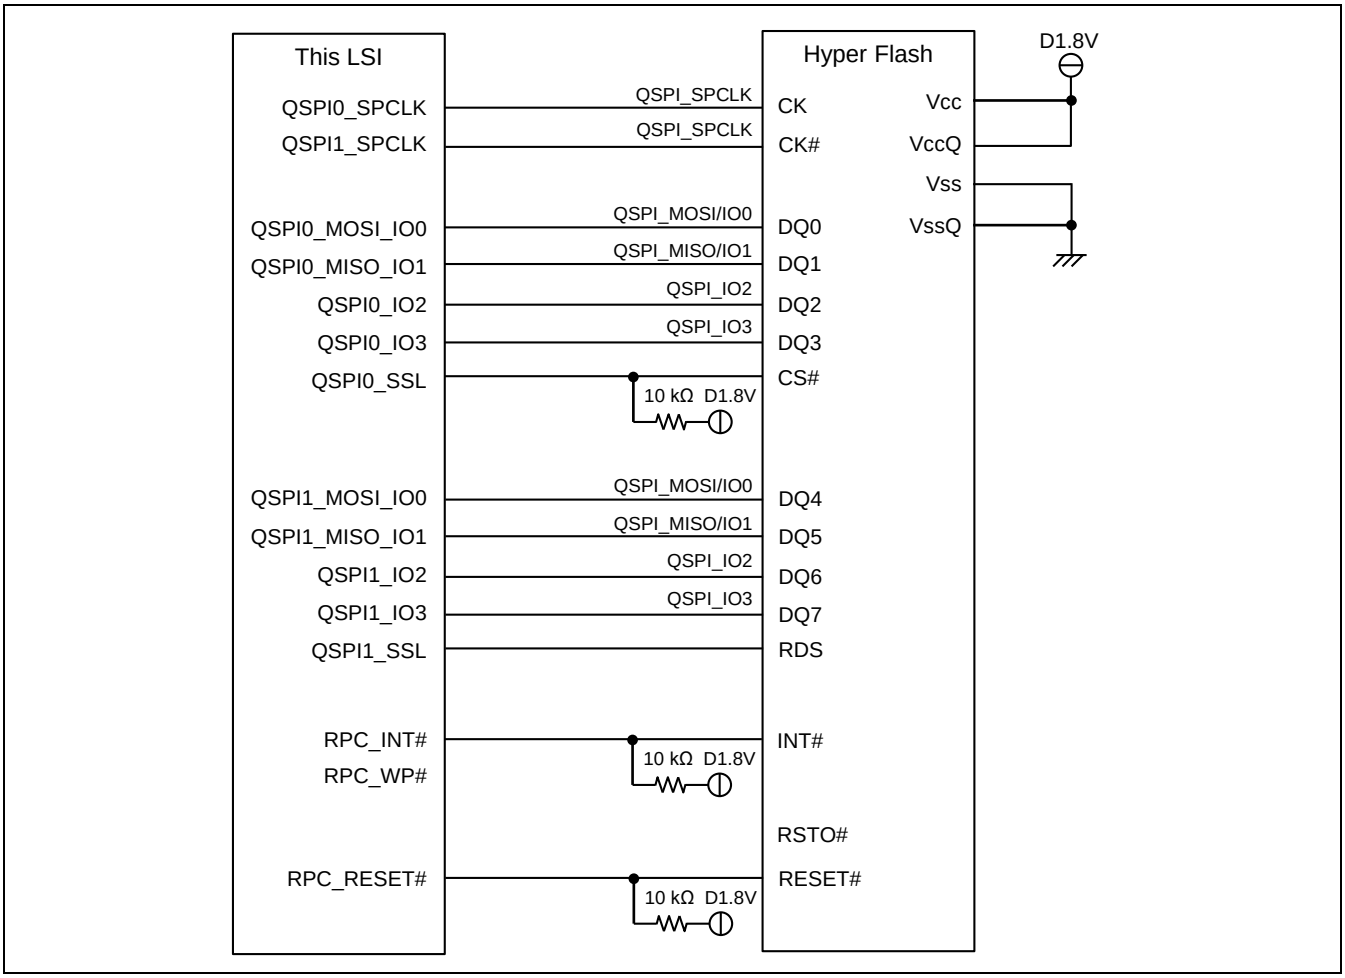


Figure 56.4 Example of System Configuration with HyperFlash Connected

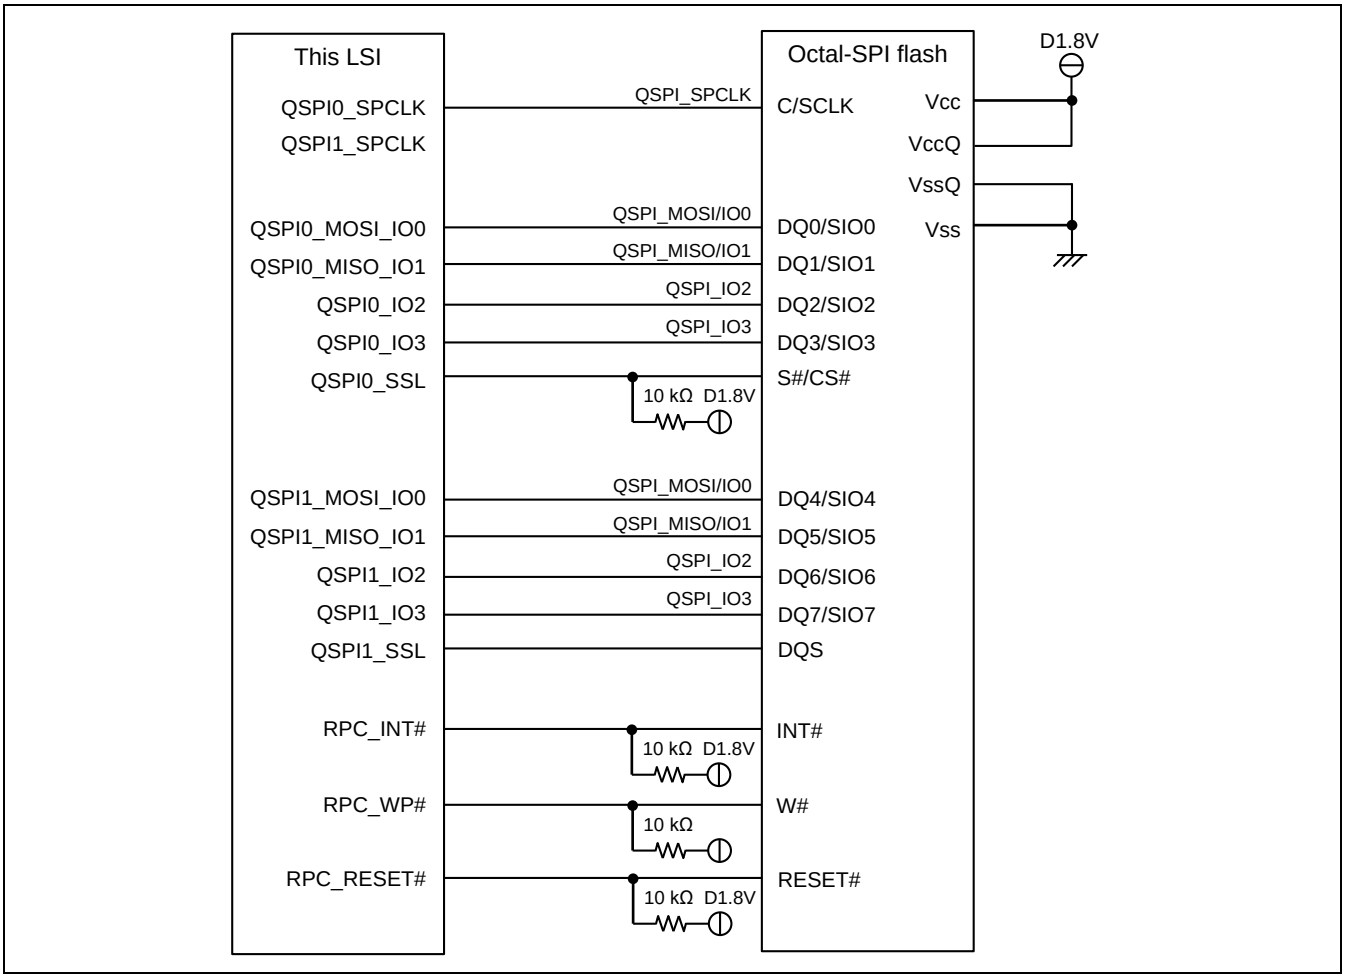

Figure 56.5 Example of System Configuration with Octal-SPI Flash Memory Device Connected

56.3.2 Address Map

In external address space read mode, the serial flash memory and HyperFlash to be connected are assigned in the SPI multi I/O bus space. The internal address space is 64MB, but with the DREAR register to specify the offset, a maximum of 4 Gbytes can be accessed when one serial flash memory is connected, and a maximum of 8 Gbytes can be accessed when two memory devices or a HyperFlash or an Octal-SPI flash memory are connected.

Table 56.4 Address Map

Internal Address	Maximum Access Area
H'0800_0000 to H'0BFF_FFFF	Serial flash × 1: 4 Gbytes Serial flash × 2 or HyperFlash × 1 or Octal-SPI flash × 1: 8 Gbytes

56.3.3 32-Bit Address Area in the Serial Flash Memory

Since the SPI multi I/O bus space is 64 Mbytes (with 26-bit address width), only a part of the 32-bit serial flash address area can be directly accessed. The fixed value set in the DREAR register is used as the upper-order bit value of a 32-bit address.

To output the address of the serial flash memory in 32 bits, set the ADE[3] bit in DRENR to 1, set the range of the external addresses used as the serial flash addresses to the EAC[2:0] bits in DREAR, and set the upper bit value of the 32-bit address as the fixed value to the EAV[7:0] bits in DREAR.

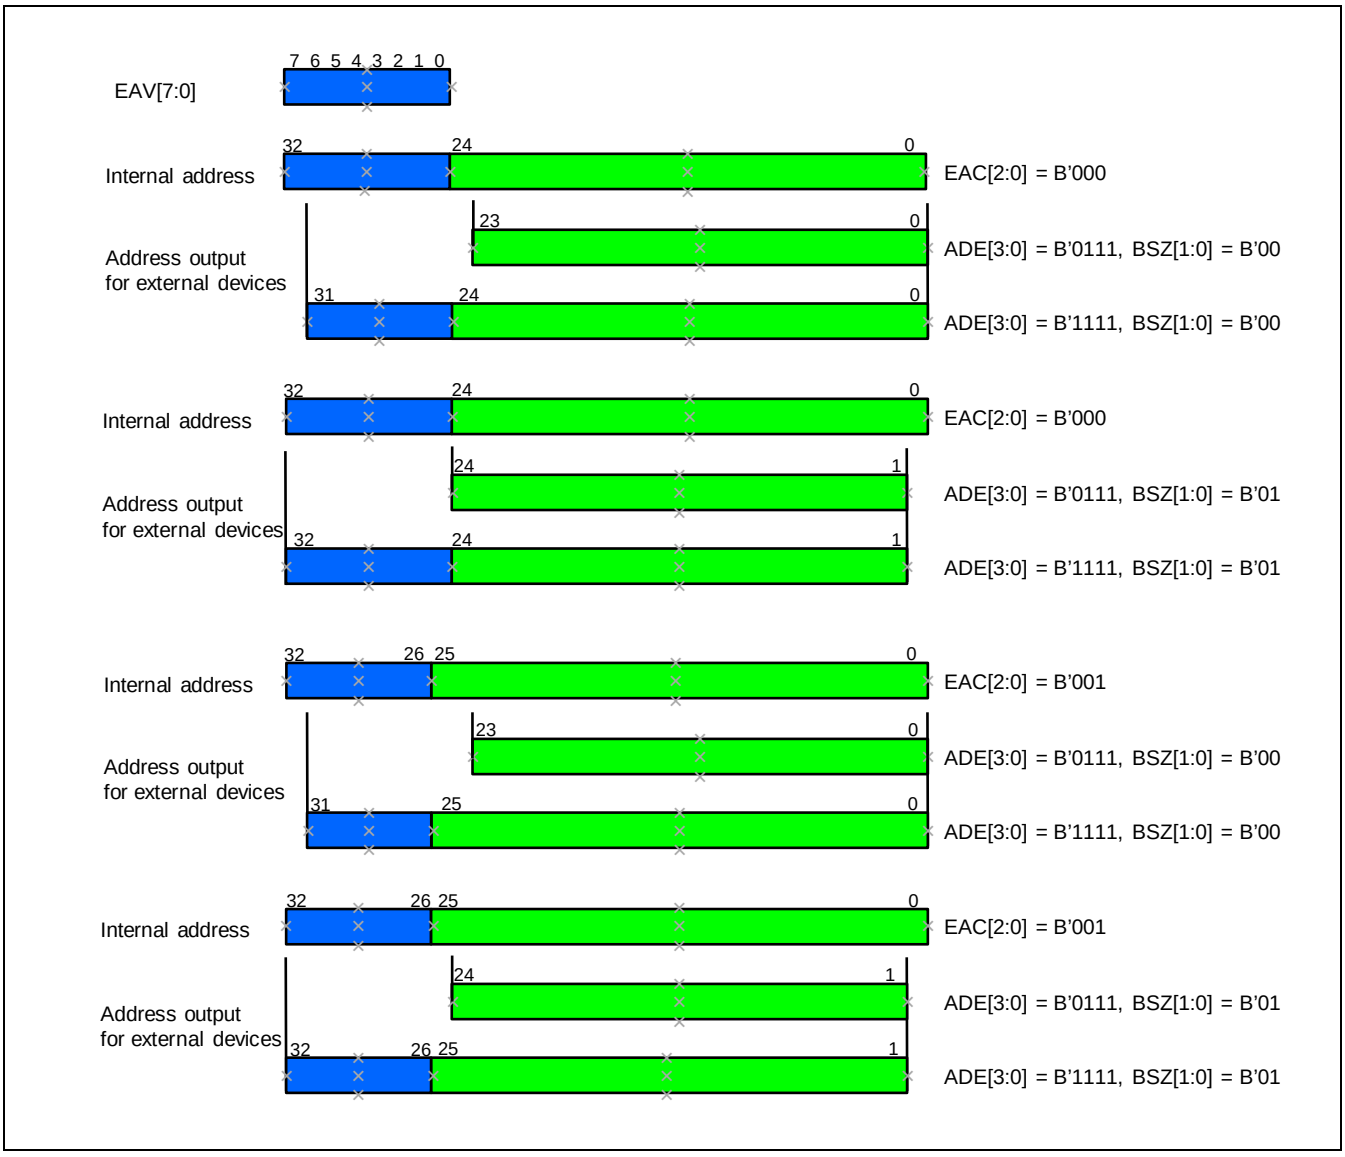

Figure 56.6 32-Bit Address Setting

Setting the ADE[3] bit in DRENR to 1 allows the serial flash address to be output using [31:0] bits. When EAC[2:0] = 000, external address bits [24:0] are valid. Set the value for [32:25] bits to EAV[7:0]. When EAC[2:0] = 001, external address bits [25:0] are valid. Set the value for [32:26] bits to EAV[7:1]. The address bits actually used for the external device are shown below.

When one serial flash memory is connected, internal address bits [31:0] are used.

When two serial flash memory devices are connected, internal address bits [32:1] are used.

When HyperFlash or an Octal SPI flash is connected, this address extension with DRENR.ADE[3] is not available, and internal address bits [25:0] (64 Mbytes area) are used. Use manual mode when access to the bigger area than 64 Mbytes area.

56.3.4 Operating Modes

This module has two operating modes: external address space read mode and manual mode.

In external address space read mode, a read access to the SPI multi I/O bus space is converted into the data read protocol and data is received from the external device. After data acquisition from the external device, data is returned to the bus master that is the issuing source of read access. For details, see section 56.3.5, External Address Space Read Mode.

The manual mode carries out an arbitrary protocol by using the register settings. For details, see section 56.3.7, Manual Mode.

56.3.5 External Address Space Read Mode

By external address space read mode, a read access to the SPI multi I/O bus space is converted into the data read protocol. Further, the commands, optional commands, option data, and dummy cycle issued for reading external device can be modified using registers.

In external address space read mode, either normal read operation or burst read operation can be selected. The transfer format is determined based on the common control register (CMNCR), SSL delay register (SSLDR), data read control register (DRCR), data read command setting register (DRCMR), data read extended address setting register (DREAR), data read option setting register (DROPR), data read enable setting register (DRENR), data read dummy cycle setting register (DRDMCR), and data read DDR enable register (DRDRENR).

Note: The RZ/G2M V1.3 (not RZ/G2M V3.0) does not support DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit). In the following description, do not set the related operation.

(1) Normal Read Operation

When the RBE bit in DRCR is set to 0, normal read operation is performed.

In the normal read operation, the data is read from external device by reading access from bus master. After reading from external device, the QSPIn_SSL pin is negated.

The normal read operation timing with serial flash is shown in Figure 56.7, Normal Read Operation Timing.

t1 is the time period from QSPIn_SSL pin assertion to QSPIn_SPCLK oscillation (clock delay), t2 is the time period from transmission of the last QSPIn_SPCLK edge of a transfer to QSPIn_SSL pin negation (QSPIn_SSL negation delay), and t3 is the time period from one transfer end to the next transfer start (next access).

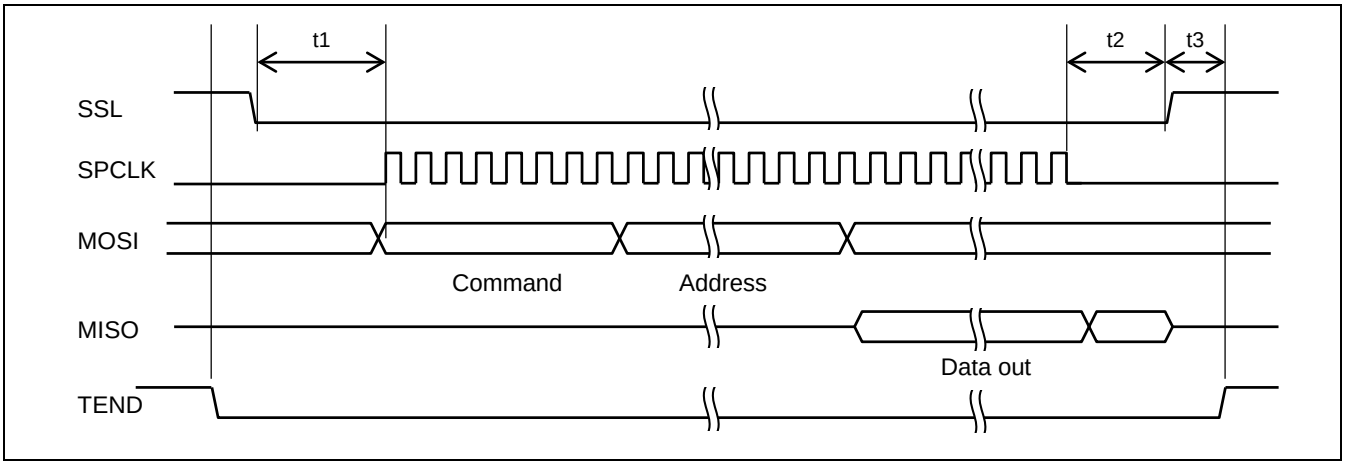

Figure 56.7 Normal Read Operation Timing

Note: t1 to t3 are specified in SSLDR.SCKDL, SSLDR.SLNDL and SSLDRSPNDL bits respectively.

(2) Burst Read Operation

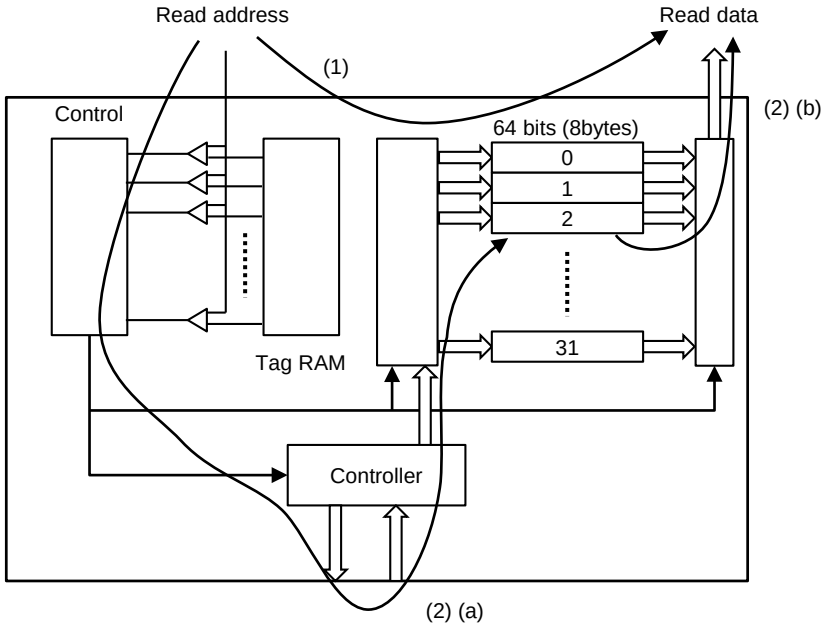
When the RBE bit in DRCR is set to 1, burst read operation is performed.

Read cache is enabled in the burst read operation. For read cache operation, see section 56.3.6, Read Cache.

For reading access from bus master, the read cache is first referred to for checking whether the data of read address of bus master is contained in the read cache memory. When the read cache memory contains the data, the data contained in the cache memory is returned to the bus master without accessing the external device. When the read cache memory does not contain the data, burst read is performed in the external device, the read data is stored in the read cache memory and the data is returned to the bus master. The data transfer length at that time is 64 bits x RBURST[4:0] bits and the data is always read from the 64-bit boundary.

The QSPIn_SSL pin status after data transfer can be selected by using the SSLE bit in DRCR. When the SSLE bit is set to 0, the QSPIn_SSL pin is always negated after data transfer. For an operation performed when the SSLE bit is set to 1, see (3) Burst Read Operation with Automatic QSPIn_SSL Negation, just below.

A pattern diagram of this operation and a burst read operation timing diagram with serial flash when SSLE bit is set to 0 are shown in Figure 56.8 and 56.9.



(1) When the read cache contains data;
Data is read from the read cache, and returned to the bus master.
The external device is not accessed.
(2) When the read cache does not contain data;
(a) Data is read from the external device, and stored in the read cache.
(b) Data is read from the read cache, and returned to the bus master.

Figure 56.8 Read Operation in Burst Read Operation

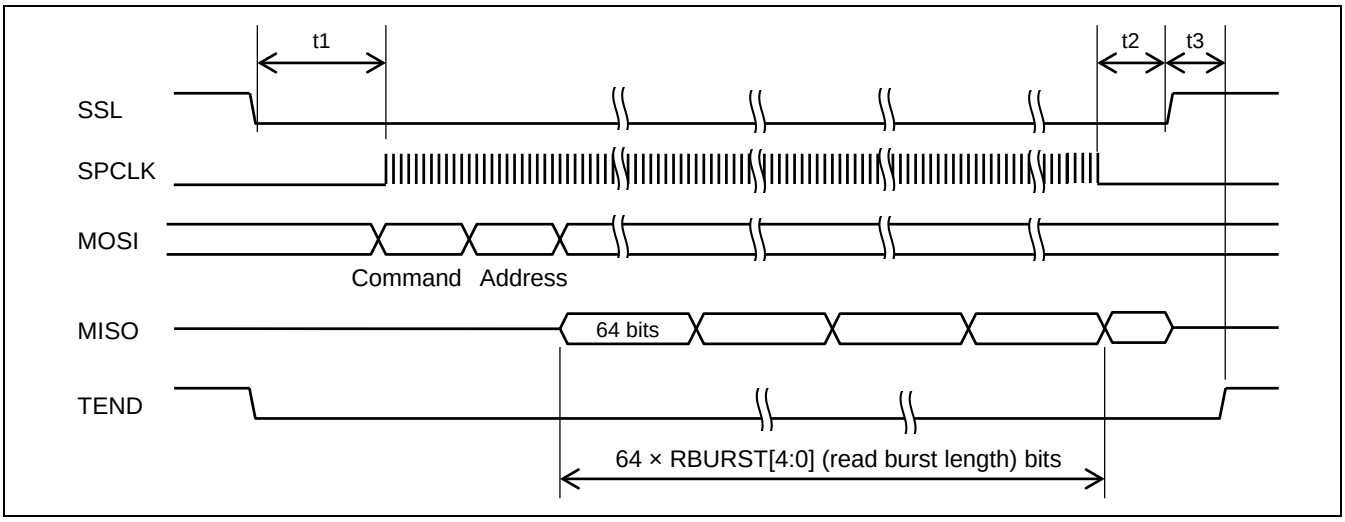


Figure 56.9 Read Timing in Burst Read Operation (SSLE Bit = 0)

Note: t1 to t3 are specified in SSLDR.SCKDL, SSLDR.SLNDL and SSLDRSPNDL bits respectively.

(3) Burst Read Operation with Automatic QSPIn_SSL Negation

When SSLE bit in DRCR is set to 1, this module does not negate the QSPIn_SSL pin after the burst read transfer on serial flash connection. When accessing the next time, if the address is continuous with the previous read address, the burst read operation is performed without issuing the command, optional command, address, option data, or dummy cycle. If the address is not continuous with the previous read address, the QSPIn_SSL pin is once negated and the burst read operation is performed after issuing the command, optional command, address, option data, or dummy cycle.

Burst read timing diagrams for continuous address and non-continuous address with serial flash are shown in Figure 56.10 and 56.11.

For the next access after negation of the QSPIn_SSL with the SSLN bit in DRCR with this operation, read SSLF = 0 in CMNSR to confirm that the QSPIn_SSL has been negated. This function is only supported to connect to serial flash memory.

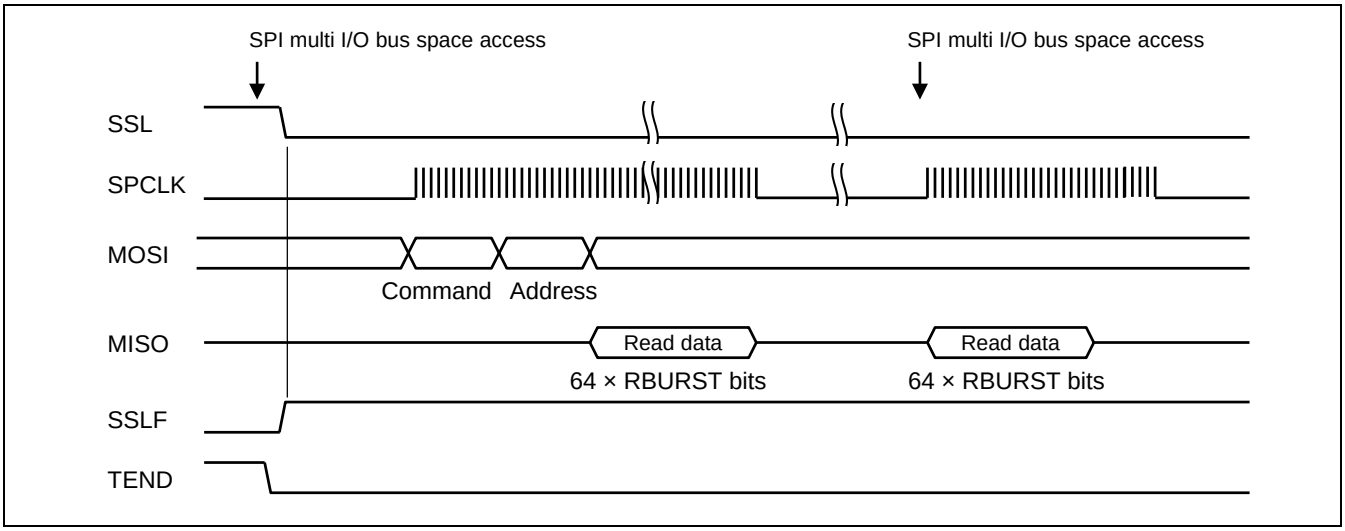

Figure 56.10 Burst Read Timing for Continuous Address (SSLE Bit = 1)

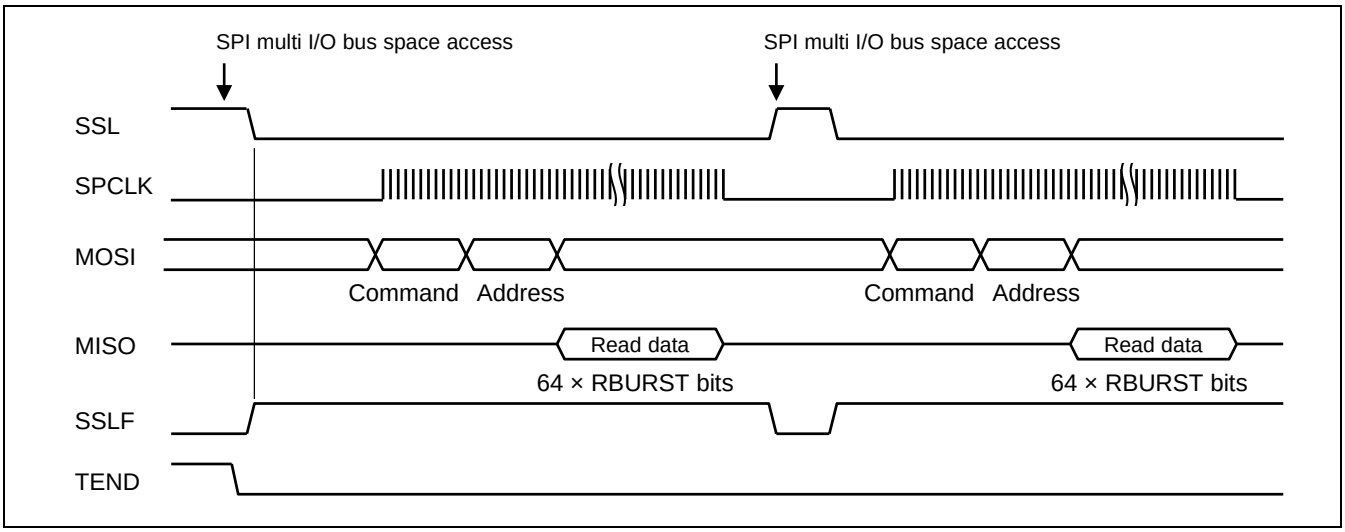

Figure 56.11 Burst Read Timing for Non-Continuous Address (SSLE Bit = 1)

(4) Initial Setting Flow

An example of an initial setting flow in external address space read mode is shown in Figure 56.12.

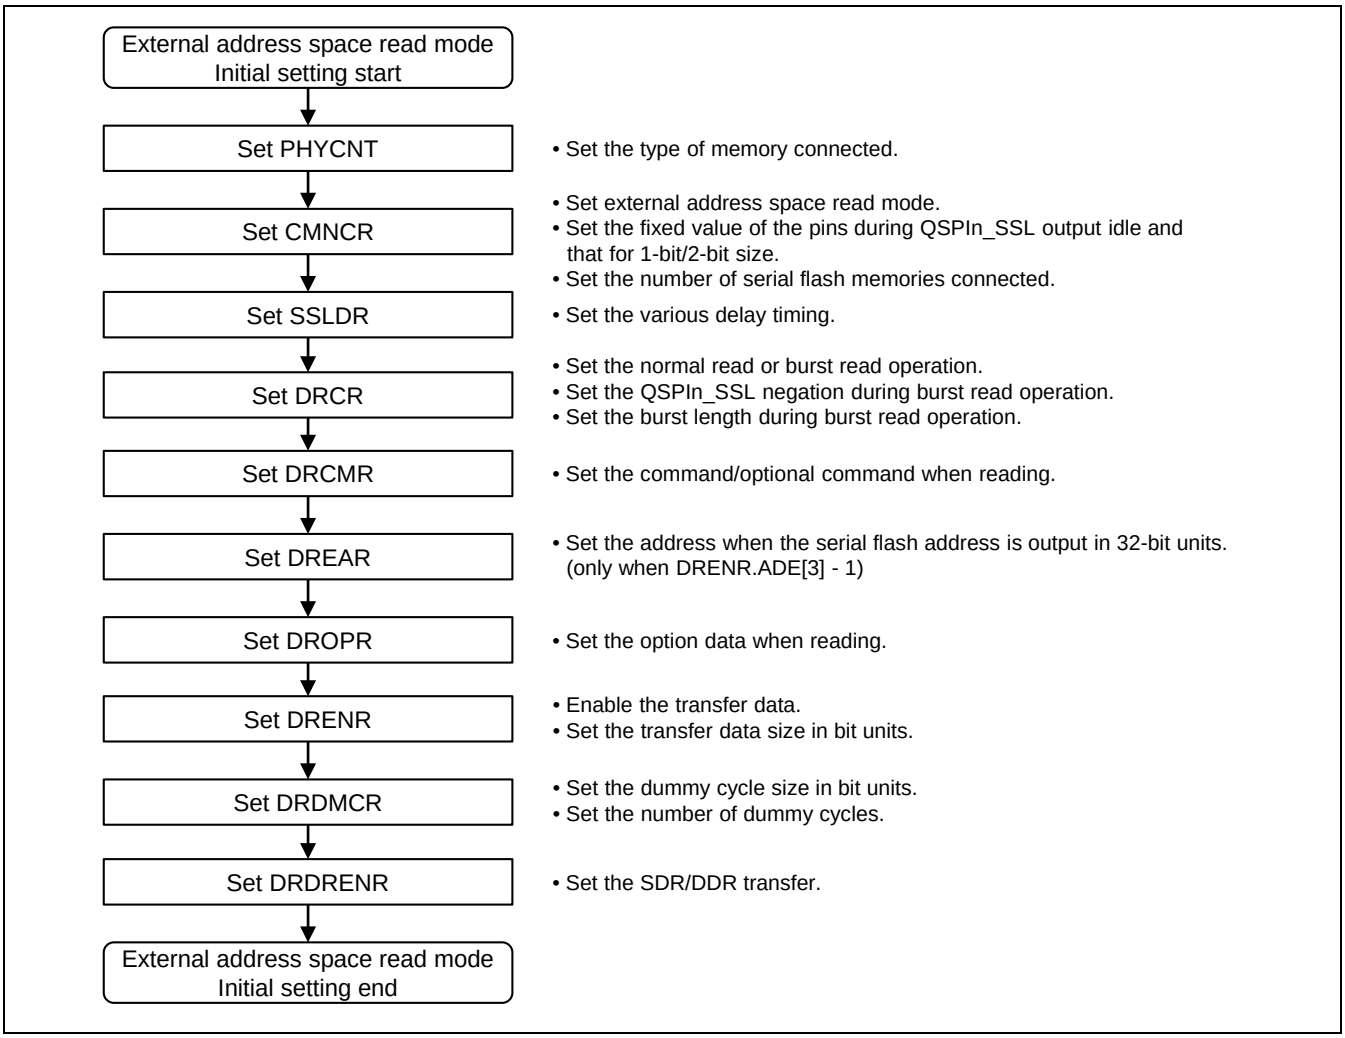

Figure 56.12 Example of Initial Setting Flow in External Address Space Read Mode

56.3.6 Read Cache

This module has a simple built-in read cache. The read cache can be used during external address space read mode and burst read operation. The read cache is configured with a line size of 64 bits and 32 entries.

Read cache configuration is shown in Figure 56.13.

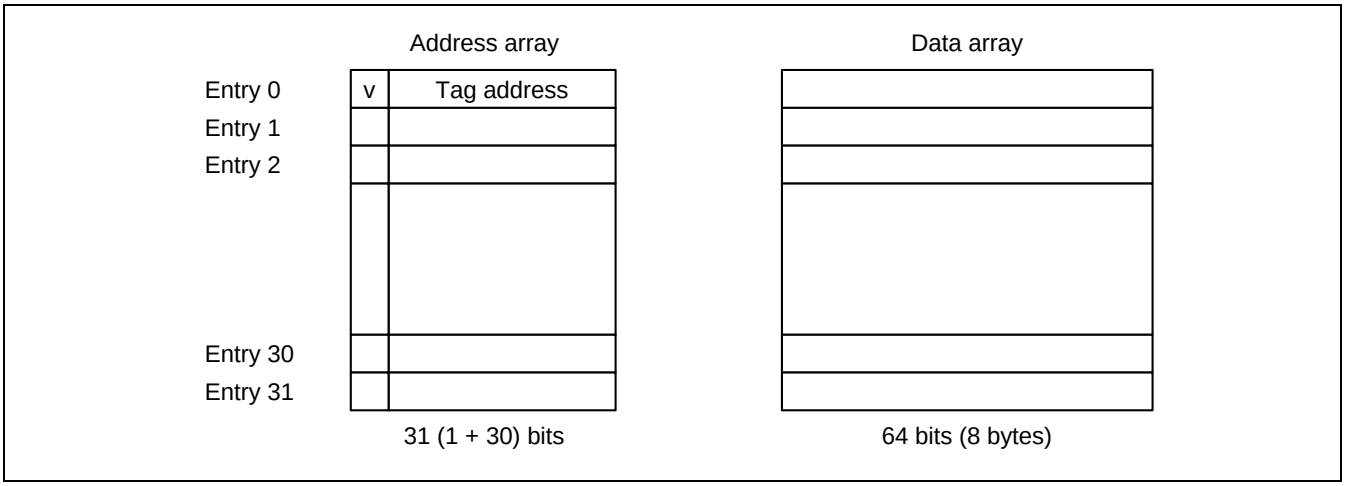

Figure 56.13 Read Cache Configuration

(1) Address Array

The V bit indicates whether the entry data is valid. When the V bit is 1, the data is valid and when V bit is 0, the data is invalid.

The tag address bits hold the address used for the serial flash memory. Address bits 32 to 3 are used for the purpose. Address bits 23 to 3 are enabled when address output is 24 bits and one serial flash memory is connected; and address bits 24 to 3 are enabled when two serial flash memory devices are connected.

Address bits 31 to 3 are enabled when address output is 32 bits and one serial flash memory is connected; and address bits 32 to 3 are enabled when two serial flash memory devices are connected.

(2) Data Array

It retains the 64-bit read data. Registration in the read cache is performed in line units.

(3) Read Operation

In case of read-hit, data is read from the read cache. In case of read-miss, after the 64 × RBURST (read burst length) data is read from the serial flash memory and the read cache is updated, the data is returned to the bus master.

(4) Data Replacement

The write pointer is used to update data. In case of read-miss, the RBURST (read burst length) portion data is replaced starting at the entry specified by the write pointer. In other words, the data is replaced in the storage order of the data. Whether data is referred to or not will not affect the replacement order of data.

56.3.7 Manual Mode

This module can carry out an arbitrary serial transfer operation by using the register settings.

The transfer format is determined based on the common control register (CMNCR), SSL delay register (SSLDR), manual mode control register (SMCR), manual mode command setting register (SMCMR), manual mode address setting register (SMADR), manual mode option setting register (SMOPR), and manual mode enable setting register (SMENR), manual mode read data register (SMRDR), manual mode write data register (SMWDR), manual mode dummy cycle setting register (SMDMCR), and manual mode DDR enable register (SMDRENR).

Manual mode can be used for reading the status of the serial flash memory and writing to the serial flash memory.

In this mode, one transfer refers to the operation from when the SPIE bit in SMCR is set to 1 to when the TEND bit is set to 1.

Note: The RZ/G2M V1.3 (not RZ/G2M V3.0) does not support DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit). In the following description, do not set the related operation.

(1) Transfer Start

The transfer of data is started in the set transfer format by setting the SPIE bit in SMCR to 1. When write operation is enabled, the manual mode write data register is transmitted to the serial flash memory. When read operation is enabled, data read from the serial flash memory is stored into the manual mode read data register.

The operation timing of serial transfer is shown in Figure 56.14.

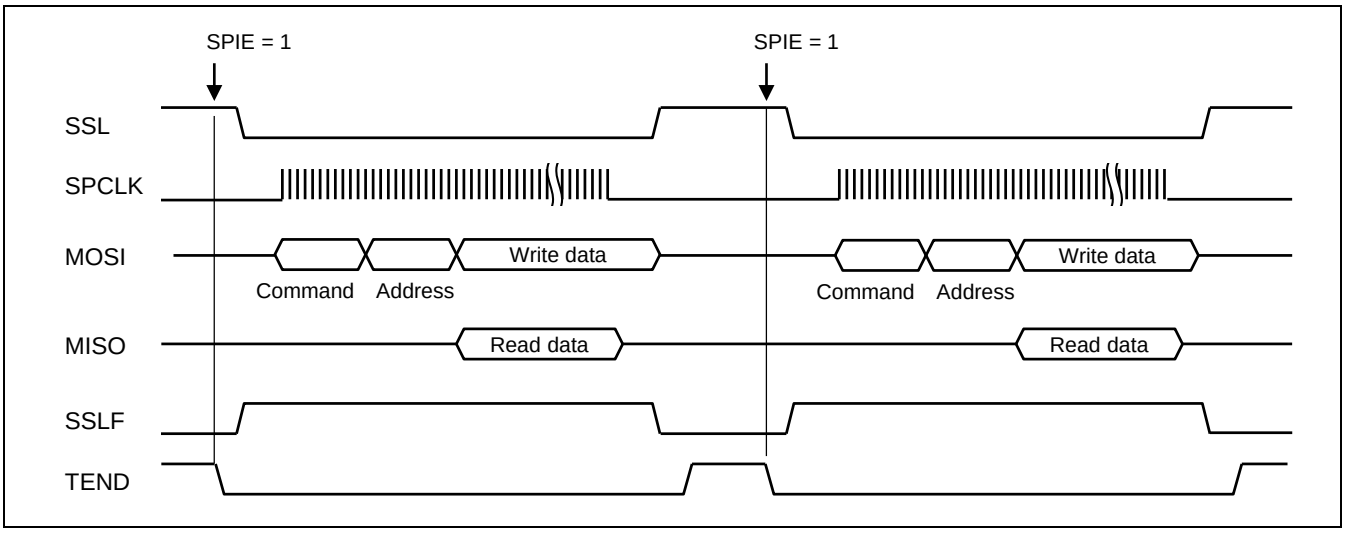

Figure 56.14 Operation Timing of Serial Transfer

(2) Read/Write Enable

Read operation: Data can be read by setting the SPIRE bit in SMCR to 1. The read data is stored into SMRDR.

Write operation: Data can be written by setting the SPIWE bit in SMCR to 1. The data stored in SMWDR is output.

When the data size is set to 1 bit using the SPIDB[1:0] bits in SMENR, data can be transmitted and received by setting the SPIRE and SPIWE bits to 1. However, when the data size is set to 4 bits by using the SPIDB[1:0] bits, only one of the SPIRE and SPIWE bits should be enabled. The operation is not guaranteed if both the bits are enabled.

(3) Retention of QSPIn_SSL Pin Assertion

By setting the SSLKP bit in SMCR to 1, assertion of the QSPIn_SSL pin can be continued till the next transfer. With this function, the transfer can be carried out continuously with the QSPIn_SSL kept in the asserted state.

The data transfer timing using the SSLKP bit is shown in Figure 56.15.

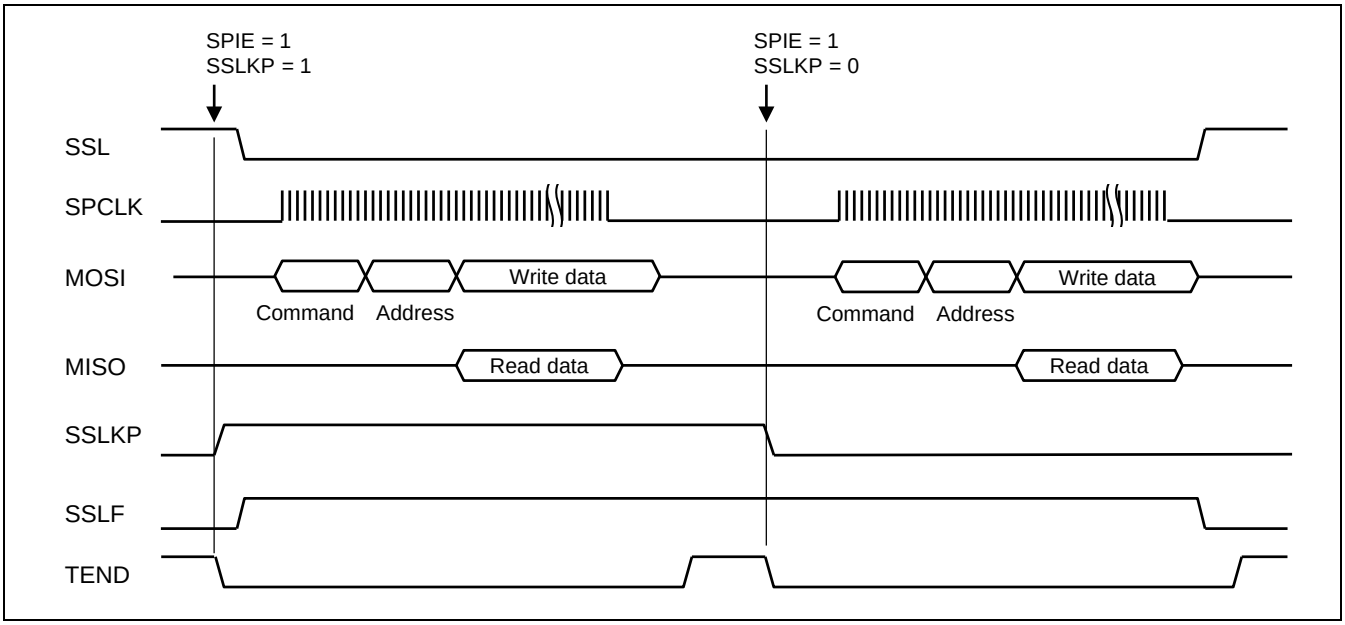

Figure 56.15 Data Transfer Timing Chart Using the SSLKP Bit

(4) Initial Setting Flow

An example of an initial setting flow in manual mode is shown in Figure 56.16.

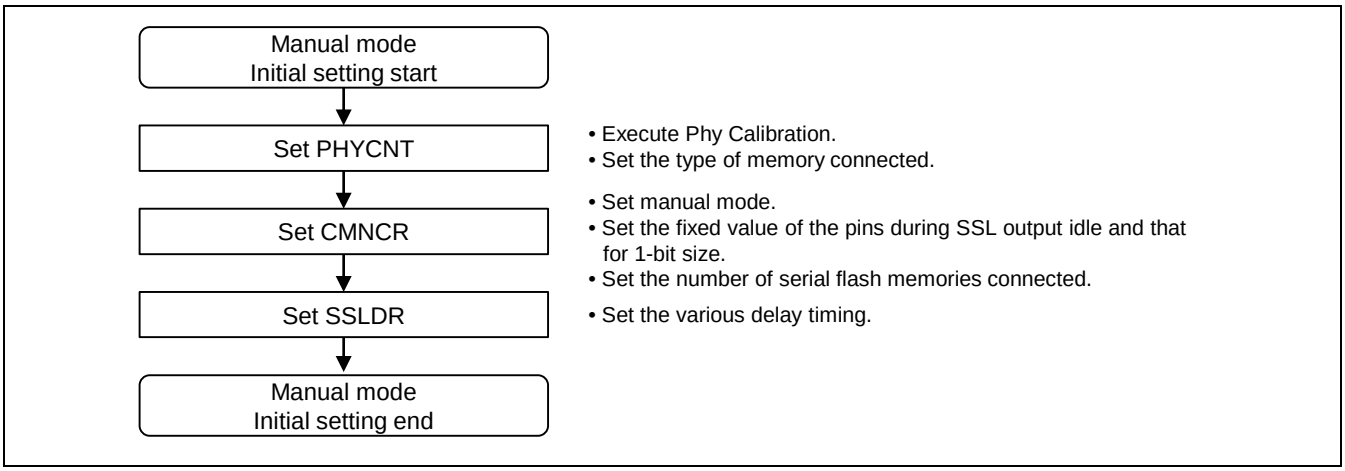

Figure 56.16 Example of Initial Setting Flow in Manual Operating Mode

(5) Data Transfer Setting Flow

An example of a data transfer setting flow in manual mode is shown in Figure 56.17.

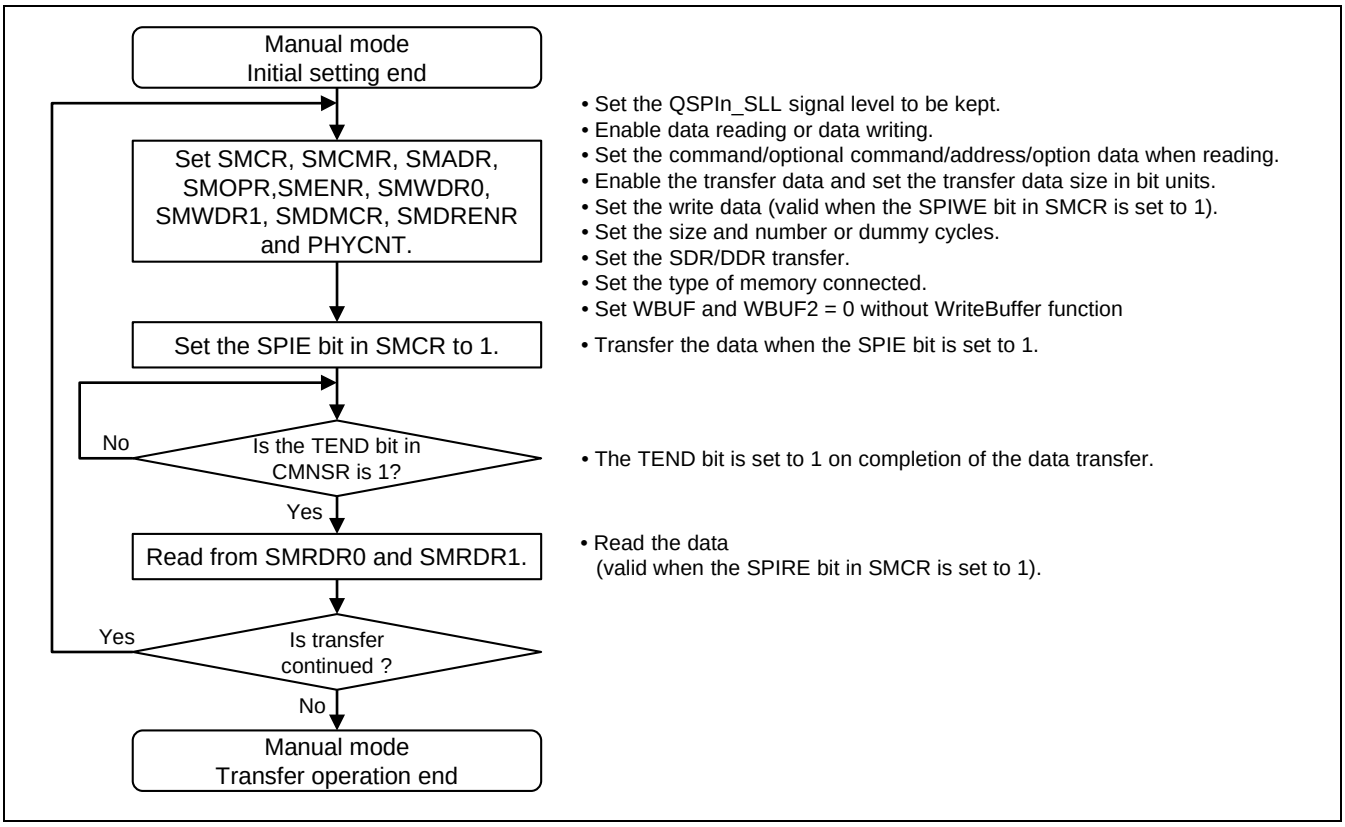

Figure 56.17 Example of Data Transfer Setting Flow in Manual Operating Mode

56.3.8 Command Sequence

This module handles input and output data in the order of command, optional command, address, option data, dummy cycle, and data.

Note: The RZ/G2M V1.3 (not RZ/G2M V3.0) does not support DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit). In the following description, do not set the related operation.

(1) Data Registers

Table 56.5 and Table 56.6 shows the input and output data.

Table 56.5 Data Registers (serial flash)

Data		External Address Space Read Operation	Manual Operation
Command (8 bits)		CMD[7:0] bits in DRCMR	CMD[7:0] bits in SMCMR
Optional Command (8 bits)		OCMD[7:0] bits in DRCMR	OCMD[7:0] bits in SMCMR
Address (32/24 bits)	BSZ[1:0] = 00 (one serial flash memory connected)	32 bits: DREAR.EAV[7:1 to 0] bits + lower [25 to 24:0] bits of the read address. 24 bits: Lower [23:0] bits of the read address	32 bits: ADR[31:0] bits in SMADR. 24 bits: ADR[23:0] bits in SMADR
	BSZ[1:0] = 01 (two serial flash memory devices connected)	32bits: DREAR.EAV[7:1 to 0] bits + lower [25 to 24:1] bits of the read address 24bits: Lower [24:1] bits of the read address	
Option data (8 bits × 4)		DROPR	SMOPR
Dummy cycle (1 to 20 cycles)		DRDMC	SMDMC register (only when read)
Transfer Data		Normal read: 8, 16, and 32 bits, Burst read: 64 x RBURST bits	Read: SMRDR0 and SMRDR1 Write: SMWDR0 and SMRDR1

Table 56.6 Data Registers (HyperFlash)

Data	External Address Space Read Operation	Manual Operation
CA0 (47-40)	CMD[7:5] bits in DRCMR + [31:27] bits of the read address	CMD[7:5] bits in SMCMR + ADR[31:27] bits in SMADR
CA0 (39-32)	[26:19] bits of the read address	ADR[26:19] bits in SMADR
CA0 (31-24)	[18:11] bits of the read address	ADR[18:11] bits in SMADR
CA0 (23-16)	[10:3] bits of the read address	ADR[10:3] bits in SMADR
CA0 (15-8)	DROPR[15:8]	SMOPR[15:8]
CA0 (7-0)	DROPR[7:3] + [2:0] bits of the read address	SMOPR[7:3] + ADR[2:0] bits in SMADR
Dummy cycle (1 to 20 cycles)	DRDMC	SMDMC register
Transfer Data	Normal read: 8, 16, and 32 bits, Burst read: 64 x RBURST bits	Read: SMRDR0 and SMRDR1 Write: SMWDR0 and SMRDR1

(2) Data Enable

In external address space read mode, transfer enable or disable of the command, optional command, address, option data, and dummy cycle can be controlled with the CDE, OCDE, ADE[3:0], OPDE[3:0], and DME bits in DRENR, respectively. The size and number of dummy cycles can be controlled with the data read dummy cycle setting register (DRDMCR).

Similarly, in manual mode, enable or disable of the command, optional command, address, option data, dummy cycle, and transfer data can be controlled with the CDE, OCDE, ADE[3:0], OPDE[3:0], DME, and SPIDE[3:0] bits in SMENR, respectively. However, disabling all the above parameters is prohibited in manual mode. At least one of them except dummy cycle must be enabled. The size and number of dummy cycles can be controlled with the manual mode dummy cycle setting register (SMDMCR).

For the address and option data in external address space read mode; and the address, option data, and transfer data in manual mode, the enable bit setting allowed is determined according to the transfer data size. For the allowed setting combinations of the enable bits and transfer data size, refer to the description of the pertinent register.

If data is disabled, that data is skipped, and input and output of the next data is carried out. The command, optional command, address, and option data are always output. During dummy cycles, the state of the used pins is Hi-Z. In external address space read mode, data is always input; and in manual mode, input and output of data is determined based on the settings of the SPIRE and SPIWE bits in SMCR.

There are some restrictions on dummy cycle insertion. Refer to the description of the DME bits in DRENR and SMENR for details.

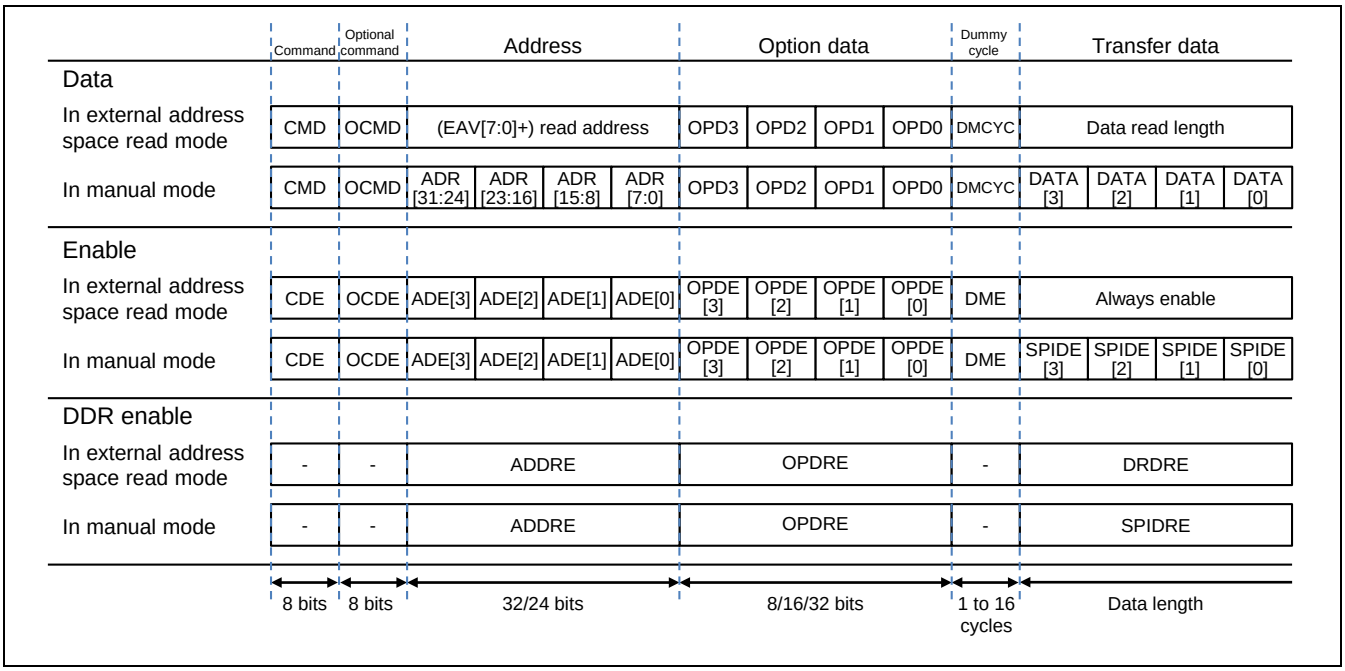

Figure 56.18 The relationship between Data and Enable (serial flash)

When HyperFlash is connected to this LSI, specify enable bits in CDE, OCDE, ADE[3:0], OPDE[3:0], and DME bits in DRENR and HYPE[2:0], ADDRE, OPDRE and DRDRE in DRDRENR in external address space read mode, and CDE, OCDE, ADE[3:0], OPDE[3:0],DME and SPIDE[3:0] in SMENR and HYPE[2:0], ADDRE, OPDRE and SPIDRE in SMDRENR manual mode.

Table 56.7 Enable Registers (HyperFlash)

External Address Space Read Operation			**Manual Operation**		
Register	Bits	Setting Value	Register	Bits	Setting Value
DRENR	CDE	B’1	SMENR	CDE	B‘1
	OCDE	B’1		OCDE	B‘1
	ADE[3:0]	B’0100		ADE[3:0]	B‘0100
	OPDE[3:0]	B’0000		OPDE[3:0]	B’0000
	DME	B’1		DME	Read: B’1 Write: B’0
DRDRENR	HYPE[2:0]	B’101		SPIDE[3:0]	16bit: B’1000 32bit: B’1100 64bit: B’1111
	ADDRE	B’1	SMDRENR	HYPE[2:0]	B’101
	OPDRE	B’0		ADDRE	B’1
	DRDRE	B’1		OPDRE	B’0
				SPIDRE	B’1

(3) Bit Size

In external address space read mode, the size of the command, optional command, address, option data, and the read data in bit units is respectively controlled with the CDB[1:0], OCDB[1:0], ADB[1:0], OPDB[1:0], and DRDB[1:0] bits in DRENR. The size of the dummy cycle in bit units is also controlled with the DMDB[1:0] bits in DRDMCR.

Similarly, in manual mode, the size of the command, optional command, address, option data, and read write data in bit units is controlled with the CDB[1:0], OCDB[1:0], ADB[1:0], OPDB[1:0], and SPIDB[1:0] bits in SMENR. The size of the dummy cycle in bit units is also controlled with the DMDB[1:0] bits in SMDMCR.

(a) 1-bit Size

When the size is set to 1 bit, QSPI0_MISO_IO1 and QSPI1_MISO_IO1 pins will be the input pins and QSPI0_MOSI_IO0 and QSPI1_MOSI_IO0 pins will be the output pins. QSPI0_IO2, QSPI1_IO2, QSPI0_IO3, and QSPI1_IO3 pins are not used.

Figure 56.19 and 56.20 show the examples of the transfer format.

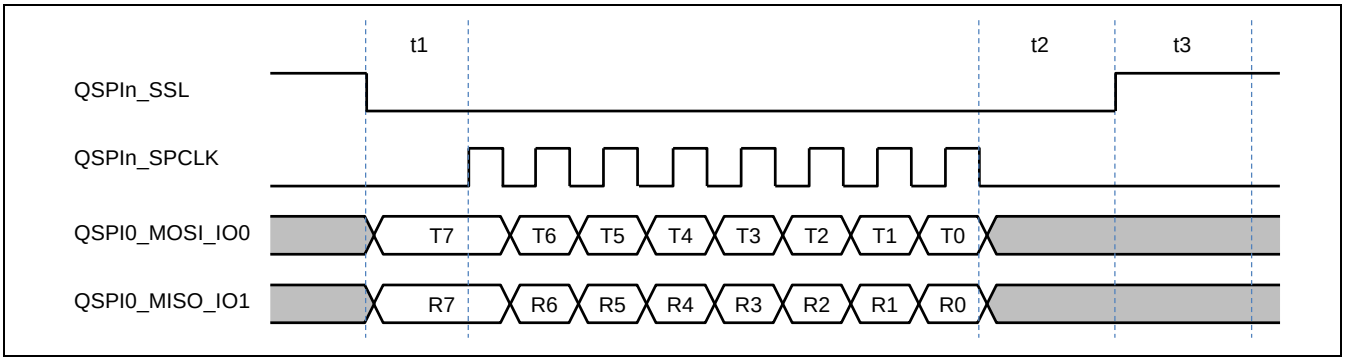

Figure 56.19 Example of Transfer Format with 1-Bit Data Size and One Serial Flash Memory Connected

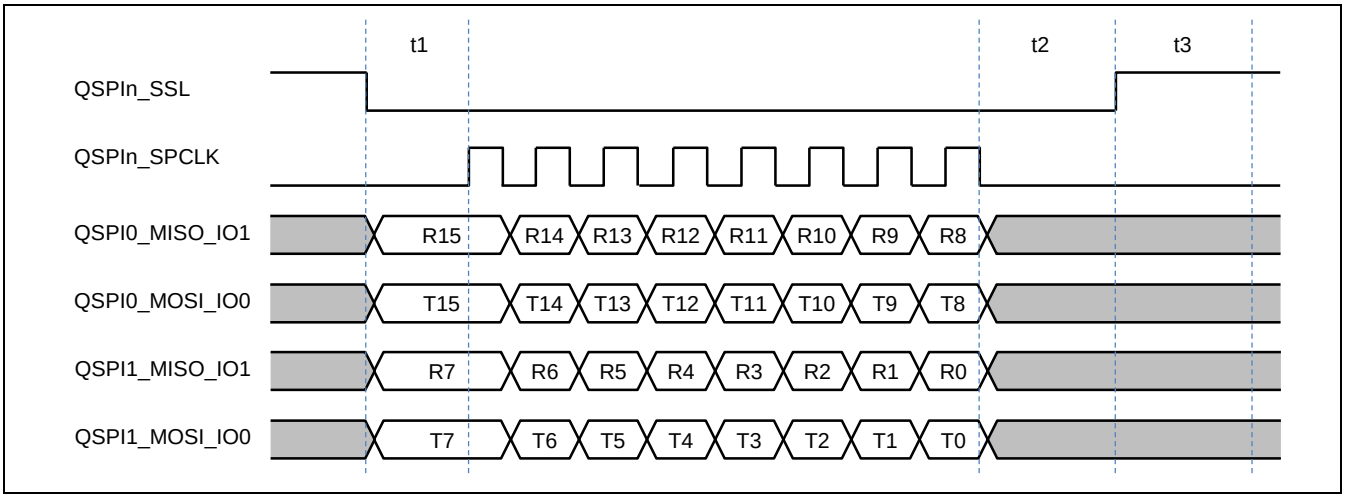

Figure 56.20 Example of Transfer Format with 1-Bit Data Size and Two Serial Flash Memory Devices Connected

(b) 4-bit Size (serial flash)

When the size is set to 4-bit, QSPI0_MOSI_IO0, QSPI1_MOSI_IO0, QSPI0_MISO_IO1, QSPI1_MISO_IO1, QSPI0_IO2, QSPI1_IO2, QSPI0_IO3, and QSPI1_IO3 pins will be either the input pins or the output pins. Figure 56.21 and 56.22 show the examples of the transfer format.

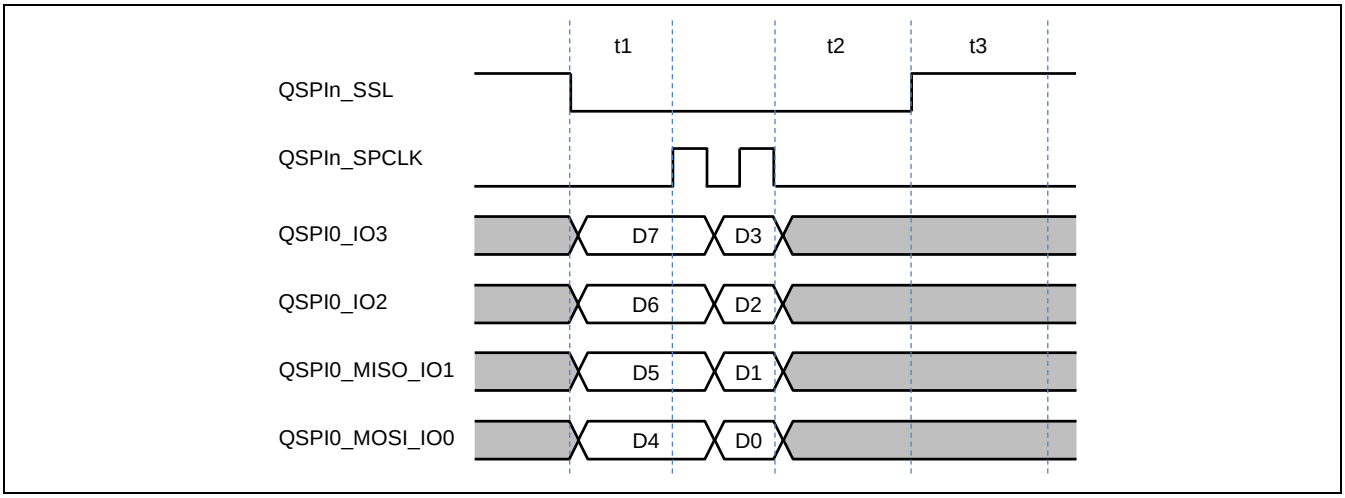

Figure 56.21 Example of Transfer Format with 4-Bit Data Size and One Serial Flash Memory Connected

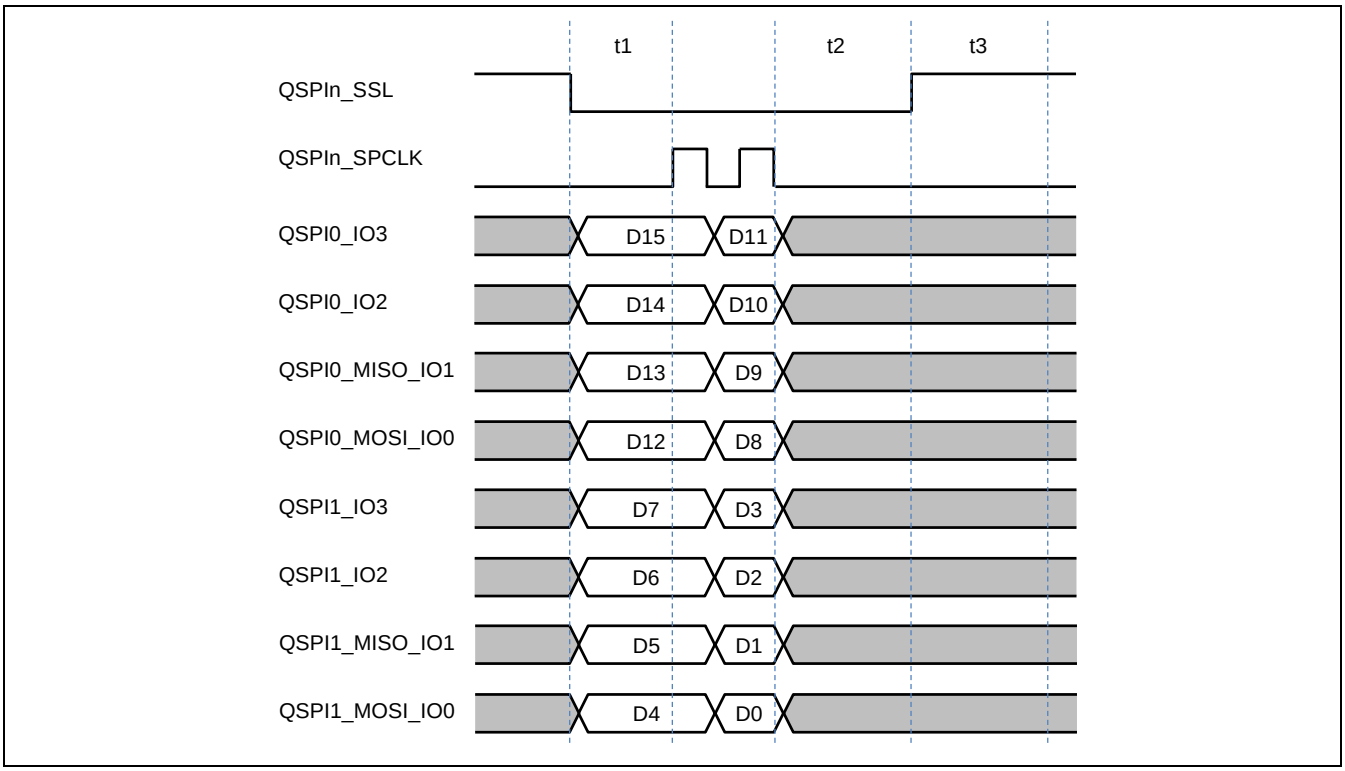

Figure 56.22 Example of Transfer Format with 4-Bit Data Size and Two Serial Flash Memory Devices Connected

(c) 4-bit Size (Hyperflash)

When HyperFlash is connected to this LSI, QSPI0_SPCLK and QSPI1_SPCLK will be differential clock, QSPI1_SSL will be input pin for RDS (Read Data Strobe) and QSPI0_MOSI_IO0, QSPI1_MOSI_IO0, QSPI0_MISO_IO1, QSPI1_MISO_IO1, QSPI0_IO2, QSPI1_IO2, QSPI0_IO3, and QSPI1_IO3 pins will be either the input pins or the output pins. Figure 56.23 shows the command/address sequence, and Figure 56.24 shows example of read data. In manual mode, the read data alignment is sequential, {DQ3[7:0], DQ2[7:0], DQ1[7:0], DQ0[7:0]} is stored in SMRDR1[31:0] and {DQ7[7:0], DQ6[7:0], DQ5[7:0], DQ4[7:0]} is stored in SMRDR0[31:0]. In external address space read mode, the read data is stored in little endian. For example, the 64-byte read data on RPC-IF area (H'0800_0000 ~ H'0BFF_FFFF) is {DQ7[31:0], DQ6[7:0], DQ5[7:0], DQ4[7:0], DQ3[7:0], DQ2[7:0], DQ1[7:0], DQ0[7:0]}.
Figure 56.25 shows example of write data(64bit). In manual mode, the write data alignment is sequential, the data in SMWDR1[7:0] is on DQ0, SMWDR1[15:8] is on DQ1, …, SMWDR0[31:24] is on DQ7. Figure 56.26 shows example of write data(16 bit). In manual mode, the write data alignment is sequential, the data in SMWDR0[23:16] is on DQ6, SMWDR0[31:24] is on DQ7. In Write Buffer mode, the write data alignment is little endian. The data stored in Write Buffer is output from H'EE20_8000 to H'EE20_80FF sequentially.

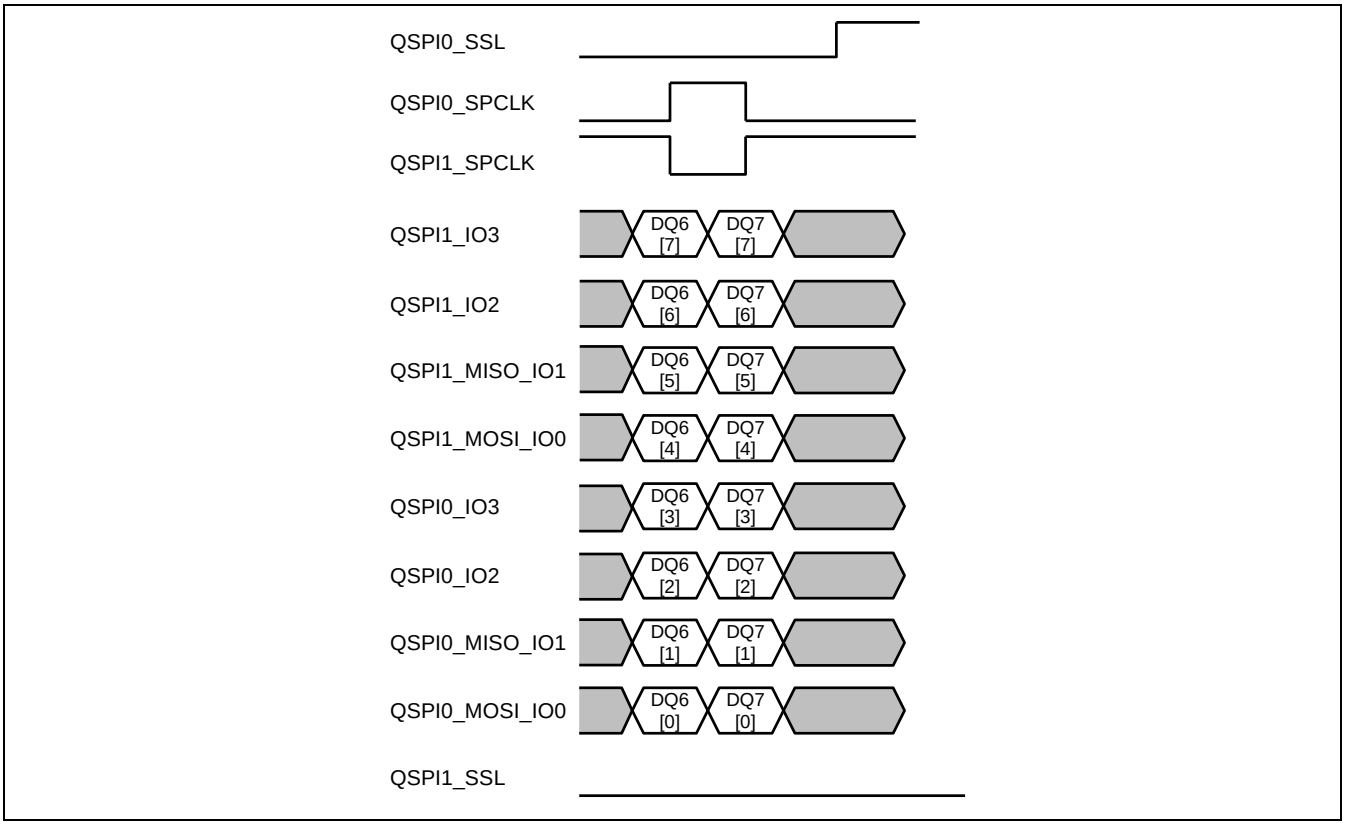

Figure 56.26 Example of Transfer Format in Write phase with HyperFlash (16 bit)

56.3.9 Data Pin Control

With this module, the status of pins can be automatically changed based on the data size to be used and the read/write settings. The pin status during the QSPIn_SSL negation can be set with the MOIIO3, MOIIO2, MOIIO1, and MOIIO0 bits in CMNCR.

The QSPI0_SSL and QSPIn_SPCLK pins are always output pins. The status of respective pins is specified in Table 56.8 to 56.11.

Note that connection with ch1 pins in 1 x serial flash configuration is prohibited.

Table 56.8 Pin Status (1)

		QSPIn_SSL Assertion	
		Command, Optional Command, Address, Option Data	
Pin	QSPIn_SSL Negation	1-bit Size	4-bit Size
QSPI0_IO0, QSPI1_IO0	MOIIO0 bit value	Output	Output
QSPI0_IO1, QSPI1_IO1	MOIIO1 bit value	Hi-Z	Output
QSPI0_IO2, QSPI1_IO2	MOIIO2 bit value	specified in PFC *	Output
QSPI0_IO3, QSPI1_IO3	MOIIO3 bit value	specified in PFC *	Output

Note: * QSPI0_IO2, QSPI1_IO2, QSPI0_IO3 and QSPI1_IO3 pin state should be controlled by PFC function. Refer to "8. and 9. Pin Function Controller"

Table 56.9 Pin Status (2)

	Transfer Data			
	External Address Space Read Operation		SPI Operation	
			SPIRE Bit = 1, SPIWE Bit = 0	
Pin	1-bit Size	4-bit Size	1-bit Size	4-bit Size
QSPI0_IO0, QSPI1_IO0	IO0FV bit value	Input	IO0FV bit value	Input
QSPI0_IO1, QSPI1_IO1	Input	Input	Input	Input
QSPI0_IO2, QSPI1_IO2	specified in PFC *	Input	specified in PFC *	Input
QSPI0_IO3, QSPI1_IO3	specified in PFC *	Input	specified in PFC *	Input

Note: * QSPI0_IO2, QSPI1_IO2, QSPI0_IO3 and QSPI1_IO3 pin state should be controlled by PFC function. Refer to the section 8. and 9. Pin Function Controller in User's Manual.

Table 56.10 Pin Status (3)

	Transfer Data			
	SPI Operation			
	SPIRE Bit = 0, SPIWE Bit = 1		SPIRE Bit = 1, SPIWE Bit = 1	
Pin	1-bit Size	4-bit Size	1-bit Size	4-bit Size
QSPI0_IO0, QSPI1_IO0	Output	Output	Output	Setting prohibited
QSPI0_IO1, QSPI1_IO1	Hi-Z	Output	Input	Setting prohibited
QSPI0_IO2, QSPI1_IO2	specified in PFC *	Output	specified in PFC *	Setting prohibited
QSPI0_IO3, QSPI1_IO3	specified in PFC *	Output	specified in PFC *	Setting prohibited

Note: * QSPI0_IO2, QSPI1_IO2, QSPI0_IO3 and QSPI1_IO3 pin state should be controlled by PFC function. Refer to the section 8. and 9. Pin Function Controller in User's Manual.

Table 56.11 Pin Status (4)

	Dummy Cycle	
Pin	1-bit Size	4-bit Size
QSPI0_IO0, QSPI1_IO0	IO0FV bit value	Hi-Z
QSPI0_IO1, QSPI1_IO1	Hi-Z	Hi-Z
QSPI0_IO2, QSPI1_IO2	specified in PFC *	Hi-Z
QSPI0_IO3, QSPI1_IO3	specified in PFC *	Hi-Z

Note: * QSPI0_IO2, QSPI1_IO2, QSPI0_IO3 and QSPI1_IO3 pin state should be controlled by PFC function. Refer to "8. and 9. Pin Function Controller"

56.3.10 QSPIn_SSL Pin Control

Negation conditions of the QSPIn_SSL pin are as follows.

(1) External Address Space Read Operation

(a) Normal read operation (RBE bit in DRCR = 0)

QSPIn_SSL negated after completing the data transfer and t2 cycle.

(b) Burst read operation without automatic QSPIn_SSL negation (RBE bit in DRCR = 1, SSLE bit in DRCR = 0)

QSPIn_SSL negated after completing the data transfer and t2 cycle.

(c) Burst read operation with automatic QSPIn_SSL negation (RBE bit in DRCR = 1, SSLE bit in DRCR = 1)

- QSPIn_SSL negated after t2 cycle when the read address is not continuous with the previously read address
- QSPIn_SSL negated after the SSLN bit in DRCR is set to 1.

Note: This function is available when connecting to serial flash.

(2) Manual Mode

(a) QSPIn_SSL pin assertion not retained (SSLKP bit in SMCR = 0)

QSPIn_SSL negated after completing the data transfer.

(b) QSPIn_SSL pin assertion retained (SSLKP bit in SMCR = 1)

QSPIn_SSL not negated.

When to be negated, data should be transferred after setting the SSLKP bit to 0.

Note: QSPI1_SSL is used as input pin for data strobe when connecting to HyperFlash or Octal-SPI flash.

56.3.11 QSPIn_SPCLK Pin Control

QSPI0_SPCLK and QSPI1_SPCLK are output depending on the following setting

Table 56.12 QSPIn_SPCLK output

Pin	HyperFlash (CMNCR.BSZ = 01 PHYCNT.PHYMEM = 11)	Serial flash x 1ch (CMNCR.BSZ = 00 PHYCNT.PHYMEM = 00 or 01)	Serial flash x 2ch (CMNCR.BSZ = 01 PHYCNT.PHYMEM = 00 or 01)
QSPI0_SPCLK	Output	Output	Output
QSPI1_SPCLK	Output in differential relation with QSPI0_SPCLK	Hi-Z	Output

56.3.12 Flags

This module has two flag bits SSLF and TEND in CMNSR. These bits are read-only bits.

(1) SSLF Bit

This bit indicates the QSPIn_SSL pin status. The status is 1 when the QSPIn_SSL is asserted, and the status is 0 when the QSPIn_SSL is negated.

(2) TEND Bit

This bit indicates whether transfer of data is in progress or the transfer of data has ended.

During t1 time period, data transfer, t2 time period, t3 time period, and waiting for read access by burst read and QSPIn_SSL automatic negation, the TEND bit is read as 0 to indicate that the transfer of data is in progress.

When other than the above, the TEND bit is read as 1 to indicate that transfer of data has ended.

(3) Register Re-writing Timing

The status of the TEND bit determines the rewritable registers.

The registers which can be written to, except the SSLN bit in DRCR, should be modified when TEND = 1.

The data should be read when the TEND flag in SMRDR0 or SMRDR1 is 1;

CMNSR can always be read.

56.3.13 Write Buffer Operation

This module uses read cache as write buffer in write operation. This write buffer improve the performance.

Table 56.13 Write Buffer Area

Address	Access Size
H'EE20_8000 to H'EE20_80FF	4, 8, 16, 32, 64 Byte

Note: This area should be accessed sequentially from the start address and transfer size to the device is 256-byte unit.
All Write Buffer area should be filled with transfer data in every transfer.
When accessing non-sequentially or at random, the operation is not guaranteed.
After Write Buffer Operation, this cache area must be cleared by DRCR.RCF bit.
Write Buffer operation supports 24bit or 32bit address only. SMENR.ADE should be specified 0111 (ADR[23:0]) or 1111 (ADR[31:0]).

Figure 56.27 shows the sequence to use write buffer. About the initial setting of Manual mode, refer to Figure 56.16.

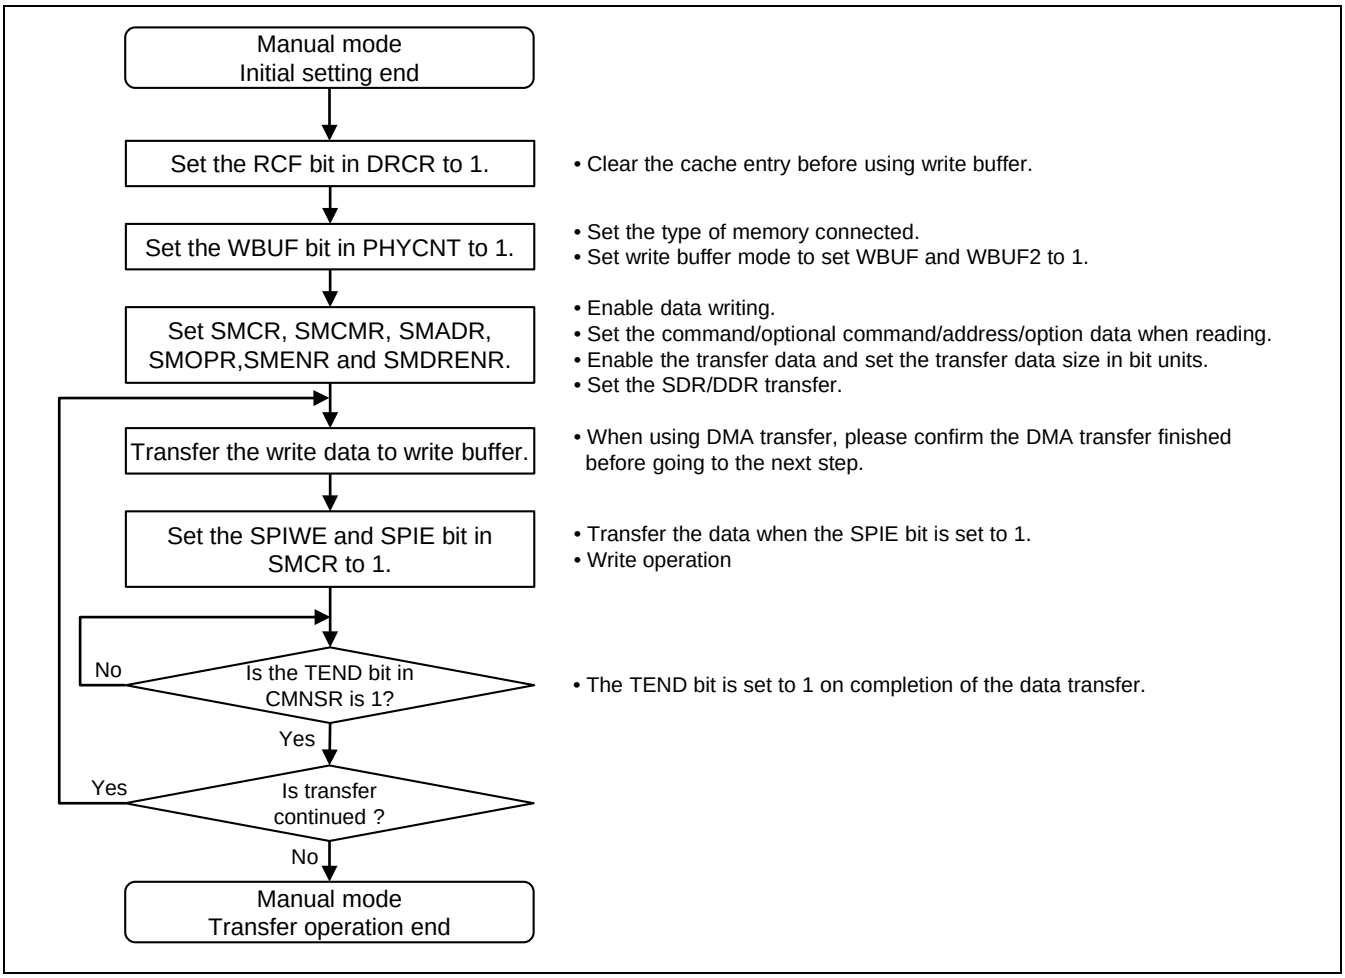

Figure 56.27 Write Buffer Usage Sequence

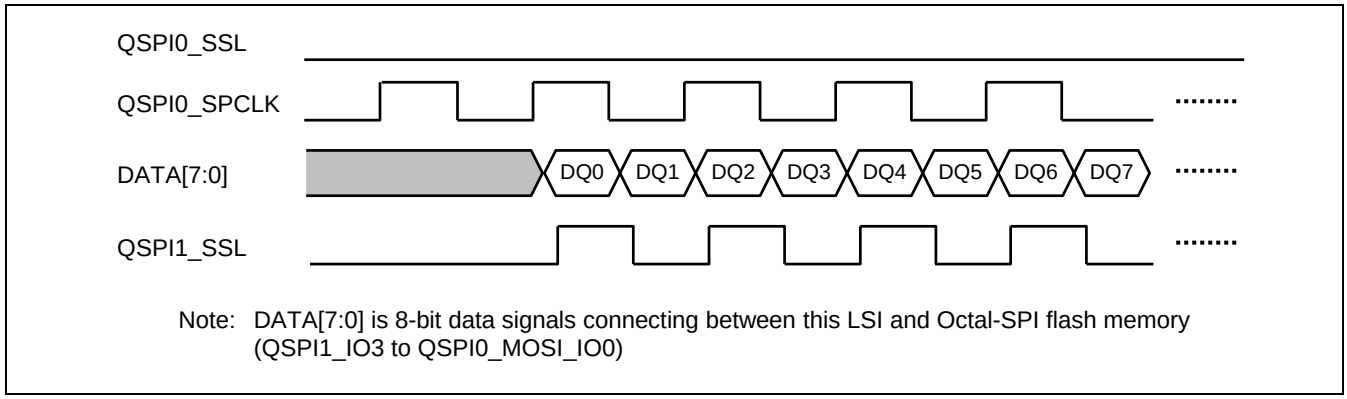
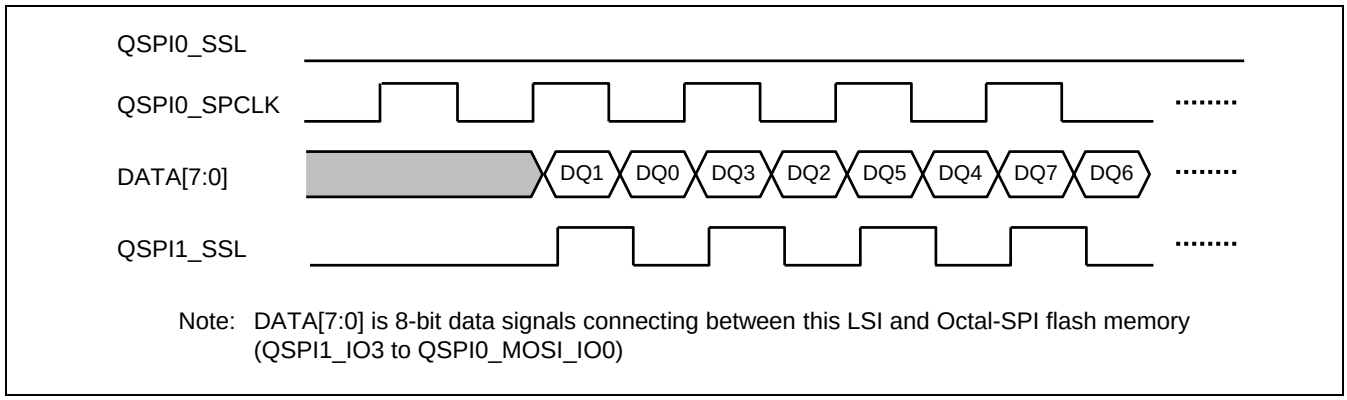
56.3.14 Data Alignment with Octal-SPI flash memory

When this LSI connects to Octal-SPI flash memory, this controller support two types of data alignment. Figure 56.28 and Figure 56.29 show sequential and alternate alignment respectively. Write data alignment in Write Buffer operation is same.



Note: DATA[7:0] is 8-bit data signals connecting between this LSI and Octal-SPI flash memory (QSPI1_IO3 to QSPI0_MOSI_IO0)

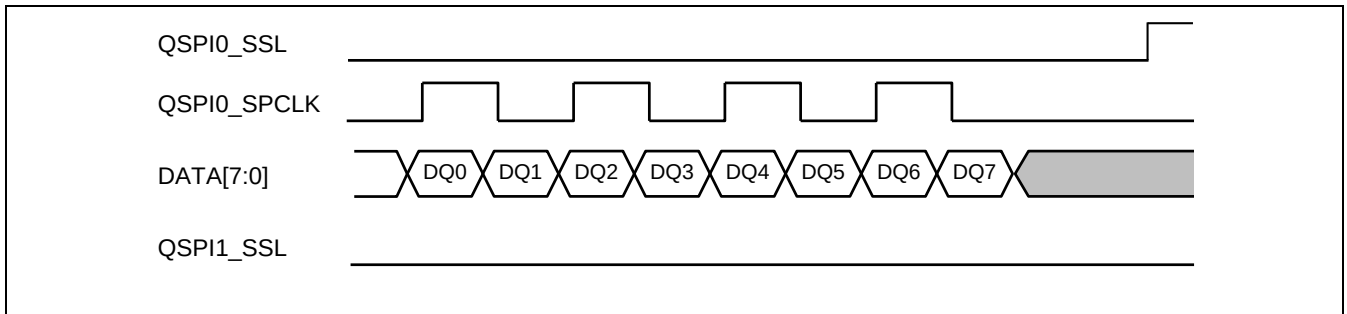
Figure 56.28 Sequential Data Alignment with Octal-SPI flash (PHYCNT.OCTA = 10)



Note: DATA[7:0] is 8-bit data signals connecting between this LSI and Octal-SPI flash memory (QSPI1_IO3 to QSPI0_MOSI_IO0)

Figure 56.29 Alternate Data Alignment with Octal-SPI flash (PHYCNT.OCTA = 01)

Figure 56.30 shows the write data alignment in 8-8-8 protocol in manual mode operation.



DQ0[7:0]	SMWDR1[15:12], SMWDR1[7:4]	DQ4[7:0]	SMWDR0[15:12], SMWDR0[7:4]
DQ1[7:0]	SMWDR1[11:8], SMWDR1[3:0]	DQ5[7:0]	SMWDR0[11:8], SMWDR0[3:0]
DQ2[7:0]	SMWDR1[31:28], SMWDR1[23:20]	DQ6[7:0]	SMWDR0[31:28], SMWDR0[23:20]
DQ3[7:0]	SMWDR1[27:24], SMWDR1[19:16]	DQ7[7:0]	SMWDR0[27:24], SMWDR0[19:16]

Figure 56.30 Write Data Alignment with Octal-SPI flash in manual mode

56.3.15 Supported Serial Flash Protocol

Table 56.14 shows the protocols of serial flash memory which are supported in this LSI.

Note: The RZ/G2M V1.3 (not RZ/G2M V3.0) does not support DDR operation with QSPI (1-/4-bit) and QSPIx2 (8-bit). In the following description, do not set the related operation.

Table 56.14 Supported protocols of serial flash memory

Bit width (Command-Address-Data)	Command	Address	Data
1-0-0	SDR	NA	NA
1-0-1	SDR	NA	SDR
1-1-1	SDR	SDR	SDR
	SDR	DDR	DDR
1-1-4	SDR	SDR	SDR
1-4-4	SDR	SDR	SDR
	SDR	DDR	DDR

56.3.16 Supported Octal-SPI Flash Protocol

Table 56.15 shows the protocols of Octal-SPI flash memory which are supported in this LSI.

Table 56.15 Supported protocols of Octal-SPI flash memory

Bit width (Command-Address-Data)	Command	Address	Data
1-0-0	SDR	NA	NA
1-0-1	SDR	NA	SDR
1-1-1	SDR	SDR	SDR
8-0-0	SDR	NA	NA
	DDR	NA	NA
8-0-8	DDR	NA	DDR
8-8-8	DDR	DDR	DDR

56.3.17 DDR operation

This controller supports hardware calibration to adjust the timing of data strobe to support DDR protocol. When this LSI connects to the device with data strobe like HyperFlash or Octal SPI flash, this controller adjusts the strobe point automatically. When this LSI connects to the device without data strobe like serial flash memory in DDR mode, more adjustment is necessary to support DDR operation.

To adjust the timing of DDR operation without data strobe flash device, dummy read operation is necessary by software to change the delay of the internal strobe. PHYCNT.STRTIM bits change the delay. The delay depends on the specified value, 000(biggest) > 001 > … > 110 > 111 (smallest), of PHYCNT.STRTIM bits. The maximum value of tVSD in Table 73.21.1 can be achieved among these setting value, so software can find the appropriate timing for changing these values one by one. Figure 56.31 shows the flow of this timing adjustment.

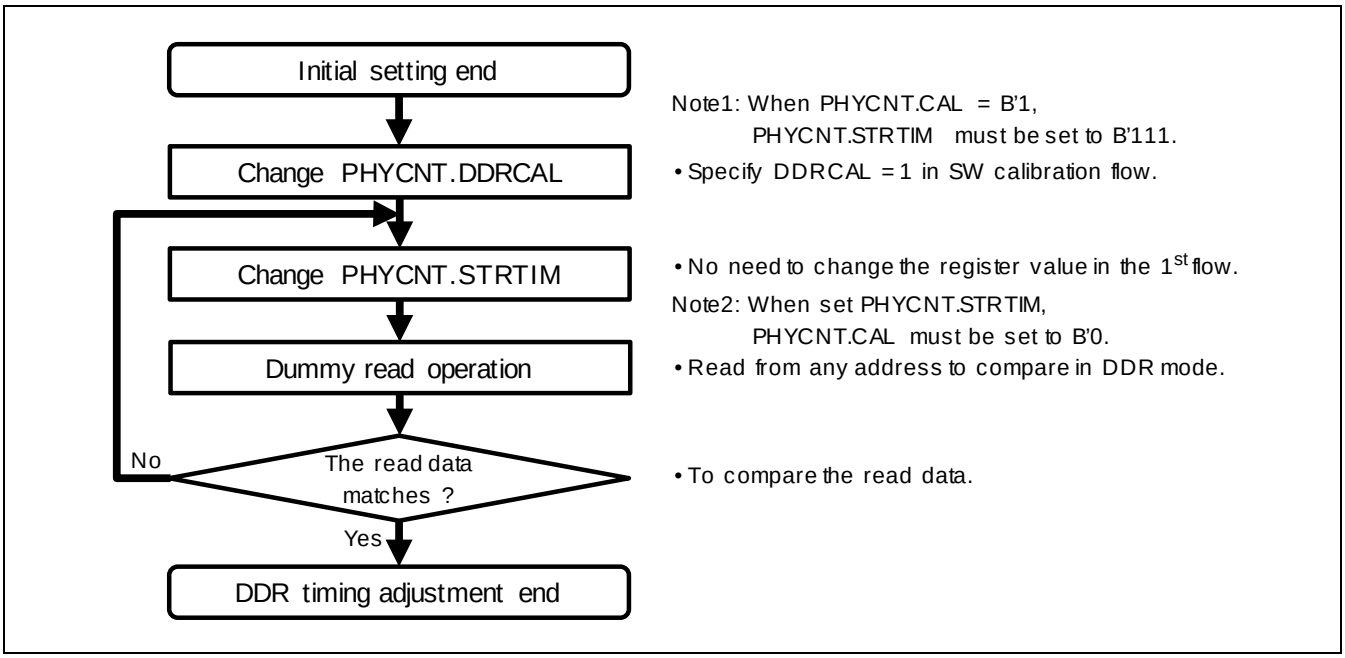


Figure 56.31 DDR timing adjustment to connect to the device without data strobe

This timing adjustment should be done in periodically because the timing changes with PVT condition in both this LSI and the connected device.

Note: The RZ/G2M V1.3 (not RZ/G2M V3.0) does not support DDR operation with QSPI (1/4bit) and QSPIx2 (8bit).

56.3.18 Security function

This controller supports security function to protect the data on the Flash device.

(1) SPI multi I/O bus space division

ADD_DIVn.ADD_DIVn (n = 1, 2, 3) bit specifies the address space division to separate the area into four. And SEC_CONF.AREAn (n = 0, 1, 2, 3) specifies the attribution of each area. The address specified ADD_DIVn.ADD_DIVn[19:0] bit are shifted and evaluate the bus address with 4K granularity. For example, when ADD_DIV1.ADD_DIV1[19:0] is specified to 20'h09FFF and SEC_CONF.AREA0 is specified to 2'b01 (non-secure) setting, Area0 becomes H'0800_0000 – H'09FF_FFFF and Non-Secure attribution, and Area1 starts from H'0A00_0000.

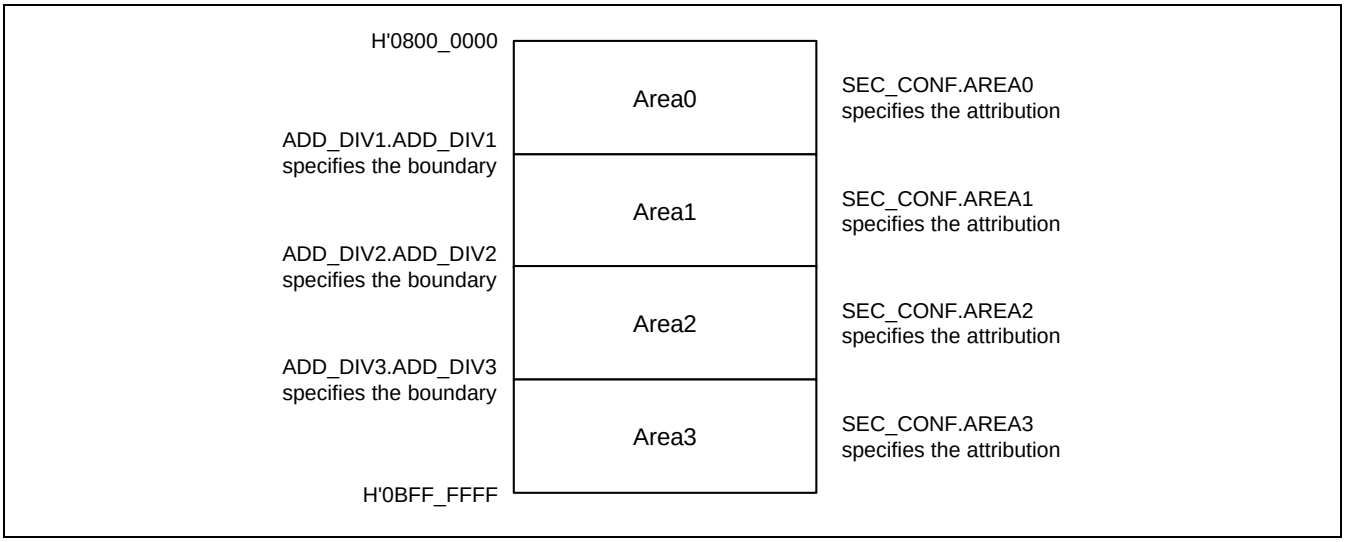

Figure 56.32 Area protection to divide the address space

Note that ADD_DIVn (n = 1 to 3) should be specified to keep the order of H'0800_0000 < ADD_DIV1.ADD_DIV1 < ADD_DIV2.ADD_DIV2 < ADD_DIV3.ADD_DIV3 < H'0BFF_FFFF. If this order is not kept, the operation of this module is not guaranteed. Specifying ADD_DIV1.ADD_DIV1 = 20h'0_8000 to make H'0800_0000 ~ H'0800_0FFF in Area0 is not available.

(2) Command restriction for serial flash

This controller can limit the command to issue to the connected serial flash. SEC_CMDn (n = 0 to 15) and NON_SEC_CMDn (n = 0 to 15) specify the limited command. For example, when H'FF is specified in SEC_CMD0.LIMCMD[7:0] bit and H'FF command is specified in SMCMR.CMD bit, the operation by Secure CPU is not issued. LIMEN bit in each register enables this function.

(3) Write/Erase protect function for serial flash

This controller can protect the mistaken overwrite or erase on the other attribution to limit the Write/Erase command to the specific area on serial flash. ERASELISTn (n = 1, 2) and WRITELISTn (n = 1, 2) specify the prohibited command. When the target address belongs to secure attribution area specified in ADD_DIVn and SEC_CONF registers, the operation by non-secure attribution is not issued.

(4) Access Right

This controller has access right function for the register setting. There are two attribution, Secure and Non-Secure same as area protection. The master which specifies ARIGHT.RIGHT_EN bit has the right to access. The access right is reflected in each bit 3 to 1 according to the attribution of each master. To cancel the access right, the same attribution master should access to this register with RIGHT_EN = 0. The access is ignored when the attribution of access is different.

56.3.19 PHY register interface

This register interface is for the additional timing adjustment of DDR operation without data strobes from flash devices in 56.3.17.

(1) Register Configuration

Table 56.16 shows the register configuration of the PHY register interface.

Table 56.16 Register Configuration of PHY register interface

Register Name	Abbreviation	R/W	Address	Initial value	Access Size	Second Generation RZ/G Series Products			
						RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
PHY Address register	PHYADD	R/W	H'EE20_0070	H'0000_0000	32	—	—	—	√
PHY Write Data register	PHYWR	R/W	H'EE20_0074	H'0000_0000	32	—	—	—	√
PHY Read Data register	PHYRD	R/W	H'EE20_0078	H'0000_0000	32	—	—	—	√

Note: Do not write to any other addresses than listed above. Operations are not guaranteed if such attempt is made.
Values read from addresses other than those listed above are undefined.

Table 56.17 shows the register configuration of PHY. The registers in Table 56.17 can only be accessed by the registers in Table 56.16.

Table 56.17 Register Configuration of PHY register interface

Register Name	Abbreviation	R/W	Address	Initial value	Access Size	Second Generation RZ/G Series Products			
						RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
Mode register	MD	R/W	H'00	H'0000_0000	32	—	—	—	√

Fall Edge Delay Line Tap Monitor	FDLMON	R	H'28	undefined	32	—	—	—	√

Note: Do not write to any other addresses than listed above. Operations are not guaranteed if such attempt is made.
Values read from addresses other than those listed above are undefined.

(2) Register Description

The registers of the RPC-IF are assigned to and located in the address space of the internal bus.

[Legend for Register Descriptions]

Initial value: Register value after a reset.

—: Undefined value

R/W: Readable/writable. The written value can be read.

R: Read-only. The write value should always be initial value. For details of initial value, refer to Table 56.3.

W: Write-only.

(a) PHY Address Register (PHYADD)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	—	—	√

PHYADD is a 32-bit register that controls access to the PHY registers.

This register is used for the flow in Figure 56.34.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ACCEN	RW	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	ADD					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	ACCEN	B'0	W	When writing or reading from a PHY register, set this bit to 1. The RW bit should be set simultaneously to access the PHY registers.
30	RW	B'0	W	Specifies write or read from a PHY register. 1: Read 2: Write The ACCEN bit should be set simultaneously to access the PHY registers.
29 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	ADD[5:0]	H'00	R/W	Specifies the addresses of the PHY registers.

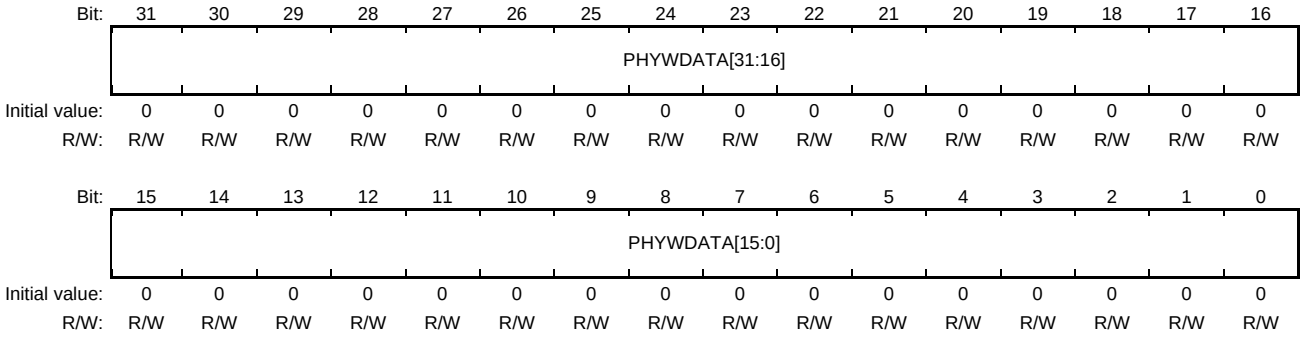
(b) PHY Write Data Register (PHYWR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	—	—	√

PHYWR is a 32-bit register that writes data to the PHY registers.

This register is used for the flow in Figure 56.34.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PHYWDATA[31:0]	H'0000_0000	R/W	Writes data to the PHY registers.

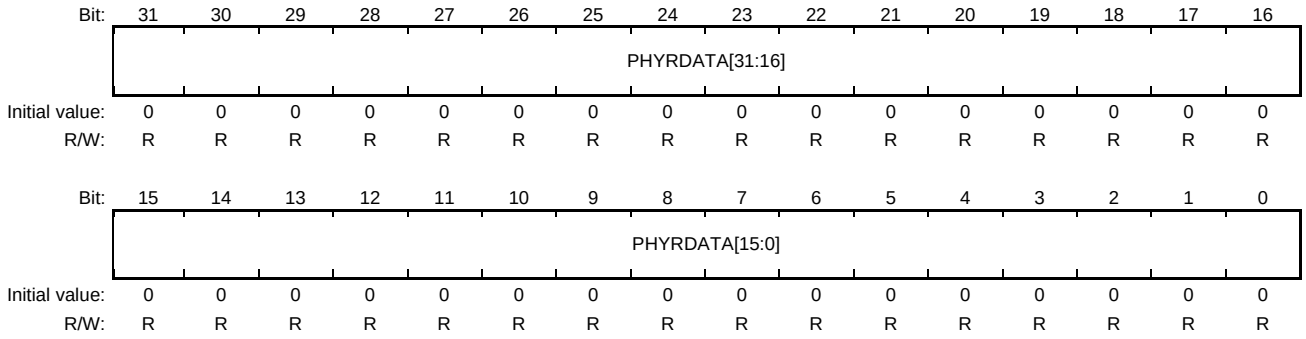
(c) PHY Write Data Register (PHYRD)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	—	—	√

PHYRD is a 32-bit register bit register where the value of the PHY registers is read when reading from the PHY registers.

This register is used for the flow in Figure 56.34.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PHYRDATA[31:0]	H'0000_0000	R	When reading from a PHY register, the register value is read from this register.

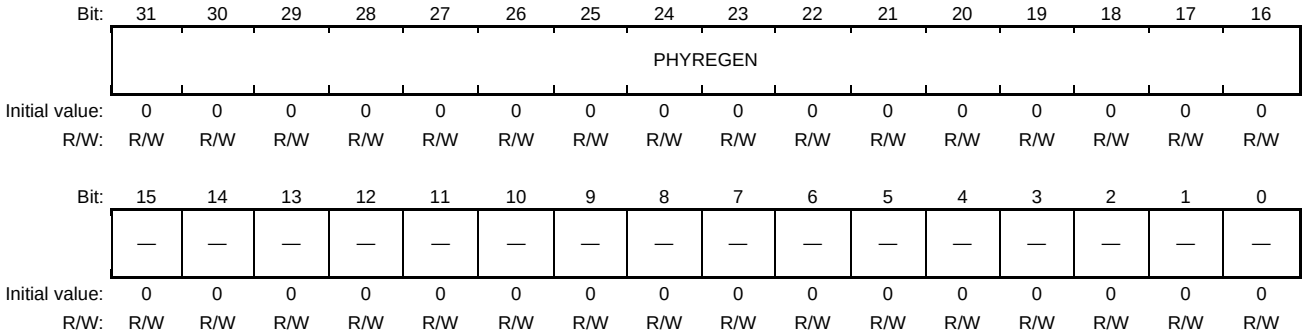
(d) Mode Register (MD)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	—	—	√

MD is a 32-bit register that specifies the mode of the PHY registers.

This register is used for the flow in Figure 56.34.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PHYREGEN[15:0]	H'0000_0000	R/W	Writes data to the PHY registers.
15 to 0	—	All 0	R	Reserved The write value should always be set to the initial value.

(e) Rise Edge Delay Line Tap Selection (RDLSEL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	—	—	√

RDLSEL is a 32-bit register that specifies Rise Edge Delay Line Tap Selection.

This register is used for the flow in Figure 56.34.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	QSPI1 DLSET	—	—	QSPI1DLTAPSEL					QSPI0 DLSET	—	—	QSPI0DLTAPSEL				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The write value should always be set to the initial value.
15	QSPI1DLSETEN	B’0	R/W	When this bit is 1, QSPI1DLTAP is used to set Delay Line Tap Selection.
14 to 13	—	All 0	R	Reserved The write value should always be set to the initial value.
12 to 8	QSPI1DLTAPSEL [4:0]	H’00	R/W	Select the delay line tap of the QSPI1 side. B'0_0000: The delay is the smallest. . . B'1_1111: The delay is the largest.
7	QSPI0DLSETEN	B’0	R/W	When this bit is 1, QSPI1DLTAP is used to set Delay Line Tap Selection.
6 to 5	—	All 0	R	Reserved The write value should always be set to the initial value.
4 to 0	QSPI0DLTAPSEL [4:0]	H’00	R/W	Select the delay line tap of the QSPI0 side. B’0_0000: The delay is the smallest. . . B’1_1111: The delay is the largest.

(f) Fall Edge Delay Line Tap Selection (FDLSEL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	\RZ/G2N	RZ/G2E
—	—	—	√

FDLSEL is a 32-bit register that specifies Fall Edge Delay Line Tap Selection.

This register is used for the flow in Figure 56.34.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	QSPI1 DLSET	—	—	QSPI1DLTAPSEL					QSPI0 DLSET	—	—	QSPI0DLTAPSEL				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The write value should always be set to the initial value.
15	QSPI1DLSETEN	B’0	R/W	When this bit is 1, QSPI1DLTAP is used to set Delay Line Tap Selection.
14 to 13	—	All 0	R	Reserved The write value should always be set to the initial value.
12 to 8	QSPI1DLTAPSEL [4:0]	H’00	R/W	Select the delay line tap of the QSPI1 side. B'0_0000: The delay is the smallest. . . B'1_1111: The delay is the largest.
7	QSPI0DLSETEN	B’0	R/W	When this bit is 1, QSPI1DLTAP is used to set Delay Line Tap Selection.
6 to 5	—	All 0	R	Reserved The write value should always be set to the initial value.
4 to 0	QSPI0DLTAPSEL [4:0]	H’00	R/W	Select the delay line tap of the QSPI0 side. B’0_0000: The delay is the smallest. . . B’1_1111: The delay is the largest.

(g) Rise Edge Delay Line Tap Monitor (RDLMON)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	—	—	√

RDLMON is a 32-bit register that specifies Rise Edge Delay Line Tap Selection.

This register is used for the flow in Figure 56.34.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	QSPI1DLTAPMON					—	—	—	QSPI0DLTAPMON				
Initial value:	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	—	R	Reserved
12 to 8	QSPI1DLTAPMON[4:0]	—	R	Monitor the selected delay line tap of the QSPI1 side. When QSPI1DLSETEN of the Delay Line Tap Selection register is 1, the read value is QSPI1DLTAPSEL of the Delay Line Tap Selection register. When QSPI1DLSETEN of the Delay Line Tap Selection register is 0, the read value is the calibration result of PHYCNT.CAL. B'0_0000: The delay is the smallest. . . B'1_1111: The delay is the largest.
7 to 5	—	—	R	Reserved
4 to 0	QSPI0DLTAPMON[4:0]	—	R	Monitor the selected delay line tap of the QSPI0 side. When QSPI1DLSETEN of the Delay Line Tap Selection register is 1, the read value is QSPI1DLTAPSEL of the Delay Line Tap Selection register. When QSPI1DLSETEN of the Delay Line Tap Selection register is 0, the read value is the calibration result of PHYCNT.CAL. B’0_0000: The delay is the smallest. . . B’1_1111: The delay is the largest.

(h) Fall Edge Delay Line Tap Monitor (FDLMON)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	—	—	√

FDLMON is a 32-bit register that specifies Fall Edge Delay Line Tap Selection.

This register is used for the flow in Figure 56.34.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	QSPI1DLTAPMON					—	—	—	QSPI0DLTAPMON				
Initial value:	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	—	R	Reserved
12 to 8	QSPI1DLTAPMON[4:0]	—	R	Monitor the selected delay line tap of the QSPI1 side. When QSPI1DLSETEN of the Delay Line Tap Selection register is 1, the read value is QSPI1DLTAPSEL of the Delay Line Tap Selection register. When QSPI1DLSETEN of the Delay Line Tap Selection register is 0, the read value is the calibration result of PHYCNT.CAL. B'0_0000: The delay is the smallest. . . B'1_1111: The delay is the largest.
7 to 5	—	—	R	Reserved
4 to 0	QSPI0DLTAPMON[4:0]	—	R	Monitor the selected delay line tap of the QSPI0 side. When QSPI1DLSETEN of the Delay Line Tap Selection register is 1, the read value is QSPI1DLTAPSEL of the Delay Line Tap Selection register. When QSPI1DLSETEN of the Delay Line Tap Selection register is 0, the read value is the calibration result of PHYCNT.CAL. B’0_0000: The delay is the smallest. . . B’1_1111: The delay is the largest.

(3) The ways of access to the PHY registers

For both the write and read sequences, it is mandatory to set the MD.PHYREGEN register to H'A539.

(a) The write sequence

Execute the write sequence according to the following procedures.

1.Specify the write data in PHYWR.

2.Specify the PHY register address in PHYADD.ADD.PHYADDRW=0 (write) and PHYADD.ACCEN=1 to start the write sequence.

(b) The read sequence

Execute the read sequence according to the following procedures.

1.Specify the PHY register address in PHYADD.ADD.PHYADDRW=1 (read) and PHYADD.ACCEN=1 to start the readsequence.

2.Dummy read PHYRD to make time to finish reading from the PHY registers.

3.Read the PHYRD register to get the read value.

If the result of a dummy read does not match the settings of PHYCN.STRTIM bits, the Delay Line in Figure 56.33 is adjusted in an additional process by the software according to the flowchart in Figure 56.34. Figure 56.35 shows the adjustment method of the delay circuit. Refer to section 56.3 for registers set in Figure 56.35.

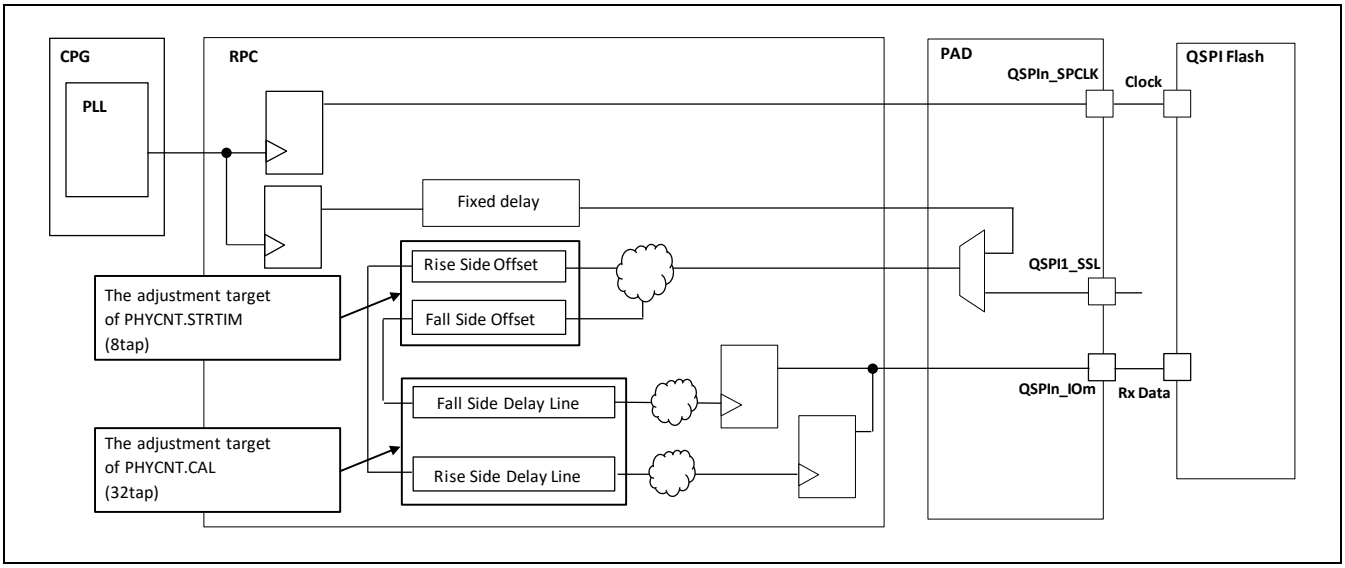


Figure 56.33 Circuit of data receiving

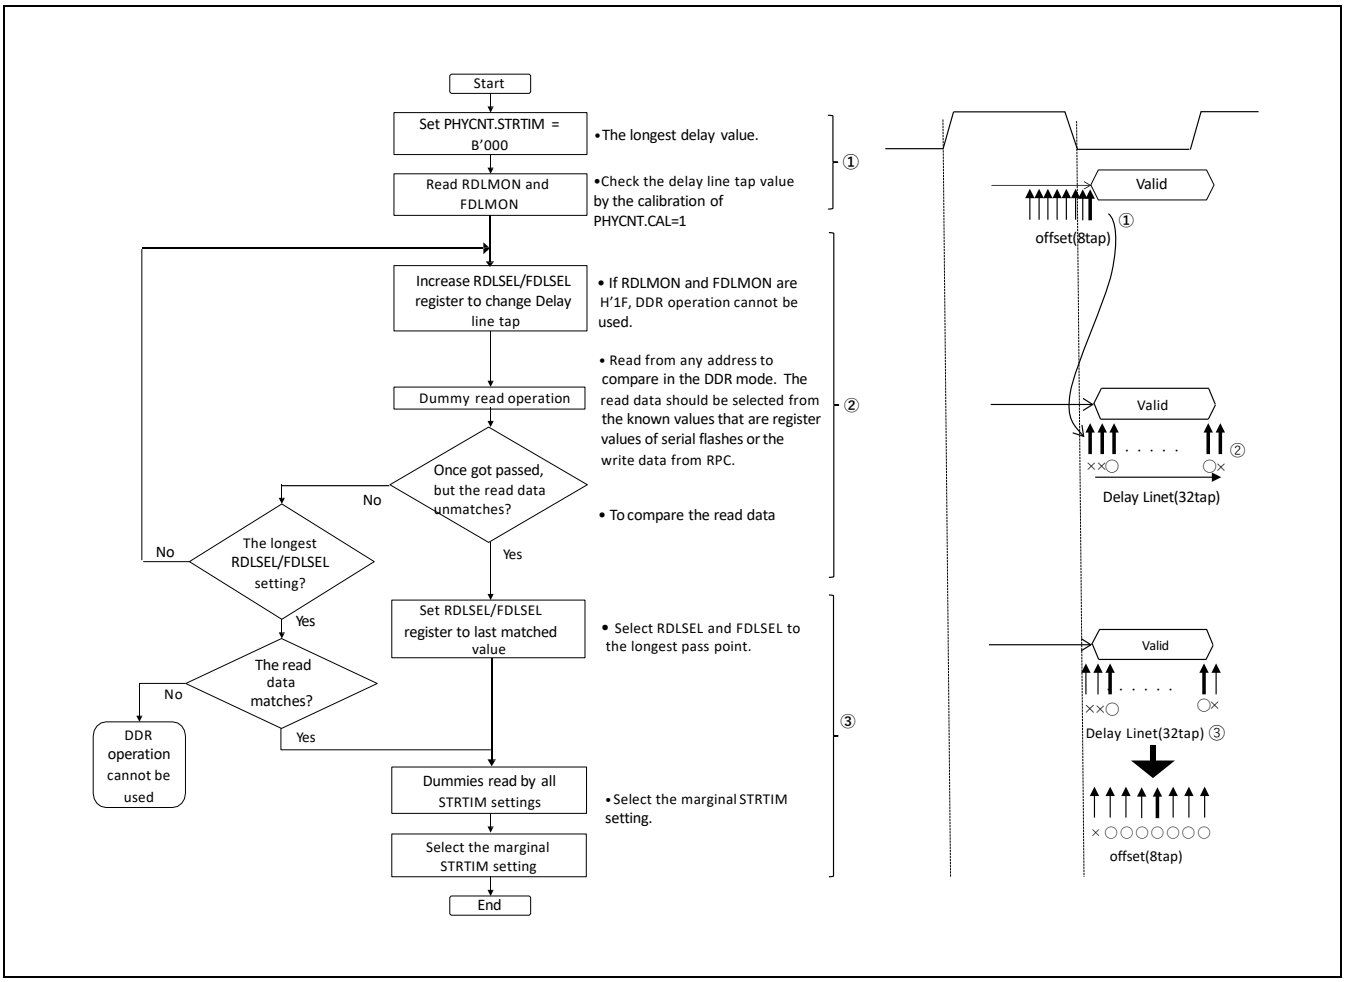

Figure 56.35 Delay line manual setting operation

56.4 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

56.4.1 Transfer to Read Data while the Signal on the QSPIn_SSL Pin is Negated

Set the SMENR.SPIDE[3:0] bits to B'1100 or B'1111 when transfer only for reading data is to proceed.

Transfer will not proceed normally if the setting of the SMENR.SPIDE[3:0] bits is B'1000.

56.4.2 Transfer to Read Data while the Signal on the QSPIn_SSL Pin is Asserted

When transfer only for reading data is to proceed, set the SMENR.SPIDE[3:0] bits to B'1100 or B'1111, or end the immediately preceding transfer with reading data.

When the immediately preceding transfer is of a command, optional command, address, or option data, or is transfer for writing data, the subsequent transfer only for reading data will not proceed normally if the setting of the SMENR.SPIDE[3:0] bits is B'1000.

56.4.3 Notes on Starting Transfer from the QSPIn_SSL Retained State in Manual Mode

Be sure to set the SPIWE bit in the SMCR register to 1 when the transfer of a command, optional command, address, or option data is started while the QSPIn_SSL pin is being asserted in manual mode.

56.4.4 RPC_RESET# operation

There are two ways to operate RPC_RESET# pins.

1. Use PHYINT.RSTEN, PHYINT.RSTVAL to operate.
   The RPC_RESET# state depends on PHYINT.RSTVAL value.
2. Activate reset to this module
   During reset period by Power-on-reset or Software Reset, RPC_RESET# pin state is L. After reset is deactivated, RPC_RESET# pin state is H.

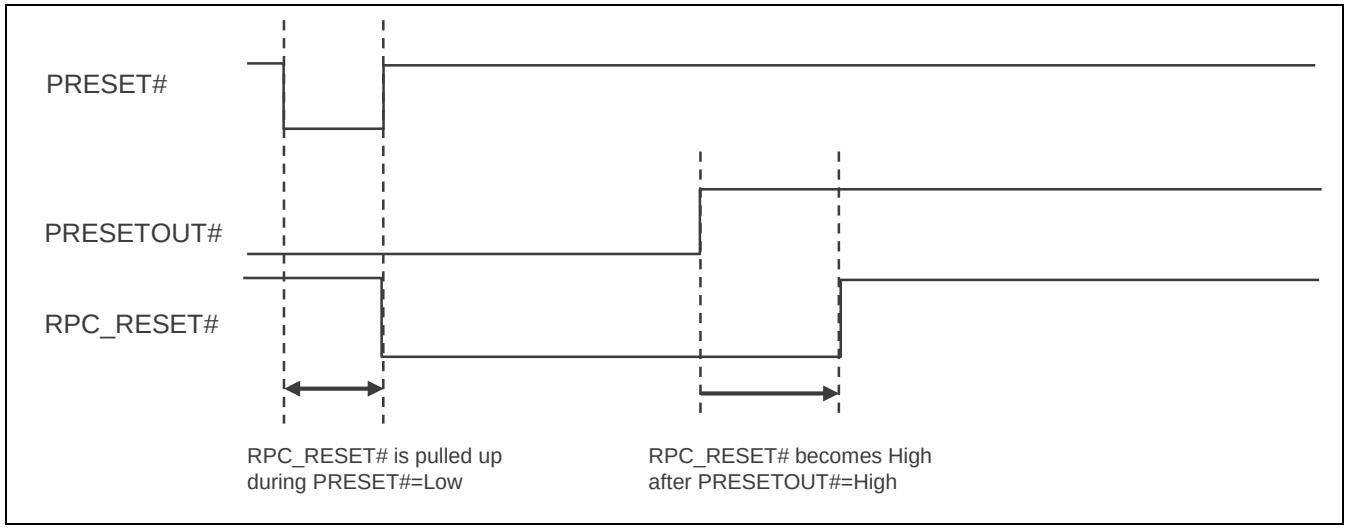

Figure 56.36 Relationship of RPC_RESET# and PRESET# timing

56.4.5 Software Reset after Module Stop operation

Be sure to supply software reset to this module after module stop is deactivated. Note that RPC_RESET# pin state is L while software reset is activated. Guarantee the reset period and accessible period after reset which are required in the connected devices.

56.4.6 DMA transfer

In read operation by DMA transfer, external address space read mode is available. The read address (source address in DMAC) is the memory area (H’0800_0000 – H’0BFF_FFFF) by Auto-Request mode. In High Speed response mode (PHYCNT.HS = 1), DRCR.RBURST should be set to B'1_1111 and access address alignment from RPC to flash memory should be 256Byte align. Accessing to register area during DMA transfer is prohibited during High Speed response mode.
In write operation, refer to 56.3.13.

56.4.7 Frequency change

(1) RPCCKCR

When the operation frequency changes by setting RPCCKCR in CPG, read after write operation on this register is necessary to guarantee the setting to be applied.

56.4.8 QSPI1 pins switched to high impedance [RZ/G2M V1.3] (not RZ/G2M V3.0)

Applying QSPI0 single boot (Mode pins MD[4:1] = 0100) the QSPI1 terminals are switched to high impedance. In case using a second QSPI flash device on the QSPI1 interface for 8-bit access later on, apply external pull-up resistors to the signal lines.

57. SD Card/MMC Interfaces

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

57.1 Overview

57.1.1 Features

This LSI has four SD card interfaces (SDHI0 to SDHI3), two of which can also be used as MMC interfaces (SDHI2 and SDHI3). The select setting of SDHI and MMC is unnecessary.

- SD memory/IO card interface (1-bit/4-bit SD bus)
- SD, SDHC, and SDXC SD memory card access supported
- Default, high-speed, UHS-I/SDR50, and SDR104 transfer modes supported
- SD clock (SDCLK) frequency = internal SDxϕ frequency/2^n (n = 0 to 9)
  SDCLK = 200 MHz (SDR104)
  SDCLK = 100 MHz (SDR50)
- Error check function: CRC7 (for command/response), CRC16 (for data)
- Interrupt request: 2
- Card detect function
- Write protect support
- MMC interface (1-bit/4-bit/8-bit MMC bus)
- e-MMC device access supported
- Backward-compatible, high-speed, HS200, and HS400 transfer modes supported
  SDCLK = 200 MHz (HS200)
- High-priority interrupt (HPI) supported
- Alternative Boot operation supported
- Sequencer function (SEQ)
  The SEQ can issue maximum 8 commands sequentially.

Development of the SD-related products needs the conclusion of the following agreement.

SD Host/Ancillary Product License Agreement (SD HALA)

x = 0 to 3

57.1.2 Block Diagram

Figure 57.1 shows a block diagram of the SD host interface.

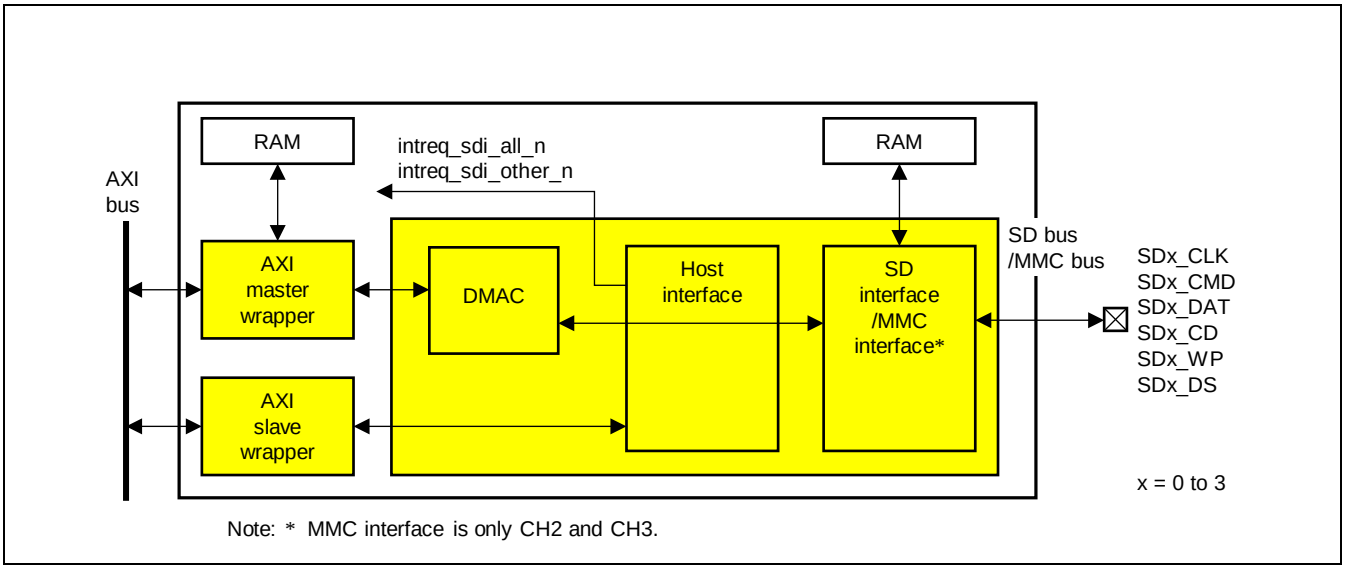

Figure 57.1 Block Diagram of SD Host Interface

57.1.3 External Pins

Table 57.1 lists the input and output pins used by the interface. The voltage of the SDHI terminal is variable. Therefore a power network is separate. When choosing the function of GPIO and the other ones, be careful.

Table57.1 Pin Configuration

Notes: 1. When a pin is not in use, fix the corresponding signal to High level by external input.
2 x = 2 to 3: This is used by both of SDHI and MMC.
3 x = 2 to 3: This is used only MMC.

57.1.4 Register Configuration

The base addresses for each interface are as follows. The select setting of SDHI and MMC is unnecessary. The difference between SDHI and MMC is only the command type by Command type register (SD_CMD).

SDHI0: H'00_EE10_0000
SDHI1: H'00_EE12_0000
SDHI2: H'00_EE14_0000
SDHI3: H'00_EE16_0000
MMC0: H'00_EE14_0000
MMC1: H'00_EE16_0000

Note: The two pairs of interfaces (SDHI2 and MMC0, SDHI3 and MMC1) can only be used for either the SDHI or MMC interface.

57.2 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

(1) Designing the board

SDHI and MMC interface transfer performance has been improved. When designing the board, run the SI simulation using the IBIS model.

(2) Initial value of drivability at eMMC boot (RZ/G2N)

At eMMC boot, initial value of eMMC pin drivability of RZ/G2N is set to B’100 in the eMMC boot program. When operating eMMC with HS200, HS400, reset the optimum setting value that matches the characteristics of the board on which RZ/G Gen 2 is used with the eMMC driver.

Since RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0 uses the initial value of PFC at eMMC boot time, drivability can’t be adjusted. Adjusting the damping resistance for the eMMC terminal on the board at eMMC boot is needed time to suppress overshoot / undershoot.

58. rawNAND Controller (R-NANDC)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

58.1 Overview

The NAND Flash Memory Interface controller implements the function of a high level interface to one NAND flash device. It supports the functionality of the high speed NAND Flash devices described in the ONFI 1.x specifications.

58.1.1 Features

- Compatibility
  - Compatible with the ONFi 1.x specification. (8/16-bit)
    except the "EDO data output timing mode" which is not supported.
    * No full support of timing mode 4 and 5 due to missing EDO mode.
    * Timing mode 4 or 5 memory devices can be used in non-EDO mode.
    * NFMA fast transition mode can be used for timing mode 4 or 5 memory devices.
    (Refer to section 58.2.2 Main configurations register (CONTROL)).
  - Support for the Small Block devices - only devices that allow to disable CE signal when device is in the busy state are supported.
  - Support for the low capacity device (which use four address bytes) with the help of generic sequence.
- DMA Controller
  - Scatter-gather mode is supported.
  - Single transfer mode is supported.
  - Supports precise and imprecise burst modes.
  - Supports configurable burst types: single transfer, incrementing and stream.
  - 32-bit system memory addressing.
  - Triggering mechanism that depends on the programmable FIFO data level.
- Interrupt Controller
  - Each interrupt can be masked.
  - Each interrupt has its own status flag.
  - The status flags are also valid when the given interrupt is masked, and can be checked by the software polling mechanism.
  - Single interrupt signal output
- Data buffering
  - FIFO module based on dual port memory.
- ECC unit
  - The ECC module is based on the BCH algorithms.
  - The syndrome calculation, error detection and error correction phases in the BCH-based modules are pipelined.
  - The ECC unit supports the following options: 256, 512 bytes and 1024 bytes data blocks. The data block size depends on the selected ECC option.
- Advanced features
  - The page cache read/write sequences are supported.
  - The multiple planes read/write sequences are supported.
  - The multi-LUN work mode is supported.
  - Command queuing mechanism. *1

Note 1.

The queue is used when write access to Registers is performed by the host. It is valid for all registers except:

- INT_STATUS
- STATUS
- FIFO_INIT
- ECC_STAT
- FIFO_DATA

Write to registers listed above will be performed immediately. Write to any other register will be performed through the command queue.

- The advanced Bad Blocks Management system
  - Records tables are stored in the system memory.
  - Hardware implementation of the search algorithm.

58.1.2 Block Diagram

Figure 58.1 is a block diagram of the R-NANDC.

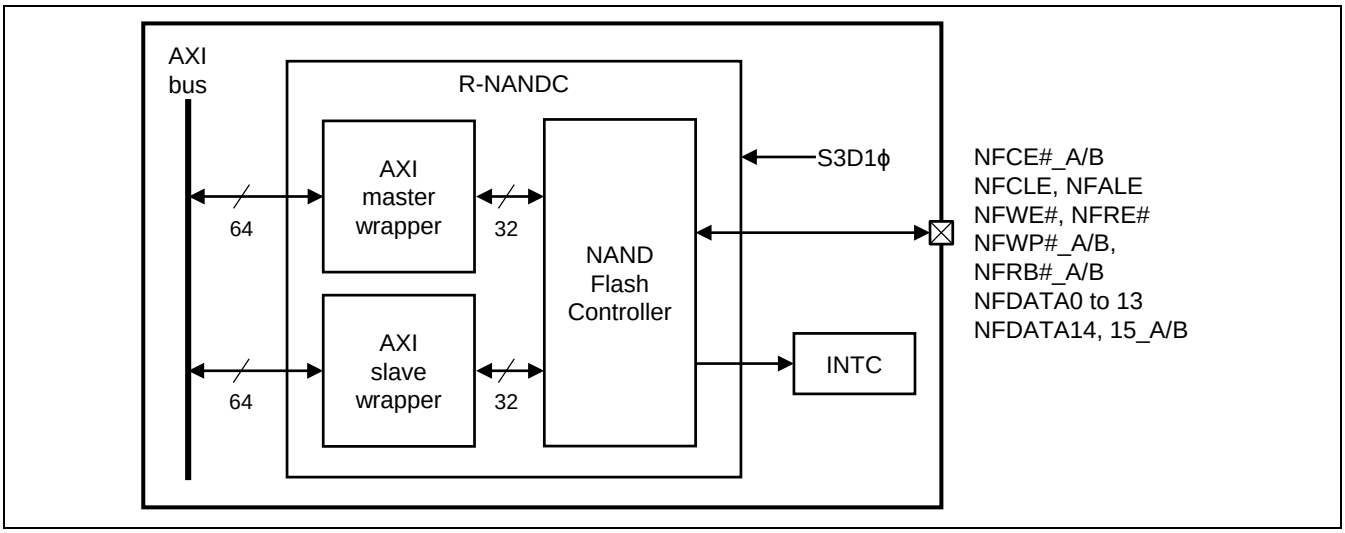

Figure 58.1 Block Diagram [RZ/G2M V1.3] [RZ/G2M V3.0] [RZ/G2N]

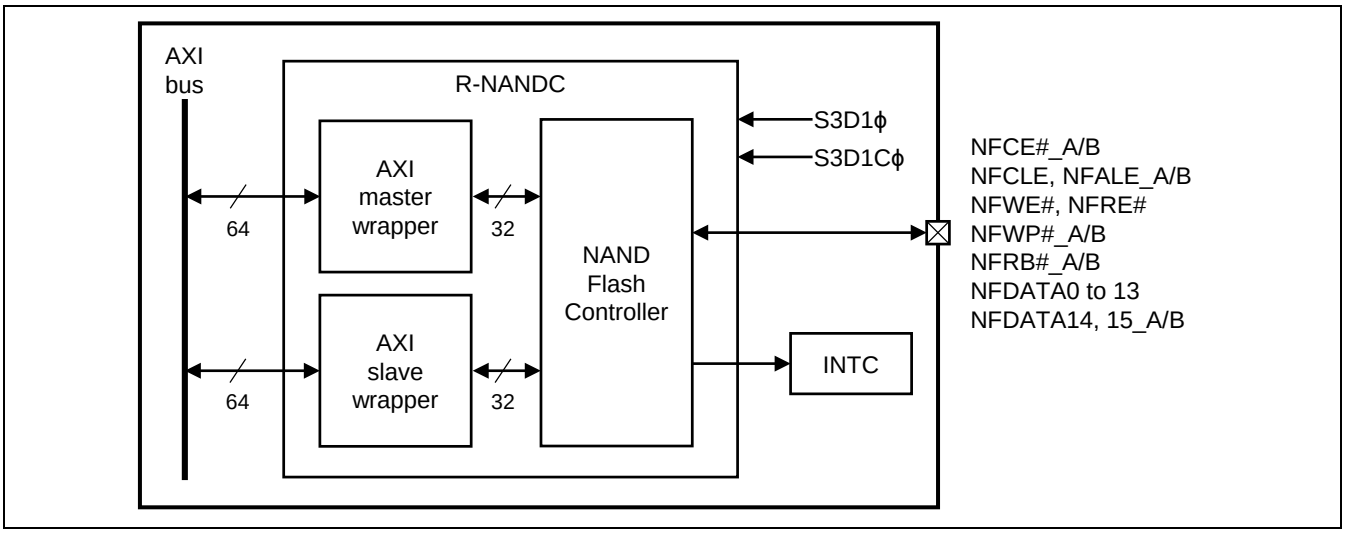

Figure 58.2 Block Diagram [RZ/G2E]

58.1.3 External Pins

Table 58.1 lists the input and output pins used by the interface. The voltage of the R-NANDC terminal is variable. Therefore a power network is separate. When choosing the function of GPIO and the other ones, be careful.

58.1.5 Connected Module

Table 58.3 Connected Module

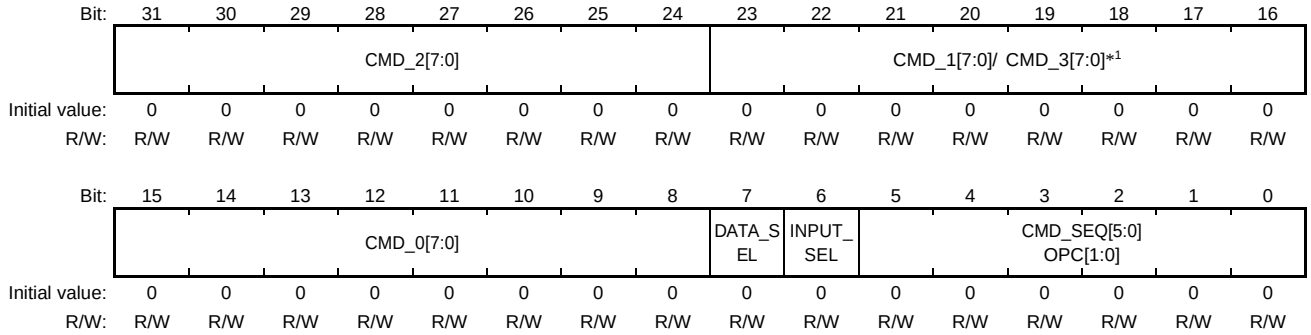
Module name	Connected module name	Function of connected module
R-NANDC	AXI-bus	Register access of CPU DMA access of R-NANDC
	CPG	Clock output
	PFC	Selection of external pins
	Module Standby, Software Reset	Clock stop control
	RST	reset execution
	INTC	Interrupt control

58.2 Register Description

58.2.1 Controller commands register (COMMAND)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The write of the command sequence code to the COMMAND register triggers the programmed command sequence execution as soon as it is possible. If the execution cannot be started immediately, the transfer to this register is prolonged by the series of the WAIT responses. Each command sequence can trigger the interrupt when it is completed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	CMD_2[7:0]	H'00	R/W	Code of the third command in a sequence.
23 to 16	CMD_1[7:0]/ CMD_3[7:0]*1	H'00	R/W	Code of the second command in a sequence.
15 to 8	CMD_0[7:0]	H'00	R/W	Code of the first command in a sequence.
7	DATA_SEL	B'0	R/W	Data / FIFO selection flag: 0 – the FIFO module selected 1 – the DATA register selected
6	INPUT_SEL	B'0	R/W	Input module selection flag: 0 – select the registers Slave I/F Unit (SIU) module as input 1 – select the DMA module as input
5 to 0	CMD_SEQ[5:0]	B'00_0000	R/W	Command code.

Note 1. Depending on the selected command sequence, this field will store CMD1 or CMD3 code.
Generic Sequence is only one case where both commands are used in a single sequence

58.2.2 Main configurations register (CONTROL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The CONTROL register stores the configuration parameters that are common to all controller modules.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	AUTO_READ_STAT_EN	MLUN_EN	SMALL_BLOCK_EN	—	—	—	ADDR1_AUTO_INCR	ADDR0_AUTO_INCR

	NFMA FASTTR	—	BBM_EN	IO_WIDTH	—	—	—	—	BLOCK_SIZE[1:0]		ECC_EN	INT_EN	—	ECC_BLOCK_SIZE[1:0]		READ_STATUS_EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
23	AUTO_READ_STAT_EN	B'0	R/W	Auto Read Status mode enable. If active, the controller reads the status after the PROGRAM PAGE and BLOCK ERASE commands. It can trigger interrupt. The ERROR_MASK field in the STATUS_MASK register must be configured when this feature is enabled. It enables operation status checking after PROGRAM_PAGE/ERASE commands. It allow to detect that those operations failed. 0: Auto Read Status mode disabled 1: Auto Read Status mode enabled
22	MLUN_EN	B'0	R/W	Multi LUN mode enables. If active, it enables controller multi LUN work mode 0: Multi LUN mode disabled 1: Multi LUN mode enabled For more details, see section 58.3.4, Multi LUN Work Mode.
21	SMALL_BLOCK_EN	B'0	R/W	Enable small block mode. In this mode, the controller sends only a single byte as the column address instead of two bytes, as done in the big block NAND Flash devices. 0: big block mode enabled 1: small block mode enabled Note: Only devices that allow to disable CE signal when device is in the busy state are supported.
20 to 18	—	B'000	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.

Bit	Bit Name	Initial Value	R/W	Description
17	ADDR1_ AUTO_INCR	B’0	R/W	Address auto increment for row address register 1 (ADDR1_ROW). 0: auto increment disabled 1: auto increment enabled When this bit is set, sending any command sequence using address register 1 causes the increment of address register 1.
16	ADDR0_ AUTO_INCR	B’0	R/W	Address auto increment for row address register 0 (ADDR0_ROW). 0: auto increment disabled 1: auto increment enabled When this bit is set, sending any command sequence using address register 0 causes the increment of address register 0
15	NFMA FASTTR	B’0	R/W	NFMA fast transition mode control 0: normal mode 1: fast mode When using NAND flash memory which support ONFI 1.0 EDO mode, TIMINGS_ASYN.TRWP value can be one reduced (-1) from normal setting by setting this bit. With this setting, data read transfer speed is improved.
14	—	B’0	R	Reserved bit. This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to the bit.
13	BBM_EN	B’0	R/W	Bad Block Management enable flag For more details, see section 58.3.5, Remapping Mechanism.
12	IO_WIDTH	B’0	R/W	NAND Flash I/O width 0: 8 bits 1: 16 bits
11 to 8	—	H’0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
7, 6	BLOCK_SIZE [1:0]	B’00	R/W	The Block Size. B’00: 32 pages per block B’01: 64 pages per block B’10: 128 pages per block B’11: 256 pages per block
5	ECC_EN	B’0	R/W	Hardware ECC support enable 0: ECC disabled 1: ECC enabled Hardware ECC can be used only when m * (ECC_BLOCK_SIZE) ≤ DATA_SIZE ≤ m * (ECC_BLOCK_SIZE + 32),where m is 1,2,3,..
4	INT_EN	B’0	R/W	Global Interrupt enable 0: Interrupts disabled 1: Interrupts enabled For more details, see section 58.3.6, Interrupts Mechanism.
3	—	0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.

Bit	Bit Name	Initial Value	R/W	Description
2, 1	ECC_BLOCK _SIZE[1:0]	B’00	R/W	The ECC Block Size (depends on core configuration): B’00: 256 bytes B’01: 512 bytes B’10: 1024 bytes B’11: not available The ECC block size can be changed only when all memory devices are ready.
0	READ_ STATUS_EN	B’0	R/W	Automatically READ STATUS / check RnB lines. The STATUS_MASK field in the STATUS_MASK register must be configured when this feature is enabled. It select how controller detect device ready/busy state: 0: The controller checks RnB lines 1: The controller sends READ STATUS commands Note: Automatically sent READ STATUS command is only available in devices compatible with ONFI 1.0

58.2.3 GENERIC_SEQ register (GEN_SEQ_CTRL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The GENERIC_SEQ register is used to parameterize the generic command sequences.For more details, see section 58.3.2, Generic Command Sequence. For examples, see Table 58.7

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	CMD_3[7:0]

5, 4	COL_A0[1:0]	B'00	R/W	Column Address Cycles. Number of the column address bytes sent to NAND Flash device. B'00: 0 address cycles B'01: 1 address cycles B'10: 2 address cycles B'11: not available
3	CMD3_EN	B'0	R/W	This bit allows enabling or disabling the presence of the "command 3" phase in the universal command sequence. 1: enable 0: disable
2	CMD2_EN	B'0	R/W	Enable Command 2 phase This bit allows enabling or disabling the presence of the "command 2" phase in the universal command sequence. 1: enable 0: disable
1	CMD1_EN	B'0	R/W	Enable Command 1 phase. This bit allows enabling or disabling the presence of the "command 1" phase in the universal command sequence. 1: enable 0: disable
0	CMD0_EN	B'0	R/W	Enable Command 0 phase. This bit allows enabling or disabling the presence of the "command 0" phase in the universal command sequence. 1: enable 0: disable

58.2.4 Controller status register (STATUS)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The STATUS register stores the NAND Flash controller and connected device status flags. These flags can be used to obtain the current controller internal state.

The CTRL_STAT flag is set after the controller starts to execute the requested command for the selected NAND Flash device, and it is active while the command execution is not completed. Command execution can be divided into two phases. In the first phase, the command sequence is executed at the moment when the NAND Flash device goes into the busy state. After that, the controller stores information about the pending operation on the selected device, but is also able to execute a new command on any other device. In the second phase, the controller automatically finishes the pending command execution based on the previously stored data. As long as this flag is set, the controller does not accept any new commands.

The MEMx_ST flags correspond to the NAND Flash device with the same index value. The flags give information about the NAND Flash devices' state. The flag has the same function as the NAND Flash device RnB line.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
23 to 16	CMD_ID[7:0]	H'00	R	Command ID The current command under execution identification marker added before command was put in to the command FIFO.
15 to 11	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
10	DATA_REG_ST	B'0	R	The DATA_REG: Resetting of this flag is possible only by reading the data from the DATA_REG register. 1: data in DATA_REG is available 0: data in DATA_REG is not available
9	DATASIZE_ERROR_ST	B'0	R	The Data Size value error: When the ECC is enabled, this bit signal incorrect value in the DATA_SIZE register. The algorithm for correct data size value can be found in the DATA_SIZE register description. 0: correct value 1: incorrect value

Bit	Bit Name	Initial Value	R/W	Description
8	CTRL_STAT	B'0	R	The main controller status bit: 0: controller ready 1: controller busy
7 to 1	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
0	MEM0_ST	B'1	R	Device 0 status flag: 1: device ready 0: device busy

Note: When using "READ PARAMETER PAGE" command, ECC Block Size should same with DATA SIZE.
When using "SET FEATURES" or "GET FEATURES" or "READ ID" commands, ECC function should be disabled.

58.2.5 LUN per device status register (LUN_STATUS_0)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The LUN_STATUS0 register allows to access the LUN status information for devices 0-3. Each bit of the LUN status field contain the status of single LUN of device. The busy status is marked as logical ‘0’, the ready state is marked as logical ‘1’.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

7 to 0	MEM0_LUN [7:0]	H’FF	R	Memory 0 LUN-s status field.

58.2.6 Interrupts mask register (INT_MASK)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The INT_MASK register allows masking of the selected interrupts source in the NAND Flash controller. The masked interrupts still set the appropriate bits in the status register, but do not assert the interrupt signal.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
24	ECC_INT0_EN	B'0	R/W	Enables the interrupt from the ECC module status for Memory device 0. 0: interrupt disabled 0: interrupt disabled 1: interrupt enabled
23 to 17	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
16	STAT_ERR_INT0_EN	B'0	R/W	Enables the interrupt when the most recently finished operation on the Memory device 0 failed. This applies to PROGRAM PAGE and BLOCK ERASE operations. It is not valid following a READ-series operation. 0: interrupt disabled 1: interrupt enabled
15 to 9	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
8	MEM0_RDY_INT_EN	B'0	R/W	The memory device 0 is ready for the new command: 0: interrupt disabled 1: interrupt enabled For more details see Figure 58.32
7	—	B'0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.

Bit	Bit Name	Initial Value	R/W	Description
6	PG_SZ_ERR_INT_EN	B'0	R/W	Data Size error occur. 0: interrupt disabled 1: interrupt enabled
5	—	B'0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
4	TRANS_ERR_EN	B'0	R/W	The transfer on the slave interface error: 0: interrupt disabled 1: interrupt enabled
3	DMA_INT_EN	B'0	R/W	DMA transfer ended. 0: interrupt disabled 1: interrupt enabled
2	DATA_REG_INT_EN	B'0	R/W	Data in DATA_REG is available. 0: interrupt disabled 1: interrupt enabled
1	CMD_END_INT_EN	B'0	R/W	Command sequence ended 0: interrupt disabled 1: interrupt enabled For more details see Figure 58.32
0	—	B'0	R	Reserved bit. This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to the bit.

58.2.7 Interrupts status register (INT_STATUS)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The INT_STATUS register stores the NAND Flash controller interrupt flags. If the given bit is 0, the corresponding interrupt condition is not met. If the given bit is 1, the corresponding interrupt condition is met.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R/W	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
24	ECC_INT0_FL	B'0	R/W	Selected flag (source is ECC_UNC_0, ECC_ERROR_0 or ECC_OVER_0) in the ECC module is set.
23 to 17	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
16	STAT_ERR_INT0_FL	B'0	R/W	Most recently finished operation on the Memory device 0 failed. This applies to PROGRAM PAGE and BLOCK ERASE operations. It is not valid following a READ-series operation.
15 to 9	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
8	MEM0_RDY_INT_FL	B'0	R/W	The memory device 0 is ready for the new command.
7	—	B'0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
6	PG_SZ_ERR_INT_FL	B'0	R/W	Data Size error flag. When the ECC is enabled, the value written into the DATA_SIZE register has some restrictions. Interrupt condition is met when the value written to the DATA_SIZE register is not correct.
5	—	B'0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.

Bit	Bit Name	Initial Value	R/W	Description
4	TRANS_ERR_FL	B'0	R/W	The transfer on the slave interface error. The flag is set when the access to the FIFO memory has the opposite direction to the current FIFO configuration.
3	DMA_INT_FL	B'0	R/W	DMA transfer ended flag.
2	DATA_REG_INT_FL	B'0	R/W	Data in DATA_REG is available.
1	CMD_END_INT_FL	B'0	R/W	Transfer sequence ended.
0	—	B'0	R	Reserved bit. This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to the bit.

58.2.8 ECC module control register (ECC_CTRL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The ECC_CTRL register stores all configuration parameters required by the ECC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECC_SEL[1:0]

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	ERR_THRESHOLD[5:0]						—	—	—	—	—	ECC_CAP[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
17,16	ECC_SEL [1:0]	B’00	R/W	The ECC interrupt source select. These bits selects the ECC module flag that will be used as a source for the interrupt signal: B’00: select ECC_ERROR (correctable error) flag as interrupt source. B’01: select ECC_UNC (uncorrectable error) flag as interrupt source. B’1x: select ECC_OVER (acceptable errors level overflow) flag as interrupt source. (ECC_OVER flag is not set by uncorrectable errors (ECC_UNC_0 = 1))
15,14	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
13 to 8	ERR_THRESHOLD[5:0]	B’00_0000	R/W	The acceptable errors level. The value of this field contains the number of errors that is acceptable. This field must be initialized by the application program.
7 to 3	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
2 to 0	ECC_CAP [2:0]	B’000	R/W	The ECC module correction ability. The correction ability can be changed only when all memory devices are ready. B’000: 2 B’001: 4 B’010: 8 B’011: 16 B’100: 24 All others: 32

58.2.9 ECC module status register (ECC_STAT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The ECC_STAT register stores all ECC module status information.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECC_OVER_0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ECC_UNC_0	—	—	—	—	—	—	—	ECC_ERROR_0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
16	ECC_OVER_0	B'0	R/W	The Memory device 0 acceptable errors level overflow. The bit is set when the number of errors is bigger than the value of declared ERR_THRESHOLD bits. (uncorrectable errors are not counted)
15 to 9	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
8	ECC_UNC_0	B'0	R/W	The Memory device 0 uncorrectable error flag. The bit is set when the uncorrectable errors occur during the read operation
7 to 1	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
0	ECC_ERROR_0	B'0	R/W	The Memory device 0 correctable error flag. The bit is set when the correctable errors or the uncorrectable errors (ECC_UNC_0 = 1) occur during the read operation.

58.2.10 ECC offset in the spare area register (ECC_OFFSET)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The ECC_OFFSET register stores the offset value from the beginning of the page to the place where correction words will be stored.

The value of the ECC_OFFSET register must be bigger than the value in the DATA_SIZE register.

In small block mode, the value in the ECC_OFFSET is ignored and the correction words are located in the NAND Flash memory device just behind the data.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ECC_OFFSET[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
15 to 0	ECC_ OFFSET [15:0]	H'0000	R/W	Correction words block offset.

58.2.11 ECC error level counter register (ECC_CNT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The ECC_CNT register stores number of value detected during last page read operation. This register content is not automatically cleared, it must be done by software. The new page read operation does not overwrite previous register value. Register contain value of the largest error level detected in processed ECC blocks.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADDR[1:0]_ROW[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
23 to 0	ADDR[1:0]_ ROW[23:0]	H'00_0000	R/W	Row address. A39-A16 address bits (Page address, Block address and LUN address in the ONFI case).

Notes:

1. There is no register that defines the total memory size of the NAND Flash memory chip, thus the controller is not able to determine which address bits in ADDR [1:0]_COL and ADDR[1:0]_ROW are important and which must be zero. For this reason, the software must take special care with the values written to these registers. Incorrect values of unused address bits (none '0' values) can cause errors in memory access.

   A relation between address registers and memory device address width is configured by the command sequence field of the COMMAND register. This field determines which command sequence has to be used and how many address bytes are used when addressing a NAND Flash memory device. (Example: In order to erase blocks, the three address cycles containing the row address are written into the NAND Flash memory device. The NAND Flash Controller automatically writes bits A39-A16 to the NAND Flash device). Refer to section 58.3.1.(2), Command Sequence Encoding and Table 58.8 in order to see how many address cycles are written into the NAND Flash memory device by each Command Sequence.

   The address written to the address register must be aligned according to the NAND Flash device. Unused bits must be padded with zeros.

2. When the auto increment for the row address register is enabled, the proper value of this register can be read only when the bit CTRL_STAT in STATUS register is clear.

Table 58.4 Address Registers and Address Bytes Relationship

Address Cycle	I/O 0	I/O 1	I/O 2	I/O 3	I/O 4	I/O 5	I/O 6	I/O 7
1st cycle	A0	A1	A2	A3	A4	A5	A6	A7
2nd cycle	A8	A9	A10	A11	A12	A13	A14	A15

4th cycle	A24	A25	A26	A27	A28	A29	A30	A31
5th cycle	A32	A33	A34	A35	A36	A37	A38	A39

58.2.13 Page size value register (DATA_SIZE)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The DATA_SIZE register stores the value of the data block size. The data size value is remembered as the number of bytes per transferred block, but its size must be declared as the multiple of the chosen NAND Flash word size. The unused bits for the given word size configuration are ignored and replaced with zeros.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
14 to 0	DATA_SIZE [14:0]	H'0000	R/W	Data size. The value of this field defines data size.

Note:
Write the proper value to the DATA_SIZE register when ECC is enabled:
(ECC_BLOCK_SIZE) × m ≤ DATA_SIZE ≤ (ECC_BLOCK_SIZE + 32) × m,
Where m is 1, 2, 3 …

Here is an example of which values are correct when ECC_BLOCK_SIZE equals 512 bytes:

Table 58.5 Example, in which DATA_SIZE Values are Correct

DATA_SIZE	Value Correctness
H'0000	Not available
….	….
H'001F	Not available
H'0020	Not available
H'0021	Not available
….	….
H'01FF	Not available

DATA_SIZE	Value Correctness
H'0200	Available
H'0201	Available
….	….
H'0220	Available
H'0221	Not available

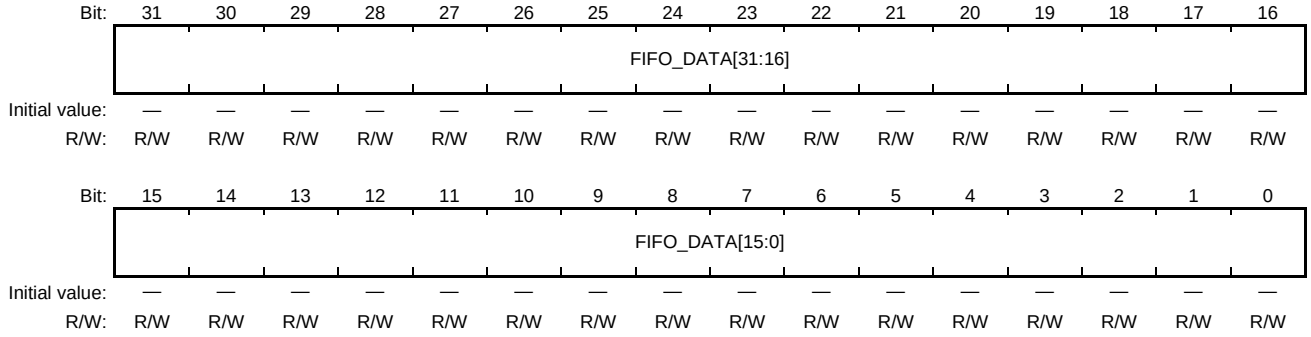
H'03FF	Not available
H'0400	Available
H'0401	Available
….	….
H'0440	Available
H'0440	Not available
….	….

Note: ECC_BLOCK_SIZE equals 512 bytes.

58.2.14 FIFO module interface register (FIFO_DATA)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The FIFO_DATA register is used as an entry point to the FIFO module. The CPU can access the FIFO module by reading from or writing to the FIFO_DATA register in the same way as it accesses any other register.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	FIFO_DATA [31:0]	—	R/W	FIFO Data.

Note:
FIFO_DATA register is able to access after issuing read or write command.

58.2.15 Bad block management (BBM) module control register (BBM_CTRL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The BBM control register stores the BBM specific control parameters.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RMP_INIT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
0	RMP_INIT	B'0	R/W	Remap initial flag. If set, this flag forces the BBM module to reread the remapping table after it was updated by software. This flag is set by software and cleared by hardware after rereading the remapping table.

58.2.16 Records table pointer register (DEV0_PTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The bad block management mechanism uses the tables in the system memory to store the remapping records. The DEV0_PTR register stores the table of the remapping record address.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	PTR_ADDR[11:2]										—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
11 to 2	PTR_ADDR [11:2]	B'00_0000_0 000	R/W	Remap table pointer. The field contains an address of the remap table in the internal memory.
1 to 0	—	ALL 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.

58.2.17 Records table size register (DEV0_SIZE)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The bad block management mechanism implemented in the controller uses the tables in the system memory to store the remapping records. Each table can store a variable number of records depending on the number of bad blocks in the NAND Flash device.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

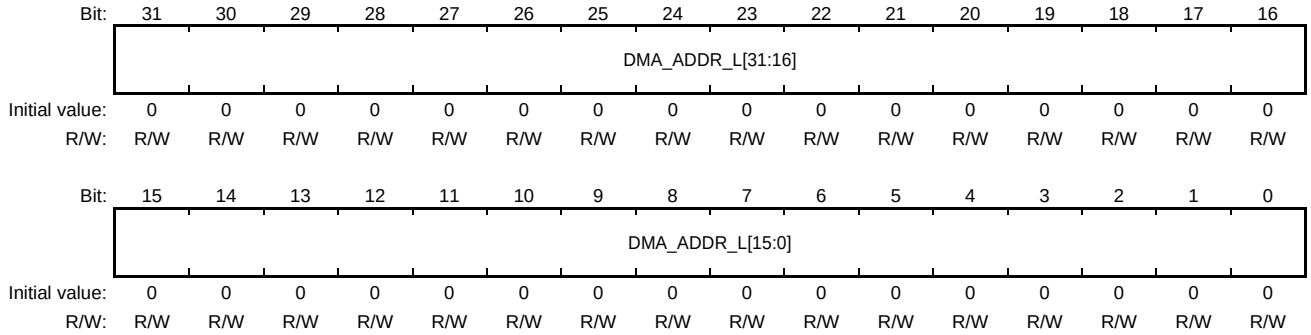
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	DEV_SIZE[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
11 to 0	DEV_SIZE [11:0]	H'000	R/W	Number of record

58.2.18 DMA base address - least significant part register (DMA_ADDR_L)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The DMA_ADDR_L register is the least significant part of the 64-bit DMA base address. The register contains an address for the first data in the data block in the system memory, or the address of the first descriptor. The DMA module can read data from the memory location set by DMA_ADDR and write it to the FIFO module, or read data from the FIFO module and write it to the memory, starting from the location indicated by the DMA_ADDR.

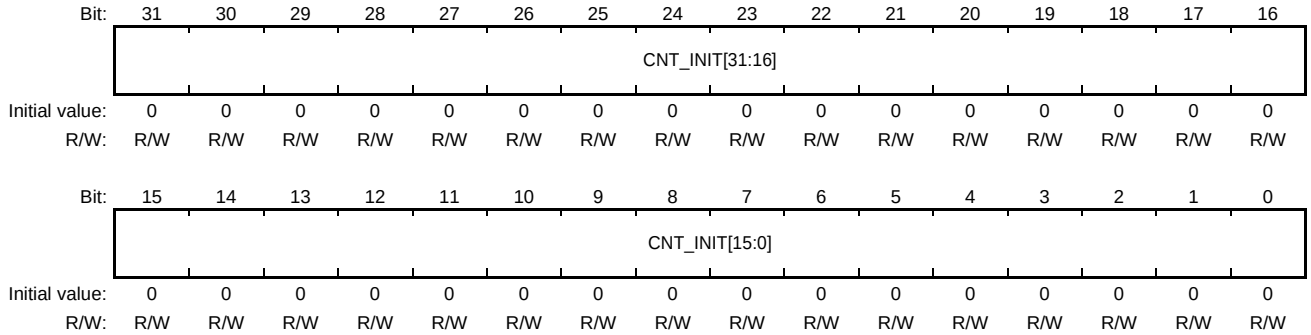


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMA_ADDR_L[31:0]	H'0000_0000	R/W	The least significant part of the DMA base address. The two least significant bits are ignored, thus the address must be aligned to 32-bit words

58.2.19 DMA counter initial value register (DMA_CNT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The DMA_CNT defines the number of bytes that will be transferred by the DMA module. The register remains unchanged during the transfer process.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CNT_INIT [31:0]	H'0000_0000	R/W	Bytes counter initial value. The field contains data page length in bytes (H'0000_0004 – H'FFFF_FFFC). The number of the bytes has to be divided by 4.

58.2.20 DMA control register (DMA_CTRL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

DMA_CTRL is a control register for the DMA channel. This register defines the parameters of the DMA transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DMA_START	—	DMA_MODE	DMA_BURST[2:0]			—	DMA_READY
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
7	DMA_START	B’0	R/W	Set bit DMA_START to start DMA when the command sequence is sent to the NAND Flash memory. For more details see section 58.4.2.(2), DMA Description.
6	—	B’0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
5	DMA_MODE	B’0	R/W	DMA work mode: 0: the registers managed mode 1: the Scatter-Gather mode
4 to 2	DMA_BURST [2:0]	B’000	R/W	Burst type These bits define the main transfer type used by the DMA to precede the requested transfer B’000: incrementing precise burst of precisely four transfers (address increment) B’001: stream precise burst of precisely sixteen transfers (address constant) B’010: single transfer (address increment) B’011: burst of unspecified length (address increment) B’100: incrementing precise burst of precisely eight transfers (address increment) B’101: incrementing precise burst of precisely sixteen transfers (address increment)
1	—	B’0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
0	DMA_READY	B’1	R	DMA ready flag. The flag is set when transfer is completed.

58.2.21 DMA trigger level value register (DMA_TRIG_TLVL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

This register allows the setting of the data FIFO occupancy level that will trigger the DMA module. For more details see section 58.4.2. (2), DMA Description.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DMA_TRIG_TLVL[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

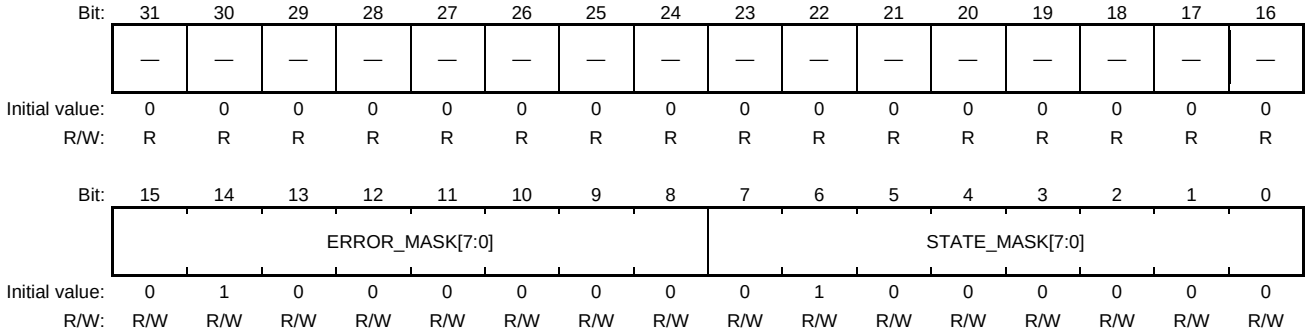
Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
7 to 0	DMA_TRIG_TLVL[7:0]	H'00	R/W	DMA trigger level The trigger level is counted using the 32-bit words as entity.

58.2.22 Mask register for the READ STATUS commands (STATUS_MASK)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The STATE_MASK field is used to mark the ready/busy bits in the NAND Flash device status byte. This field is used during the internal read status operation. In the case of ONFI, the user must mask all fields except RDY or ARDY (depending on the application).

The ERROR_MASK field is used to mask unused fields when the controller automatically reads the status of the NAND Flash memory device. In the case of ONFI, the user must mask all fields except FAIL or FAILC (depending on the application).



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
15 to 8	ERROR_ MASK[7:0]	H'40	R/W	Error State Mask used to mask the error bits if automatic read status feature is enabled.
7 to 0	STATE_ MASK[7:0]	H'40	R/W	State Mask used to mask status bits when the read status command is used to obtain the NAND flash status

58.2.23 Command sequence timing configuration register 0 (TIME_SEQ_0)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

[RZ/G2M V1.3] [RZ/G2M V3.0] [RZ/G2N]

Some waveform configuration parameters are defined in the TIME_SEQ_0 register. The time delay generated by the controller equals the minimum value written into the register, increased by 1. All the timings are generated using the S3D1ϕ clock signal.

[RZ/G2E]

Some waveform configuration parameters are defined in the TIME_SEQ_0 register. The time delay generated by the controller equals the minimum value written into the register, increased by 1. All the timings are generated using the S3D1Cϕ clock signal.

31 to 14	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
13 to 8	TRR[5:0]	B'00_0000	R/W	Read high to Read low TRR time period from rising edge on read/busy input line to the moment when the read enable signal can be asserted
7 to 6	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
5 to 0	TWB[5:0]	B'00_0000	R/W	tWB delay. Time period measured from rising edge of the NFWE# or CLK signal to a falling edge on the RnB line or the NAND flash device SR[6] low.

58.2.25 Generic command sequence timing configuration register 0 (TIME_GEN_SEQ_0)

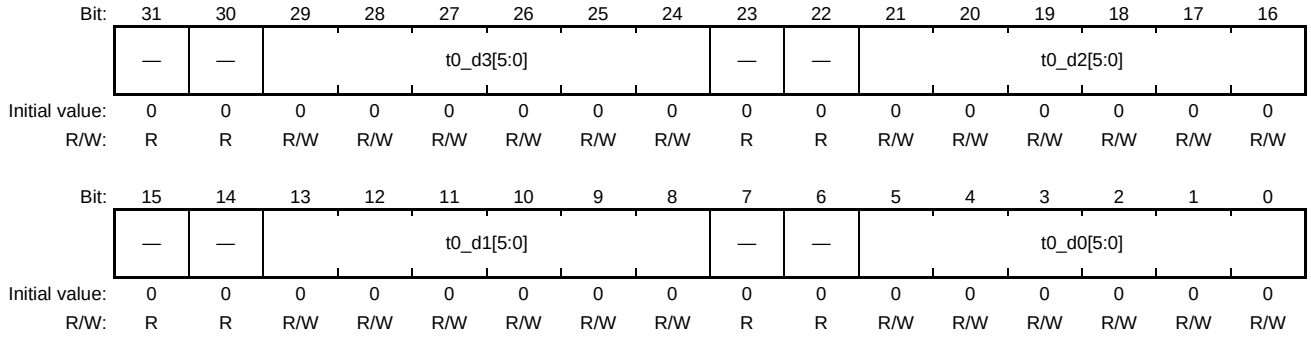
RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

[RZ/G2M V1.3] [RZ/G2M V3.0] [RZ/G2N]

Some waveform configuration parameters for the Generic Sequence are defined in the TIME_GEN_SEQ_0 register. The time delay generated by the controller equals the minimum value written into the register, increased by 1. For more detail see section 58.3.2, Generic Command Sequence. All the timings are generated using the S3D1ϕ clock signal.

[RZ/G2E]

Some waveform configuration parameters for the Generic Sequence are defined in the TIME_GEN_SEQ_0 register. The time delay generated by the controller equals the minimum value written into the register, increased by 1. For more detail see section 58.3.2, Generic Command Sequence. All the timings are generated using the S3D1Cϕ clock signal.



Bit	Bit Name	Initial Value	R/W	Description
31 to 30	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
29 to 24	t0_d3[5:0]	B'00_0000	R/W	Command to Data time. The time between sending a command and data transferring.
23 to 22	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
21 to 16	t0_d2[5:0]	B'00_0000	R/W	Command to Delay time. The time between sending a command to the NAND Flash memory device and waiting until the memory is ready
15 to 14	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
13 to 8	t0_d1[5:0]	B'00_0000	R/W	Command to Command time. The time between two subsequent commands sent to the NAND Flash memory device.
7 to 6	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.

Bit	Bit Name	Initial Value	R/W	Description
5 to 0	t0_d0[5:0]	B'00_0000	R/W	Command to Address time. The time between sending a command and sending the address to the NAND Flash memory device.

58.2.26 Generic command sequence timing configuration register 1 (TIME_GEN_SEQ_1)

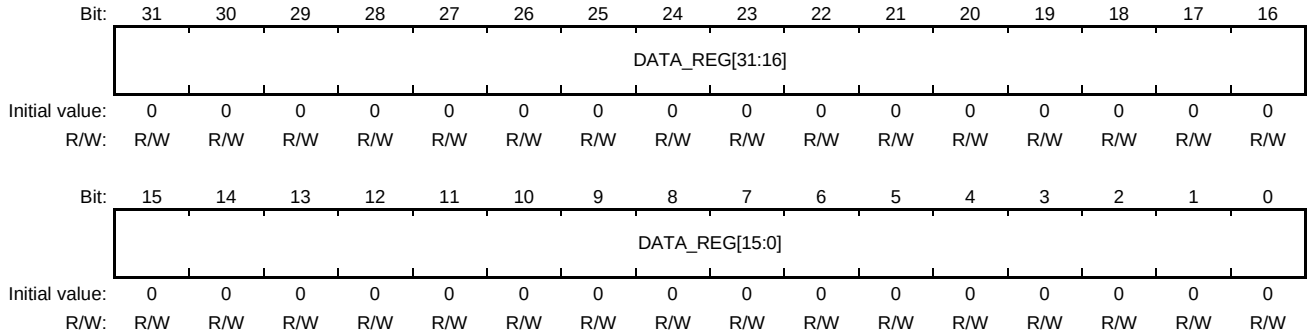
58.2.30 Data register (DATA_REG)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The DATA register is used for storage of the data that is read in the registered mode. The registered mode is allowed in the read direction only.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DATA_REG [31:0]	H'0000_0000	R/W	FIFO DATA

58.2.31 Data register size selection register (DATA_REG_SIZE)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The DATA_REG_SIZE register allows the selection of data size in the registered work mode. The data size in the registered mode is limited to four bytes.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
1 to 0	DATA_REG_SIZE[1:0]	B’00	R/W	DATA_REG_SIZE register. Allows selection of the number of valid bytes in the DATA register: B’00: single byte valid B’01: two lower bytes valid B’10: three lower bytes valid B’11: all four bytes valid

58.2.32 FIFO module control register (FIFO_INIT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The FIFO_INIT register contains the FIFO_INIT bit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FIFO_INIT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
0	FIFO_INIT	B'0	W	FIFO init bit The setting of this bit causes the flushing of FIFO. It is not necessary to set this bit before sending each command to the NAND Flash memory device. This feature is reserved only for a situation where previous FIFO content must be purged before a new operation.

58.2.33 FIFO module status register (FIFO_STATE)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The FIFO_STATE register contains the data buffer status.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DF_W_EMPTY	DF_R_FULL	CF_ACCPT_W	CF_ACCPT_R	CF_FULL	CF_EMPTY	DF_W_FULL	DF_R_EMPTY
Initial value:	0	0	0	0	0	0	0	0	1	0	0	1	0	1	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
7	DF_W_EMPTY	B'1	R	FIFO empty state bit. This bit indicates that there is no data in the FIFO available. This flag is valid for the write direction.
6	DF_R_FULL	B'0	R	FIFO full state bit. This bit indicates that there is no free space for the data in FIFO available. This flag is valid for the read direction.
5	CF_ACCPT_W	B'0	R	Command FIFO accept flag – write direction. If this flag is set then next write access will finish with any additional delay.
4	CF_ACCPT_R	B'1	R	Command FIFO accept flag – read direction.
3	CF_FULL	B'0	R	Command FIFO full flag. It can't be used to check if next transfer will be accepted.
2	CF_EMPTY	B'1	R	Command FIFO empty flag. It can't be used to check if next transfer will be accepted.
1	DF_W_FULL	B'0	R	FIFO full state bit. This bit indicates that there is no free space for the data in FIFO available. This flag is valid for the write direction.
0	DF_R_EMPTY	B'1	R	FIFO empty state bit. This bit indicates that there is no data in the FIFO available This flag is valid for the read direction.

58.2.34 MLUN register (MLUN)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The MLUN register contains the LUN address offset bits and number of available LUNs.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	LUN_SEL[1:0]		—	—	—	—	—	MLUN_IDX[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
9,8	LUN_SEL [1:0]	B’00	R/W	LUN number. B’00: two LUN-es B’01: four LUN-es. B’10: eight LUN-es.
7 to 3	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
2 to 0	MLUN_IDX [2:0]	B’000	R/W	LUN address offset. The content of this field is used as the bit offset value from the bit zero of the last address byte. This fields point to the bit index in the address that identify active LUN.

58.2.35 CMD ID initial value register (CMD_MARK)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The CMD MARK register allows to write initial value to the command marking generator in the register Slave I/F Unit (SIU).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CMD_ID[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
7 to 0	CMD_ID[7:0]	H'00	W	CMD ID initial value.

58.2.36 Memory device control register (MEM_CTRL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
—	√	√	√

The MEM_CTRL register stores the WP line control.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MEM0_WP	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
8	MEM0_WP	B'0	R/W	The WP line control bit.
7 to 0	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.

58.3.1 Command Generation

The NAND Flash devices are constantly extended and evaluated to the larger capacities and higher data

Through put. Frequently during this process, new commands appear in the next generation of devices.

To allow use of the NAND Flash controller with future generations of devices, the parameterizable command sequences have been added.

The parameterization allows for a defining set of parameters for each supported command sequence.

(1) Instruction Encoding

The controller instruction field is constant and has 32 bits. The instruction field contains the command sequence code and optional parameters. Those parameters are:

- The command codes present in the instruction sequence.
- The flag used to select data destination; possible options are data register and FIFO module.
- The flag used to select data source/sink for the command sequence. The possible choices are the registers or the DMA unit.
- The command sequence code.

If the given command sequence does not use all parameter fields, unused fields are ignored. The instruction encoding scheme is presented in the table below:

Table 58.6 Instruction Encoding

Field Name	Bits	Description
CMD_2	[31:24]	Code of the third command in a sequence.
CMD_1/CMD3*	[23:16]	Code of the second or fourth command in a sequence.
CMD_0	[15:8]	Code of the first command in a sequence.
DATA_SEL	[7]	Data register / FIFO select flag: 0 – the FIFO selected 1 – the DATA register selected
INPUT_SEL	[6]	Input module select flag: 0 – select the register as input 1 – select the DMA module as input
CMD_SEQ	[5:0]	Command code.

Note: Depending on the selected command sequence, this field will store the CMD1 or CMD3 code. Both commands are never used in a single sequence.

(2) Command Sequence Encoding

The NAND Flash devices use the same set of signals independently of the memory capacity. This allows upgrading of obsolete devices with newer ones without PCB redesign. The NAND Flash devices use common IO bus to transfer commands, addresses and data. The predefined set of command sequences is used for the read and write operations on those devices. The set of supported command sequences is not constant for all NAND Flash device producers and evolves as the devices are more capable.

The NAND Flash controller must be able to support the new NAND Flash device features as they appear with a minimum effort from the designer side. This objective can be achieved in many cases because most of the new instructions use the previously defined sequence of commands and addresses, along with new command codes, data page size, data spare area size, etc.

The NAND Flash controller defines the set of commands, addresses and data sequences that allows implementation of all present and many future instructions. The following description of those sequences is adequate to define most of the future NAND Flash device instructions.

Table 58.7 contains the command sequence encoding details. Each sequence is encoded according to the fields defined in the GEN_SEQ_CTRL register.

For more details, section 58.2.3, GENERIC_SEQ register (GEN_SEQ_CTRL)

Table 58.7 Command Sequence Encoding

Sequence symbol	Sequence encoding	CMD0	CMD1	CMD2	CMD3	COL_A0*2	COL_A1	ROW_A0	ROW_A1	DATA_EN	DELAY_EN	IMD_SEQ*3
SEQ_0	B'00_0000	√	—	—	—	—	—	—	—	—	DELAY_1	—

SEQ_18	B'11_0010	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
SEQ_19	B'01_0011	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
SEQ_20	B'11_0100	√	—	—	—	—	—	3	—	—	DELAY_1	—
SEQ_21	B'01_0101	√	—	—	—	1	—	—	—	—	—	—
SEQ_22	B'11_0110	√	—	√	—	2(1)	2	—	3	√	DELAY_0	—
SEQ_23	B'01_0111	√	√	—	—	—	—	3	—	√	DELAY_1	—
SEQ_24	B'01_1000	√	—	√	√	—	—	3	3	—	DELAY_0	—
SEQ_25	B'11_1001	√	—	√	√	2(1)	2	3	—	√	—	—

Note 1. SEQ_18 and SEQ_19 are the parameterized Generic Sequences. The GENE_SEQ_CTRL register defines which parts of sequences are executed.

Note 2. The value given in the brackets relates to the small block mode. In this mode, the controller sends only a single byte as the column address.

Note 3. IMD_SEQ - The command will be sent immediately.

Note: Gray rows – read from NAND Flash memory; White rows – write to NAND Flash memory; Blue rows – Non-directional commands

(a) Sequence SEQ_0

This non-directional sequence is composed from only one command. After the command is written to the NAND Flash device, the controller waits until the device goes into the busy state and drives the RnB line low, or sends the READ STATUS command. When delay time (tWB) passes or the device is ready, the sequence ends. The figure below shows the sequence：

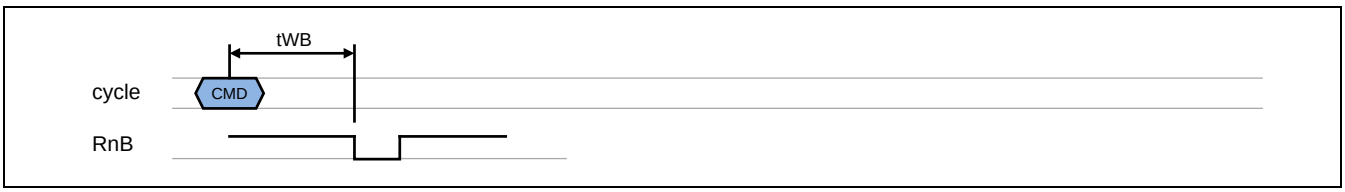

Figure 58.4 SEQ_0 Sequence

(b) Sequence SEQ_1

This is a read-sequence that is composed from a single command cycle, single address cycle and the single data cycle with a programmable number of read sequences. After the address sequence is finished, the controller measures the standard delay of first data read after the last write (tWHR). Next, the read data words are written to the FIFO module. The input module is selected by the INPUT_SEL field of the COMMAND register, the source for the address is placed in the ADDR0_COL register, and the commend code is stored in the CMD_0 field. The figure below shows the sequence execution:

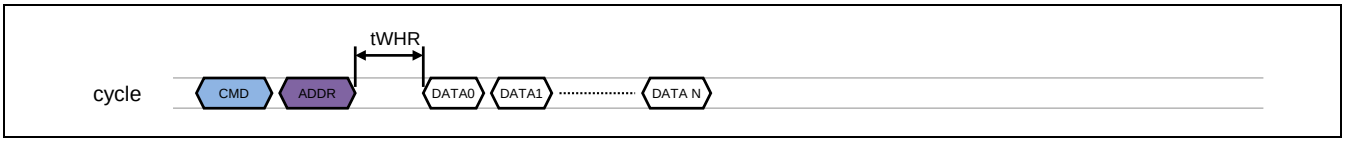

Figure 58.5 SEQ_1 Sequence

(c) Sequence SEQ_2

This is a read-sequence and it is similar to the SEQ_1 sequence except that after the address cycle the controller expects that device goes to the busy state. The controller sequentially checks state of the RnB line or send READ STATUS command to obtain the NAND Flash device status. The figure below shows the sequence execution:

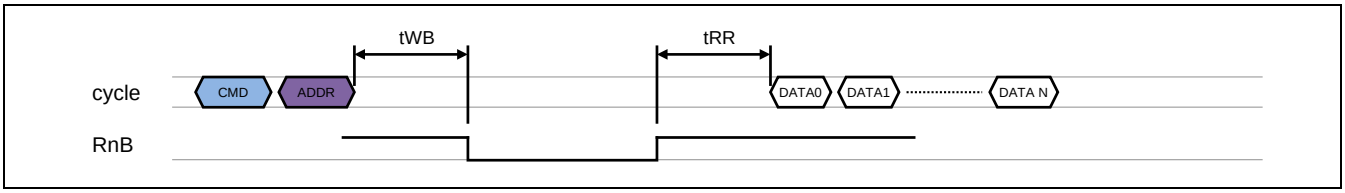

Figure 58.6 SEQ_2 Sequence

(d) Sequence SEQ_3

This is a write-sequence that is composed from a single command cycle, single address cycle and single data cycle with a programmable number of write sequences. After the address sequence is finished, the controller measures the standard delay of first data write after the last address cycle (tADL). The written words are read from the FIFO module. The controller sequentially checks the state of the RnB line or sends the READ STATUS command to obtain the NAND Flash device status. The input module is selected by the INPUT_SEL field of the COMMAND register; the source for the address is placed in the ADDR0_COL register, and the commend code is stored in the CMD_0 field. The figure below shows the sequence execution:

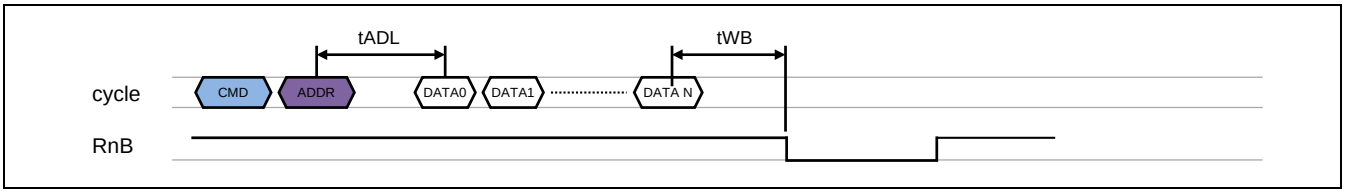

Figure 58.7 SEQ_3 Sequence

(e) Sequence SEQ_4

This is a special read-sequence that is used to implement the read status command sequences. The command is sent immediately. The sequence is composed of a single command cycle and a single data cycle. Between those cycles, the delay is counted (tWHR). The command code is read from the CMD_0 field.

When the DATA register is selected in the COMMAND register, the data is stored in the DATA register. The user defines the number of data in the DATA_REG_SIZE register. The registered mode is allowed only for the read direction.

When the FIFO register is selected in the COMMAND register, the data is stored in the FIFO. Because user has to change DATA_SIZE register, the command will be sent when all memories are ready and the Controller is in the idle state. The figure below shows the sequence execution:

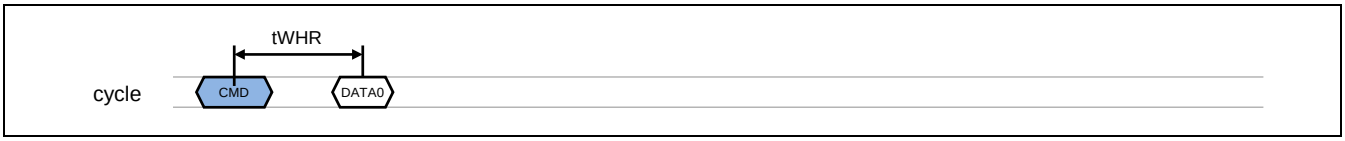

Figure 58.8 SEQ_4 Sequence

(f) Sequence SEQ_5

This is a read-sequence and it is similar to the SEQ_4 sequence. The command is sent immediately. The only difference is that after the command cycle, an additional address cycle is performed. The ADDR0_ROW register is used in this sequence. The figure below shows the sequence execution:

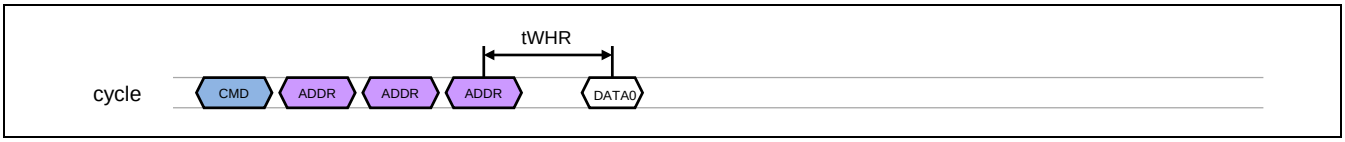

Figure 58.9 SEQ_5 Sequence

(g) Sequence SEQ_6

This is a read-sequence. The sequence of command cycle, address cycle, command cycle is executed. After that, the delay from the change column to the next operation (tCCS) is measured. Finally, the read data cycle is executed. The first command code is encoded in the CMD_0 instruction field; the second command code is encoded in the CMD_2 instruction field; the ADDR0_COL register is used in this sequence; the input module is selected by the INPUT_SEL field. The figure below shows the sequence execution:

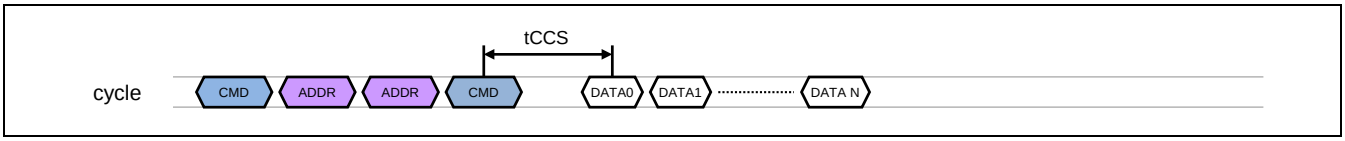

Figure 58.10 SEQ_6 Sequence

(h) Sequence SEQ_7

This read-sequence is similar to the SEQ_6 sequence, differing only because the address cycle in this sequence is composed of five bytes (ADDR0_COL and ADDR0_ROW) instead of three bytes. All else is the same as in the SEQ_6 sequence. The figure below shows the sequence execution:

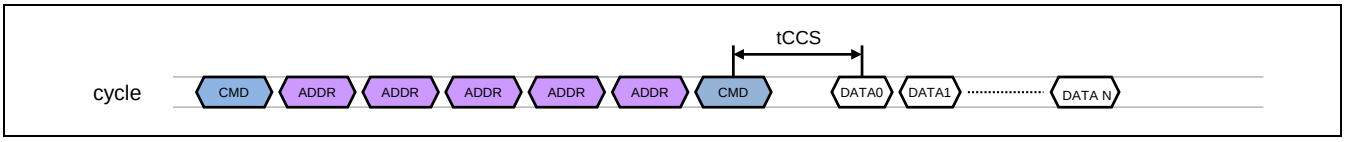

Figure 58.11 SEQ_7 Sequence

(i) Sequence SEQ_8

This is a write-sequence. First, the sequence of command cycle and two bytes address cycle is executed. Next, the delay after the column address changes (tCCS) is measured. Finally, the single data cycle with programmable number of write sequences is executed. The first command code is encoded in the CMD_0 instruction field; the ADDR0_COL register is used in this sequence; the input module is selected by the INPUT_SEL field. The figure below shows the sequence execution:

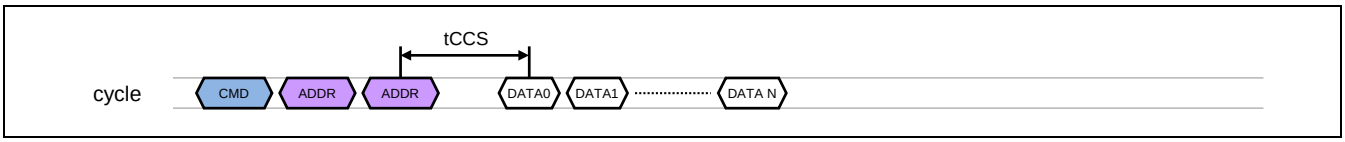

Figure 58.12 SEQ_8 Sequence

(j) Sequence SEQ_9

This is a non-directional sequence. The first step is to execute the five bytes address command cycle. The controller sequentially checks the state of the RnB line or sends the READ STATUS command to obtain the NAND Flash device status. The first command code is encoded in the CMD_0 instruction field; the second command code is encoded in the CMD_1 instruction field; the ADDR0_COL and ADDR0_ROW registers are used in this sequence. The figure below shows the sequence execution:

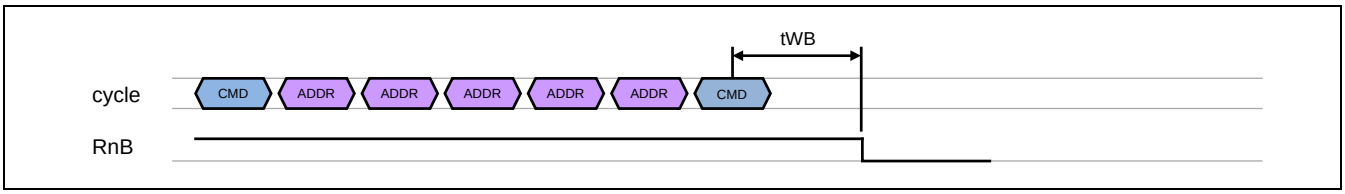

Figure 58.13 SEQ_9 Sequence

(k) Sequence SEQ_10

This is a non-directional sequence. The first step is to execute the five bytes address command cycle. The controller sequentially checks the state of the RnB line or sends the READ STATUS command to obtain the NAND Flash device status. Finally data block is read. The first command code is encoded in the CMD_0 instruction field; the second command code is encoded in the CMD_2 instruction field; the ADDR0_COL and ADDR0_ROW registers are used in this sequence. The figure below shows the sequence execution:

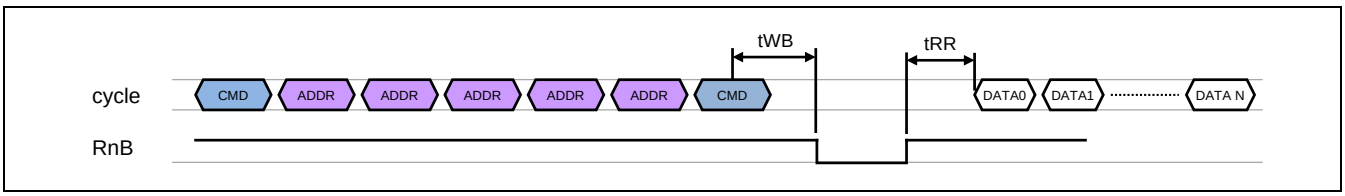

Figure 58.14 SEQ_10 Sequence

(l) Sequence SEQ_11

This is the read-sequence. The first step is to execute the command cycle. Next, the device goes to the busy state. The controller sequentially checks the state of the RnB line or sends the READ STATUS command to obtain the NAND Flash device status. As soon as the device reaches the ready state, the write data cycle with configurable read sequences is executed. The command code is encoded in the CMD_0 instruction field; the input module is selected by the INPUT_SEL field. The number of transferred bytes are configured using the DATA_SIZE register. The figure below shows the sequence execution:

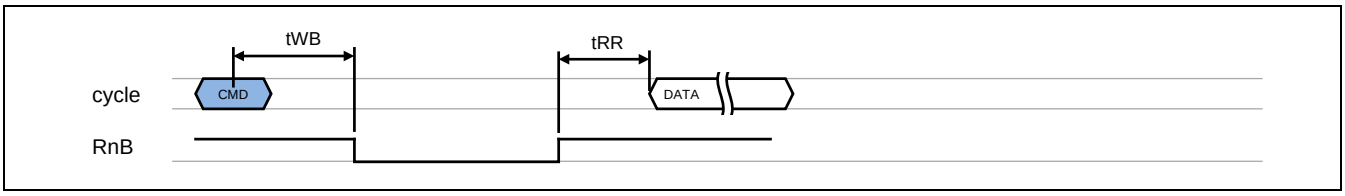

Figure 58.15 SEQ_11 Sequence

(m) Sequence SEQ_12

This is a write-sequence. The SEQ_12 sequence is a series of command cycle, address cycle, and data cycle with a configurable number of write operations and another command cycle. Between the last address cycle and first data cycle, a delay is measured (tADL) and, after the second command cycle, another delay is measured (tWB). The first command code is encoded in the CMD_0 instruction field; the second command code is encoded in the CMD_1 instruction field; the ADDR0_COL and ADDR_ROW registers are used in this sequence; the input module is selected by the INPUT_SEL field. The figure below shows the sequence execution:

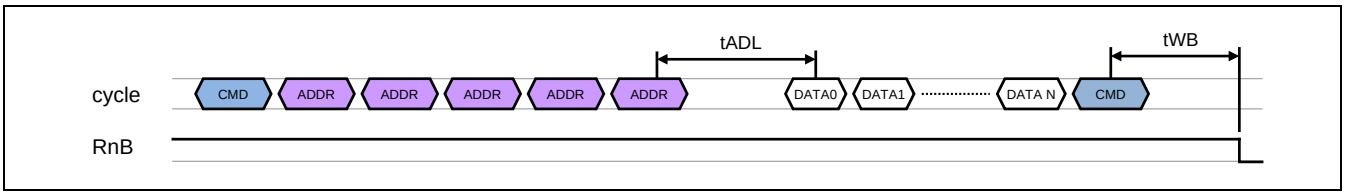

Figure 58.16 SEQ_12 Sequence

(n) Sequence SEQ_13

This is a write-sequence. The SEQ_13 sequence is a series of command cycle and address cycles, data cycle with a configurable number of write operations. Between the last address cycle and first data cycle, a delay is measured (tADL). The command code is encoded in the CMD_0 instruction field; the ADDR0_COL and ADDR0_ROW registers are used in this sequence; the input module is selected by the INPUT_SEL field. The figure below shows the sequence execution:

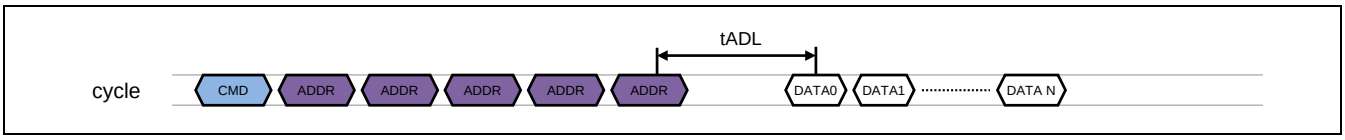

Figure 58.17 SEQ_13 Sequence

(o) Sequence SEQ_14

This is a non-directional sequence. First, the series of command cycle, address cycle, command cycle is executed. The controller sequentially checks the state of the RnB line or sends the READ STATUS command to obtain the NAND Flash device status. The first command code is encoded in the CMD_0 instruction field; the second command code is encoded in the CMD_1 instruction field; the ADDR0_ROW and ADDR0_COL registers are used in this sequence. The figure below shows the sequence execution:

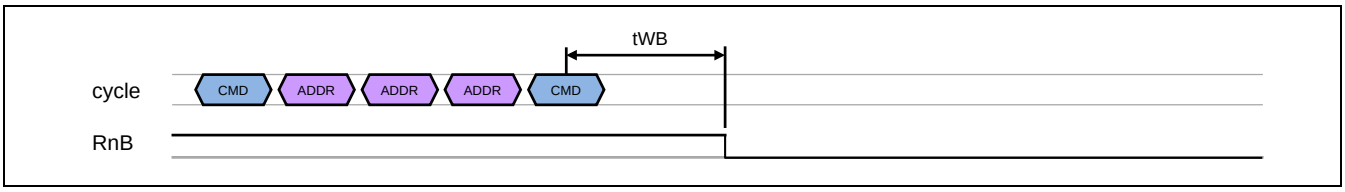

Figure 58.18 SEQ_14 Sequence

(p) Sequence SEQ_15

This is a read-sequence. First, the series of command cycle, address cycle, second command cycle, second address cycle, third command cycle is executed. The controller sequentially checks the state of the RnB line or sends the READ STATUS command to obtain the NAND Flash device status. After the NAND Flash device returns to the ready state, the data sequence, with a configurable number of read operations, is executed. The first command code is encoded in the CMD_0 instruction field; the second command code is encoded in the CMD_1 instruction field; the third command code is encoded in the CMD_2 instruction field. In this sequence, both address registers are used. The ADDR0_ROW and ADDR0_COL register content is sent after the first command in the sequence, the ADDR1_ROW and ADDR1_COL register content is sent after the second command in the sequence. The figure below shows the sequence execution:

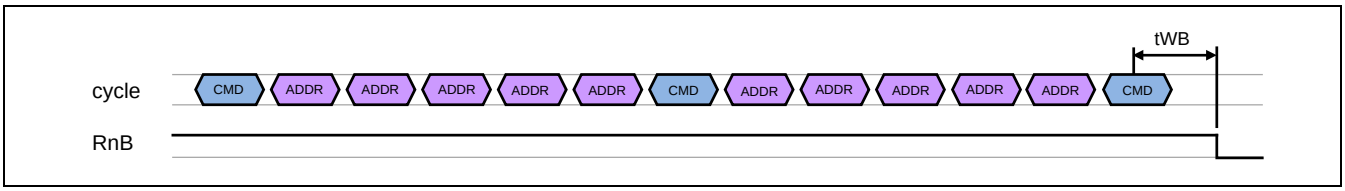

Figure 58.19 SEQ_15 Sequence

(q) Sequence SEQ_17

This is a read-sequence. This sequence is similar to the SEQ_10 sequence, except that the second command cycle is omitted. This sequence is implemented to use small block memories. The controller sends only four bytes of the address when the small block mode is enabled. The figure below shows the sequence execution:

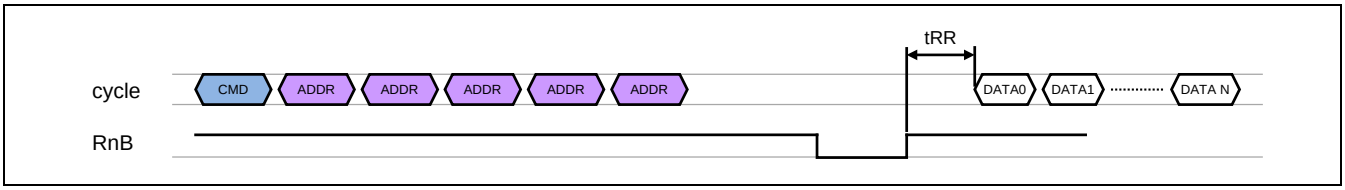

Figure 58.20 SEQ_17 Sequence

(r) Sequence SEQ_18

This generic read sequence is described in detail in section 58.3.2, Generic Command Sequence.

(s) Sequence SEQ_19

This generic write sequence is described in detail in section 58.3.2, Generic Command Sequence.

(t) Sequence SEQ_20

This non-directional sequence is composed from one command and three addresses bytes. After the command and addresses are written to the NAND Flash device, the controller waits until the device goes into the busy state and drives the RnB line low, or sends the READ STATUS command. When delay time (tWB) passes or the device is ready, the sequence ends. The figure below shows the sequence execution:

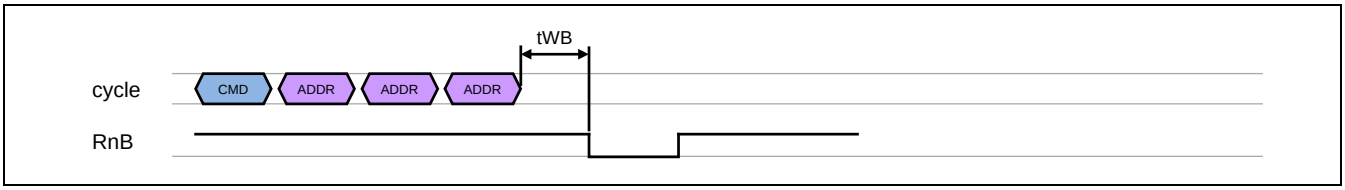

Figure 58.21 SEQ_20 Sequence

(u) Sequence SEQ_21

This non-directional sequence is composed from one command and one addresses byte. After the command and address are written to the NAND Flash device, the sequence ends. The figure below shows the sequence execution:

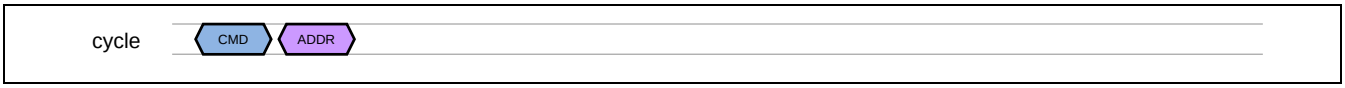

Figure 58.22 SEQ_21 Sequence

(v) Sequence SEQ_22

This is a read-sequence. The first step is to execute the five bytes address command cycle. The controller sequentially checks the state of the RnB line or sends the READ STATUS command to obtain the NAND Flash device status. The first command code is encoded in the CMD_0 instruction field; the second command code is encoded in the CMD_1 instruction field; the ADDR0_COL, ADDR1_COL and ADDR1_ROW registers are used in this sequence. The figure below shows the sequence execution:

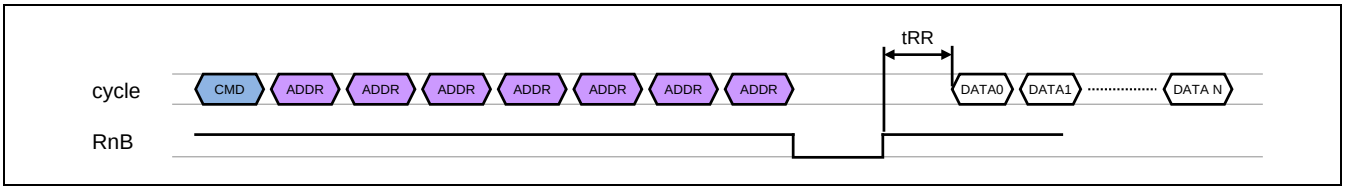

Figure 58.23 SEQ_22 Sequence

(w) Sequence SEQ_23

This is a write-sequence. The SEQ_23 sequence is a series of command cycle, address cycle, and data cycle with a configurable number of write operations and another command cycle. Between the last address cycle and first data cycle, a delay is measured (tADL) and, after the second command cycle, another delay is measured (tWB). The first command code is encoded in the CMD_0 instruction field; the second command code is encoded in the CMD_1 instruction field; the ADDR0_ROW registers is used in this sequence; the input module is selected by the INPUT_SEL field. The figure below shows the sequence execution:

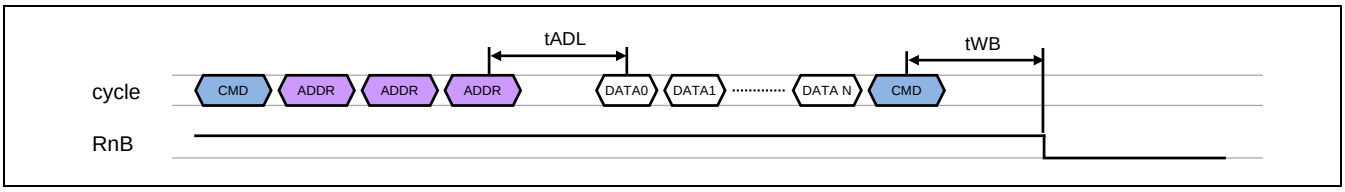

Figure 58.24 SEQ_23Sequence

(x) Sequence SEQ_24

This is a write-sequence. It is composed from the three commands cycles and two addresses cycles. Both addresses cycle contain the row address part. After the last command cycle the tWB delay is measured. The figure below shows the sequence execution:

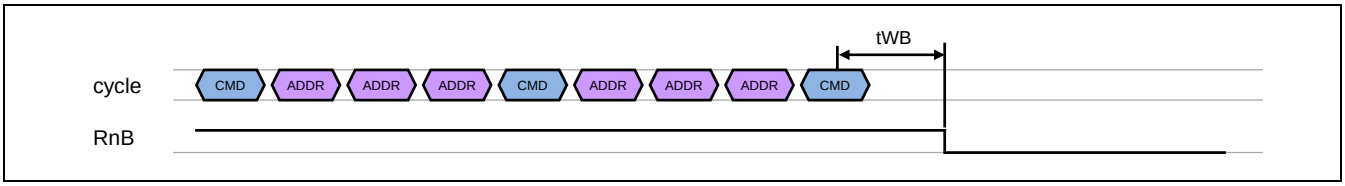

Figure 58.25 SEQ_24 Sequence

(y) Sequence SEQ_25

This is a read-sequence. It is composed from the three commands cycles and two addresses cycles. the first addresses cycle contain the column and row address part. The second address cycle contain only the column address part. After the last command cycle the tWHR delay is measured. The figure below shows the sequence execution:

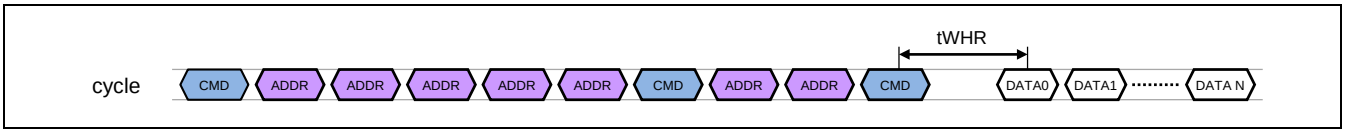

Figure 58.26 SEQ_25 Sequence

(z) Sequence SEQ_26

This is a write-sequence. The SEQ_26 sequence is a series of command cycle, address cycle, and data cycle with a configurable number of write operations and another command cycle. Between the last address cycle and first data cycle, a delay is measured (tADL). The first command code is encoded in the CMD_0 instruction field; the second command code is encoded in the CMD_1 instruction field; the ADDR0_ROW registers is used in this sequence; the input module is selected by the INPUT_SEL field. The figure below shows the sequence execution:

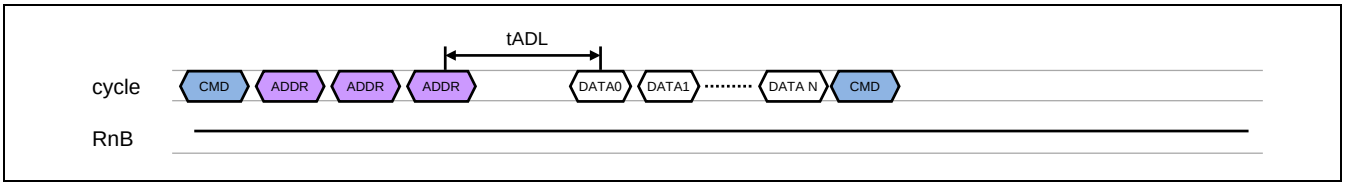

Figure 58.27 SEQ_26 Sequence

58.3.2 Generic Command Sequence

There will be cases where the set of predefined sequences above will not be sufficient to handle a new command equence. If that occurs, the generic command sequence feature of the NAND flash controller can be used. There will be cases where the set of predefined sequences above will not be sufficient to handle a new command sequence. If that occurs, the generic command sequence feature of the NAND flash controller can be used.

This sequence is designed to mimic almost every available command supported by the NAND Flash devices; however, additional effort required to trigger such commands.

Generic command sequence is executed in the following steps:

CMD0 – The first command in the sequence. The value of this command is stored in the CMD_0 field of the COMMAND register, described in 58.2.1 Controller commands register (COMMAND)

ADDR0 – The first address sequence. This is enabled if the COL_A0 and ROW_A0 fields in the GEN_SEQ_CTRL register described in 58.2.3 GENERIC_SEQ register (GEN_SEQ_CTRL) have values other than zero. In this phase, the address is sent to the NAND Flash device and is read from the ADDR0_COL and ADDR0_ROW registers. The number of the bytes in the address cycle is configured by the COL_A0 and ROW_A0 fields of the GEN_SEQ_CTRL register.

CMD1 – The fourth command in the sequence. The value of this command is stored in the CMD_1 field of the COMMAND register, described in 58.2.1 Controller commands register (COMMAND). This is enabled by the CMD1_EN field in the GEN_SEQ_CTRL register, described in 58.2.3 GENERIC_SEQ register (GEN_SEQ_CTRL).

ADDR1 – The second address in the sequence. This is enabled if the COL_A1 and ROW_A1 fields of the GEN_SEQ_CTRL register described in 58.2.3 GENERIC_SEQ register (GEN_SEQ_CTRL) have a value other than zero. In this phase, the address is sent to the NAND Flash device from the ADDR1_COL and ADDR1_ROW registers. The number of bytes in the address cycle is configured by the COL_A1 and ROW_A1 fields of the GEN_SEQ_CTRL register.

CMD2 – The third command in the sequence. The value of this command is stored in the CMD_2 field of the COMMAND register described in 58.2.1 Controller commands register (COMMAND). This is enabled by the CMD2_EN field in the GEN_SEQ_CTRL register, described in 58.2.3 GENERIC_SEQ register (GEN_SEQ_CTRL).

DELAY0 – Waiting for the device to return to the ready state and continue the sequence. This is enabled by the DELAY_EN field in the GEN_SEQ_CTRL register, described in 58.2.3 GENERIC_SEQ register (GEN_SEQ_CTRL). Only one delay phase can be present in the generic sequence. For more details, see 58.2.3 GENERIC_SEQ register (GEN_SEQ_CTRL).

DATA – The data phase of the sequence. This is enabled by the DATA_EN field in the GEN_SEQ_CTRL register described in 58.2.3 GENERIC_SEQ register (GEN_SEQ_CTRL). Additionally, the transfer direction must be selected by the sequence number. Sequence number 18 reads data from the NAND Flash memory, sequence number 19 writes data to the NAND Flash memory. The size of the transferred data block is configured by the DATA_SIZE register value.

CMD3 – The second command in the sequence. This is enabled by the CMD3_EN field in the GEN_SEQ_CTRL register described in the 58.2.3 GENERIC_SEQ register (GEN_SEQ_CTRL). The value of this command is stored in the CMD_3 field of the GEN_SEQ_CTRL register.

DELAY1 – Waiting for the device to return to the ready state and finish the sequence. This is enabled by the

DELAY_EN field in the GEN_SEQ_CTRL register described in 58.2.3 GENERIC_SEQ register (GEN_SEQ_CTRL). The controller waits for the device to return to the ready state and finish the sequence. Only one delay phase can be present in generic sequence.
The figure below presents the generic sequence composition:

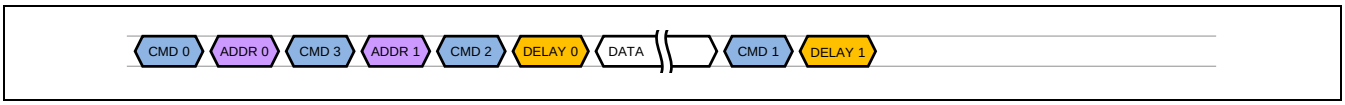

Figure 58.28 Generic Sequence

There are few constraints on the generic sequence usage:

- The DEL0 and DEL1 delay phases cannot both be enabled in a single command sequence
- The TIMINGS _ASYN register must be set even when the generic sequence is used.

It is possible to force an immediate command sequence execution by enabling the IMD_SEQ bit in the GEN_SEQ_CTRL register. In this case, the triggered command will be executed even if the previously sent command for a selected device is not completed. If both the IMD_SEQ and DATA_EN flags are enabled in a single sequence, then the register must be selected as data source/sink. The IMD_SEQ is valid only for the read direction. This feature is intended to implement all state read operations.

After each step of the generic sequence, the programmable time delay is measured. These delays are configured using the TIME_GEN_SEQ[0-3] registers. Refer to the TIME_GEN_SEQ[0-3] registers description for further information and see figures below.

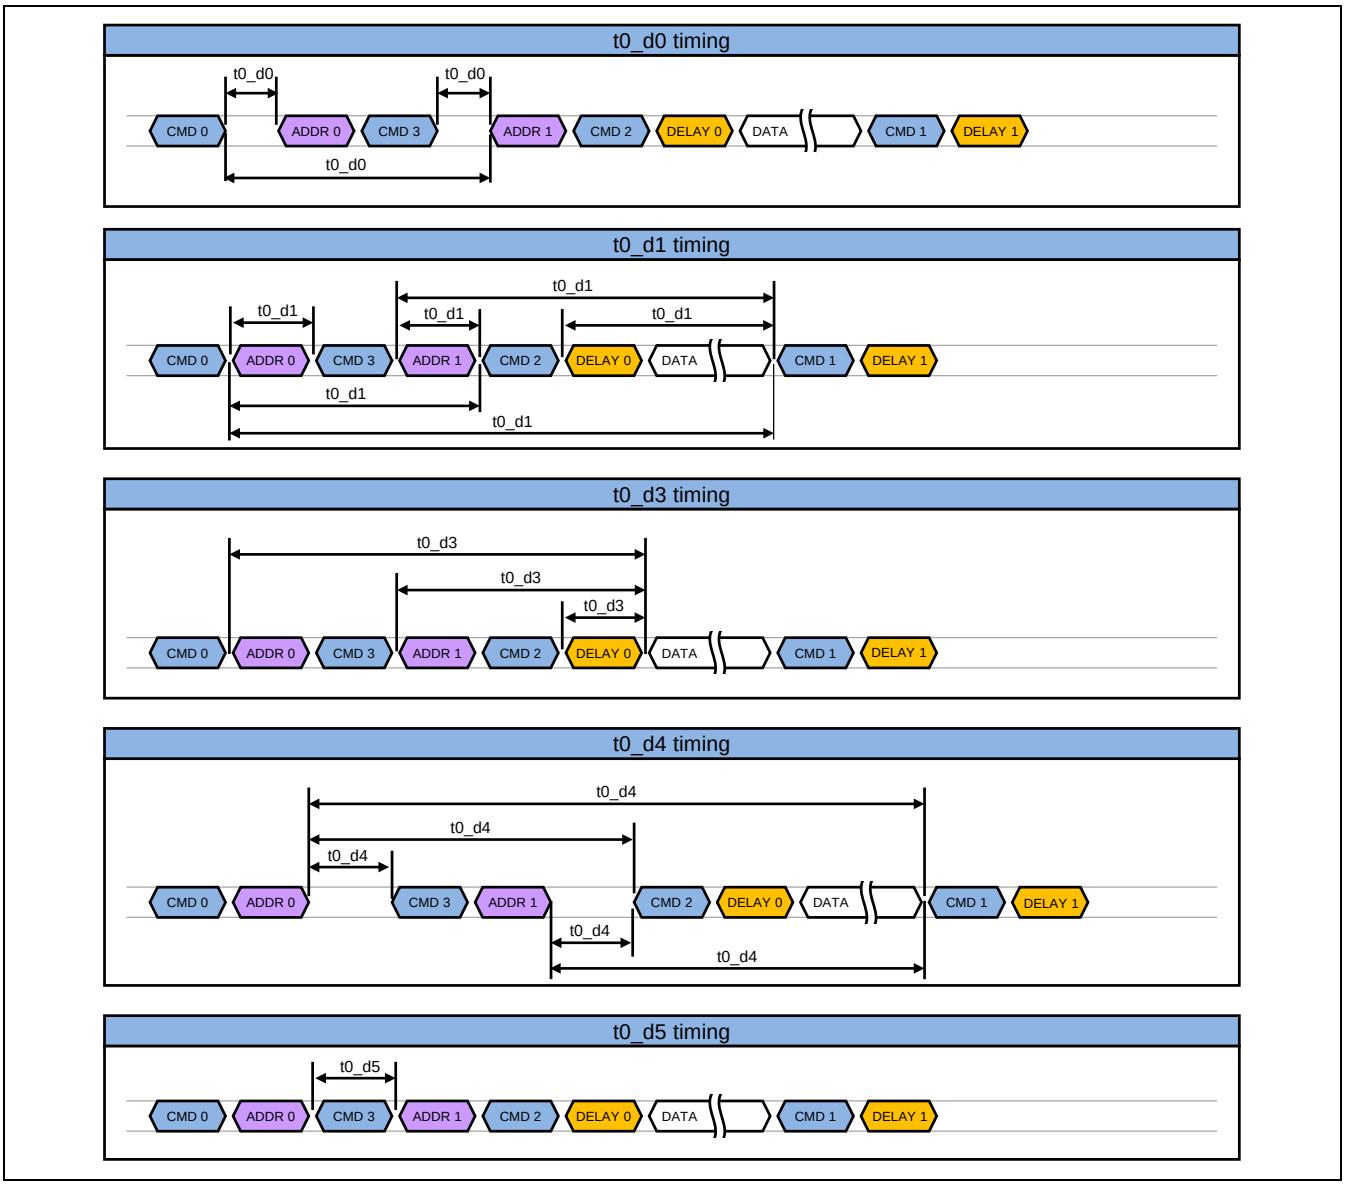

Figure 58.29 Generic Sequence Timing parameters

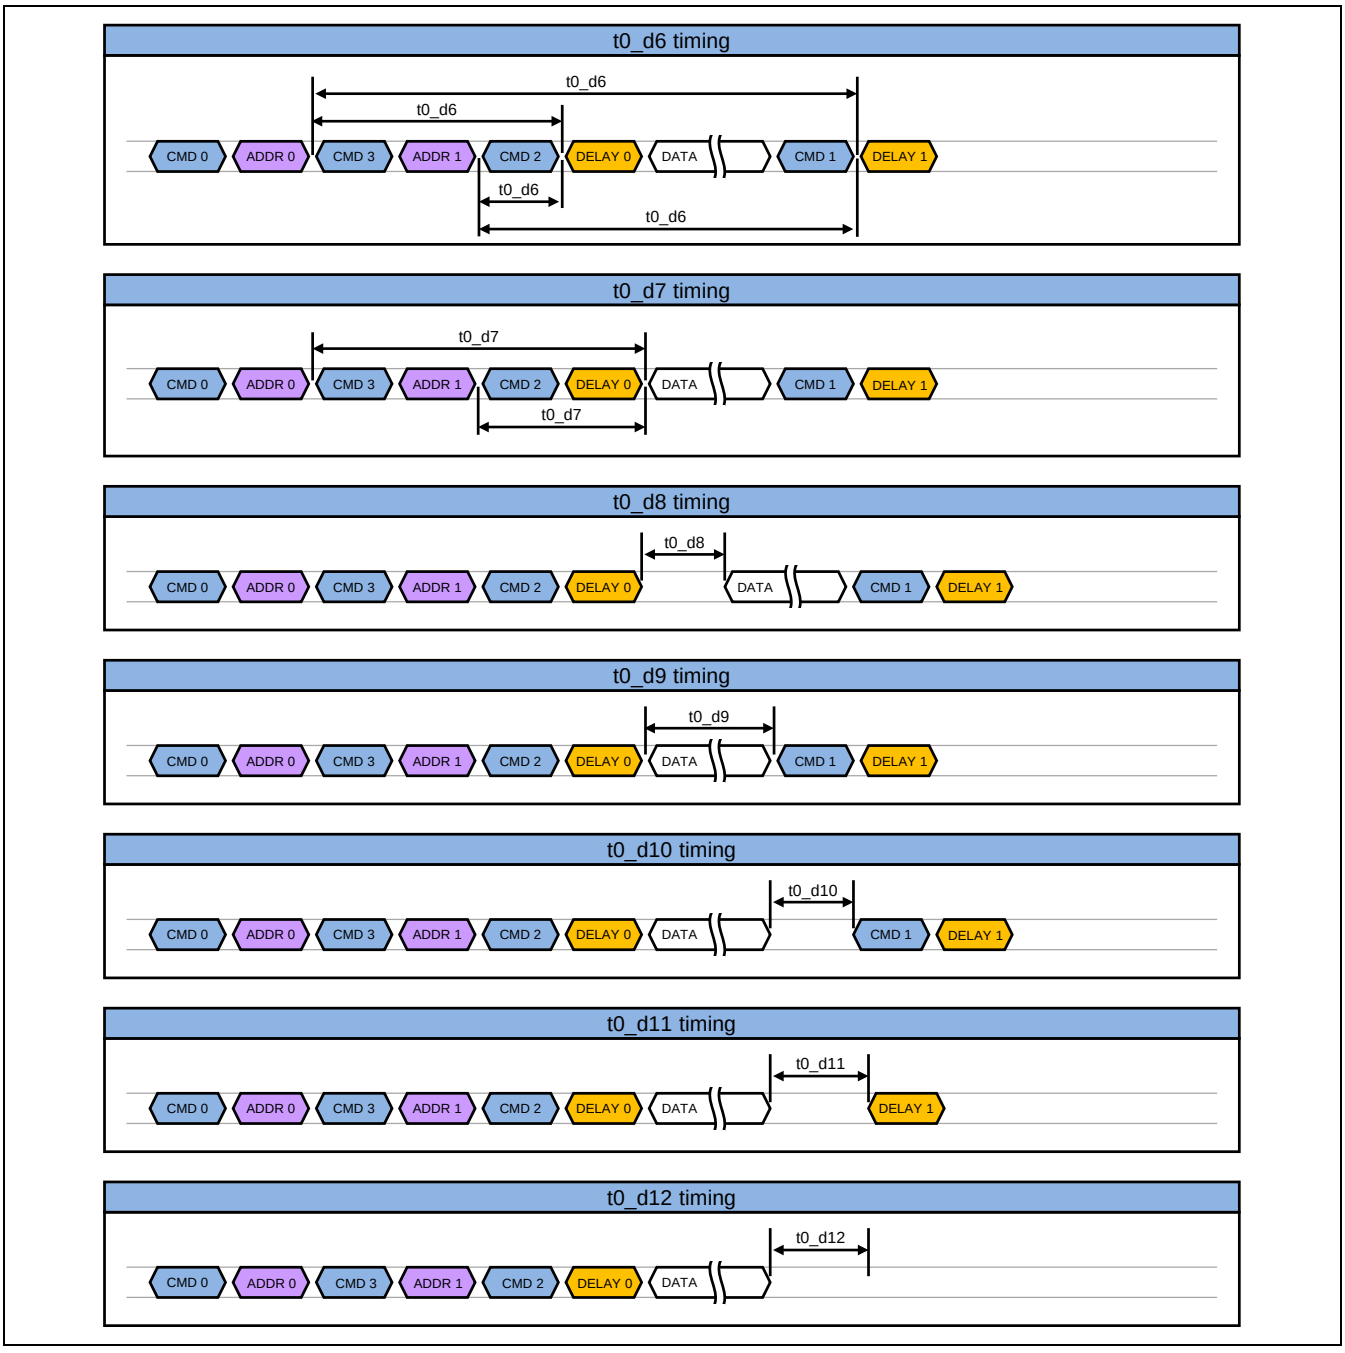

Figure 58.30 Generic Sequence Timing parameters

58.3.3 Instructions

The implementation of the instruction set presented at this point is an example of how to use the instruction encoding scheme presented in section 58.3.1 (1), Instruction Encoding. This chapter and the command sequences presented previously give sufficient information to implement new commands and command sequences for future NAND Flash devices.

(1) Instructions Set

The table below contains the basic instruction defined to implement the all command sequences accessible in the ONFI 1.x standards.

Table 58.8 Instructions set

Instruction	CMD_0	CMD_1/ CMD_3	CMD_2	CD_SEQ	Send when memory is busy
Reset Commands					
RESET	H'FF	—	—	SEQ_0	No
Identification Operations					
READ ID	H'90	—	—	SEQ_1	No
READ PARAMETER PAGE	H'EC	—	—	SEQ_2	No
READ UNIQUE ID	H'ED	—	—	SEQ_3	No
Configuration Operations					
GET FEATURES	H'EE	—	—	SEQ_2	No
SET FEATURES	H'EF	—	—	SEQ_3	No
Status Operations					
READ STATUS	H'70	—	—	SEQ_4	Yes
SELECT LUN WITH STATUS	H'78	—	—	SEQ_5	Yes
LUN STATUS	H'71	—	—	SEQ_5	Yes
DEVICE STATUS	H'72	—	—	SEQ_4	Yes
VOLUME_SELECT	H'E1	—	—	SEQ21	Yes
Column Address Operations					
CHANGE READ COLUMN	H'05	—	H'E0	SEQ_6	No
SELECT CACHE REGISTER	H'06	—	H'E0	SEQ_7	No
CHANGE WRITE COLUMN	H'85	—	—	SEQ_8	No
CHANGE ROW ADDRESS	H'85	H'11	—	SEQ_12	No
Read Operations					
READ PAGE	H'00	—	H'30	SEQ_10	No
READ PAGE CHANGE	H'31	—	—	SEQ_11	No
READ PAGE CHANGE LAST	H'3F	—	—	SEQ_11	No
READ MULTIPLANE	H'00	H'32	—	SEQ_9	No
TWO PLANE PAGE READ	H'00	H'00	H'30	SEQ_15	No
QUEUE PAGE READ	H'07	—	H'37	SEQ_22	No
Program Operation					
PROGRAM PAGE	H'80	H'10	—	SEQ_12	No
PROGRAM PAGE IMD	H'80	H'10	—	SEQ_23	No
PROGRAM PAGE DEL	H'80	H'13	—	SEQ_23	No
PROGRAM PAGE 1	H'80	—	—	SEQ_13	No
PROGRAM PAGE CACHE	H'80	H'15	—	SEQ_12	No

Instruction	CMD_0	CMD_1/ CMD_3	CMD_2	CD_SEQ	Send when memory is busy
PROGRAM MULTIPLANE	H'80	H'11	—	SEQ_12	No
WRITE PAGE	H'10	—	—	SEQ_0	No
WRITE PAGE CACHE	H'15	—	—	SEQ_0	No
WRITE MULTIPLANE	H'11	—	—	SEQ_0	No
Erase Operations					
ERASE BLOCK	H'60	H'D0	—	SEQ_14	No
ERASE MULTIPLANE	H'60	H'D1	—	SEQ_14	No
Copyback Operations					
COPYBACK READ	H'00	—	H'35	SEQ_10	No
COPYBACK PROGRAM	H'85	H'10	—	SEQ_9	No
COPYBACK PROGRAM 1	H'85	—	—	SEQ_13	No
COPYBACK MULTIPLANE	H'85	H'11	—	SEQ_12	No
OTP Operations					
PROGRAM OTP	H'A0	H'10	—	SEQ_12	No
DATA PROTECT OTP	H'A5	H'10	—	SEQ_9	No
READ PAGE OTP	H'AF	—	H'30	SEQ_10	No

(2) RESET Command

(a) Command Description

The RESET command is used to put a target into a known condition and to abort command sequences in progress.

(b) Command Encoding

The RESET instruction uses the SEQ_0 commands sequence. The command is encoded, as shown in the table below:

Table 58.9 RESET Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'FF	—	—	SEQ_0_ID

(3) READ ID Command

(a) Command Description

The READ ID command is used to read identifier codes programmed into the target. This command is accepted by the target only when all LUNs on the target are in the IDLE state.

When the command is followed by an address cycle of H'00, the target returns a 5-byte identifier code that includes the manufacturer's ID, device configuration, and part-specific information.

When the READ ID command is followed by an address cycle of H'20, the target returns the 4-byte ONFI identifier code.

(b) Command Encoding

The READ ID instruction uses the SEQ_1 commands sequence. The command is encoded, as shown in the table below:

Table 58.10 READ ID Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'90	0/1	0/1	SEQ_1_ID

(4) READ PARAMETER PAGE Command

(a) Command Description

The READ PARAMETER PAGE command is used to read the ONFI parameter page programmed into the target. This command is accepted by the target only when all LUNs on the target are idle.

When the command is followed by an address cycle of H'00, the target goes into busy state. After the read process is completed, the controller enables the data output mode to read the parameter page.

(b) Command Encoding

The READ PARAMETER PAGE instruction uses the SEQ_2 commands sequence. The command is encoded, as shown in the table below:

Table 58.11 READ PARAMETER PAGE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'EC	0/1	0/1	SEQ_2_ID

(5) READ UNIQUE ID Command

(a) Command Description

The READ UNIQUE ID instruction is used to read a unique identifier programmed into the target. This command is accepted by the target only when all LUNs on the target are idle.

When the address cycle of H'00 is written to the target, then the target goes into busy state. After the read process is complete, the controller enables the data output mode to read the unique ID. Sixteen copies of the unique ID data are stored in the device. Each copy is 32 bytes. The first 16 bytes are unique data and the second 16 bytes are the complement of the first 16 bytes. The application program will XOR the first 16 bytes with the second 16 bytes. If the result is 16 bytes of H'FF, then that copy of the unique ID data is correct. In the event that there is a non-H'FF result, the application program repeats the XOR operation on a subsequent copy of the unique ID data.

(b) Command Encoding

The READ UNIQUE ID instruction uses the SEQ_2 commands sequence. The command is encoded, as shown in the table below:

Table 58.12 READ UNIQUE ID Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'ED	0/1	0/1	SEQ_2_ID

(6) GET FEATURES Command

(a) Command Description

The GET FEATURES instruction reads the sub-feature parameters (P1-P4) from the specified feature address. This command is accepted by the target only when all LUNs on the target are idle.

When the H'EE command is followed by a feature address, the target goes into busy state. After the target internal read operation completes, the controller enables the data output mode to read the subfeature parameters.

(b) Command Encoding

The GET FEATURES instruction uses the SEQ_2 commands sequence. The command is encoded, as shown in the table below:

Table 58.13 GET FEATURES Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'EE	0/1	0/1	SEQ_2_ID

(7) SET FEATURES Command

(a) Command Description

The SET FEATURES instruction writes the sub-feature parameters (P1-P4) to the specified feature address to enable or disable target-specific features. This command is accepted by the target only when all LUNs on the target are idle.

The H'EF command is followed by a valid feature address. The possible address value depends on the features set implemented in the target device. The address cycle is followed by the configurable number of data cycles. Values of the address and data encoding scheme allowed are found in the device vendor documentation.

(b) Command Encoding

The SET FEATURES instruction uses the SEQ_3 commands sequence. The command is encoded, as shown in the table below:

Table 58.14 SET FEATURES Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'EF	—	0/1	SEQ_3_ID

(8) READ STATUS Command

(a) Command Description

Each LUN provides its status independently of other LUNs on the same target through its 8-bit status register. Once the READ STATUS instruction is issued, status register output is enabled. The contents of the status register are returned on DQ[7: 0] for each data output request.

The READ STATUS command returns the status of the most recently selected LUN.

(b) Command Encoding

The READ STATUS instruction uses the SEQ_4 commands sequence. The command is encoded, as shown in the table below:

Table 58.15 READ STATUS Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'70	0/1	—	SEQ_4_ID

This instruction has special meaning because it can be executed when the target is in the BUSY state.

The FIFO cannot be used to access the read data because it can be occupied by the operation under execution. For the sequence the data field of command must select the DATA_REG register as data destination. The DATA_REG_SIZE must be select single byte.

(9) DEVICE STATUS Command

(a) Command Description

Each LUN provides its status independently of other LUNs on the same target through its 8-bit status register. Once the DEVICE STATUS instruction is issued, status register output is enabled. The contents of the status register are returned on DQ[7:0] for each data output request.

The DEVICE STATUS command returns the status of the most recently selected LUN.

(b) Command Encoding

The DEVICE STATUS instruction uses the SEQ_4 commands sequence. The command is encoded, as shown in the table below:

Table 58.16 DEVICE STATUS Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'72	0/1	—	SEQ_4_ID

This instruction has special meaning because it can be executed when the target is in the BUSY state.

The FIFO cannot be used to access the read data because it can be occupied by the operation under execution. For the sequence the data field of command must select the DATA_REG register as data destination. The DATA_REG_SIZE must be select single byte.

(10) VOLUME SELECT Command

(a) Command Description

This command is accepted by all initialized devices that share a CE pin. The command may be executed with any volume on the target in any state. When the VOLUME SELECT command is issued, all volumes with unselected volume addresses will be deselected to save power. If the Volume address entered is invalid or does not match any appointed volume address, all volume addresses will be deselected. If the VOLUME SELECT command is not issued after CE high time then all volumes.

(b) Command Encoding

The VOLUME SELECT instruction uses the SEQ_21 commands sequence. The command is encoded, as shown in the table below:

Table 58.17 VOLUME SELECT Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'E1	0/1	—	SEQ_21_ID

(11) SELECT LUN WITH STATUS Command

(a) Command Description

Each LUN provides its status independently of other LUNs on the same target through its 8-bit status register. Once the SELECT LUN WITH STATUS instruction is issued, status register output is enabled. The contents of the status register are returned on DQ[7:0] for each data output request.

The SELECT LUN WITH STATUS command returns the status of the selected LUN.

(b) Command Encoding

The SELECT LUN WITH STATUS instruction uses the SEQ_5 commands sequence. The command is encoded, as shown in the table below:

Table 58.18 SELECT LUN WITH STATUS Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'78	0/1	—	SEQ_5_ID

This instruction has special meaning because it can be executed when the target is in the BUSY state.

The FIFO cannot be used to access the read data because it can be occupied by the operation under execution. For the sequence the data field of command must select the DATA_REG register as data destination. The DATA_REG_SIZE must be select single byte.

(12) LUN STATUS Command

(a) Command Description

Each LUN provides its status independently of other LUNs on the same target through its 8-bit status register. Once the SELECT LUN WITH STATUS instruction is issued, status register output is enabled. The contents of the status register are returned on DQ[7: 0] for each data output request.

The LUN STATUS command returns the status of the selected LUN.revert to their previous state.

(b) Command Encoding

The LUN STATUS instruction uses the SEQ_5 commands sequence. The command is encoded, as shown in the table below:

Table 58.19 LUN STATUS Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'71	0/1	—	SEQ_5_ID

This instruction has special meaning because it can be executed when the target is in the BUSY state.

The FIFO cannot be used to access the read data because it can be occupied by the operation under execution. For the sequence the data field of command must select the DATA_REG register as data destination. The DATA_REG_SIZE must be select single byte.

(13) CHANGE READ COLUMN Command

(a) Command Description

The CHANGE READ COLUMN command changes the column address of the selected cache register and enables data output of the last selected LUN. This command is accepted by the selected LUN when it is ready. Writing H’05 to the target command register, followed by two column address cycles containing the column address, followed by the H’E0 command puts the selected LUN into data output mode. The selected LUN stays in data output mode until another valid command is issued.

(b) Command Encoding

The CHANGE READ COLUMN instruction uses the SEQ_6 commands sequence. The command is encoded, as shown in the table below:

Table 58.20 CHANGE READ COLUMN Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
H’E0	—	H’05	0/1	—	SEQ_6_ID

(14) SELECT CACHE REGISTER Command

(a) Command Description

The SELECT CACHE REGISTER command enables data output on the addressed LUN and cache register at the specified column address. This command is accepted by a LUN when it is ready. Writing the H’06 to the target internal command register, followed by two column address cycles and three row address cycles, followed by H’E0 enables data output mode on the address LUN and cache register at the specified column address.

(b) Command Encoding

The SELECT CACHE REGISTER instruction uses the SEQ_7 commands sequence. The command is encoded, as shown in the table below:

Table 58.21 SELECT CACHE REGISTER Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
H’E0	—	H’06	0/1	—	SEQ_7_ID

(15) CHANGE WRITE COLUMN Command

(a) Command Description

The CHANGE WRITE COLUMN command changes the column address of the selected cache register and enables data input on the last selected LUN. Writing the H’85 to the target internal command register, followed by two column address cycles containing the column address puts the selected LUN into data input mode.

(b) Command Encoding

The CHANGE WRITE COLUMN instruction uses the SEQ_8 commands sequence. The command is encoded, as shown in the table below:

Table 58.22 CHANGE WRITE COLUMN Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H’85	—	—	SEQ_8_ID

(16) CHANGE ROW ADDRESS Command

(a) Command Description

The CHANGE ROW ADDRESS command changes the row address (block and page) where the cache register contents are to be programmed in the NAND array. It also changes the column address of the selected cache register and enables data input on the specified LUN.

(b) Command Encoding

The CHANGE ROW ADDRESS instruction uses the SEQ_12 commands sequence. The command is encoded, as shown in the table below:

Table 58.23 CHANGE ROW ADDRESS Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H'11	H'85	0	—	SEQ_12_ID

(17) READ PAGE Command

(a) Command Description

The READ PAGE command copies a page from the NAND Flash array to its respective cache register and enables data output. This command is accepted by the LUN when it is ready. To read a page from the NAND Flash array, the controller writes the H'00 command to the target internal command register, then writes 5 address cycles to the address registers, and concludes with the H'30 command. The selected LUN will go into busy state as the data is transferred. When the LUN is ready, data output is enabled for the cache register linked to the plane addressed in the READ PAGE command. The controller reads the programmed number of bytes to the FIFO.

(b) Command Encoding

The READ PAGE instruction uses the SEQ_10 commands sequence. The command is encoded, as shown in the table below:

Table 58.24 READ PAGE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
H'30	—	H'00	0/1	0/1	SEQ_10_ID

(18) READ PAGE CACHE Command

(a) Command Description

The READ PAGE CACHE command reads the next sequential page within a block into the data register, while the previous page is output from the cache register. To issue this command, the controller writes H'31 to the target internal command register. After this command is issued, the R/B# goes LOW and the LUN goes into busy state. Afterwards, the R/B# goes HIGH and the LUN is busy with a cache operation, indicating that the cache register is available and that the specified page is copying from the NAND Flash array to the data register. At this point, data is read from the cache register.

(b) Command Encoding

The READ PAGE CACHE instruction uses the SEQ_11 commands sequence. The command is encoded, as shown in the table below:

Table 58.25 READ PAGE CACHE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H’31	0/1	0/1	SEQ_11_ID

(19) READ PAGE CACHE LAST Command

(a) Command Description

The READ PAGE CACHE LAST command ends the READ PAGE CACHE sequence and copies a page from the data register to the cache register. This command is accepted by the LUN when it is ready. To issue the READ PAGE CACHE LAST command, the controller writes H’3F to the target internal command register. After this command is issued, R/B# goes LOW and the LUN goes into busy state. Afterwards, the R/B# goes HIGH and the LUN is ready. At this point, data from the targets cache register is read into the FIFO.

(b) Command Encoding

The READ PAGE CACHE LAST instruction uses the SEQ_11 commands sequence. The command is encoded, as shown in the table below:

Table 58.26 READ PAGE CACHE LAST Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H’3F	0/1	0/1	SEQ_11_ID

(20) READ MULTIPLANE Command

(a) Command Description

The READ MULTIPLANE command queues a plane to transfer data from the NAND array to its cache register. This command can be issued one or more times. Each time a new plane address is specified, that plane is also queued for data transfer. To select the final plane and to begin the read operation for all previously queued planes, issue the READ PAGE command. All queued planes will transfer data from the NAND array to their cache registers.

(b) Command Encoding

The READ MULTIPLANE instruction uses the SEQ_9 commands sequence. The command is encoded, as shown in the table below:

Table 58.27 READ MULTIPLANE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H’32	H’00	—	—	SEQ_9_ID

(21) QUEUE PAGE READ Command

(a) Command Description

The QUEUE PAGE READ operation allows for partial-page reads by using a 7-address cycle. The first two bytes of the address cycle indicate the length of the page to read - those bytes are stored in ADDR0 register, followed by the column and row addresses - those bytes are stored in the ADDR1 register.

This can help overall performance should only a portion of the page data be needed because only the codeword containing the requested data will have ECC decoded. This command is exclusive for the CLEAR NAND devices.

(b) Command Encoding

The QUEUE PAGE READ instruction uses the SEQ_22 commands sequence. The command is encoded, as shown in the table below:

Table 58.28 QUEUE PAGE READ Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H’37	H’07	—	—	SEQ_22_ID

(22) TWO PLANE PAGE READ command

(a) Command Description

This command was implemented to preserve the compatibility with the ONFI 1.x and some older devices.

The TWO PLANE PAGE READ (H’00-H’00-H’30) operation is similar to the PAGE READ (H’00-H’30) operation. It transfers two pages of data from the NAND Flash array to the data registers. Each page must be from a different plane on the same die. The software is responsible for generating correct addresses for the requested pages. Both the ADDR0 and ADDR1 address registers are used in this case.

(b) Command Encoding

The TWO PLANE PAGE READ instruction uses the SEQ_15 commands sequence. The command is encoded, as shown in the table below. In this case, both the address registers are used.

Table 58.29 TWO PLANE PAGE READ Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
H’30	H’00	H’00	0/1	0/1	SEQ_15_ID

(23) PROGRAM PAGE Command

(a) Command Description

The PROGRAM PAGE command allows the application program to input data to a cache register and moves the data from the cache register to the specified block and page address in the array of the selected LUN. This command is accepted by the LUN when it is ready. To input a page to the cache register and move it to the NAND array at the block and page address specified, the controller writes H’80 to the target internal command register. Then five address cycles containing the column address and row address are written. Data input cycles follow. Serial data is input, beginning at the column address specified. When data input is complete, the controller writes H’10 to the target internal command register. The selected LUN goes into the busy state.

(b) Command Encoding

The PROGRAM PAGE instruction uses the SEQ_12 commands sequence. The command is encoded, as shown in the table below:

Table 58.30 PROGRAM PAGE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H’10	H’80	0	0/1	SEQ_12_ID

(24) PROGRAM PAGE IMMEDIATE Command

(a) Command Description

The PROGRAM PAGE IMMEDIATE command allows the application program to input data to a cache register and moves the data from the cache register to the specified block and page address in the array of the selected LUN. This command is accepted by the LUN when it is ready. To input a page to the cache register and move it to the NAND array at the block and page address specified, the controller writes H’80 to the target internal command register. Then five address cycles containing the column address and row address are written. Data input cycles follow. Serial data is input, beginning at the column address specified. When data input is complete, the controller writes H’10 to the target internal command register. The selected LUN goes into the busy state. This command writes only the row address to the NAND flash device

(b) Command Encoding

The PROGRAM PAGE IMMEDIATE instruction uses the SEQ_23 commands sequence. The command is encoded, as shown in the table below:

Table 58.31 PROGRAM PAGE IMD Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H’10	H’80	0	0/1	SEQ_23_ID

(25) PROGRAM PAGE DELAYED Command

(a) Command Description

The device's internal controller can automatically manage multi-plane programming. It does this with PROGRAM PAGE DELAYED command. When this command issued, the controller will delay issuing the program operation to the array until the address for the subsequent program operation is examined. If that operation allows the previous operation to complete as part of multi-plane operation, the controller will issue a multi-plane program to the array. Multi-plane operations are only completed if an LUN address from plane 0 is issued prior to a LUN address from plane 1. If the subsequent program operation does not allow the multi-plane operation, the controller will immediately start the previous program. It is presumed that the application program may use this command to initiate all the program operations. In this way the application program does not have to maintain information regarding multi-plane operation usage.

(b) Command Encoding

The PROGRAM PAGE DELAY instruction uses the SEQ_12 commands sequence. The command is encoded, as shown in the table below:

Table 58.32 PROGRAM PAGE DELAY Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H’13	H’80	0	0/1	SEQ_23_ID

(26) PROGRAM PAGE 1 Command

(a) Command Description

The PROGRAM PAGE 1 command allows the application program to input data to a cache register and moves the data from the cache register to the specified block and page address in the array of the selected LUN. This command is accepted by the LUN when it is ready. To input a page to the cache register and move it to the NAND array at the block and page address specified, the controller writes H’80 to the target internal command register. Then five address cycles containing the column address and row address are written. Data input cycles follow. Serial data is input, beginning at the column address specified. When data input is complete, the commands sequence ends.

(b) Command Encoding

The PROGRAM PAGE 1 instruction uses the SEQ_13 commands sequence. The command is encoded, as shown in the table below:

Table 58.33 PROGRAM PAGE 1 Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H’80	0	0/1	SEQ_13_ID

(27) PROGRAM PAGE CACHE Command

(a) Command Description

The PROGRAM PAGE CACHE command allows the controller to input data to a cache register, copies the data from the cache register to the data register, and then moves the data register contents to the specified block and page address in the array of the selected LUN. After the data is copied to the data register, the cache register is available for additional PROGRAM PAGE CACHE or PROGRAM PAGE commands. The PROGRAM PAGE CACHE command is accepted by the LUN when it is ready.

To input a page to the cache register to move it to the NAND array at the block and page address specified, the controller writes H’80 to the target internal command register. Then five address cycles containing the column address and row address are written. Data input cycles follow. Serial data is input, beginning at the column address specified. When data input is complete, H’15 is written to the command register. The selected LUN goes into busy state to allow the data register to become available from a previous program cache operation, to copy data from the cache register to the data register, and then to begin moving the data register contents to the specified page and block address.

(b) Command Encoding

The PROGRAM PAGE CACHE instruction uses the SEQ_12 commands sequence. Command is encoded as shown in the table below.

Table 58.34 PROGRAM PAGE CACHE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H’15	H’80	0	0/1	SEQ_12_ID

(28) PROGRAM MULTIPLANE Command

(a) Command Description

The PROGRAM MULTIPLANE command allows the controller to input data to the addressed plane’s cache register and queue the cache register to ultimately be moved to the NAND array. This command can be issued one or more times. Each time a new plane address is specified that plane is also queued for data transfer. This command is accepted by the LUN when it is ready. The controller writes H’80 to the target internal command register. Then five address cycles containing the column address and row address are written. Data input cycles follow. Serial data is input beginning at the column address specified. When data input is complete, the controller writes H’11 to the target internal command register.

(b) Command Encoding

The PROGRAM PAGE CACHE instruction uses the SEQ_12 commands sequence. Command is encoded as shown in the table below.

Table 58.35 PROGRAM MULTIPLANE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H’11	H’80	0	0/1	SEQ_12_ID

(29) WRITE PAGE Command

(a) Command Description

The WRITE PAGE command allows the controller to move data from the targets cache register to the NAND array. This command is accepted by the LUN when it is ready. The controller writes H'10 to the target internal command register.

(b) Command Encoding

The WRITE PAGE instruction uses the SEQ_0 commands sequence. The command is encoded, as shown in the table below:

Table 58.36 WRITE PAGE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'10	—	—	SEQ_0_ID

(30) WRITE PAGE CACHE Command

(a) Command Description

The WRITE PAGE CACHE command allows the controller to move data from the targets cache register to the targets data register. This command is accepted by the LUN when it is ready. The controller writes H'15 to the target internal command register.

(b) Command Encoding

The WRITE PAGE CACHE instruction uses the SEQ_0 commands sequence. The command is encoded, as shown in the table below:

Table 58.37 WRITE PAGE CACHE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'15	—	—	SEQ_0_ID

(31) WRITE MULTIPLANE Command

(a) Command Description

The WRITE MULTIPLANE command allows the controller to queue data from the targets cache register to the NAND array. This command is accepted by the LUN when it is ready. The controller writes H'11 to the target internal command register.

(b) Command Encoding

The WRITE MULTIPLANE instruction uses the SEQ_0 commands sequence. The command is encoded, as shown in the table below:

Table 58.38 WRITE MULTIPLANE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'11	—	—	SEQ_0_ID

(32) ERASE BLOCK Command

(a) Command Description

The ERASE BLOCK command erases the specified block in the NAND array. This command is accepted by the LUN when it is ready. To erase a block, the controller writes H’60 to the target internal command register. Then three address cycles containing the row address are written; the column address is ignored. Finally, H’D0 is written to the target internal command register.

(b) Command Encoding

The ERASE BLOCK instruction uses the SEQ_14 commands sequence. The command is encoded, as shown in the table below:

Table 58.39 ERASE BLOCK Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H’D0	H’60	—	—	SEQ_14_ID

(33) ERASE MULTIPLANE Command

(a) Command Description

The ERASE MULTIPLANE command queues a block in the specified plane to be erased from the NAND array. This command can be issued one or more times. Each time a new plane address is specified, that plane is also queued for a block to be erased. This command is accepted by the LUN when it is ready. To queue a block to be erased, the controller writes H’60 to the command register.

Then three address cycles containing the row address are written; the column address is ignored.

Finally, H’D1 is written to the command register.

(b) Command Encoding

The ERASE MULTIPLANE instruction uses the SEQ_14 commands sequence. The command is encoded, as shown in the table below:

Table 58.40 ERASE MULTIPLANE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H’D1	H’60	—	—	SEQ_14_ID

(34) COPYBACK READ Command

(a) Command Description

The COPYBACK READ command is functionally identical to the READ PAGE command, except that H’35 is written to the target internal command register instead of H’30. For more details, see section 58.3.3 (17), READ PAGE Command.

(b) Command Encoding

The COPYBACK READ instruction uses the SEQ_10 commands sequence. The command is encoded, as shown in the table below:

Table 58.41 COPYBACK READ Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
H'35	—	H'00	0/1	0/1	SEQ_10_ID

(35) COPYBACK PROGRAM Command

(a) Command Description

The Copyback function reads a page of data from one location and then moves that data to a second location. The COPYBACK PROGRAM command is functionally identical to the PROGRAM PAGE command, except that when H'85 is written to the target internal command register, the cache register contents are not cleared. The SEQ_9 command sequence does not have the data phase, so the data from the cache register are written into the second location without modification. If data must be written with modification to the second location, the SEQ_12 command sequence, which includes the data phase, is used.

(b) Command Encoding

The COPYBACK PROGRAM instruction uses the SEQ_9 commands sequence. The command is encoded, as shown in the table below:

Table 58.42 COPYBACK PROGRAM Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H'10	H'85	—	—	SEQ_9_ID

(36) COPYBACK PROGRAM 1 Command

(a) Command Description

The COPYBACK PROGRAM 1 command is functionally identical to the PROGRAM PAGE 1 command, except that when H'85 is written to the target internal command register, the cache register contents are not cleared. See section 58. 3.3 (26), PROGRAM PAGE 1 Command for further details.

(b) Command Encoding

The COPYBACK PROGRAM 1 instruction uses the SEQ_13 commands sequence. The command is encoded as shown in the table below:

Table 58.43 COPYBACK PROGRAM 1 Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	—	H'85	0	—	SEQ_13_ID

(37) COPYBACK MULTIPLANE Command

(a) Command Description

The COPYBACK MULTIPLANE command is functionally identical to the PROGRAM MULTIPLANE command, except that when H'85 is written to the target internal command register, cache register contents are not cleared. See section 58. 3.3 (28), PROGRAM MULTIPLANE Command for further details.

(b) Command Encoding

The COPYBACK MULTIPLANE instruction uses the SEQ_12 commands sequence. The command is encoded, as shown in the table below:

Table 58.44 COPYBACK MULTIPLANE Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H'11	H'85	0	0/1	SEQ_12_ID

(38) PROGRAM OTP Command

(a) Command Description

The PROGRAM OTP command is used to write data to the pages within the OTP area. An entire page can be programmed at one time, or a page can be partially programmed up to four times. There is no ERASE operation for the OTP pages. To use the PROGRAM OTP command, the controller issues the H'A0 command. Next, 5 address cycles are issued. The address write is followed by a programmable number of data cycles. After data input is complete, the controller issues the H'10 command. The internal control logic automatically executes the proper programming algorithm and controls the necessary timing for programming and verification.

(b) Command Encoding

The PROGRAM OTP instruction uses the SEQ_12 commands sequence. The command is encoded as shown in the table below:

Table 58.45 PROGRAM OTP Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H'10	H'A0	0	0/1	SEQ_12_ID

(39) DATA PROTECT OTP Command

(a) Command Description

The DATA PROTECT OTP command is used to protect all the data in the OTP area. After the data is protected. it cannot be further programmed. When the OTP area is protected, the pages within the area are no longer programmable and cannot be unprotected. To use the DATA PROTECT OTP command, the controller issues the H'A5 command. Next, the controller issues the following 5 addresses cycles.

Finally, the H'10 command is issued.

(b) Command Encoding

The DATA PROTECT OTP instruction uses the SEQ_9 commands sequence. The command is encoded, as shown in the table below:

Table 58.46 DATA PROTECT OTP Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
—	H'10	H'A5	—	—	SEQ_9_ID

(40) PAGE READ OTP Command

(a) Command Description

The PAGE READ OTP command is used to read data from a page within the OTP area. An OTP page within the OTP area is available for reading data whether or not the area is protected. To use the PAGE READ OTP command, the controller issues the H'AF command. Next, 5 address cycles are issued.

Finally, the H'30 command is issued. After internal read from the NAND matrix is ended, the data is copied to the FIFO.

(b) Command Encoding

The PAGE READ OTP instruction uses the SEQ_9 commands sequence. The command is encoded, as shown in the table below:

Table 58.47 PAGE READ OTP Instruction Encoding

CMD_2	CMD_1/CMD_3	CMD_0	DATA_SEL	INPUT_SEL	CMD_SEQ
H'30	—	H'AF	0/1	0/1	SEQ_10_ID

58.3.4 Multi LUN Work Mode

The multi LUN work mode is enabled by setting the MLUN_EN bit in the CONTROL register. In this mode, each LUN is handled as separate target. The active LUN number is decoded directly from the address value.

This multi LUN mode is parameterized by the following parameters:

The LUN_IDX field in the MLUN register. This parameter provides the bits index for the last address byte where the LUN select bits is present. This parameter must be set according to the NAND Flash device datasheet in use.

The LUN_SEL bits in MLUN register is used to configure the number of LUN-s per device.

The LUN STATUS 0 and 1 holds the LUN-s statuses, each bit correspond to the single LUN status.

The STATE_MASK field in the STAT_RSP register. This parameter is used to mask the part of the LUN status byte that will be ignored during the LUN ready/busy check.

58.3.5 Remapping Mechanism

The remapping mechanism supports the bad blocks management (BBM) solution. The hardware remapping mechanism relieves software from the time-consuming operations of finding the physical address for the given linear address in the requested operation. The software initializes only the remapping tables for uses in the application of the NAND Flash device. It sorts those tables in ascending order, and then the whole operation of searching tables and substituting addresses is accomplished automatically.

The remapping solution uses two groups of the control registers:

- The pointer register DEV0_PTR. This register stores the address in the internal memory where record tables used by the BBM mechanism are placed.
- The size register DEV0_SIZE. This register stores the number of records in a table.

Note for Figure 58.31:

Block Number are written to Destination Address and Source Address.

The table have to set by ascending order of Source Address.

When some Address of one record is unused, these Address should filled by H’FFFF_FFFF.

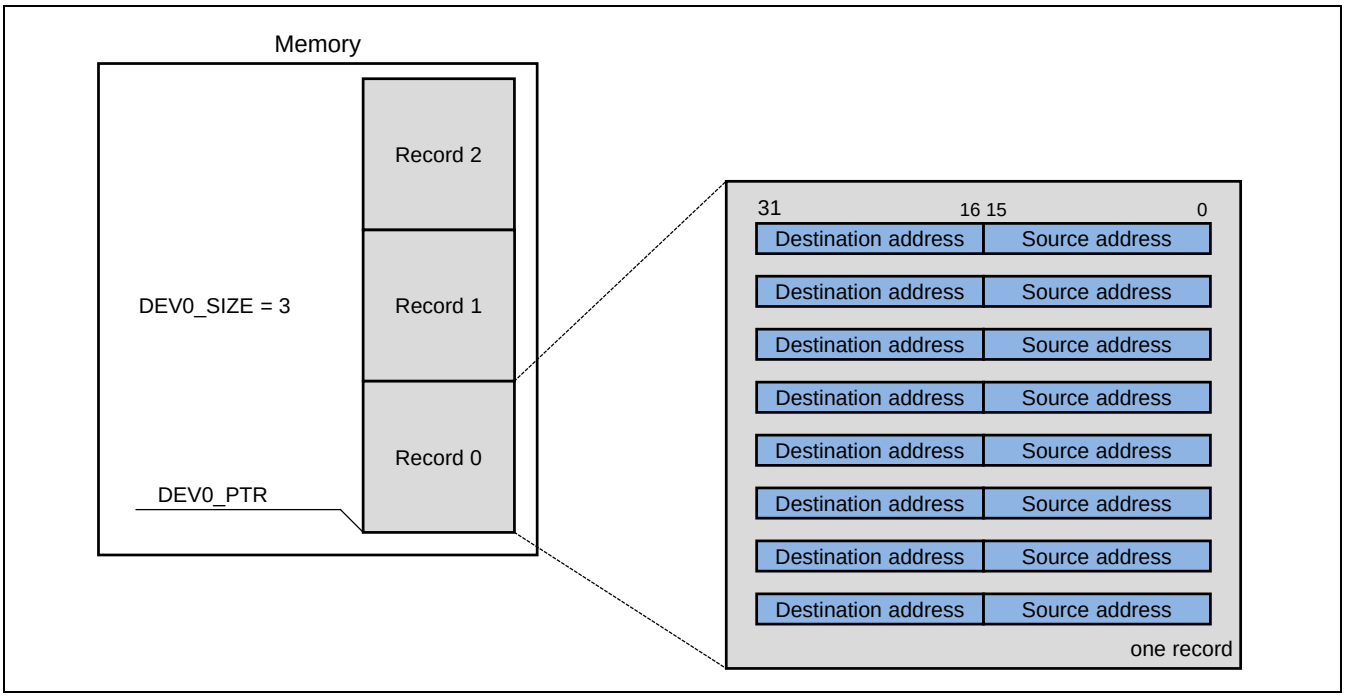

Figure 58.31 Example of BBM records

58.3.6 Interrupts Mechanism

The NAND Flash controller interrupt system uses two control registers:

The interrupt mask register – each bit of this register masks a single interrupt. The register is described in more detail in section 58.2.6, Interrupts mask register (INT_MASK).

The interrupt flag register – each bit of this register is an active flag from the single interrupt source.

The register is described in more detail in section 58.2.7, Interrupts status register (INT_STATUS).

In case an interrupt event occurs, i.e. the respective interrupt flag in INT_STATUS is 1, and its respective mask bit in INT_MASK is 1, the interrupt signal INTNFMA is asserted.

Note that the interrupt mask bits in INT_MASK affects only the interrupt signal INTNFMA, but not the flags in INT_STATUS.

A set flag in INT_STATUS must be cleared by the application program.

The available interrupt sources and their respective INT_STATUS flags are:

INT_STATUS.CMD_END_INT_FL

Command sequence finished interrupt – This interrupt occurs when the previously triggered command sequence is finished and the new one can be started. The command sequence is marked as finished when the full sequence is executed or when the NAND Flash device goes into the busy state.

INT_STATUS.ECC_INT0_FLAG

The ECC module detects an uncorrectable error in the transmitted data.

The ECC module detects when the configured errors threshold level is exceeded.

INT_STATUS.MEM0_RDY_INT_FL

The memory device is ready – This interrupt occurs when the NAND Flash device finishes executing the programmed command sequence and is ready for the new one. Each NAND Flash device has a single interrupt flag. The difference between “command sequence finished” interrupt and “memory device is ready” interrupt is presented in Figure 58.32.

INT_STATUS.TRANS_ERR_FL

The error on the slave interface during access to the controller FIFO – This interrupt occurs if the access to the FIFO memory has the opposite direction to the current FIFO configuration: the FIFO is read when it is configured for write, or the FIFO is write when it is configured for read.

INT_STATUS.STAT_ERR_INT0_FL

Most recently finished operation on the memory device failed. This applies to PROGRAM PAGE and BLOCK ERASE operations. It is not valid following a READ-series operation.

INT_STATUS.PG_SZ_ERR_INT_FL

Data Size error flag.

When the ECC is enabled, the value written into the DATA_SIZE register has some restrictions.

Interrupt condition is met when the value written to the DATA_SIZE register is not correct.

INT_STATUS.DMA_INT_FL

DMA transfer ended flag.

INT_STATUS.DATA_REG_INT_FL

Data in DATA_REG is available

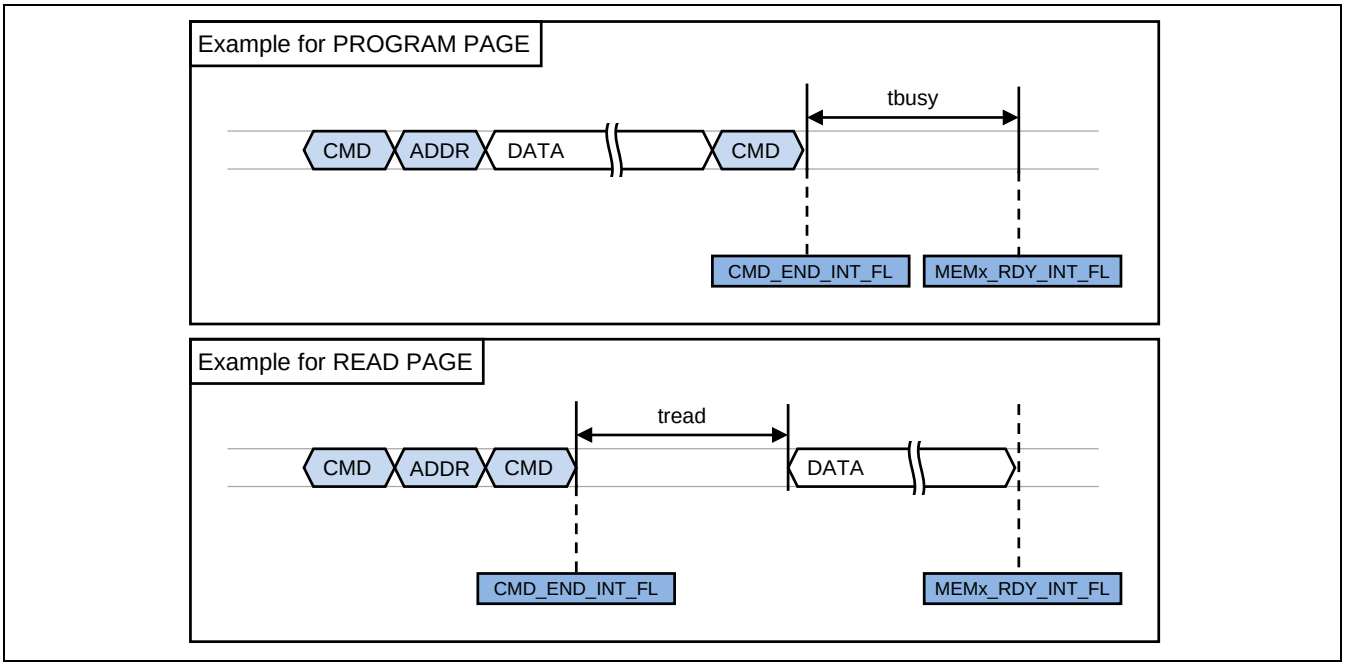

Figure 58.32 Command Sequence End and Memory-Ready Interrupts

Notes:

Interrupt is asserted before bus transaction completion.

Dedicated workaround to avoid data coherency issues needs to be implemented:

Always load additional, not used 64 byte of data in that way it is ensured that the interrupt asserted when the previous intended data was completely transferred to SDRAM.

58.3.7 Setup and Configuration

The CONTROL register is the main control register in the NAND Flash controller.

The following bits configure basic settings of the controller:

- INT_EN – Bit which enables Global Interrupt.
- ECC_EN – Bit which enables Hardware ECC.
- BLOCK_SIZE – Bits which configure block size.
- IO_WIDTH – Bit which configures width of the I/O bus connected to the NAND Flash memory device.
- BBM_EN – Bit which enables remapping process.
- ADDRx_AUTO_INCR - Addresses auto increment for row address register 0 or 1.
- SMALL_BLOCK_EN – Bit which enables Small Block Mode.
- MLUN_EN – Bit which enables Multi LUN mode.
- AUTO_READ_STAT_EN – Bit which activates automatic read status after the PROGRAM PAGE and BLOCK ERASE commands.
- READ_STATUS_EN – Bit which chooses whether the controller checks RnB lines or sends READ_STATUS commands.
- ECC_BLOCK_SIZE – Bits which define ECC Block Size.

The registers described below are configured according to the settings of other bits in the CONTROL register:

- If INT_EN bit is set, the software must write the mask into the INT_MASK register, which masks the selected interrupts source in the NAND Flash controller.
- If ECC_EN bit is set, the software must correctly configure the ECC module by writing the appropriate configuration into the ECC_CTRL. Additionally, the software configures the offset in the ECC_OFFSET register. In small block mode, the value in the ECC_OFFSET is ignored and the correction words are located in the NAND Flash memory device, right behind the data.
- The write number of the data which will be transferred by the controller (DATA_SIZE register).
  When ECC is enabled, there are some restrictions to the DATA_SIZE value.
- If the BBM_EN bit is set, the software must initialize the remapping tables (DEVn_PTR and DEVn_SIZE registers).
- Additionally, the software must configure time parameters which can be found in the TIMINGS_ASYN register. Additionally, the software must configure the TIME_SEQ_0 and TIME_SEQ_1 registers.

When the NAND Flash controller uses DMA to transfer data, the software must configure the DMA_ADDR, DMA_CTRL and DMA_CNT registers. The software can modify these registers before any transfer or during the initialization procedure.

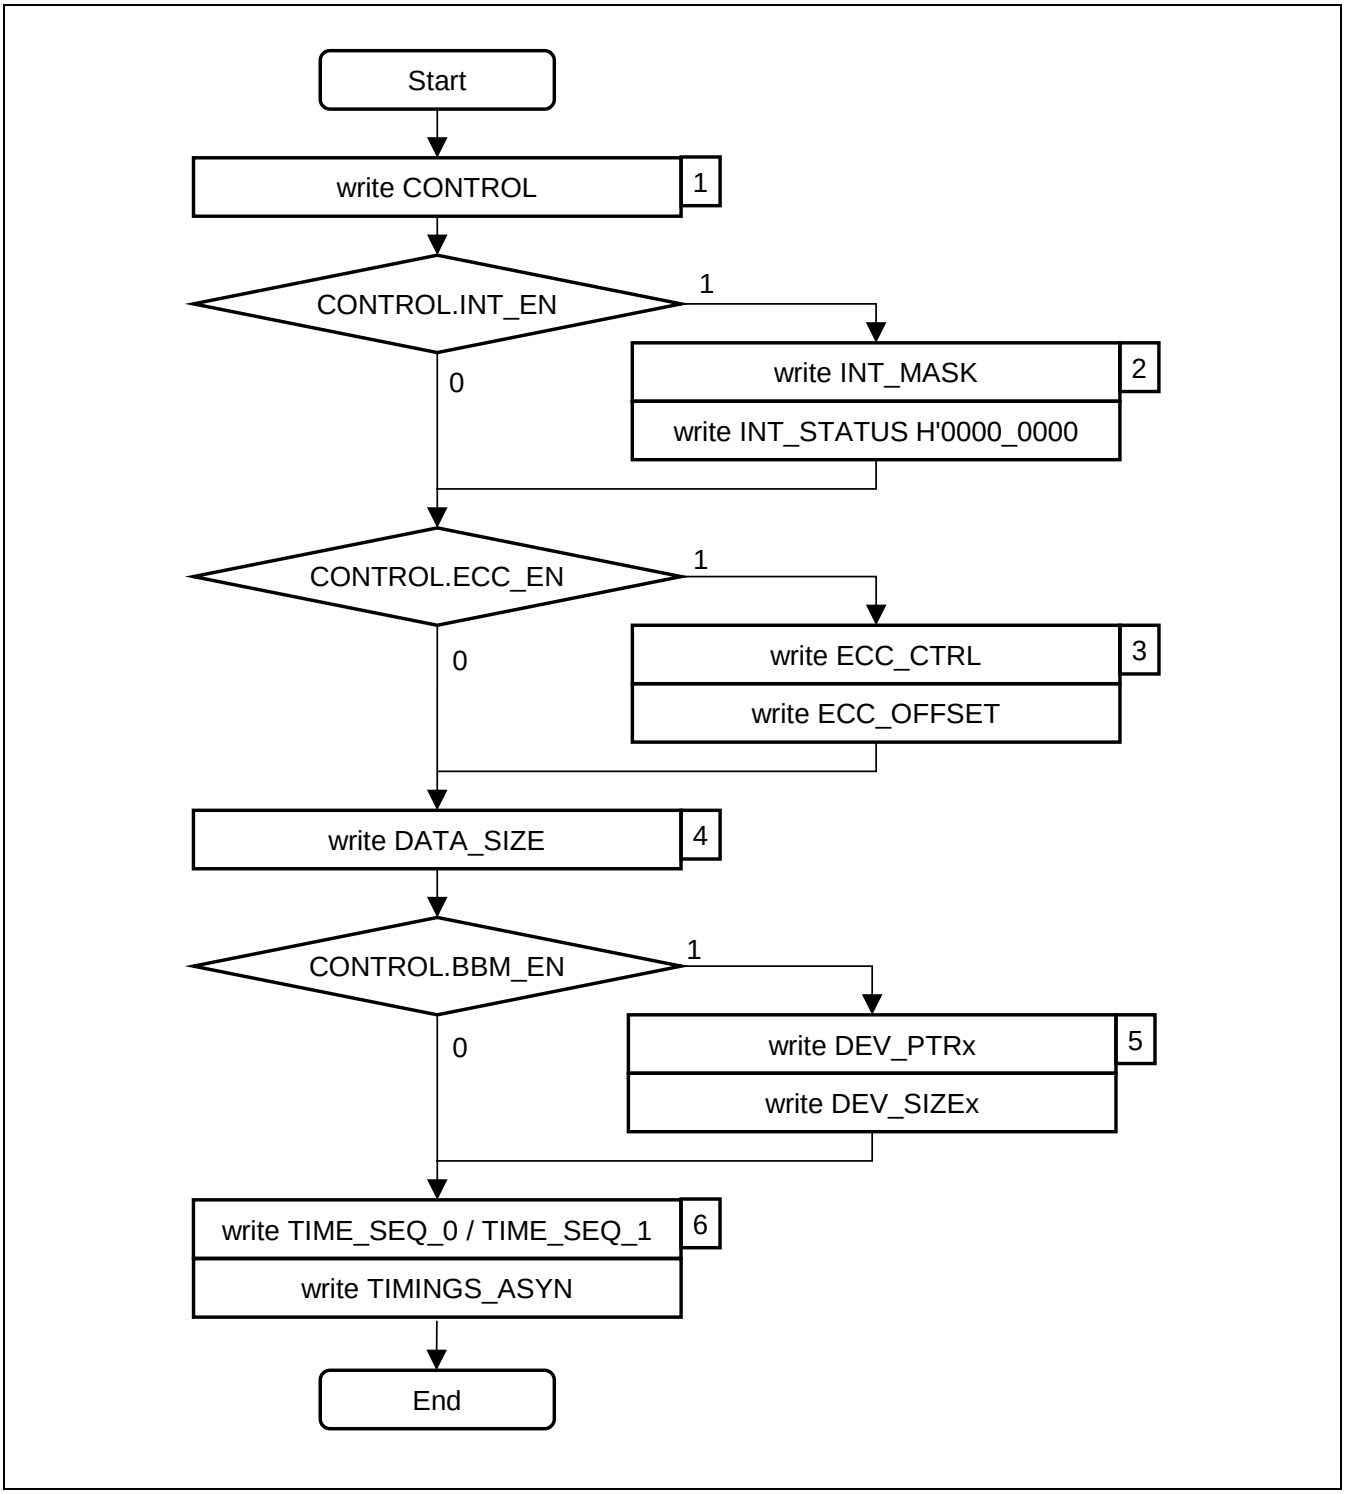

Figure 58.33 Configuration

(1) Send Data to NAND Flash via Slave Interface

The NAND Flash controller must be correctly configured before sending data to the NAND Flash memory device. The setup process is described in detail in section 58.3.7, Setup and Configuration and section 58.2, Register Descriptions.

1. Write the address of the data in NAND Flash memory into the address register 0 (ADDR_COL and ADDR_ROW registers). Write the number of data which you want to read (DATA_SIZE register).
2. To use the simplest program command, write H'0010_800C to the COMMAND register (PROGRAM PAGE command, FIFO module selected, registers as input).
3. Write data to the FIFO using the FIFO_DATA register. Data is sent to the NAND Flash memory device.

When the memory is ready for further work, the appropriate bit MEMx_ST is set. When the software needs to send the command to another memory, it is not necessary to wait for the MEMx_ST bit to be set.

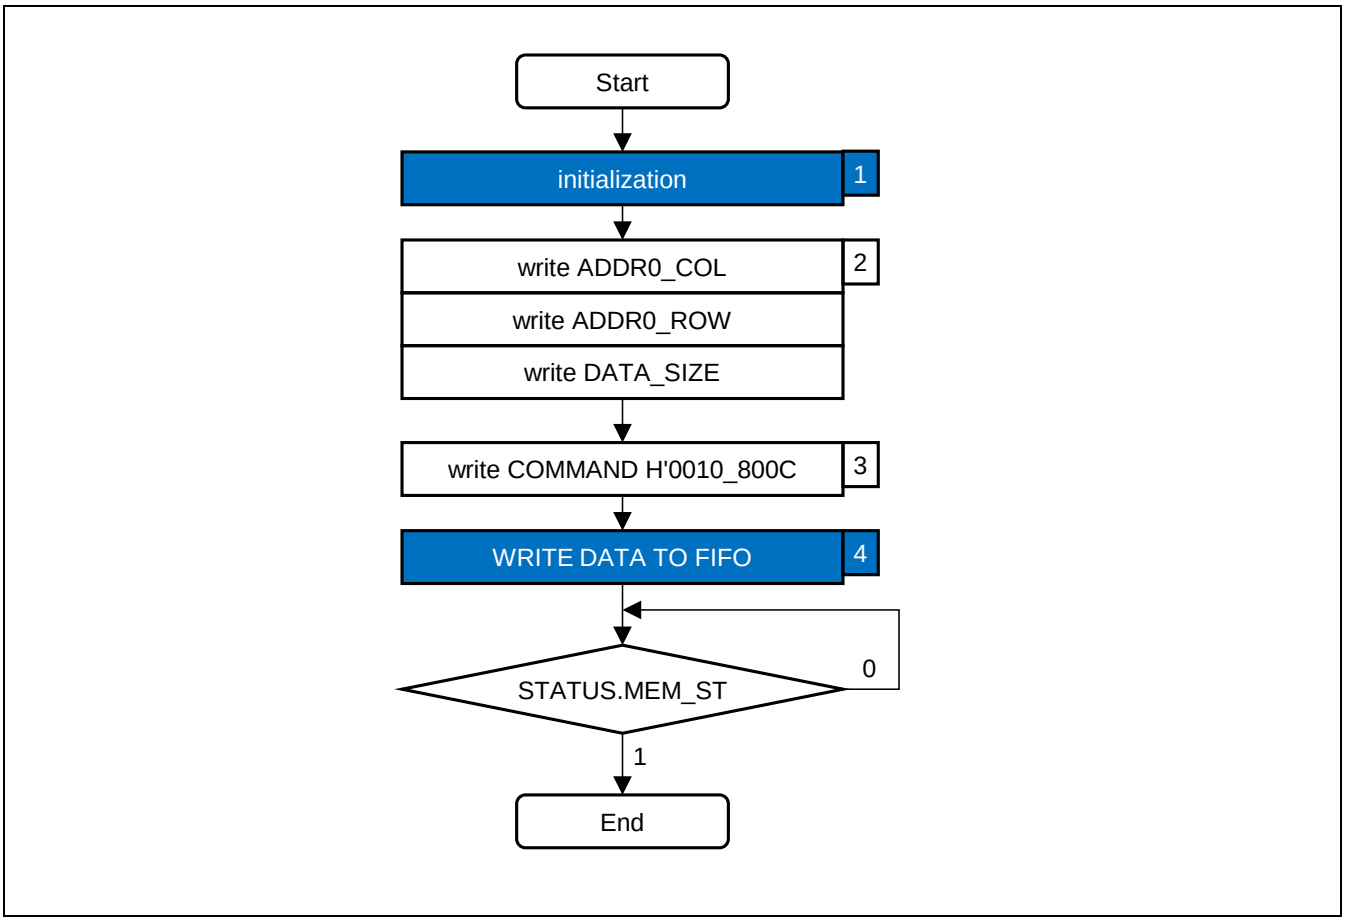

Figure 58.34 Write data to NAND Flash memory via Slave Interface

(2) Read Data from NAND Flash via Slave Interface

1. The NAND Flash controller must be correctly configured before sending data to the NAND Flash memory device. The setup process is described in detail in section 58.3.7, Setup and Configuration and section 58.2, Register Descriptions.
2. Write the address of the data in NAND Flash memory into the address register 0 (ADDR_COL and ADDR_ROW registers).
3. To use the simplest read command, write H'3000_002A to the COMMAND register (READ PAGE command, FIFO module selected, registers as input).
4. The application program can read data immediately after sending the command but in this case the NAND flash controller will send a very few WAIT replies.

   If this situation shall be avoided the application program must read FIFO_STATE register and wait when CF_EMPTY bit is set. After that wait for the DF_R_EMPTY bit in the FIFO_STATE register to be clear.
5. Read data from the FIFO using the FIFO_DATA register.

When the memory is ready for further work, the appropriate bit MEMx_ST is set. When the software needs to send the command to another memory, it is not necessary to wait for the MEMx_ST bit to be set.

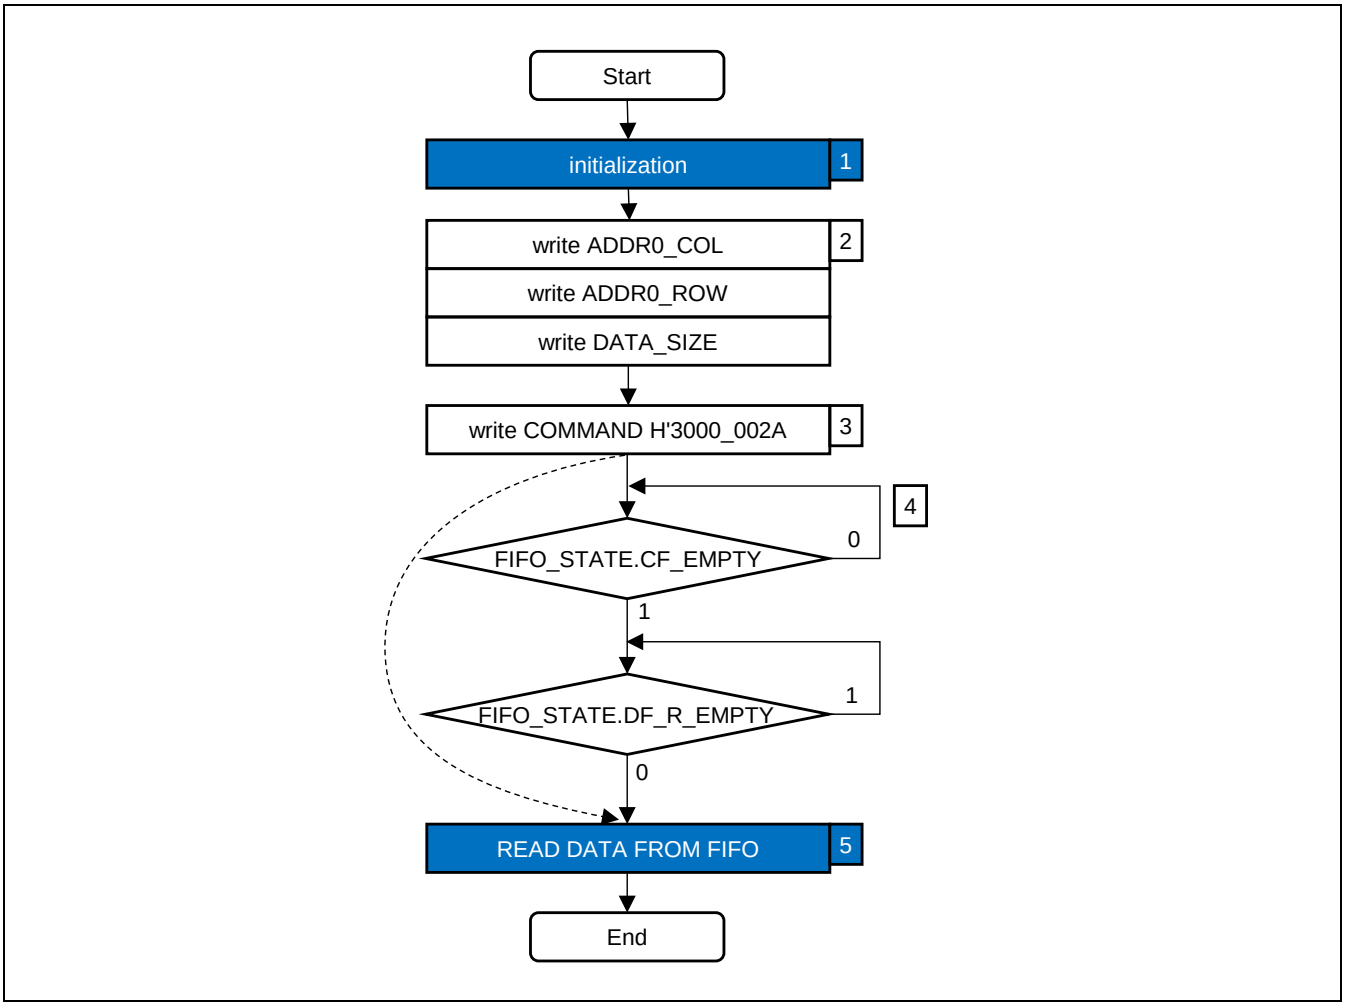

Figure 58.35 Read data from NAND Flash memory via Slave Interface

(3) Send Data to NAND Flash via Master Interface (using DMA)

1. The NAND Flash controller must be correctly configured before sending data to the NAND Flash memory device. The setup process is described in detail in section 58.3.7, Setup and Configuration and section 58.2, Register Descriptions.
2. Set the INT_EN bit in the CONTROL register to enable global interrupt.
3. Select active interrupt in the INT_MASK register and write H’0000_0000 into the INT_STATUS register to clear all interrupts.
4. Select the DMA work mode to configure the DMA module correctly:
   In registers managed mode, the address of the data is written in the system memory (DMA_ADDR_L registers). Write the number of the transferred data into the DMA_CNT register. Set bit DMA_START to start DMA when the command sequence is sent to the NAND Flash memory. Bits ERR_FLAG and DMA_READY are read-only. The first indicates the error on the internal bus while DMA is transferring data; the second indicates when DMA is ready (transfer is completed).
5. Write the address of the data in the NAND Flash memory device into the address register 0.
6. To use the simplest program command, write H’0010_804C to the COMMAND register (PROGRAM PAGE command, FIFO module selected, DMA module as input).
7. When the memory is ready for further work, the appropriate bit MEMx_ST is set and interrupt is active. (recommended interrupt is MEM0_RDY_INT)

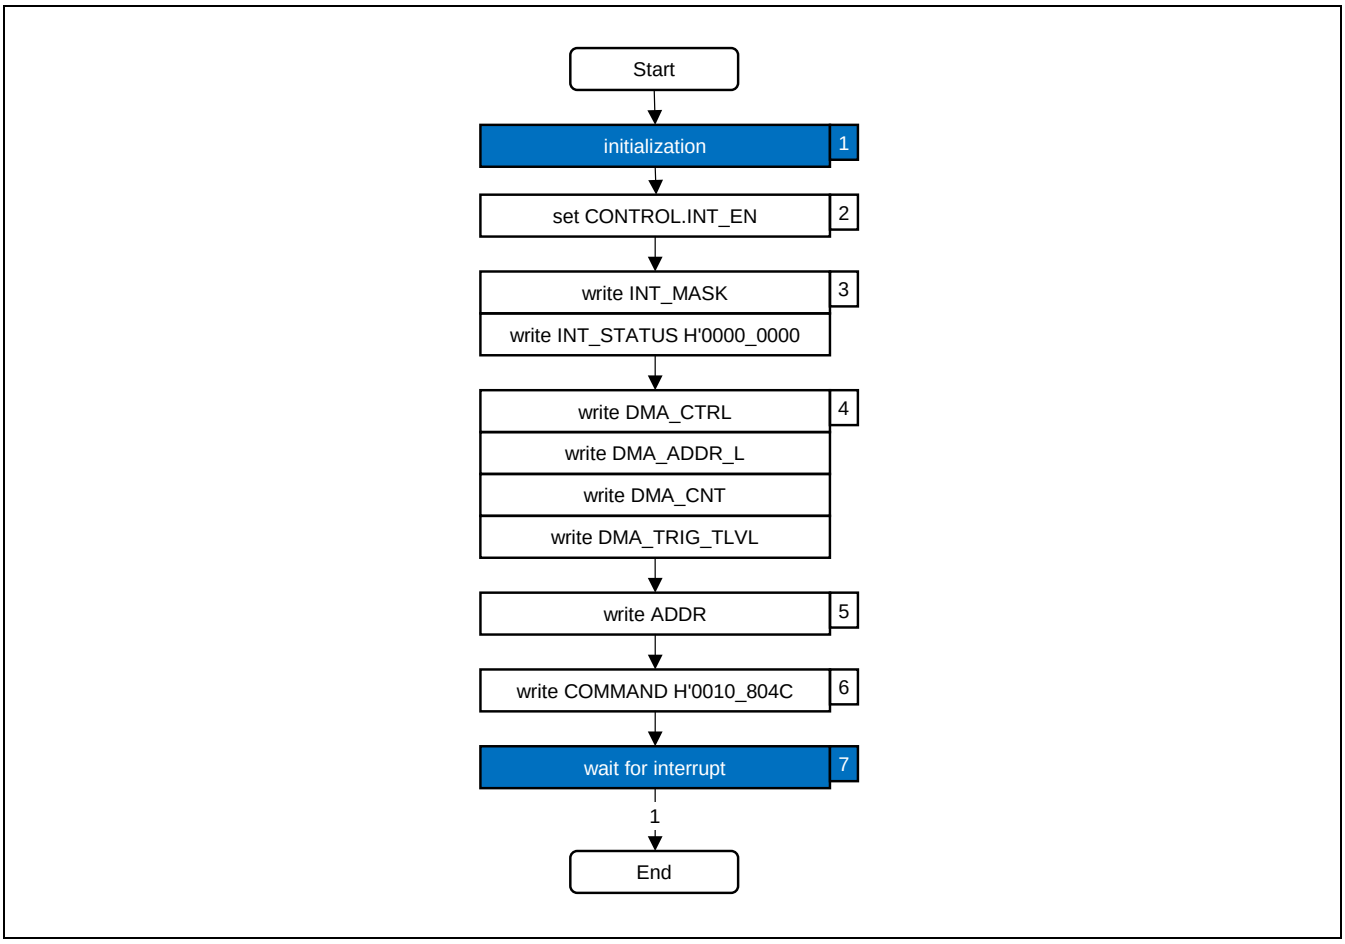

Figure 58.36 Send Data to NAND Flash Using DMA, Interrupt Enable

(4) Fast Writing and Reading of Several Pages from the Memory using DMA

1. The NAND Flash controller must be correctly configured before sending data to the NAND Flash memory device. The setup process is described in detail in section58.3.7, Setup and Configuration and section58.2, Register Descriptions.
2. Set INT_EN bit in CONTROL register to enable global interrupt.
3. Select the active interrupt (CMD_END_INT_EN) in the INT_MASK register and write H'0000_0000 into the INT_STATUS register to clear all interrupts.
4. In Scatter-Gather mode, it is necessary to write the descriptors into the system memory. Select the DMA work mode to correctly configure the DMA module.In Scatter-Gather mode, it is not necessary to configure the DMA_CNT register. For more details, see section 58.4.2 (2), DMA Description, (b)
5. Set DMA_START bit to start the DMA when the command sequence is sent to the NAND Flash memory.Bits ERR_FLAG and DMA_READY are read-only. The former indicates the error on the internal bus while DMA is transferring data, the latter indicates when the DMA is ready (transfer is completed).
6. Set the ADDR0_INCR bit to auto increment row address 0 register after each command. Write address of the data in the NAND Flash memory device into the 0 address register.
7. Write H'0000_0000 into the INT_STATUS register to clear all interrupts.
8. Write address of the first descriptor into the DMA_ADDR_L registers.
9. Write PROGRAM PAGE CACHE command to the NAND Flash memory device by writing H'0015_804C into the COMMAND register (DMA module as input, FIFO module selected). When the controller is ready for further work, the appropriate CMD_END_INT_FL bit is set and the interrupt is activated.
10. When the number of the pages to transfer does not equal one, go to step 7 of this procedure.
11. Write H'0000_0000 into the INT_STATUS register to clear all interrupts.
    Write address of the first descriptor into the DMA_ADDR_L register.
    The last command in the sequence of sending data is the PROGRAM PAGE(write H'0010_804C) into the COMMAND register (DMA module as input,FIFO module selected).
12. Wait for interrupts and write H'0000_0000 into the INT_STATUS register to clear all interrupts.
    Write the address of the read data to the NAND Flash memory device into address register 0.
13. Write the new descriptors to the system memory.
14. If DMA should work in the same work mode and burst type do not modify DMA_BURST and DMA_MODE bits. Set DMA_START bit to start DMA when the command sequence is sent to the NAND Flash memory.
15. Write the READ PAGE command into the NAND Flash memory device by writing H'3000_0069 into the COMMAND register (FIFO module selected, DMA module as input).
16. Write H'0000_0000 into the INT_STATUS register to clear all interrupts.
17. Write the address of the first descriptor to the DMA_ADDR_L registers.
18. Write READ PAGE CACHE SEQUENTIAL command to the NAND Flash memory device by writing H'0000_316B into the COMMAND register (FIFO module selected, DMA module as input).
19. When the controller is ready for further work, the appropriate CMD_END_INT_FL bit is set and the interrupt is activated.When the number of the pages to transfer does not equal zero, go to step 16 of this procedure.
20. Write H'0000_0000 into the INT_STATUS register to clear all interrupts.Write the address of the first descriptor to the DMA_ADDR_L register.The last command in the sequence of reading data is READ PAGE CACHE LAST (write H'0000_3F6B into the COMMAND register).

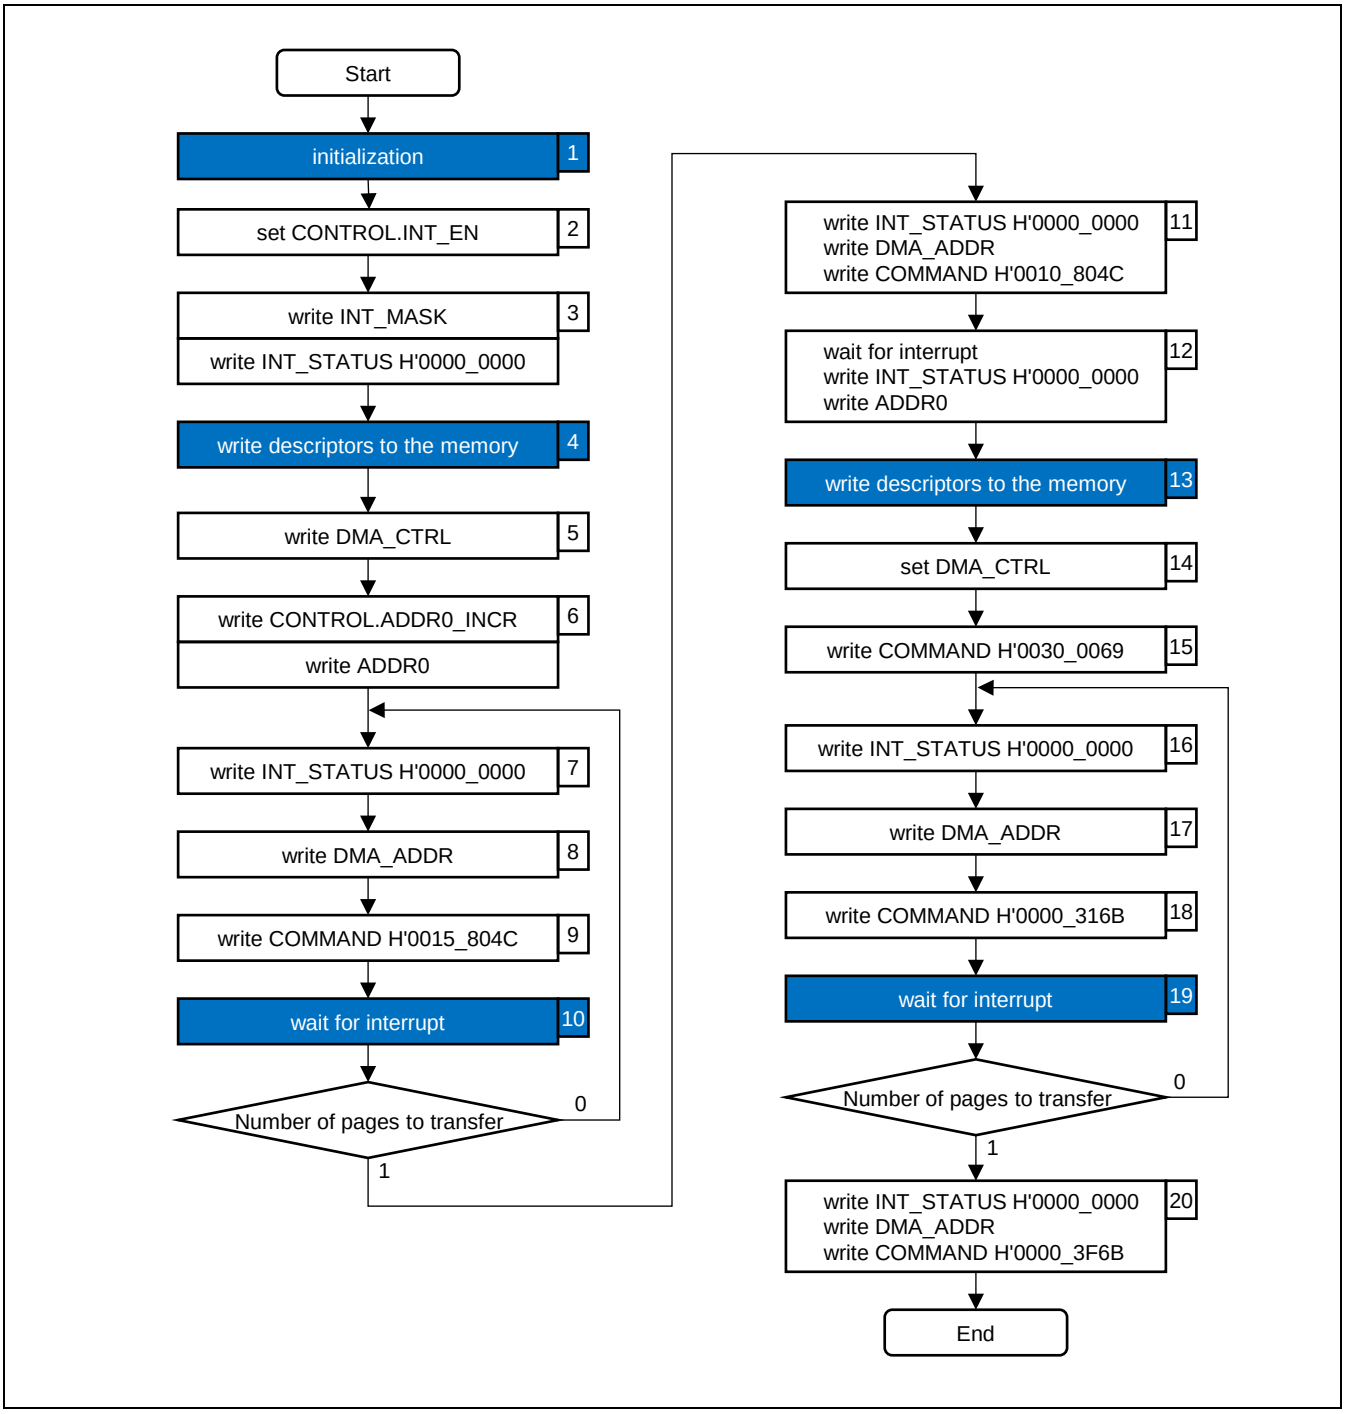

Figure 58.37 Fast Writing and Reading of Several Pages from the Memory Using DMA

(5) Writing Partial Pages

The following procedure need to be used to write partial pages with ECC engine enabled:

1. The NAND Flash controller must be correctly configured before sending data to the NAND Flash memory device. The setup process is described in detail in section 58.3.7, Setup and Configuration and section 58.2, Register Descriptions.
2. Write the address of the data in NAND Flash memory into the address register 0 (ADDR_COL and ADDR_ROW registers). You need to write partial page offset into the ADDR_COL register. Write the number of data which you want to read (DATA_SIZE register) – in this case you need to set partial sector size. Write the offset value of the ecc data into the ECC_OFFSET register.
3. To use the simplest program command, write H’0010_800C to the COMMAND register (PROGRAM PAGE command, FIFO module selected, registers as input).
4. Write data to the FIFO using the FIFO_DATA register. Data is sent to the NAND Flash memory device.

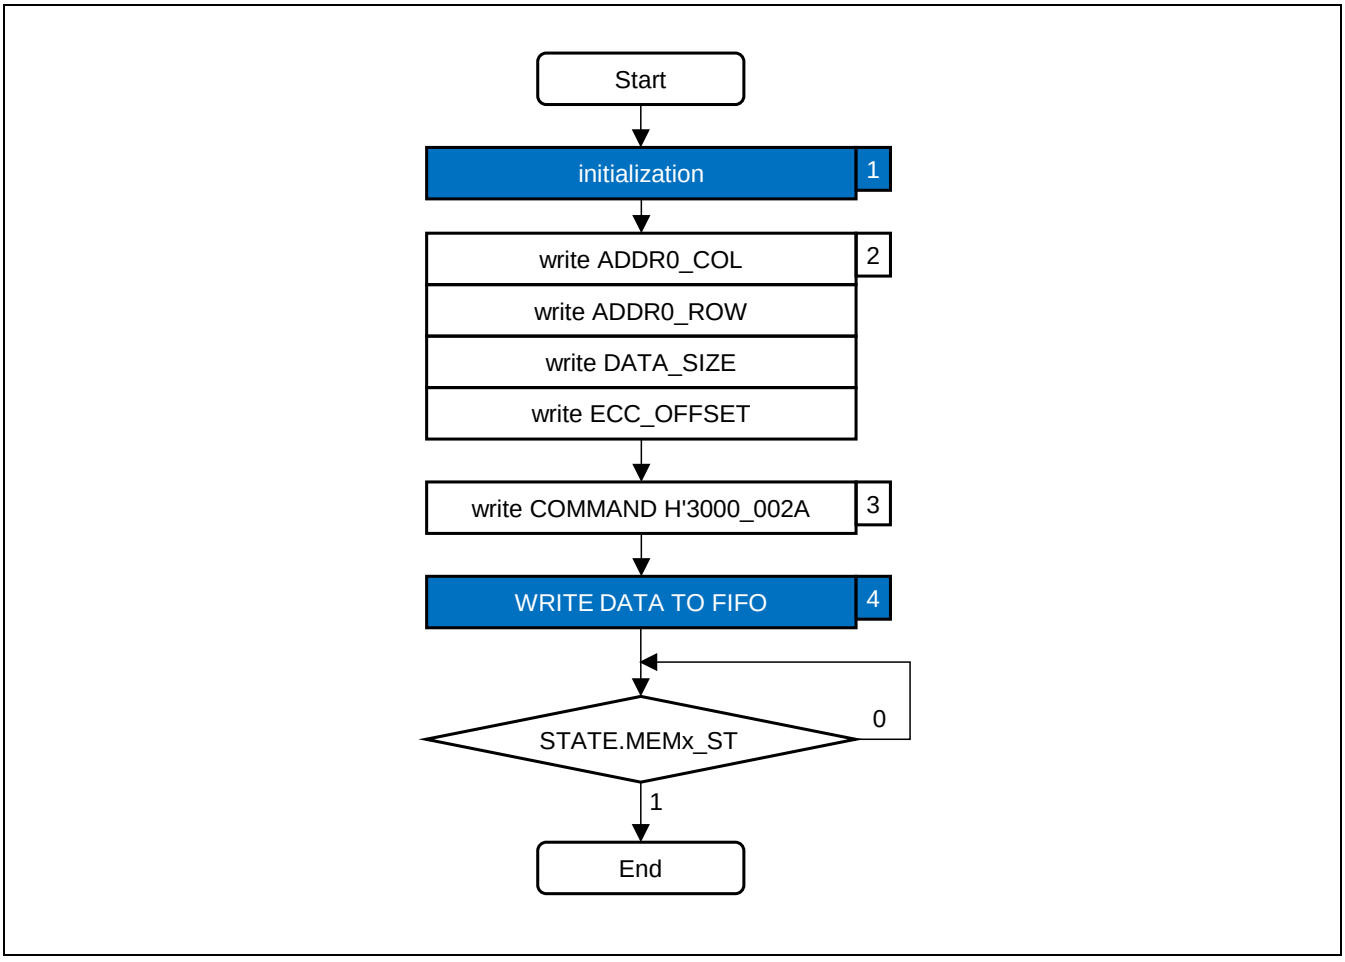

Figure 58.38 Writing Partial Pages

(6) Reading Partial Pages

1. The NAND Flash controller must be correctly configured before sending data to the NAND Flash memory device. The setup process is described in detail in section 58.3.7, Setup and Configuration and section 58.2, Register Descriptions.
2. Write the address of the data in NAND Flash memory into the address register 0 (ADDR_COL and ADDR_ROW registers). You need to write partial page offset into the ADDR_COL register. Write the number of data which you want to read (DATA_SIZE register) – in this case you need to set partial page size.
3. To use the simplest read command, write H'3000_002A to the COMMAND register (READ PAGE command, FIFO module selected, registers as input).
4. You can read data immediately after sending the command but in this case the NAND flash controller will send a very few WAIT replies. If this situation shall be avoided the application program must read FIFO_STATE register and wait when CF_EMPTY bit is set. After that wait for the DF_R_EMPTY bit in the FIFO_STATE register to be clear.
5. Read data from the FIFO using the FIFO_DATA register.

58.4.1 Block Diagram

The figure below shows the NAND Flash controller block diagram.

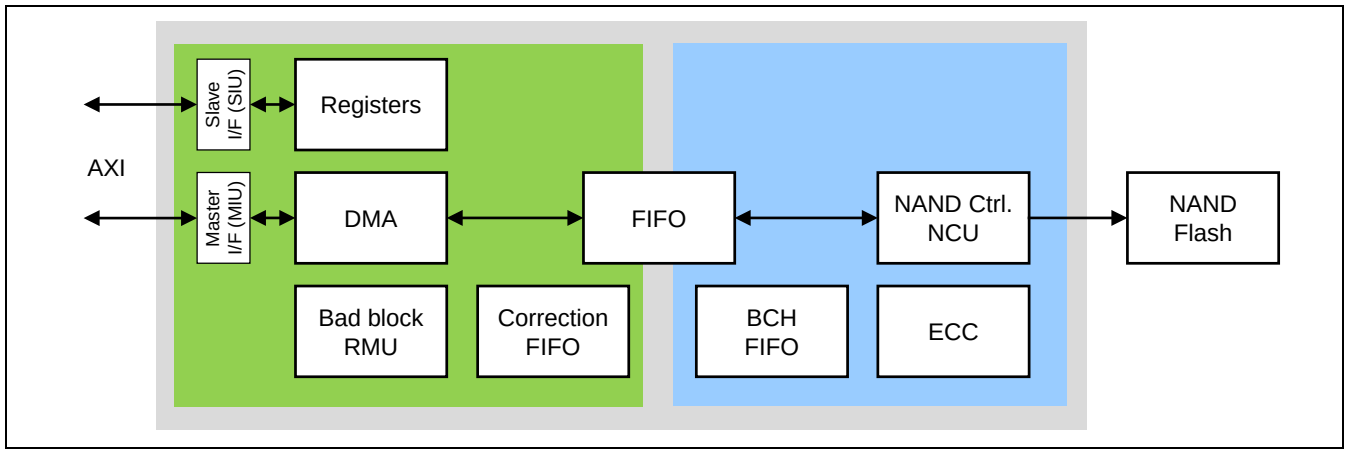

Figure 58.40 Block Diagram

The main components of the controller are:

- **FIFO** – This unit provides the FIFO queue interface to the other controller modules. Using the FIFO interface allows closing of the read and write pointers in the same module; thus, two modules can read and write in parallel. Depending on the controller software configuration, one side of the queue is the SIU or DMA module, the second one is always the NAND Control Unit (NCU).
- **DMA** – This unit is responsible for the fast transfer of data between the external memory location and the controller. The unit can works in two modes: the Scatter-Gather mode and the internally triggered single mode. DMA functions as the master side of the OCP socket. This block is optional and can be disabled during the compile process.
- **NAND control unit (NCU)** – This unit is responsible for the generation of the NAND Flash device access sequences.
- **ECC** – An error correction code calculator. A correction word is calculated for each 256B, 512B or 1024B ECC block of the NAND Flash memory page. During the read operation, the unit can automatically correct bad bits without any interaction with the CPU. It has a status register, the bits of which signal errors occurring during a read, and then it inform when errors are corrected.

  The ECC module has an integrated FIFO that is used to transfer the calculated words to the NCU modules during the encode process and to store the calculated partial syndromes during the decode process. An additional FIFO module is used to transfer correction data between the correction module and the BCH-CHIEN module.
- **Bad block (RMU)** – It is bad block remapping unit. This module remaps blocks excluded from the poll of the usable blocks into the blocks that will be its substitute. Whole process is transparent for the software.

58.4.2 DMA Module

(1) DMA Overview

The DMA engine integrated into the NAND Flash controller has the following properties:

- Two work modes:
  - The registers managed mode
  - The Scatter-Gather mode
- Supported burst types:
  - Imprecise bursts
  - Precise bursts
- Supported burst sequences:
  - The stream burst mode
  - The incrementing mode
- The DMA module preserves the configuration registers. These are copied into the DMA working registers.
- DMA trigger level enables DMA to send packet data.

(2) DMA Description

DMA_ADDR_L gives a 32-bit address when the DMA is configured as 32-bit.

DMA supports two modes:

- The registers managed mode – the DMA does one transfer depending on the contents of DMA_ADDR, DMA_CNT, and DMA_CTRL registers.
- The Scatter-Gather mode – new DMA transfer algorithm.

The DMA mode for the current transfer is selected via the DMA_CTRL.DMA_MODE bit and cannot be changed during each consecutive data transfer. The application program can change the DMA mode when the transfer is completed and the DMA_CTRL.DMA_READY bit is set.

In order to begin the transfer, the DMA should be in an IDLE state (DMA_CTRL.DMA_READY = 1).

Setting the DMA_CTRL.DMA_START bit triggers the DMA after the commands are sent to the NAND Flash memory (writing CONTROL register). When the DMA_START bit is clear, sending commands to the NAND Flash memory will not trigger the DMA. Because of this solution, it is possible to program the DMA to transfer more data than the page size of the NAND Flash memory (example: the DMA is configured to 32 kB data transfer, the size of the page in NAND Flash memory is 4 kB. In order to send 32 kB of data into the NAND Flash memory, it is necessary to set the DMA_START bit in the register DMA_CTRL, then it is necessary to send the PROGRAM PAGE command to the NAND Flash memory, clear the DMA_START bit in the DMA_CTRL register, and send seven commands to the NAND Flash memory). In this example, the DMA is set free only once at the beginning.

The DMA transfers four 32-bit words in one package when working in a 4-beat incrementing burst, eight words in an 8-beat incrementing burst, and sixteen words in a 16-beat incrementing burst. The burst size indicates the number of 32-bit words in the burst, not the number of bytes transferred.

The DMA trigger level enables the DMA to send packet data. It indicates when the DMA has to start transferring data.

The application program must set trigger level depending on arbitration type, system and NAND Flash memory performance. For example:

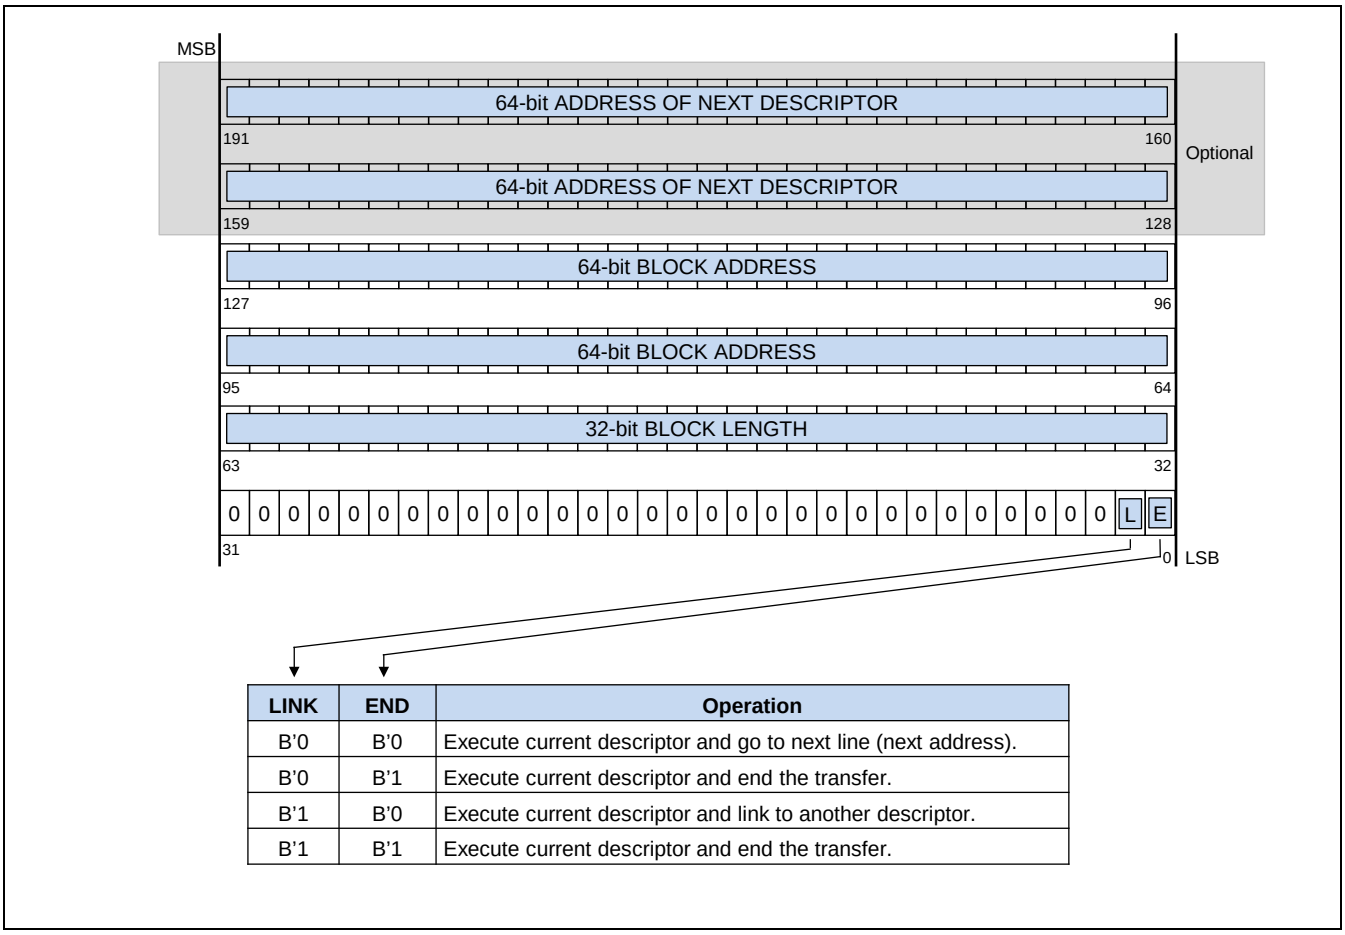
1. If the DMA trigger level equals 0, the DMA does not wait, but transfers data immediately because the trigger level is always exceeded.
2. For read from the NAND Flash memory: If the DMA trigger level equals H'40 (256 bytes), the DMA waits until data level reach the previously programmed trigger level (256 bytes). Then the DMA will transfer data until FIFO gets empty status. Next the wait for required data level cycle is repeated as long as remain data size allow to reach programmed trigger level. The trigger level value should be chosen to ensure that only the continuous data block will be transferred and the FIFO will not be overflowed.
3. For write to NAND Flash memory: If the DMA trigger level equals H'40 (256 bytes), the DMA writes data to the FIFO until the FIFO is full. Then, the DMA waits until 256 bytes are written in to the NAND Flash memory. Next, again the DMA transfers data until FIFO is full. The trigger level value should be chosen to ensure that only the continuous data block will be transferred.

(a) Registers Managed Mode:

When the DMA works in this mode, it transfers only one continuous block (DMA_CNT is block length) to or from the system memory at address DMA_ADDR. Block can be multiple of DATA_SIZE value in the DATA_SIZE register. All the registers which modify this transfer are described in 58.2.19 DMA base address - least significant part register (DMA_ADDR_L), 58.2.21 DMA counter initial value register (DMA_CNT) and 58.2.22 DMA control register (DMA_CTRL).
The DMA_BURST bit in register DMA_CTRL defines the main transfer type used by the DMA to precede the requested transfer.

(b) Scatter-Gather Mode:

The Scatter-Gather Direct Memory Access (SG-DMA) controller implements high-speed data transfer between two components, when DMA transfers and merges non-contiguous memory to a continuous address space, and vice versa.
The DMA in Scatter-Gather mode uses the Descriptors List to describe data transfers. The NAND Flash registers only points to the base address of the Descriptors List. The base address for this list is set in the DMA_ADDR register whether it is a read or write transfer. The base address, sizes of the data blocks, and flags are defined inside the descriptors.
The DMA_BURST bit in register DMA_CTRL defines the main transfer type used by the DMA to precede the requested transfer.
When in Scatter-Gather mode, the DMA transfers data from data blocks. Each descriptor can define only one data block.
The DMA adopts the scatter-gather DMA algorithm so that higher data transfer speed is available. The application program can program a list of data transfers between the system memory and NAND Flash to the Descriptor Table before executing Scatter-Gather mode.



LINK	END	Operation
B'0	B'0	Execute current descriptor and go to next line (next address).
B'0	B'1	Execute current descriptor and end the transfer.
B'1	B'0	Execute current descriptor and link to another descriptor.
B'1	B'1	Execute current descriptor and end the transfer.

Figure 58.41 Scatter-Gather DMA Descriptor Layout (64-bit system memory addressing)

The table below defines the SG-DMA descriptor fields and their functions:

Table 58.48 Scatter-Gather DMA Descriptor Fields (64-bit system memory addressing)

H'0000_0005	Not Available
H'0000_0006	Not Available
H'0000_0007	Not Available
H'0000_0008	8 bytes
….	….

The Descriptor Table is created in system memory by the application program. SG-DMA can support only 32-bit and 64-bit system memory addressing. Each descriptor line (one executable unit) consists of the address, length and flags. The flags specify operation of the descriptor line.

The figure below shows the example of Scatter-Gather programming:

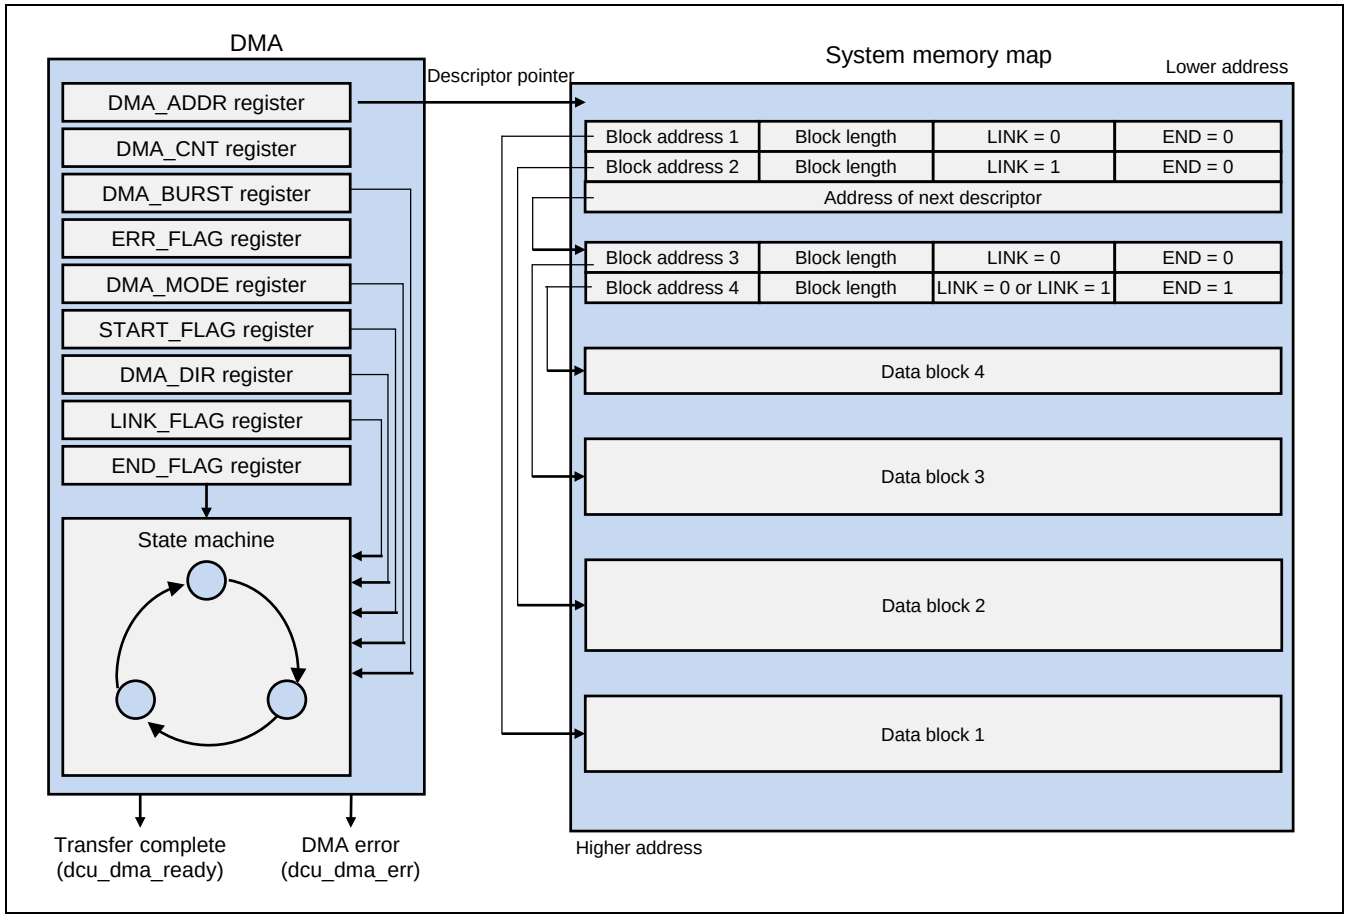

Figure 58.43 Example of Scatter-Gather DMA Data Transfer

58.4.3 ECC Module

(1) Module Overview

The ECC module is based on one of the BCH algorithms and allows correction of multiple bit errors.

The ECC engine integrated into the NAND Flash controller has the following properties:

- The encoder and decoder works on the 256, 512, 1024 bytes data blocks.
- Programmable correction capability: 2, 4, 8, 16, 24 or 32 errors.
- The corrected data words are aligned to the 32 bits.
- The correction words are aligned to the 32 bits.
- Correction words are placed after the data.

(2) Block Diagram

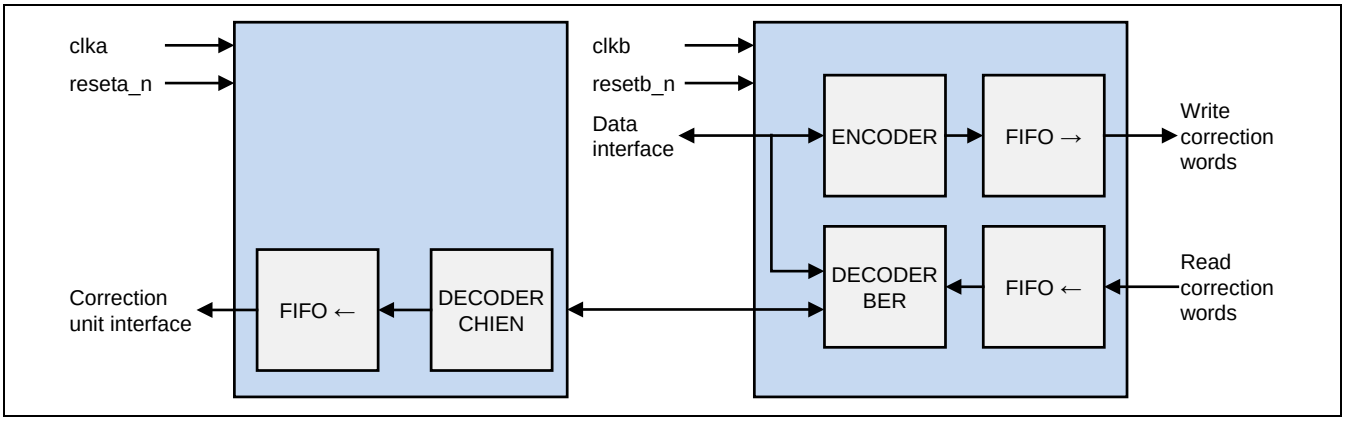

Figure 58.44 ECC Module Block Diagram

58.4.4 BCH Algorithm Implementation

- Data block length:
- Programmable memory page length, multiple of the block length by any power of 2 (optional).
- Programmable correction capability: 2, 4, 8, 16, 24 or 32 errors.
- Separate encoder and decoder modules.
- Calculation of correction data performed during write to memory.
- Error detection performed during read data from memory.
- Internal pipeline allows the correction of errors in one data block simultaneously with detection of errors in the following data block.

Table 58.51 Size of Correction Bytes

Corrction Capability	ECC Block Size	Size of Correction Bytes per one ECC Block(IO_WIDTH = 8)	Size of Correction Bytes per one ECC Block(IO_WIDTH = 16)
2	256/512/1024 B	4	4
4	256/512/1024 B	7	8
8	256/512/1024 B	14	14

59. Serial-ATA Gen3

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

59.1 Overview

The serial-ATA interface provides a serial ATA physical interface which complies with the serial-ATA standard.

59.1.1 Features

- Supports the following transfer rates: 6.0 Gbps, 3.0 Gbps, and 1.5 Gbps (respectively for the third, second, and first generation of the SATA interface standard)
- Parallel-ATA emulation
- Packet protocol transfer
- Supports SATA standard 8b/10b encoding, cyclic redundancy check (CRC), and scrambling modes.
- Supports the SATA power management mode (partial mode/slumber mode).
- Does not support reset speed negotiation (RSN).
- PHY is shared with PCIE Controller. SATA is supported with MD12 (mode pin) = 1.

59.1.2 Block Diagram

Figure 59.1 shows the block diagram of the SATA interfaces.

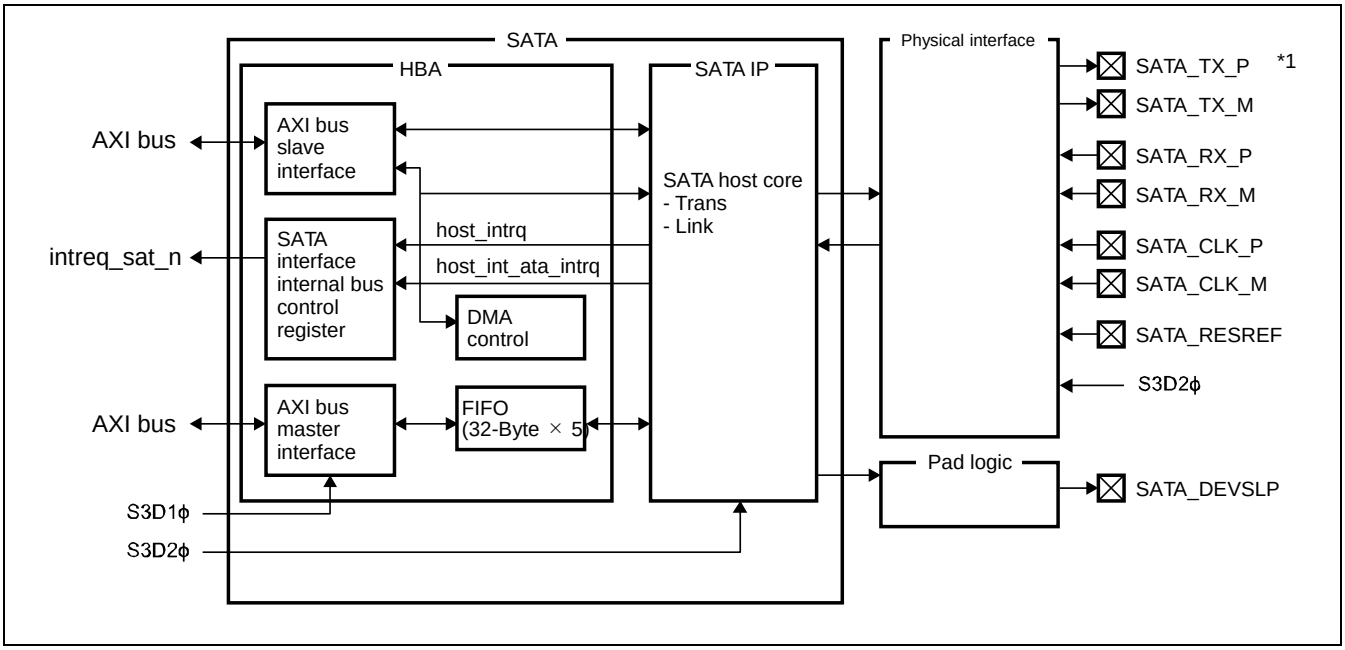

Figure 59.1 Block Diagram of SATA Interfaces

host_intrq and host_int_ata_intrq are internal interrupt request signals. For the interrupt sources of these signals, refer to the description of the SATA INT status register.

Note: 1. Refer Table 59.1.

59.1.3 External Pins

Table 59.1 shows the external pins of the SATA interface.

Table 59.1 External Pins

Name	Pin Name	SATA Symbol	I/O	Description	Second Generation RZ/G Series Products			
					RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
Reference clock	PCIE1_CLK_P (SATA_CLK_P) PCIE1_CLK_M (SATA_CLK_M)	—	Input	Reference clock input to the PLL circuit in the Serial-ATA module (differential input). Apply a 100-MHz clock.	√	—	√	—
Transmit data	PCIE1_TX_P (SATA_TX_P) PCIE1_TX_M (SATA_TX_M)	TX+ TX-	Output	Pins for data transmission pins. A 6.0-GHz (third generation) signal or 3.0-GHz (second generation) signal or 1.5-GHz (first generation) signal is transmitted through these pins. The pins with names ending in P and M are combined to provide a differential signal.	√	—	√	—
Receive data	PCIE1_RX_P (SATA_RX_P) PCIE1_RX_M (SATA_RX_M)	RX+ RX-	Input	Pins for data reception. A 1.5-GHz (first generation) or 3.0-GHz (second generation) signal or 6.0-GHz (third generation) signal is received through these pins. The pins with names ending in P and M are combined to provide a differential signal.	√	—	√	—
Reference resistor connection	PCIE1_RESREF (SATA_RESREF)	—	Input/ Output	Attach a 200-Ω ±1% ±100 ppm/°C precision resistor-to-ground on the board.	√	—	√	—
Device Sleep	SATA_DEVSLP	DEVSLP	Output	Low power consumption mode of device(HDD,SSD)	√	—	√	—

59.1.4 Register Configuration

Table 59.2 shows the register configuration of the SATA interface. The set of registers shown below are allocated to the register map space.

The area allocated for the SATA interface is from H'EE30_0000 to H'EE4F_FFFF (2-Mbyte space).

These registers must not be accessed in any access sizes other than those listed in the table.

Addresses other than those listed below must not be write-accessed to. If written to, operation is not guaranteed. If read, an undefined value is read.

Table 59.2 Register Configuration

Add the offsets under “address” below to H'EE30_0000.

						Second Generation RZ/G Series Products

Notes: See the descriptions of individual registers for the R/W attributes of the valid bits.

1. Bits 15 to 0 of the data bus are used.
2. Bits 7 to 0 of the data bus are used.

59.1.5 Connected Module

Table 59.3 Connected modules

Module name	Connected module name	Function of connected module
SATA	AP-System Core	Access the Registers
	CPG	Output clocks
	Module Standby	Control to stop clocks
	Software Reset	Execute software reset
	INTC-AP	Control to interrupt

59.2 Register Description

- Legend:

Address:	Address of the register
Bit map:	Bit configuration of the entire register. The initial value and R/W of the individual bits are also indicated.
Bit:	Bit number and range
Bit name:	Bit name or field name
Initial value:	Register value after a reset
—:	Undefined value
R/W:	Readable/writable. The written value can be read.
R/WC0:	Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.
R/WC1:	Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.
R:	Read-only. The write value should always be 0. (If a read/write value is specified in the bit description, however, it must be observed.)
—/W:	Write-only. The read value is undefined.
RC:	Read-only. The bit is cleared to 0 after it has been read.

59.2.1 Note on the Access to the Registers Allocated to H'1018 to H'10A8

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

No normal access can basically be made to the registers that are allocated to H'1018 to H'10A8 unless the PHYRDY state is established. The PHYRDY state here refers to the state in which the rate of transfer between the host and device is established and they are ready for data transfer. In this state, bits 3-0 of the SCR SStatus register described in section 59.2.27, SCR SStatus Register (SCRSSTS), is set to B'0011*. The integrity of the value of a register that is accessed in the non-PHYRDY state is not guaranteed.

59.2.2 ATAPI Control Register (ATAPI_CONTROL1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ISM
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	DTA32M	—	—	—	RESET	—	—	—	DESE	R/W	STOP	START
Initial value:	0	0	0	0	0	0	0	0	0	1	1	1	0	0	0	0
R/W:	R	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	—	R	Reserved The write value should always be 0.
16	ISM	B'0	R/W	Interrupt Status mode 0: IP compatible mode Normal operating mode of the SATA INT status register (SATAINTSTAT). 1: CIS interrupt mode A valid interrupt source specified by the SATA INT mask register is set in the SATA INT status register (SATAINTSTAT). No interrupts are generated by valid sources specified in the SATA INT mask register (SATAINTMASK). Read access to the SATA INT status register (SATAINTSTAT) will not negate the ATA-sourced DEVINT interrupt signal. Note: For details, refer to section 59.3.6, Interrupt Modes. Set ISM to 1 while the SATA-IP host core block is being reset (bit 7 (RESET) is 1). Do not change the value of ISM after the SATA-IP host core block has been released from the reset state (bit 7 (RESET) is 0).
15 to 12	—	All 0	R	This bit is fixed to 0 and cannot be set to 1.
11	DTA32M	B'0	R/W	DTA32M enables bits 31 to 29 of the descriptor DMA start address in descriptor table operation mode. This causes the termination flag to be changed from bit 31 to bit 0. 0: Reserved 1: Enabled bits of the descriptor DMA start address are bits 31 to 2.
10 to 8	—	All 0	R	These bits are fixed to 0 and cannot be set to 1.
7	RESET	B'0	R/W	RESET controls the SATA-IP host core block. Setting this bit to 1 resets the SATA-IP host core block.
6 to 4	—	All 1	R	These bits are fixed to 1. Attempting to set these bits to 0 is ignored and not reflected in the value of the bits.

Bit	Bit Name	Initial Value	R/W	Description
3	DESE	B'0	R/W	DESE controls the descriptor table operation mode. 0: Descriptor functions disabled 1: Descriptor functions enabled
2	R/W	B'0	R/W	R/W controls FIFO read/write. 0: FIFO write (data-out operation at DMA transfer) 1: FIFO read (data-in operation at DMA transfer) Set this bit to 1 when reading data from the SATA device. Clear it to 0 when writing data to the SATA device.
1	STOP	B'0	R/W	This bit forces termination of DMA transfer. When writing 0: Ignored 1: Forcibly terminates data transfer When reading 0: Forced termination command is not issued. 1: Forced termination of data transfer command is issued. This bit is cleared to 0 when the next DMA starts. To power down (SATA internal clock turns off) while DMA is active (ACT = 1), DMA transfer should be forcibly terminated. Note: Transfer cannot always be resumed from the address at which DMA transfer has been forcibly terminated.
0	START	B'0	R/W	This bit initiates DMA transfer. If this bit set to 1 then the DMA transfer is started. When cleared to 0, this bit is ignored. When writing 0: Ignored 1: Starts DMA transfer When reading 0: DMA transfer is not active 1: DMA transfer is in busy state Note: Access to the task file register is prohibited while DMA is active.

59.2.3 ATAPI Status Register (ATAPI_STATUS)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SSBSY	SSD RDY	—	—	SSDRQ	—	—	SSERR	—	—	—	—	—	—	—	—
Initial value:	0	0	—	—	0	—	—	0	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	SATAINT	—	—	SWERR	—	DNEND	DEVTRM	DEVINT	—	ERR	NEND	ACT
Initial value:	—	—	—	—	0	—	—	0	—	0	0	0	—	0	0	0
R/W:	R	R	R	R	R	R	R	R/WC0	R	R/WC0	R/WC0	R	R	R/WC0	R/WC0	R

Bit	Bit Name	Initial Value	R/W	Description
31	SSBSY	B'0	R	SSBSY corresponds to INTBSY of the SATA INT status register (SATAINTSTAT), the BSY bit value of the shadow status register (SSTATUS). This bit is enabled when ISM = 1 and disabled (0) when ISM = 0. The write value should always be 0.
30	SSDRDY	B'0	R	SSDRDY corresponds to INTDRDY of the SATA INT status register (SATAINTSTAT), the DRDY bit value of the shadow status register (SSTATUS). This bit is enabled when ISM = 1 and disabled (0) when ISM = 0. The write value should always be 0.
29, 28	—	—	R	Reserved The write value should always be 0.
27	SSDRQ	B'0	R	SSDRQ corresponds to INTDRQ of the SATA INT status register (SATAINTSTAT), the DRQ bit value of the shadow status register (SSTATUS). This bit is enabled when ISM = 1 and disabled (0) when ISM = 0. The write value should always be 0.
26, 25	—	—	R	Reserved The write value should always be 0.
24	SSERR	B'0	R	SSER corresponds to INTERR of the SATA INT status register (SATAINTSTAT), the ERR bit value of the shadow status register (SSTATUS). This bit is enabled when ISM = 1 and disabled (0) when ISM = 0. The write value should always be 0.
23 to 12	—	—	R	Reserved The write value should always be 0.
11	SATAINT	B'0	R	SATAINT indicates the status of host_intrq of the SATA-IP block. This bit is read-only. host_intrq is the internal interrupt request signal. For the interrupt source of this signal, refer to the description of the SATA INT Status register. The write value should always be 0.
10, 9	—	—	R	Reserved The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
8	SWERR	B'0	R/WC0	Software error bit. 1 in this bit indicates that the task file register is accessed when the DMA is active. This bit is set to 1 when a PIO transfer is performed during DMA transfer. In this case, no output is directed to the SATA-IP block and the access is ignored. Writing 0 resets this bit.
7	—	—	R	Reserved The write value should always be 0.
6	DNEND	B'0	R/WC0	DNEND indicates that all DMAs have successfully ended in the descriptor mode. Writing 0 resets this bit.
5	DEVTRM	B'0	R/WC0	DEVTRM is set to 1 when the DMA mode for the SATA_IP block is terminated before the number of DMA transfer bytes defined in the DMA transfer count register (ATAPI_DMA_TRANS_CNT) is reached (corresponds to P-ATA device's device termination operation). Writing 0 resets this bit.
4	DEVINT	B'0	R	DEVINT indicates the status of host_int_ata_intrq in the SATA-IP block (host_int_ata_intrq signal corresponds to the IDEINT signal of the P-ATA device and ATA of the SATA INT status register (SATAINTSTAT)). This bit is read-only. Since this LSI chip preserves no status, this bit is cleared to 0 when host_int_ata_intrq is set to 0. The SATA_HBA block regards any interrupt signal from the SATA-IP block as a level trigger input. host_int_ata_intrq is negated by the SATA device to clear the interrupt pending state after the shadow status register (SSTATUS) is read out. There is no time specification. The write value should always be 0.
3	—	—	R	Reserved The write value should always be 0.
2	ERR	B'0	R/WC0	ERR is set to 1 when the host forcibly terminated the DMA transfer. Writing 0 resets this bit.
1	NEND	B'0	R/WC0	NEND indicates that DMA has been successfully terminated. Writing 0 resets this bit.
0	ACT	B'0	R	ACT indicates that DMA is active. To power down (SATA internal clock turns off) while DMA is active (ACT = 1), DMA transfer should be forcibly terminated (STOP = 1). The write value should always be 0.

59.2.4 Interrupt Enable Register (ATAPI_INT_ENABLE)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

When 1 is written to a bit, the interrupt signal corresponding to the bit in the ATAPI status register (ATAPI_STATUS) is enabled.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	iSATAINT	—	—	iSWERR	—	iDNEND	iDEVTRM	iDEVINT	—	iERR	iNEND	iACT
Initial value:	—	—	—	—	0	—	—	0	—	0	0	0	—	0	0	0
R/W:	R	R	R	R	R/W	R	R	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	—	R	Reserved The write value should always be 0.
11	iSATAINT	B'0	R/W	SATAINT interrupt enable
10, 9	—	—	R	Reserved The write value should always be 0.
8	iSWERR	B'0	R/W	SWERR interrupt enable
7	—	—	R	Reserved The write value should always be 0.
6	iDNEND	B'0	R/W	DNEND interrupt enable
5	iDEVTRM	B'0	R/W	DEVTRM interrupt enable
4	iDEVINT	B'0	R/W	DEVINT interrupt enable
3	—	—	R	Reserved The write value should always be 0.
2	iERR	B'0	R/W	ERR interrupt enable
1	iNEND	B'0	R/W	NEND interrupt enable
0	iACT	B'0	R/W	ACT interrupt enable bit. Since ACT is cleared automatically when a DMA transfer is completed, interrupt processing should be completed during assertion.

Note: Writing 1 to a bit enables the interrupt signal corresponding to the bit in the ATAPI status register. Do not clear the interrupt mask of the INTC while the SATA module is being reset. For resetting of the SATA module, refer to the descriptions of the CPG module.For the interrupt mask of INTC, refer to the description in the section on the INTC module.

59.2.5 Descriptor Table Base Address Register (ATAPI_DTB_ADR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DTBA															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DTBA													—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	—	—	—
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	DTBA	B'0_0000_0000_0000_ 0000_0000_0000_0000	R/W	These bits indicate the descriptor table base address. Bits 31 to 0 are used to set the descriptor table base address.
2 to 0	—	—	R	Reserved The write value should always be 0.

Note: This address does not change and the set value is retained even after the DMA becomes active.

(1) Descriptor Table

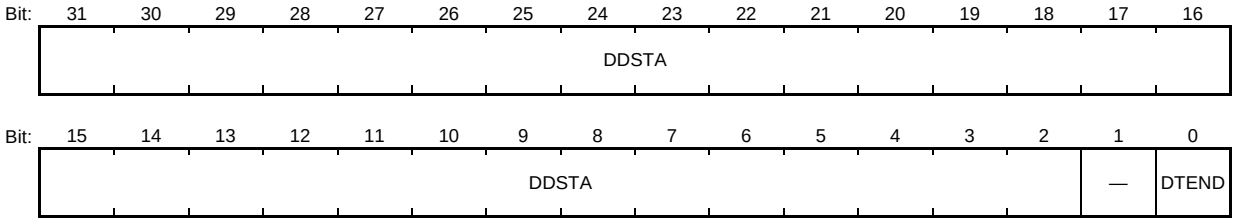
The descriptor table consists of the termination flag, the descriptor DMA start address (DDSTA), and the descriptor DMA transfer count (DDTRC).

(a) When Bits 31 to 29 of Descriptor DMA Start Address are Valid (DTA32M = 1)

Table 59.4 Descriptor Table Map in Memory

Address	Data Description
DTBA	The first termination flag (bit 0 = 0) and DDSTA
DTBA + 4	The first DDTRC
DTBA + 8	The second termination flag (bit 0 = 0) and DDSTA
DTBA + 12	The second DDTRC
…	…
DTBA + 8* (n – 1)	The n-th termination flag (bit 0 = 1) and DDSTA
DTBA + 8* (n – 1) + 4	The n-th DDTRC

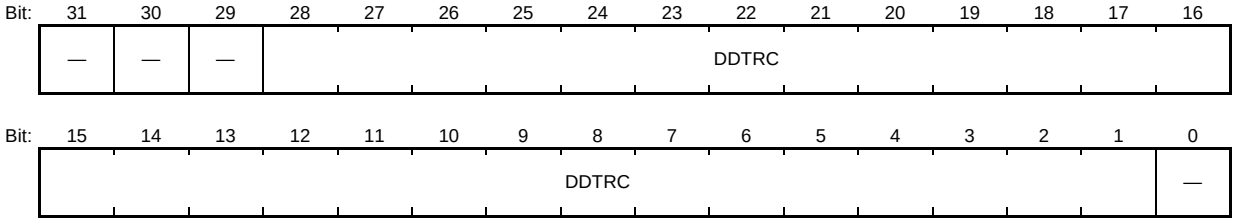
- Termination Flag and Descriptor DMA Start Address



Bit	Bit Name	Description
31 to 2	DDSTA	DDSTA shows the DMA start address in descriptor operation. Bits 31 to 0 are used to set the descriptor table start address on a byte basis. Bits 1 and 0 are ignored because it is necessary to secure the boundary of 32-bit addresses in the DMA start address.
1	—	Reserved The write value should always be 0.
0	DTEND	DTEND controls the termination of a descriptor DMA operation. 0: Validates the descriptor table When DTEND is 0, the DMA transfer count is read, DMA transfer is performed, and the next descriptor table is read. 1: Terminates the descriptor DMA operation When DTEND is 1, the last descriptor table is detected.

The valid flag and descriptor DMA start address should be set in the descriptor table base address + "m" in the memory, where m is multiple of 2 (such as 0, 2, 4 …).

- Descriptor DMA Transfer Count

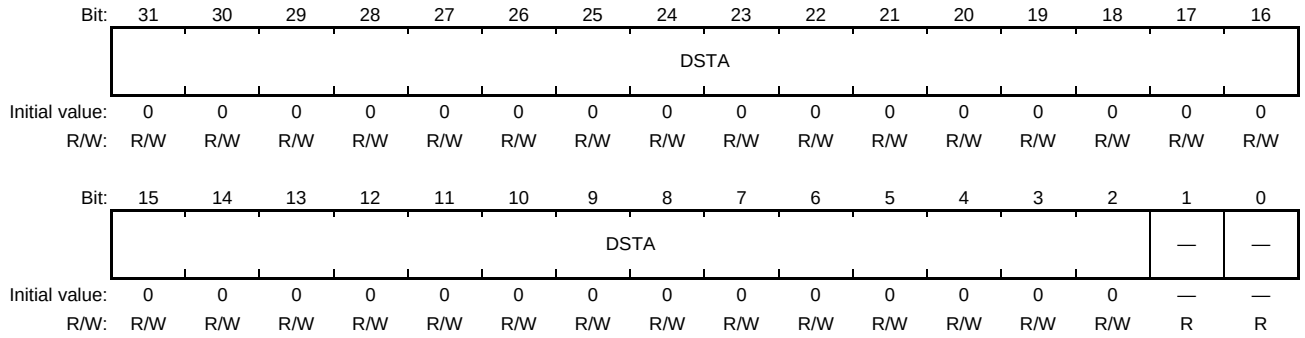


Bit	Bit Name	R/W	Description
31 to 29	—	R	Reserved The write value should always be 0.
28 to 1	DDTRC	R/W	These bits set the DMA transfer count during descriptor operation. Bits 28 to 0 are used to set the DMA transfer count on a byte basis. Bit 0 is ignored because the SATA data bus is handled on a 16-bit basis (on a word basis).
0	—	R	Reserved The write value should always be 0.

The descriptor DMA transfer count should be set in the descriptor table base address + "m" in the memory, where the value of m is any multiple number of 2 plus 1 (such as 1, 3, 5,…).

59.2.6 DMA Start Address Register (ATAPI_DMA_START_ADR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

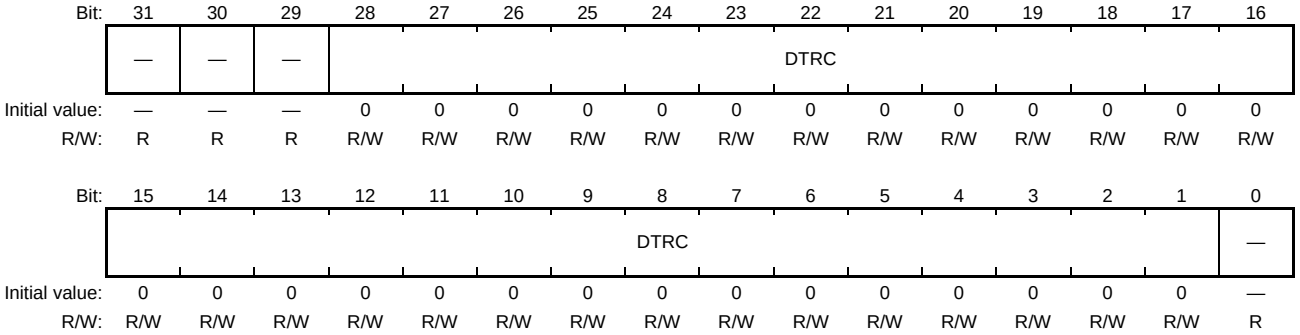


Bit	Bit Name	Initial Value	R/W	Description
31 to 2	DSTA	B'00_0000_0000_0000_ 0000_0000_0000_0000	R/W	DSTA sets a DMA start address that indicates the data transfer start address in the memory. Bits 31 to 0 are used to set the DMA start address on a byte basis. Bits 1 and 0 are ignored because it is necessary to secure the boundary of 32-bit addresses in the DMA start address.
1, 0	—	—	R	Reserved The write value should always be 0.

Note: This address does not change and the set value is retained even after the DMA becomes active.

59.2.7 DMA Transfer Count Register (ATAPI_DMA_TRANS_CNT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—



Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	—	R	Reserved The write value should always be 0.
28 to 1	DTRC	H'000_0000	R/W	DTRC sets the DMA transfer count. Bits 28 to 0 are used to set the DMA transfer count on a byte basis. Bit 0 is ignored because the ATAPI data bus is handled on a 16-bit basis (on a word basis).
0	—	—	R	Reserved The write value should always be 0.

Note: This count value does not change and the set value is retained even after the DMA becomes active.

59.2.8 ATAPI Control 2 Register (ATAPI_CONTROL2)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	LWORD SWAP	WORD SWAP	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	0	0	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	—	R	Reserved The write value should always be 0.
2	LWORDSWAP	B'0	R/W	LWORDSWAP controls the swapping of the upper 32-bit data and the lower 32-bit data on a 2-longword basis (64-bit data) on the AXI bus. 0: Longword swap is not executed. The 64-bit data on the AXI bus appears in a big endian format. 1: Longword swap is executed between the SATA interface and the AXI bus interface. Note that longword swap is only available on data transfer when bit 0 (START) in the ATAPI control register (ATAPI_CONTROL1) = 1: DMA mode start.
1	WORDSWAP	B'0	R/W	WORDSWAP controls the swapping of the upper 16-bit data and the lower 16-bit data on a longword basis when the 64-bit data bus is enabled in the AXI bus. 0: Word swap is not executed. 1: Word swap is executed between the SATA interface and the AXI bus interface. Note that word swap is only available on data transfer when bit 0 (START) in the ATAPI control register (ATAPI_CONTROL1) = 1: DMA mode start.
0	—	—	R	Reserved The write value should always be 0.

59.2.9 ATAPI Signal Status Register (ATAPI_SIG_ST)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DPIORDY	DMARQ
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	—	R	Reserved The write value should always be 0.
1	DPIORDY	—	R	DPIORDY indicates the state of the IF signal for PIO transfer in the SATA_IP block.
0	DMARQ	—	R	DMARQ indicates ATAPIDMARQ (IDEDREQ) signal state.

Note: Since the SATA interface has separate PIO and DMA interfaces, the DDMARDY signal of conventional ATAPI cannot be monitored.
The IORDY signal is not emulated. DPIORDY monitors the PIO-transfer interface signal only. Monitoring of the DMA-transfer interface signals is not possible.

59.2.10 Byte Swap Register (ATAPI_BYTE_SWAP)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BYTE SWAP
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	—	R	Reserved The write value should always be 0.
0	BYTESWAP	B'0	R/W	BYTESWAP controls the swapping of the upper 8-bit data and the lower 8-bit data in the SATA interface. 0: Byte swap is not executed between the SATA interface and the AXI bus. 1: Byte swap is executed between the SATA interface and the AXI bus. Note that byte swap is only available on data transfer when START in the ATAPI control register (ATAPI_CONTROL1) = 1: DMA mode start.

59.2.11 BIST Config Register (BISTCONF)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The BISTCONF register is used to configure the operation to be performed in BIST mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LOOPB
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

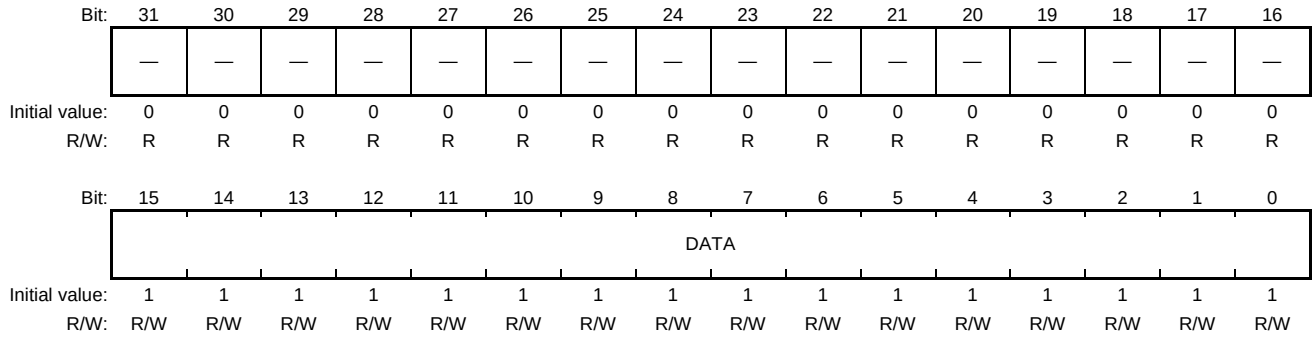
Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	LOOPB	B'0	R/W	Loopback mode bit (Loopback Mode) 0: Loopback (for far-end retimed loopback mode) is not formed in the link layer of the host. 1: Loopback (for far-end retimed loopback mode) is formed in the link layer of the host.

Note: No read access can be made to this register and no correct data can be read from this register until the PHYRDY state is established. (See section 59.2.1, Note on the Access to the Registers Allocated to H'1018 to H'10A8.)

59.2.12 Shadow Data Register (DATA) (SDATA)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The Shadow Data Register corresponds to the ATA standard's Data Register/Port. This is a data register that is read and written in PIO transfer mode.



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	DATA	H'FFFF	R/W	Transmit/receive data (SHADOW_DATA)

Notes: 1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
2. In PIO transfer mode, that is, except when the host_shdw_stat_DRQ signal is being asserted, both of R/W operations are canceled, and therefore the initial value H'FFFF is not read out but H'0000 is read out. When a read attempt is made after the PIO mode read transfer, the last read value is read out.
3. Access to the data register is prohibited while DMA is active. The SDATA register is accessible.

59.2.13 Shadow Error Register (SERR[Read Mode]) (SSERR[Read Mode])

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The shadow error register corresponds to the ATA standard's error register. (The actual register is on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	SERR							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0.
7 to 0	SERR	H'FF	R	Error monitor bit (SHADOW_ERROR) The bit definitions vary with issued commands. (Except for Bit 2) ABRT bit (Bit 2): The value is 1 when issued command is Abort.

Notes: 1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register. Note that a write to the address of this register essentially causes the shadow features register (SFEATURES[Write Mode]) (SSFEATURES[Write Mode]) to be accessed.

2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 59.3.13, Signature of the Shadow Register (INFORMATIVE).

3. Access to the SERR register is prohibited while DMA is active. The SSERR register is accessible.

59.2.14 Shadow Features Register (SFEATURES[Write Mode]) (SSFEATURES[Write Mode])

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The shadow features register corresponds to the ATA standard's features register. (* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	SFEATURES							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved The write value should always be 0.
7 to 0	SFEATURES	H'FF	W	Subcommand setup bits (SHADOW_FEATURES) The bit definitions vary with the commands.

Notes: 1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register. Note that a read from the address of this register essentially causes the shadow error register (SERR[Read Mode]) (SSERR[Read Mode]) to be accessed.

2. This register functions in a 2-stage FIFO configuration when a device that is compatible with the 48-bit Address features set is connected. For details, see section 59.3.12, Extended ATA Registers.

3. Access to the SFEATURES register is prohibited while DMA is active. The SSFEATURES register is accessible.

59.2.15 Shadow Sector CNT Register (SECCNT) (SSECCNT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The shadow sector CNT register corresponds to the ATA standard's sector count register.
(* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	SECCNT							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	SECCNT	H'FF	R/W	Sector count bits (SHADOW_SECTOR_CNT) The bit definitions vary with the commands.

Notes: 1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 59.3.13, Signature of the Shadow Register (INFORMATIVE).
3. This register functions in a 2-stage FIFO configuration when a device that is compatible with the 48-bit Address features set is connected. For details, see section 59.3.12, Extended ATA Registers.
4. Access to the SECCNT register is prohibited while DMA is active. The SSECCNT register is accessible.

59.2.16 Shadow LBA Low Register (LBALOW) (SLBALOW)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The shadow LBA low register corresponds to the ATA standard's LBA low (sector number) register.
(* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	LBALOW							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	LBALOW	H'FF	R/W	LBA_low address bits (SHADOW_LBA_LOW) The bit definitions vary with the commands.

Notes: 1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 59.3.13, Signature of the Shadow Register (INFORMATIVE).
3. This register functions in a 2-stage FIFO configuration when a device that is compatible with the 48-bit Address features set is connected. For details, see section 59.3.12, Extended ATA Registers.
4. Access to the LBALOW register is prohibited while DMA is active. The SLBALOW register is accessible.

59.2.17 Shadow LBA Mid Register (LBAMID) (SLBAMID)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The shadow LBA mid register corresponds to the ATA standard's LBA mid (cylinder low) register. (* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	LBAMID							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	LBAMID	H'FF	R/W	LBA_MID address bits (SHADOW_LBA_MID) The bit definitions vary with the commands.

Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 59.3.13, Signature of the Shadow Register (INFORMATIVE).
3. This register functions in a 2-stage FIFO configuration when a device that is compatible with the 48-bit Address features set is connected. For details, see section 59.3.12, Extended ATA Registers.
4. Access to the LBAMID register is prohibited while DMA is active. The SLBAMID register is accessible.

59.2.18 Shadow LBA High Register (LBAHIGH) (SLBAHIGH)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The shadow LBA high register corresponds to the ATA standard's LBA high (cylinder high) register. (* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	LBAHIGH							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	LBAHIGH	H'FF	R/W	LBA_high address bits (SHADOW_LBA_HIGH) The bit definitions vary with the commands.

Notes: 1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 59.3.13, Signature of the Shadow Register (INFORMATIVE).
3. This register functions in a 2-stage FIFO configuration when a device that is compatible with the 48-bit Address features set is connected. For details, see section 59.3.12, Extended ATA Registers.
4. Access to the LBAHIGH register is prohibited while DMA is active. The SLBAHIGH register is accessible.

59.2.19 Shadow Device/Head Register (DEVHEAD) (SDEVHEAD)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The shadow device/head register corresponds to the ATA standard's device/head register.
(* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DEVHEAD							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	DEVHEAD	H'FF	R/W	Device function select bits (SHADOW_DEVHEAD) The bit definitions except those for bits 7, 5, and 4 vary with the commands. Bits 7 and 5: Obsolete Bit 4: DEV bit. Selects either the Master or Slave. This bit must always be set to 0.

Notes: 1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 59.3.13, Signature of the Shadow Register (INFORMATIVE).
3. Access to the DEVHEAD register is prohibited while DMA is active. The SDEVHEAD register is accessible.

59.2.20 Shadow Status Register (SSTATUS [Read Mode]) (SSSTATUS [Read Mode])

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The SSTATUS or SSSTATUS register corresponds to the ATA standard's status register. Its value can be read out correctly only when the DEV bit (bit 4) of the shadow device/head register (DEVHEAD) (SDEVHEAD) is set to 0. Its read value is always H'0000_0000 when the DEV bit is set to 1.

Accessing this register for read causes the ATA-sourced host_intrq interrupt signal to be negated. (* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0.
7	BSY	B'0	R	BSY bit
6	DRDY	B'1	R	DRDY bit
5	DFSE	B'1	R	DF/SE bit
4	SSTATUS	B'1	R	Definition varies with the command.
3	DRQ	B'1	R	DRQ bit
2, 1	—	B'11	R	Reserved This bit is always read as 1.
0	ERR	B'1	R	ERR/CHK bit

Notes: 1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register. Note that a write to the address of this register essentially causes the shadow command register (SCOM[Write Mode]) (SSCOM[Write Mode]) to be accessed.

2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 59.3.13, Signature of the Shadow Register (INFORMATIVE).

3. Access to the SSTATUS register is prohibited while DMA is active. The SSSTATUS register is accessible.

59.2.21 Shadow Command Register (SCOM [Write Mode]) (SSCOM [Write Mode])

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The shadow command register corresponds to the ATA standard's command register. The ATA command code is set by this register.

Accessing this register for write causes the command to be issued to the device (sending command register FIS). (* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	SCOM							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved The write value should always be 0.
7 to 0	SCOM	H'FF	W	Transmit command setup bits (SHADOW_COMMAND)

Notes: 1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register. Note that a read from the address of this register essentially causes the shadow status register (SSTATUS[Read Mode]) (SSSTATUS[Read Mode]) to be accessed.
2. Access to the SCOM register is prohibited while DMA is active. The SSCOM register is accessible.

59.2.22 Shadow alternate status register (SALTSTS [Read Mode]) (SSALTSTS [Read Mode])

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The SALTSTS or SSALTSTS register is the ATA standard's alternate status register. Its value can be read out correctly only when the DEV bit (bit 4) of the shadow device/head register (DEVHEAD) (SDEVHEAD) is set to 0. Its read value is always H'0000_0000 when the DEV bit is set to 1.

The bits of this register always have the same bit value as the corresponding bits of the shadow status register. Any attempt to access this register for read, however, does not cause the ATA-sourced host_intrq interrupt signal to be negated.

(* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

control register (SDEVCON[Write Mode])

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0.
0	DEVSLP_EN	B’0	R/W	Sets the device sleep mode of the SATA host IP. 0: The device sleep mode is not set. 1: The device sleep mode is set.

59.2.27 SCR SStatus Register (SCRSSTS)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	IPM				SPD				DET			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0.
11 to 8	IPM	B’0000	R	Interface power manager state monitor bits These bits indicate the interface's Power Management mode or state. B’0000: No device is connected or the device is not ready for communication. B’0001: Active mode B’0010: Partial mode B’0110: Slumber mode B’1000: DevSleep mode Other: Setting prohibited. After a transition to the slumber mode from the partial mode by automatic partial to slumber, IPM is set to B'0110 to indicate the slumber mode.
7 to 4	SPD	B’0000	R	Communication speed monitor bits These bits indicate the speed at which the interface communicates with the device. B’0000: No device is connected or the device is not ready for communication. B’0001: First generation (1.5 Gbps) B’0010: Second generation (3.0 Gbps) B’0011: Third generation (6.0 Gbps) Other: Setting prohibited.
3 to 0	DET	B’0000	R	Device communication state monitor bits These bits indicate the PHY state with respect to device detection. B’0000: No device is detected or the device is not ready for communication. B’0001: A device is detected but the device is not ready for communication. B’0011: A device is detected and the device is ready for communication. B’0100: Offline mode or loopback mode Other: Setting prohibited.

Note: Refer to the Serial-ATA specification for further information about this register.

59.2.28 SCR SError Register (SCRSERR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	DIAGA	DIAGX	DIAGF	DIAGT	DIAGS	DIAGH	DIAGC	DIAGD	DIAGB	DIAGW	DIAGI	DIAGN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W:	R	R	R	R	R/WC1	R/WC1	R/WC1	R/WC1	R	R	R	R	R	R	R/WC1	R/WC1

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27	DIAGA	B'0	R/WC1	DIAGA is used to sense COMWAKE before detecting a device. Port Selector Presence Detect (set when COMWAKE is detected before the Phy layer detects a device)
26	DIAGX	B'0	R/WC1	DIAGX is used to sense the change in device connection state. Exchanged (Set when the Phy layer detects a device connection or disconnection)
25	DIAGF	B'0	R/WC1	FIS type error bit Unrecognized FIS Type
24	DIAGT	B'0	R/WC1	Abnormal timing transfer result reception bit Transport state transition error (Set when transfer result notification is received at an invalid timing)
23	DIAGS	B'0	R/WC1	Abnormal state transition bit Link Sequence Error (Set when an illegal state transition occurs in the Link layer)
22	DIAGH	B'0	R/WC1	Handshake error bit
21	DIAGC	B'0	R/WC1	CRC error bit
20	DIAGD	B'0	R/WC1	Disparity error bit
19	DIAGB	B'0	R/WC1	10b/8b decode error bit
18	DIAGW	B'0	R/WC1	COMWAKE detect bit COMWAKE Detect (Set when COMWAKE is detected at any timing)
17	DIAGI	B'0	R/WC1	Error state bit Phy Internal Error (Set when an error occurs in the Phy layer)
16	DIAGN	B'0	R/WC1	Transfer Ready state change bit PHYRDY change (Set when the PhyRdy signal indicating the Phy layer's transfer ready state is toggled)
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
11	ERRE	B'0	R/WC1	Internal FIFO flow error bit Internal Error (Set when a flow error occurs in the internal FIFO. Perform a software reset whenever this bit is set.)
10	ERRP	B'0	R/WC1	Protocol error bit Protocol Error (Set when either one of the following conditions occurs): An illegal state transition occurs in the Link layer (same as the DIAGS bit) An unsupported FIS is received (same as the DIAGF bit). The size of the received FIS is found invalid. A transfer result notification is received at an invalid timing (same as the DIAGT bit).
9	ERRC	B'0	R/WC1	FIS transmission PhyRdy signal negated bit Non-recovered persistent communication or data integrity error (Set when the PhyRdy signal is negated during transmission of a FIS except Data FIS (including retries))
8	ERRT	B'0	R/WC1	Data FIS transfer error bit Non-recovered transient data integrity error (Set when an error occurs during Data FIS transfer. Be sure to check this bit during PIO reads.)
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	ERRM	B'0	R/WC1	Communication error recovery monitor bit Recovered communications error (The PhyRdy signal indicating the Phy layer's transfer ready state is negated but asserted again within approximately 200 µs.)
0	ERRI	B'0	R/WC1	Retransmission result bit Recovered data integrity error (Set when retransmission of an FIS is successful)

Notes: 1. Refer to the Serial-ATA specification for further information about this register.
2. There are cases in which the DIAGW and DIAGN bits of this register are already set before a first access is made since the initial data is automatically set in the register when it is provided with a clock signal after a power-on reset. Consequently, it is recommended that all bits of this register be cleared (writing H'FFFF_FFFF) at the beginning of the startup sequence.
3. The operation of this register is irrelevant to the settings of the SATA INT status register (SATAINTSTAT) and SATA INT mask register (SATAINTMASK). The way in which the SCR SError register behaves remain unchanged even when bits b1, b2, and b3 of the SATA INT mask register are set (that is, interrupt sources are masked as the result of the update of the SCR SError result).

59.2.29 SCR SControl Register (SCRSCON)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSPM				CIPM				CSPD				CDET			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 12	CSPM	B’0000	R/W*	Power Management Mode transition request bits (SPM) CSPM is a set of bits that request for the state of the Power Management mode. Set as follows to have Power Management to transit to the required state: B’0000: No request B’0001: Request transition to the Partial Mode. B’0010: Request transition to the Slumber Mode. B’0100: Request to restoration to the Active Mode. Other: Setting prohibited. (* The transition request to the Partial/Slumber Mode is not retried. When using this field, unmask the SLUMMSK and PARTIMSK bits (bits 6 and 5) of the SATA INT mask register (SATAINTMASK) and enable "device rejects transition to Slumber Mode" and "device rejects transition to Partial Mode" interrupts.)
11 to 8	CIPM	B’0000	R/W	Interface Power Management Mode enable bit (IPM) CIPM enables or disables the interface's Power Management mode. B’0000: No limitation. B’0001: Partial Mode Disable B’0010: Slumber Mode Disable B’0011: Partial/Slumber Mode Disable B’0100: DevSleep power management state is disabled. B’0101: Partial and DevSleep power management states are disabled. B’0110: Slumber and DevSleep power management states are disabled. B’0111: Partial, Slumber, and DevSleep power management states are disabled. Other: Setting prohibited.

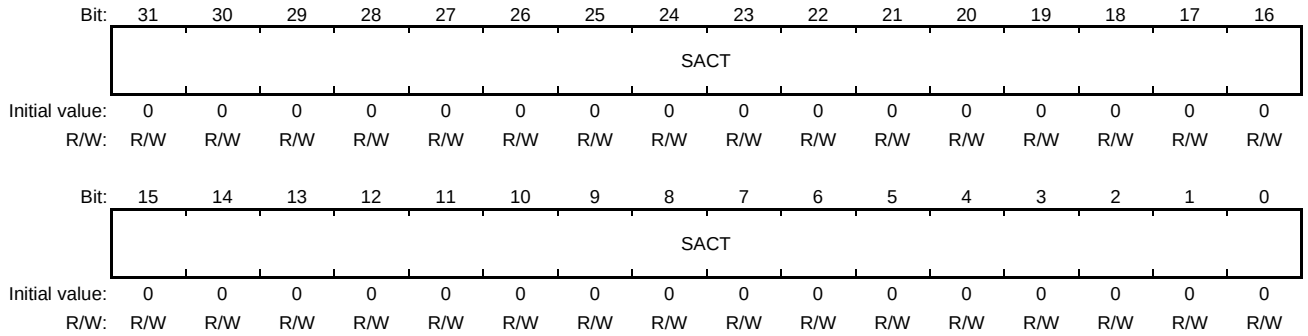
Bit	Bit Name	Initial Value	R/W	Description
7 to 4	CSPD	B’0000	R/W	Communication speed bits (SPD) The CSPD bits define the limiting speed at which communication with the device is to be made. B’0000: No limitation (same as B'0010) B’0001: First generation (1.5 Gbps) B’0010: Second generation (3.0Gbps) or less B’0011: Third generation (6.0 Gbps) or less Other: Setting prohibited. (This field is not initialized by a hardware reset. It is initialized at power-on reset time.)
3 to 0	CDET	B’0000	R/W	RESET/Offline mode bits (DET) The CDET bits specify the RESET/Offline mode. B’0000: No request B’0001: RESET. Handled as a hardware reset. B’0100: Places the PHY in offline mode. Other: Setting prohibited. (The SCR SControl register is initialized after the switching of the CDET field value from B'0001 to B'0000 is detected. Consequently, the values of the CSPM, CIPM, and CSPD fields are invalid when a write access such that the CDET field is set to B'0000 is made to this register.)

Notes: 1. Refer to the Serial-ATA specification for further information about this register.
2. It is impossible to check the value of this field since the field is reset to B'0000 as soon as setting of the value is internally detected.

59.2.30 SCR SActive Register (SCRSACT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The SCR SActive register is used to set up the TAG value to be used for Native Command Queuing.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SACT	H'0000_0000	R/W	b31: Corresponds to a TAG value of B'1_1111. b30: Corresponds to a TAG value of B'1_1110. b29: Corresponds to a TAG value of B'1_1101. b28: Corresponds to a TAG value of B'1_1100. b27: Corresponds to a TAG value of B'1_1011. b26: Corresponds to a TAG value of B'1_1010. b25: Corresponds to a TAG value of B'1_1001. b24: Corresponds to a TAG value of B'1_1000. b23: Corresponds to a TAG value of B'1_0111. b22: Corresponds to a TAG value of B'1_0110. b21: Corresponds to a TAG value of B'1_0101. b20: Corresponds to a TAG value of B'1_0100. b19: Corresponds to a TAG value of B'1_0011. b18: Corresponds to a TAG value of B'1_0010. b17: Corresponds to a TAG value of B'1_0001. b16: Corresponds to a TAG value of B'1_0000. b15: Corresponds to a TAG value of B'0_1111. b14: Corresponds to a TAG value of B'0_1110. b13: Corresponds to a TAG value of B'0_1101. b12: Corresponds to a TAG value of B'0_1100. b11: Corresponds to a TAG value of B'0_1011. b10: Corresponds to a TAG value of B'0_1010. b9: Corresponds to a TAG value of B'0_1001. b8: Corresponds to a TAG value of B'0_1000. b7: Corresponds to a TAG value of B'0_0111. b6: Corresponds to a TAG value of B'0_0110. b5: Corresponds to a TAG value of B'0_0101. b4: Corresponds to a TAG value of B'0_0100. b3: Corresponds to a TAG value of B'0_0011. b2: Corresponds to a TAG value of B'0_0010. b1: Corresponds to a TAG value of B'0_0001. b0: Corresponds to a TAG value of B'0_0000.

Notes: 1. Refer to the Serial-ATA specification for further information about this register.
2. This register is write-only. To reset this register, it is necessary to reset the device (Software Reset will do).

59.2.31 SATA INT Status Register (SATAINTSTAT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

Bits 31 to 24 of the SATA INT status register are Shadow Status bits and mirror the value of the shadow status register. As with the shadow status register, accessing this register for read causes the ATA-sourced host_int_ata_intrq interrupt signal to be negated. (* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bits 11 to 0 of this register identify the interrupt source of the host_intrq signal. The bits that are masked by the SATA INT mask register (SATAINTMASK) do not cause the host_intrq signal to be asserted when the corresponding interrupt source event occurs. In this case, the pertinent bit is not set either.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INT BSY	INT DRDY	INT DFSE	INTSST ATUS	INT DRQ	—	—	INT ERR	—	—	—	—	—	—	—	—
Initial value:	0	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	SDBF	SLUMR	PARTI R	VEND	BIST	SLUM	PARTI	DMAST	SERR	ERR	ERR CRT	ATA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	RC	RC	RC	RC	RC	RC	RC	RC	RC	RC	RC	RC

Bit	Bit Name	Initial Value	R/W	Description
31	INTBSY	B'0	R	BSY bit
30	INTDRDY	B'1	R	DRDY bit
29	INTDFSE	B'1	R	DF/SE bit
28	INTSSTATUS	B'1	R	Definition varies with the command.
27	INTDRQ	B'1	R	DRQ bit.
26, 25	—	B'11	R	Reserved These bits are always read as 1.
24	INTERR	B'1	R	ERR/CHK bit
23 to12	—	All 0	R	Reserved These bits are always read as 0.
11	SDBF	B'0	RC	Set Device Bits FIS reception
10	SLUMR	B'0	RC	A request for transition to the Slumber state has been received (for device-initiated power management, i.e. DIPM).
9	PARTIR	B'0	RC	A request for transition to the Partial state has been received (for device-initiated power management, i.e. DIPM).
8	VEND	B'0	RC	Vendor Specific FIS reception
7	BIST	B'0	RC	BIST Active FIS reception
6	SLUM	B'0	RC	Device rejects transition to Slumber Mode. Refer to notes 2.
5	PARTI	B'0	RC	Device rejects transition to Partial Mode. Refer to notes 2.
4	DMAST	B'0	RC	Same meaning as DMA Setup FIS reception (fpdma_req signal asserted)
3	SERR	B'0	RC	SCR SERROR register update

Bit	Bit Name	Initial Value	R/W	Description
2	ERR	B'0	RC	SCR SERROR register (SCRSERR) ERRE, ERRP, ERRC, ERRT, ERRM, and ERRI bits update
1	ERRCRT	B'0	RC	SCR SERROR register (SCRSERR) ERRE, ERRP, and ERRT bits update Refer to notes 1.
0	ATA	B'0	RC	ATA source (equivalent to P-ATA's INTRQ)

Notes: 1. When the "SCR SError register ERRE, ERRP, and ERRT bits update" interrupt bit is set, it indicates that the condition cannot be recovered by this host controller module. In such a case, take appropriate actions according to the operating state established before the error occurred and the value of the SCR SError register (SCRSERR).
Example:
1) When the ERRT bit of the SCR SError register (SCRSERR) is set on completion of a PIO Read (data-in) transfer:
The read data contains an error bit. Restart processing at the issuance of the command.
2) When the ERRE bit of the SCR SError register (SCRSERR) is set during DMA transfer:
The data that is being transferred contains an error but since it cannot be detected by the device, it is necessary to perform a software reset and restart processing at the issuance of the command.
3) When the ERRP bit of the SCR SError register (SCRSERR) is set:
Perform a hardware reset and re-execute the preceding operation.

2. When a "device rejects transition to Slumber Mode" or "device rejects transition to Partial Mode" interrupt occurs, no request is reissued (retried) to the device. If requests should be made again, reset the SCR SControl register with a correct value.

59.2.32 SATA INT Mask Register (SATAINTMASK)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The SATA INT mask register is used to mask the interrupt sources configured in the SATA INT status register (SATAINTSTAT). Interrupt sources corresponding to bits for which 1s have been specified are masked.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	SDBFMSK	B'1	R/W	Masks the "Set Device Bits FIS received" interrupt.
10	SLUMRMSK	B'0	R/W	Mask for the "request for transition to Slumber mode" interrupt (for DIPM).
9	PARTITMSK	B'0	R/W	Mask for the "request for transition to Partial mode" interrupt (for DIPM).
8	VENDMSK	B'1	R/W	Masks the "Vendor Specific FIS received" interrupt.
7	BISTMSK	B'1	R/W	Masks the "BIST Activate FIS received" interrupt.
6	SLUMMSK	B'1	R/W	Masks the "device reject transition to Slumber mode" interrupt.
5	PARTIMSK	B'1	R/W	Masks the "device reject transition to Partial mode" interrupt.
4	DMASTMSK	B'1	R/W	Masks the "DMA Setup FIS received" interrupt.
3	SERRMSK	B'1	R/W	Masks the "SCR SError register (SCRSERR) update" interrupt.
2	ERRMSK	B'1	R/W	Masks the "SCR SError register (SCRSERR) ERRE, ERRP, ERRC, ERRT, ERRM, and ERRI bits update" interrupt.
1	ERRCRTMSK	B'0	R/W	Masks the "SCR SError register (SCRSERR) ERRE, ERRP, and ERRT bits update" interrupt.
0	ATAMSK	B'0	R/W	Masks the "ATA source (equivalent to P-ATA's INTRQ)" interrupt. The NIEN bit of the shadow device control register (SDEVCON) provides the same effect.

59.2.33 PHY STOP Register (PHYSTOP)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PHY STOP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
0	PHY STOP	B'0	R/W	0: Normal 1: PHY STOP

Note: PHY STOP mode is used to stop the AFE. Apply a power-on reset to return the AFE from the PHY STOP mode (a software reset will not do this).

59.2.34 Rx DMA Setup FIS Dword0 Register (DMADW0)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The Rx DMA setup FIS Dword0 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

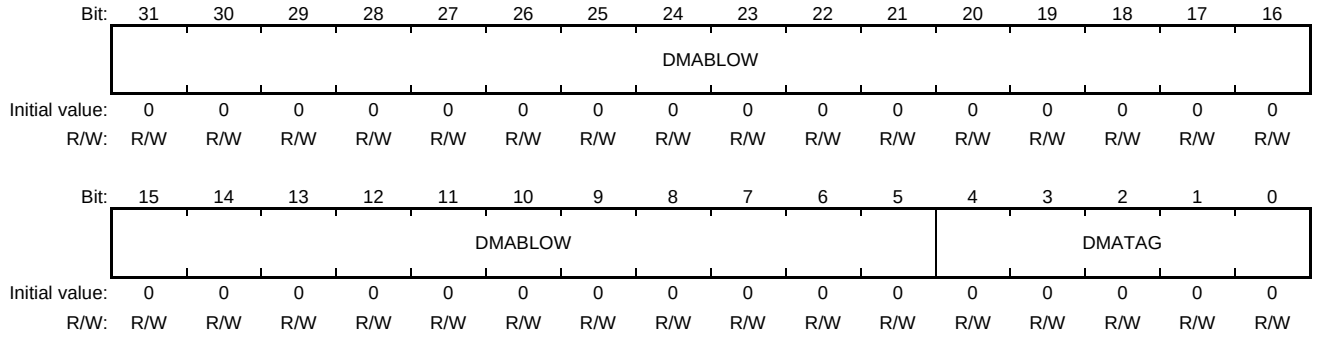
Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	AUTOACT	B'0	R/W	Auto-Activation bit 1 indicates Auto-Activation.
14	DMAINT	B'0	R/W	Interrupt bit
13	DMADIR	B'0	R/W	Data transfer direction bit The direction of the next data transfer. 0: Host → device 1: Device → host
12	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
11 to 8	PMPORT	All 0	R/W	Source device ID Always set to B'0000 in NCQ mode.
7 to 0	FISTYPE	All 0	R/W	FIS type bits FISTYPE indicates the type of a received FIS. The value is "41" when a DMA setup FIS is received.

Note: Refer to the Serial-ATA specification for further information about this register.

59.2.35 Rx DMA Setup FIS Dword1 Register (DMADW1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The Rx DMA setup FIS Dword1 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).



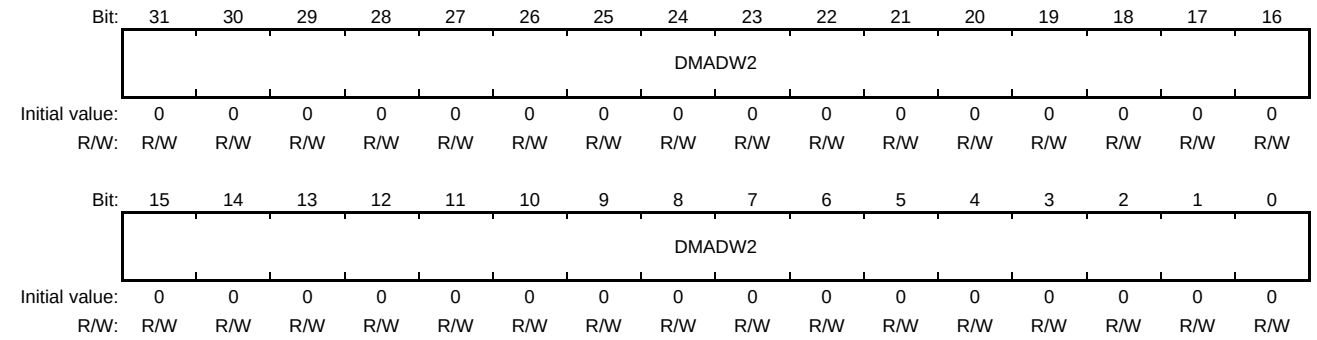
Bit	Bit Name	Initial Value	R/W	Description
31 to 5	DMABLOW	B'000_0000_0000_0000_0000_0000_0000	R/W	DMA Buffer Identifier Low field value in the DMA Setup FIS (set to H'0000_0000 in NCQ mode)
4 to 0	DMATAG	B'0_0000	R/W	TAG field for NCQ

Note: Refer to the Serial-ATA specification for further information about this register.

59.2.36 Rx DMA Setup FIS Dword2 Register (DMADW2)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The Rx DMA setup FIS Dword2 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).



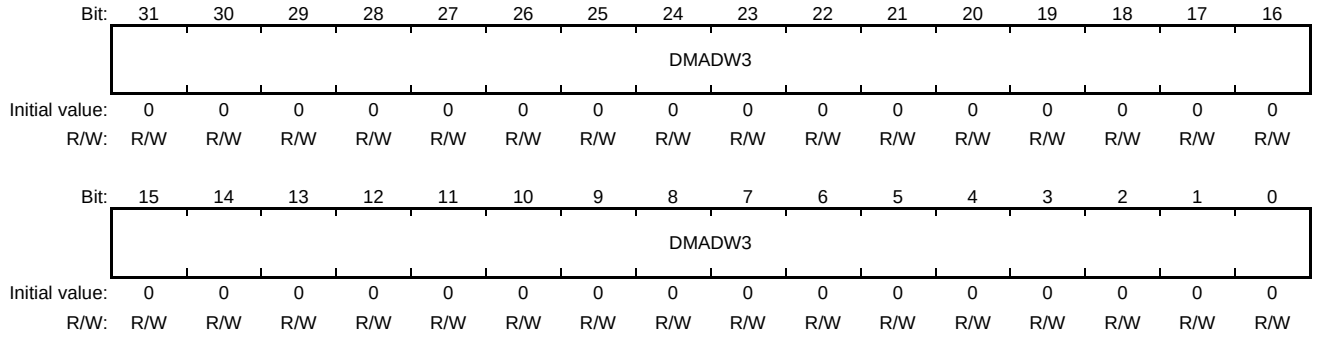
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMADW2	H'0000_0000	R/W	DMA Buffer Identifier High field value (Set to H'0000_0000 in NCQ mode)

Note: Refer to the Serial-ATA specification for further information about this register.

59.2.37 Rx DMA Setup FIS Dword3 Register (DMADW3)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The Rx DMA setup FIS Dword3 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).



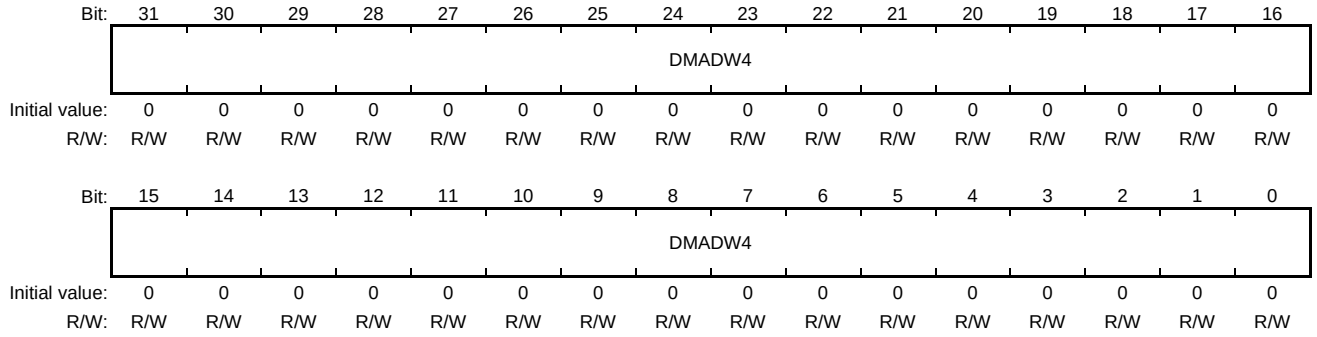
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMADW3	H'0000_0000	R/W	Dword3 value in the DMA Setup FIS (Normally set to H'0000_0000 as DMADW3 is handled as Reserved)

Note: Refer to the Serial-ATA specification for further information about this register.

59.2.38 Rx DMA Setup FIS Dword4 Register (DMADW4)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The Rx DMA setup FIS Dword4 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).



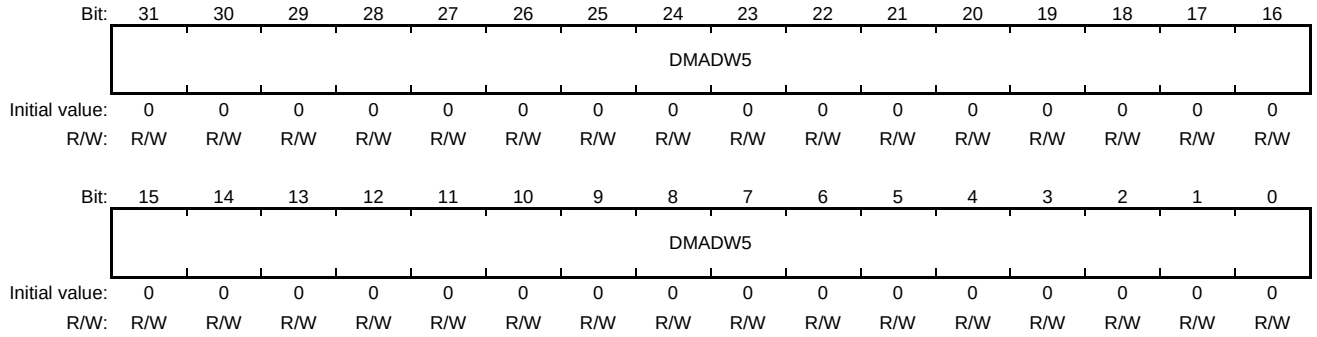
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMADW4	H'0000_0000	R/W	DMA Buffer Offset value in the DMA Setup FIS

Note: Refer to the Serial-ATA specification for further information about this register.

59.2.39 Rx DMA Setup FIS Dword5 Register (DMADW5)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The Rx DMA setup FIS Dword5 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).



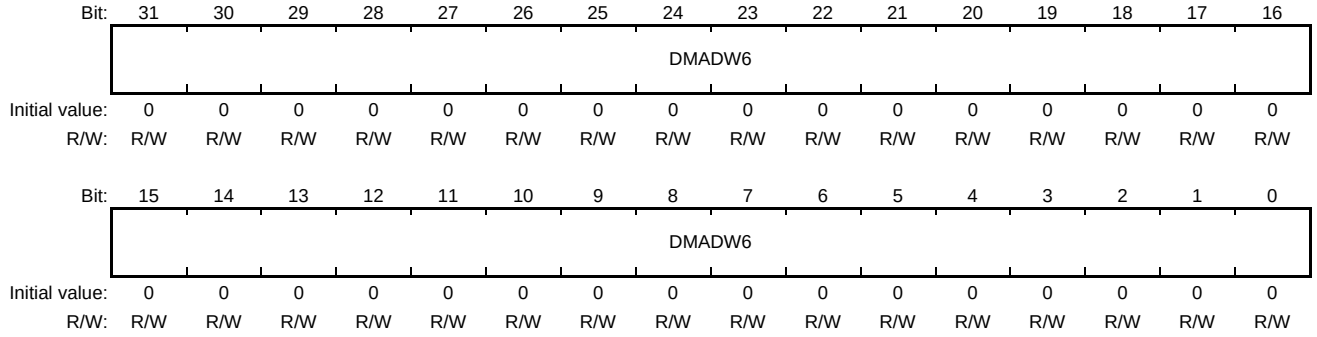
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMADW5	H'0000_0000	R/W	DMA Transfer Count value in the DMA Setup FIS

Note: Refer to the Serial-ATA Specification for further information about this register.

59.2.40 Rx DMA Setup FIS Dword6 Register (DMADW6)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	—	√	—

The Rx DMA setup FIS Dword6 register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMADW6	H'0000_0000	R/W	Dword6 value in the DMA Setup FIS (Normally set to H'0000_0000 as DMADW6 is handled as Reserved)

Note: Refer to the Serial-ATA specification for further information about this register.

59.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

59.3.1 Power Management Mode

The SATA interface can be switched into Partial, Slumber, or Active mode by setting up the CSPM field of the SCR SControl register (SCRSCON) for the required mode.

Note: Whenever restoring the SATA interface from Partial or Slumber mode to Active mode, be sure to verify with the SCR SStatus register (SCRSSTS) that the SATA interface is in Partial or Slumber mode. Any request issued to the device to switch into Power Management Mode with this register setting is not retried when it is rejected. To reissue the request, it is necessary to set up the SCR SControl register (SCRSCON) again.

59.3.2 Device Sleep

The device sleep (DevSleep) mode is a low power consumption mode which has been added to revision 3.2 of the SATA standard. The DevSleep mode dramatically reduces power consumption for devices (HDD and SSD) while the devices are placed in the standby state. To support the DevSleep mode, a side-band signal (DEVSLP pin) must be added to the host chip. For this SATA host IP, we recommend use of bit 0 (DEVSLP_EN) of the SATA extend DEVSLP register to control the DEVSLP pin.

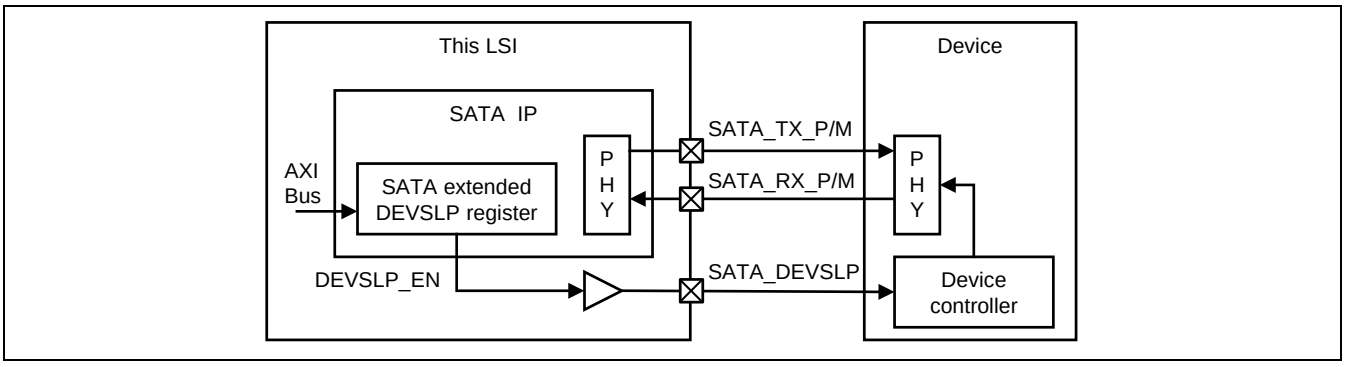


Figure 59.2 Example of DEVSLP Connection

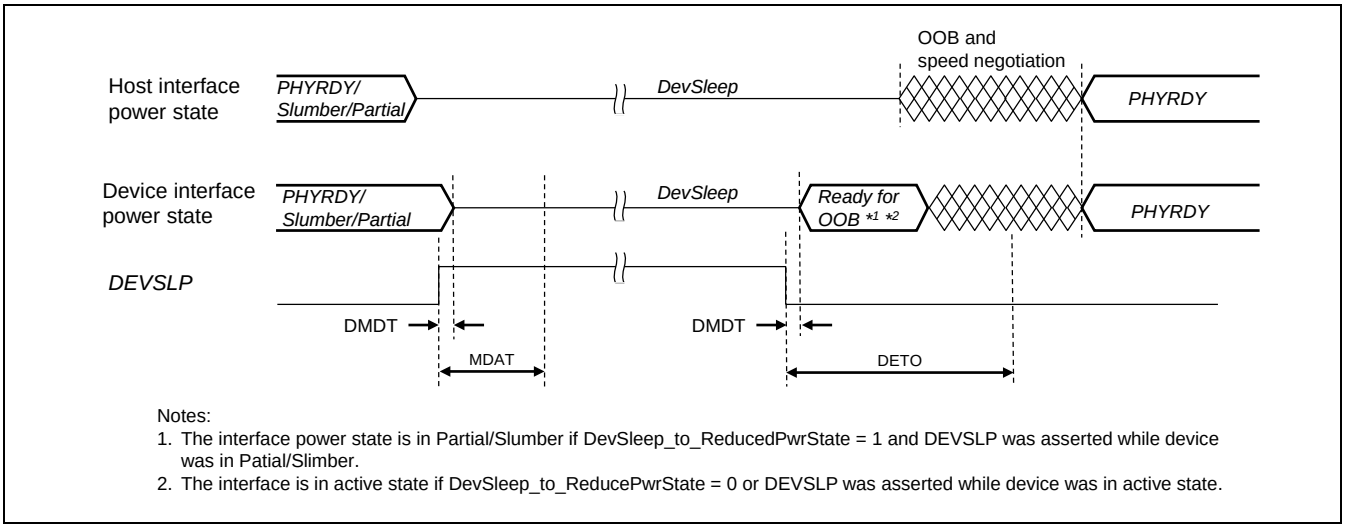

Notes:
1. The interface power state is in Partial/Slumber if DevSleep_to_ReducedPwrState = 1 and DEVSLP was asserted while device was in Patial/Slimber.
2. The interface is in active state if DevSleep_to_ReducePwrState = 0 or DEVSLP was asserted while device was in active state.

Figure 59.3 DEVSLP Protocol Overview (Source: Serial ATA Revision 3.2)

Table 59.5 DevSleep Timing Parameters (Source: Serial ATA Revision 3.2)

Symbol	Parameter	Value
MDAT	Minimum DEVSLP Assertion Time, minimum time that the host shall assert DEVSLP, once it has been asserted.	10 ms unless otherwise specified in Identify Device Data Log.
DMDT	DEVSLP Minimum Detection Time, minimum time the device needs to de-bounce the DEVSLP signal after detecting it has been asserted.	10 µs
DETO	DevSleep Exit Timeout, maximum time from when DEVSLP is negated, to when the device shall be ready to detected OOB Signals.	20 ms unless otherwise specified in Identify Device Data Log.

59.3.3 Initialization

To perform communication using this module, it is necessary to set up the bridge function and establish a SATA connection.

Follow the procedure shown below to initialize the SATA.

(1) Release the Module from Standby

After resetting, release the module from the standby state. Refer to section 12, Module Standby, Software Reset, for details on module standby. The module enters the module standby state after release from the power-on reset state.

(2) Establishing OOB and Speed Negotiation

Start OOB and speed negotiation at the resetting of the standby state.

59.3.4 Interrupt Modes

The Link block supports two operating modes in addition to the ATA compliant registers.

This section describes the interrupt source masks and the specifications with respect to the clearing of the interrupt sources.

Figure 59.4 illustrates interrupt functions.

(1) IP Compatible Mode (Initial Value, when ISM = 0)

(a) Interrupt Source Mask

When an interrupt is masked, the corresponding interrupt flag is not set in the status register.

(b) Clearing Interrupt Sources

Interrupt sources are cleared by reading the SATA INT status register (SATAINTSTAT).

As with the shadow status register (SSTATUS), a read access causes the ATA-sourced (corresponding to INTRQ of P-ATA) host_intrq interrupt signal to be negated.

The ATA-specified interrupt source, SCR SError register (SCRSERR), is cleared by writing 1.

(2) CIS Interrupt Mode (when ISM = 1)

(a) Interrupt Source Mask

Interrupts are masked but corresponding flags are still set in the status register.

During negotiation, bit 3 in the Interrupt Status register is set. After negotiation ends, all bits in the Interrupt Status register must be cleared to 0.

(b) Clearing Interrupt Sources

Interrupt sources are cleared by writing 0.

A read access does not cause the ATA-sourced (corresponding to INTRQ of P-ATA) host_intrq interrupt signal to be negated.

The ATA-specified interrupt source, SCR SError register (SCRSERR), is cleared by writing 1; there is no change with this respect.

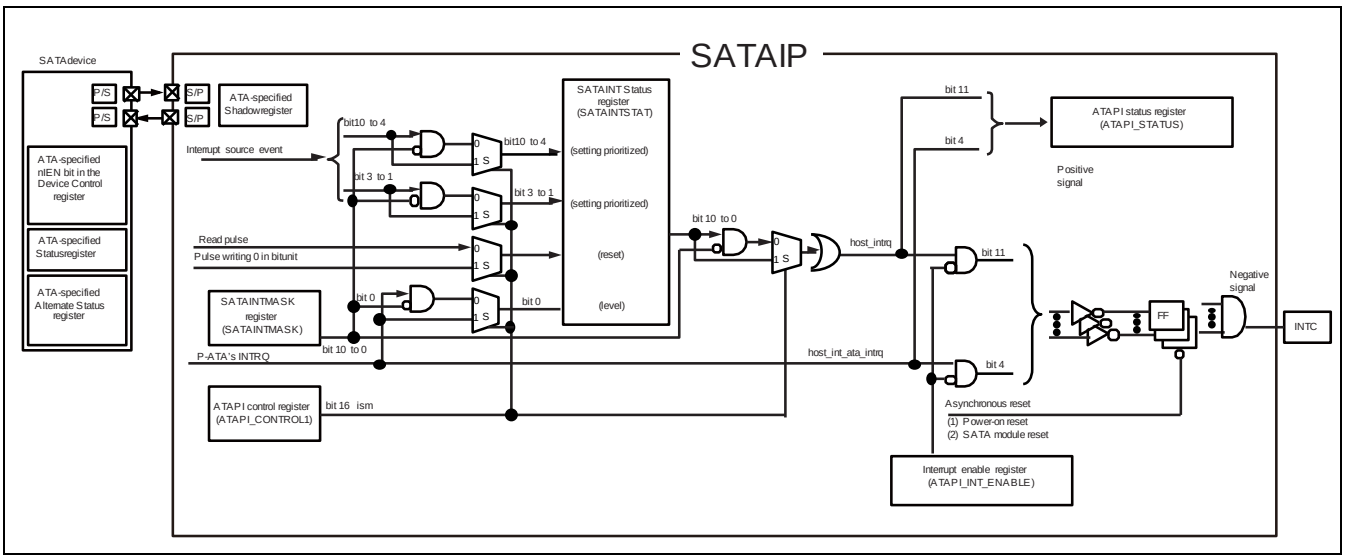

Figure 59.4 Interrupt Functions

59.3.5 Interrupt Processing Flow

The end of host device transfer interrupt and the ERR interrupt need to be considered.

The use of a timer in the wait processing is recommended to detect abnormal operations.

The device and host sources conflict. Figure 59.5 to 59.12 show the flow diagrams of interrupt processing.

The meanings of the words in the flow diagrams are given below.

CMD:	The CPU requests data transfer by writing to the SATA host and device registers.
Data ready:	Data for writing to (DATA-OUT) the SATA device by the CPU are prepared in memory.
DATA:	Data to be transferred (data to be transferred by DMA)
Data reference:	The CPU refers to data to be read from (DATA-IN) the SATA device in memory.
DMA request:	Request for DMA transfer from the SATA device
DEVINT, SERR, SATAINT:	Interrupt request originating in the device, such as the request corresponding to DEVINT (bit 4) in the ATAPI status register (ATAPI_STATUS)
NEND:	Interrupt request for the end of normal transfer of the SATA host, such as the requests corresponding to NEND (bit 1) in the ATAPI status register (ATAPI_STATUS)
Response:	Response to completion of writing to memory of data read from the SATA device
'Order may be reversed.’	The order of the error interrupt or the interrupt at the end of normal transfer to or from the device may be reversed before or after the end of normal transfer.
End of normal transfer:	The time of generation of the interrupt request corresponding to NEND (bit 1) or DNEND (bit 6) in the ATAPI status register (ATAPI_STATUS) as the source

One of the two sets of events listed below will occur according to the response time of the device and the internal response time.

States (1) to (3) occur at the end of normal transfer of DATA-OUT:

(1) Errors originating in the SATA device overlap.
(2) Errors due to SATA communications and the host overlap.
(3) The device's end interrupts will overlap if the device response is fast.

States (4) to (6) occur at the end of normal transfer of DATA-IN:

(4) Errors originating in the SATA device overlap.
(5) Errors due to SATA communications or the host overlap.
(6) The device's end interrupts will overlap if the internal response is fast.

59.3.6 Endian

This module adopts little endian. Consequently, data is represented in the same way as specified in the ATA/ATAPI-7 Specification and Serial-ATA Specification.

The bits of the registers are assigned in the order shown in Figure 59.13.

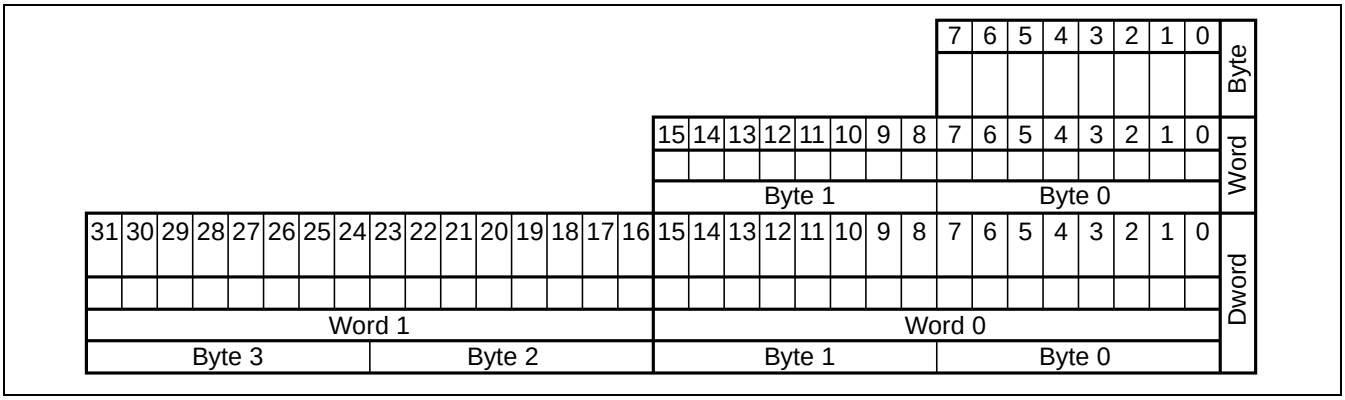

Figure 59.13 Endian and Bit Order

59.3.7 SATA BIST Modes

This module supports the Far-end Retimed Loopback and Far-end Analog Loopback modes that are stipulated in the Serial-ATA standard. The SATA BIST mode is the Loopback mode in which Loopback is formed on the host side. This mode can be configured and controlled for operation using the BIST config register (BISTCONF).

No match is performed between the transmit data from this module and the receive data from the device.

(1) Loopback Mode

In this mode, the data characters that are received are looped back to the sending side. The processing passes through the steps of input for reception → 10b/8b conversion → (Loopback)→ 8b/10b conversion → output for transmission. This corresponds to the Serial-ATA Specification's Far-end Retimed Loopback (Figure 59.14).

There are cases in which some action is requested by the device side in this mode. More specifically, the device side will request the module to transmit the BIST Activate FIS. The module, however, can reject the request.

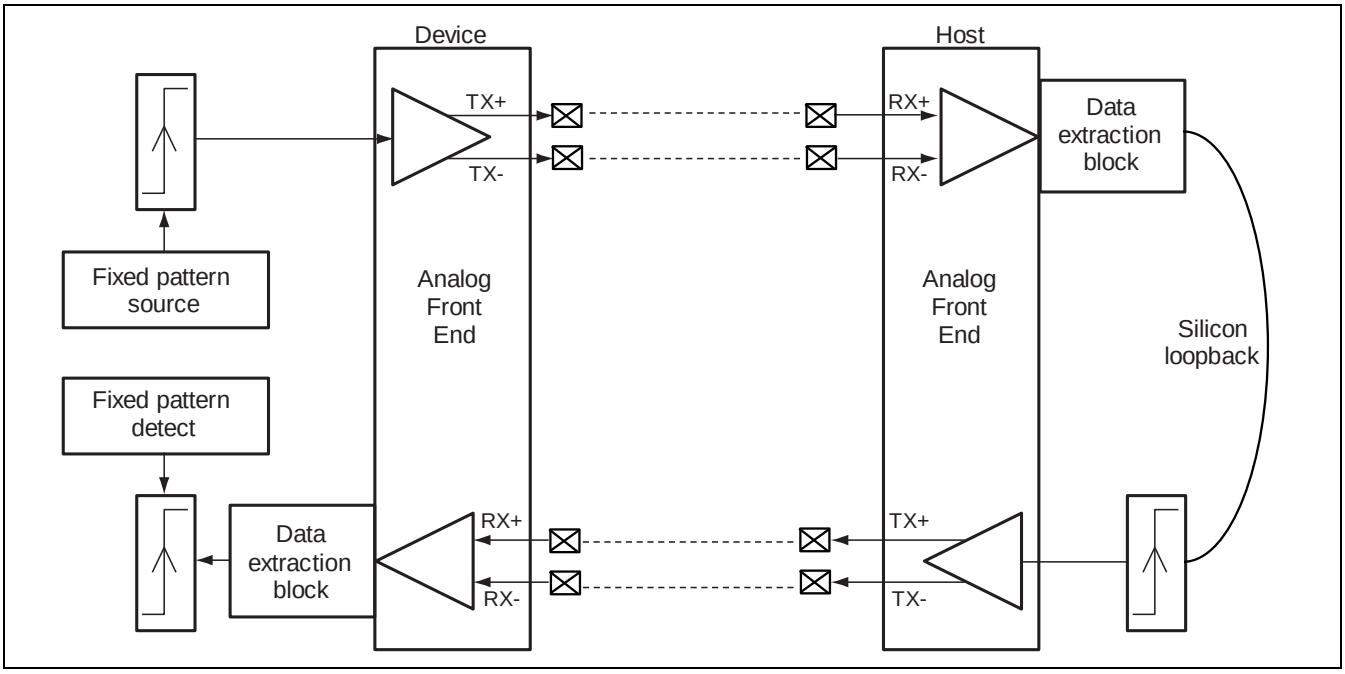

Figure 59.14 Far-End Retimed Loopback

(2) Analog Loopback Mode

This module does not support the Far-End Analog Loopback Mode (Figure 59.15) that is stipulated in the Serial-ATA Specification. In this mode, the received signal loops back through the AFE and output without modification as the result of which none of the Link and Transport layers get activated.

There are cases in which some action is requested by the device side in this mode. More specifically, the device side will request the module to transmit the BIST Activate FIS. The module, however, can reject the request.

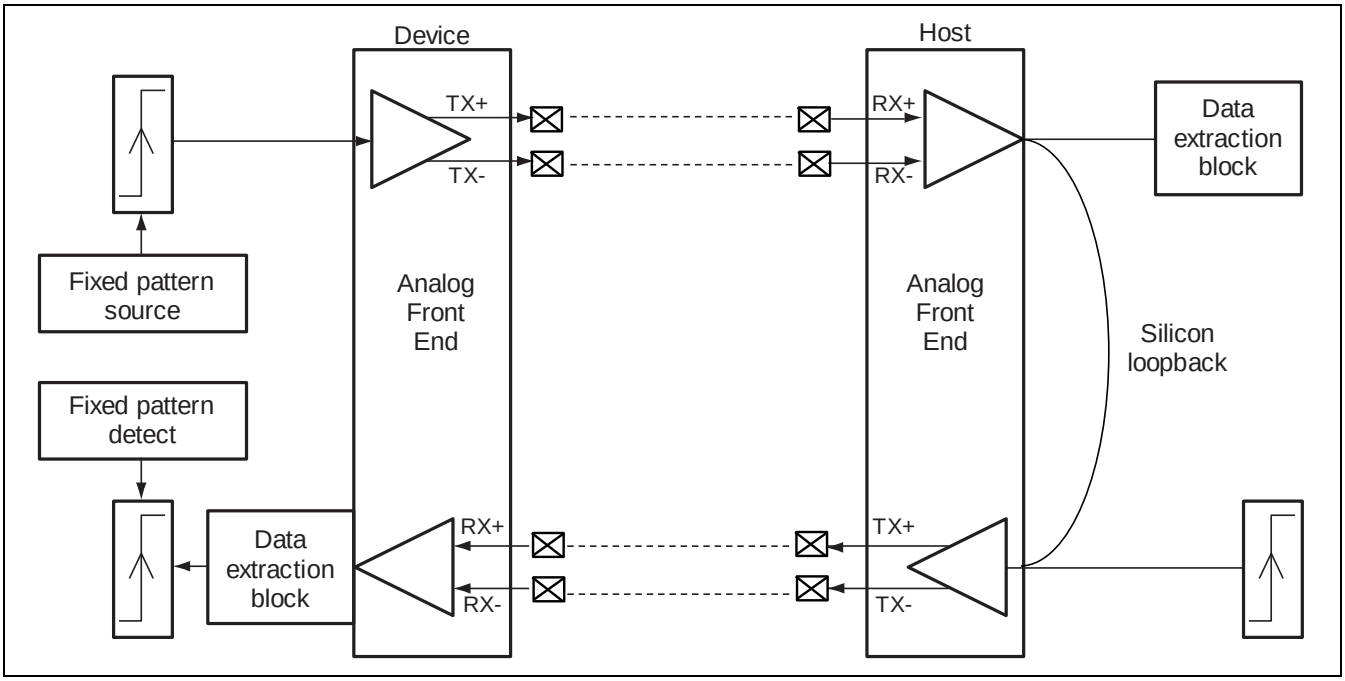

Figure 59.15 Far-End Analog Loopback

59.3.8 Operation Flow

Figure 59.16 shows the flow of operations for turning on the power, setting the interrupt mode, and initializing the PHY layer.

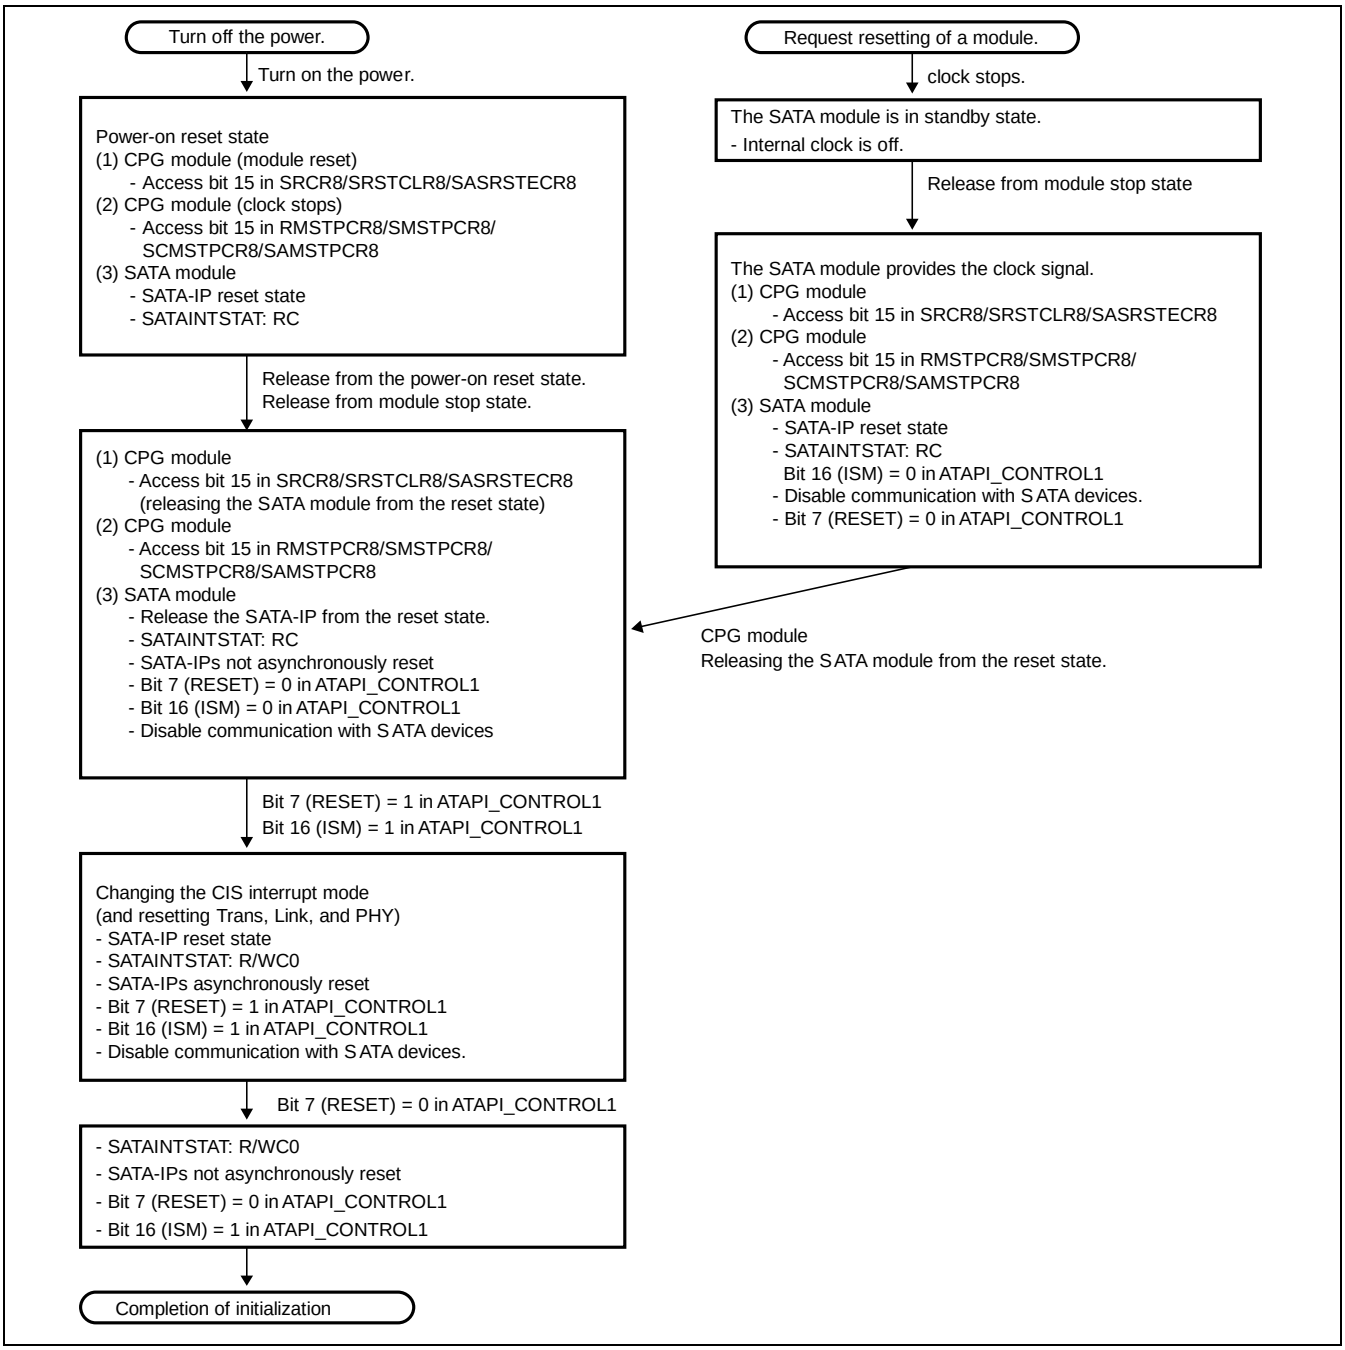

Figure 59.16 Operation Flow

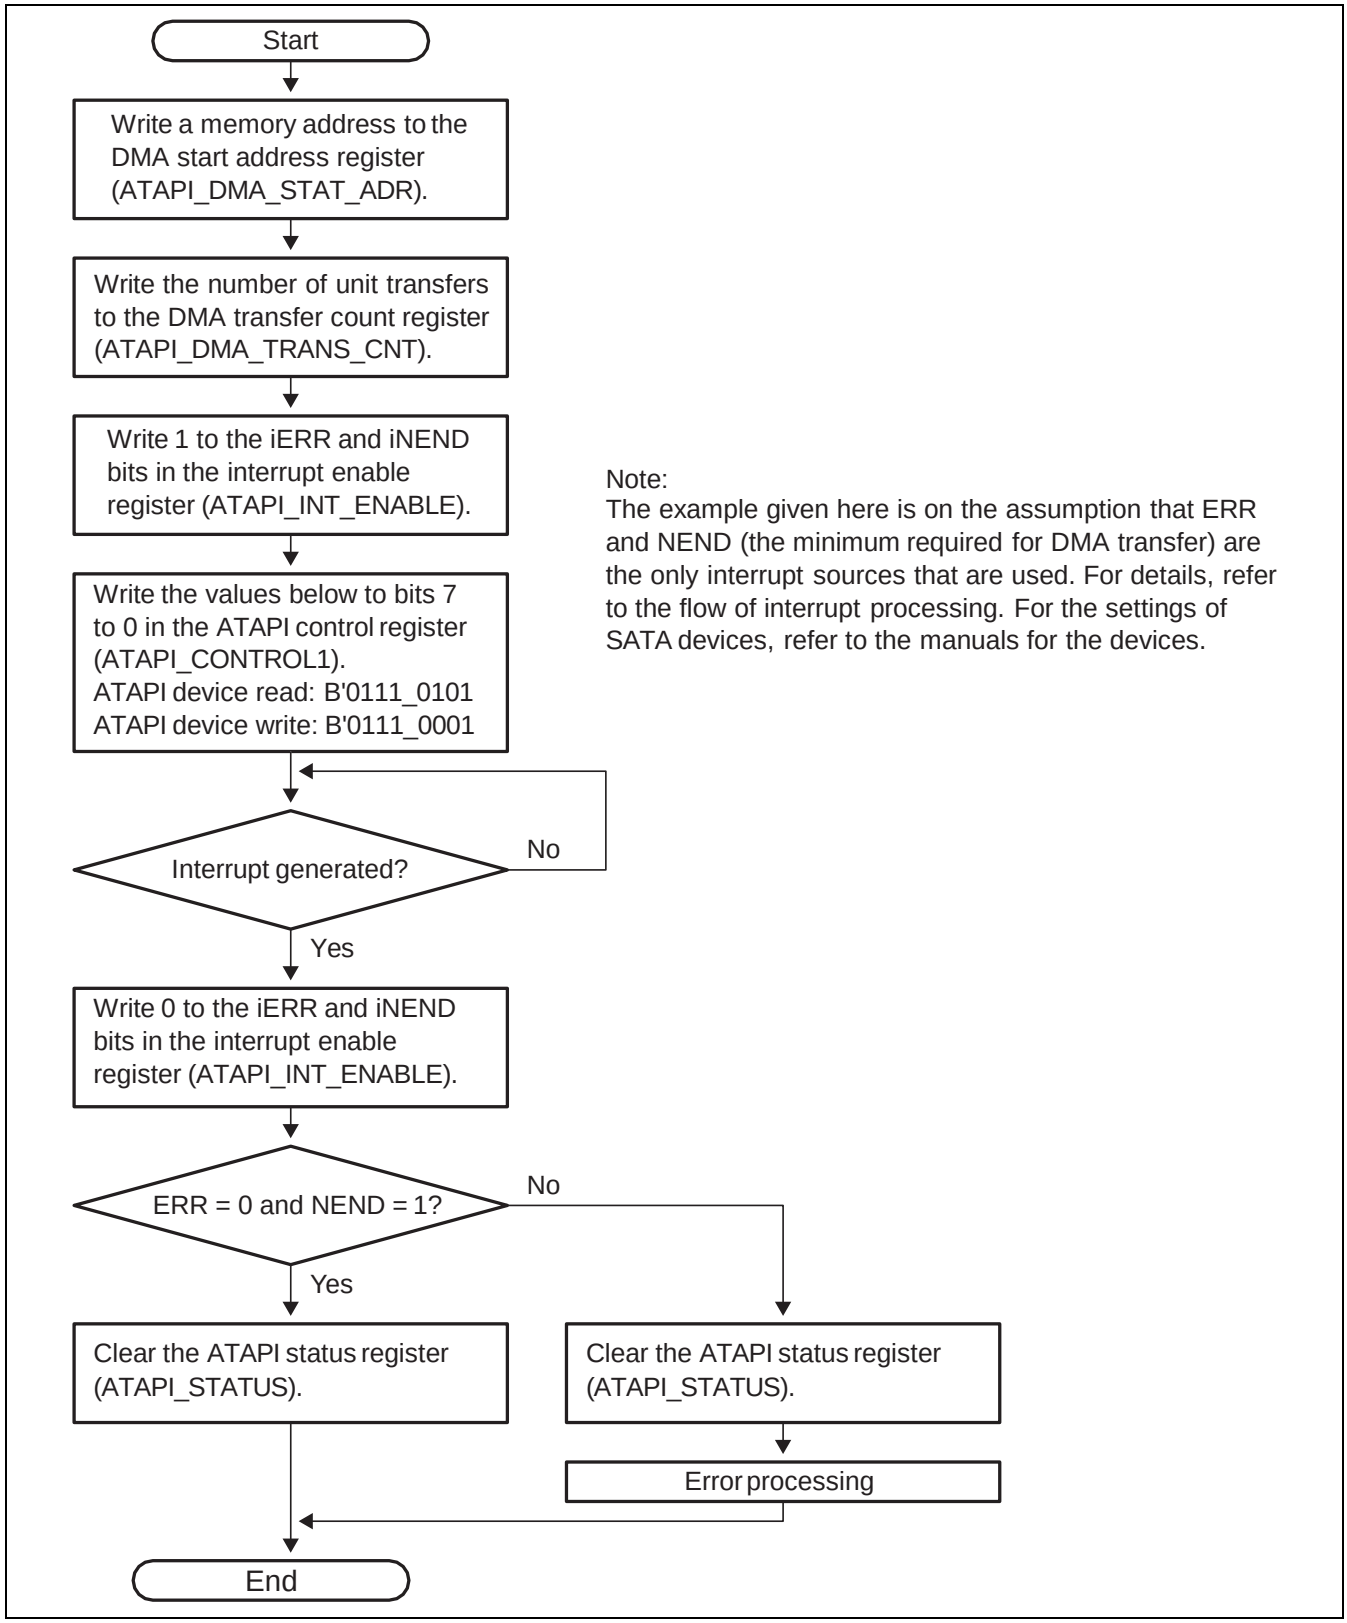

Figure 59.17 Flow of Data Transfer

59.3.9 Resets

(1) Power-on Reset

It is possible to reset this module into the initial state that is entered when the module is started by performing a power-on reset. Set and hold this line low for 25 µs or longer before releasing the signal. When the reset sequence subsequently gets completed, the BSY bit of the shadow status register (SSTATUS) is set to 0 (the same sequence as in a hardware reset is carried out after the SATA interface is stabilized).

(2) Resetting the SATA Module

The CPG module has reset functions equivalent to those of a power-on reset. For resetting of the SATA module, refer to the descriptions of the CPG module.

(3) Hardware Reset

Changing the value of the CDET field of the SCR SControl register (SCRSCON) from B'0001 to B'0000 resets the device and the Phy, Link, and Transport layers' state machines. This handling corresponds to the Hardware Reset stipulated in the ATA standard. Reset the CDET field to B'0001 and, after the lapse of 25 µs or longer, reset it to B'0000. When the reset sequence subsequently is completed, the BSY bit of the shadow status register (SSTATUS) is set to 0.

The hardware reset causes all of the shadow task registers (shadow data (DATA), shadow error (SERR), shadow features (SFEATURES), shadow sector CNT (SECCNT), shadow LBA low (LBALOW), shadow LBA mid (LBAMID), shadow LBA high (LBAHIGH), shadow device/head (DEVHEAD), shadow status (SSTATUS), shadow command (SCOM), shadow alternates status (SALTSTS), and shadow device control (SDEVCON) registers), SATA extend register and SCR registers (SCR SStatus (SCRSSTS), SCR SError (SCRSERR), SCR SControl (SCRSCON), and SCR SActive (SCRSACT) registers) to be reset.

Note: Refer also to the ATA/ATAPI-7 specification and Serial-ATA specification for further information about register update and hardware reset.

(4) Software Reset

The ATA specified software reset can be carried out by setting and resetting the SRST bit of the shadow device control register (DEVHEAD). Set the SRST bit to 1 and, after the lapse of 5 µs or longer, reset the bit to 0. When the reset sequence subsequently is completed, the BSY bit of the shadow status register (SSTATUS) is set to 0.

Note: Refer also to the ATA/ATAPI-7 specification and Serial-ATA specification for further information about register update and software reset.

59.3.10 Extended ATA Registers

The five ATA stipulated registers, i.e., Features, sector count, LBA low, LBA mid, and LBA high registers, are provided with an 8-bit extended (exp) register. This register is used by the 48-bit Address feature set commands, WRITE FPDMA QUEUED, and READ FPDMA QUEUED commands.

This host controller module implements the exp registers for the above registers according to the ATA standard.

The following steps are required when writing data into the exp register of, for example, the Sector Count register:

1) Write a desired value to be set in sector count exp register to the sector count register.
2) Write a desired value to be set in sector count register to the sector count register.

Consequently, the value that is written in step 1) is pushed into the exp register by the access that is made in step 2).

This host controller module transmits the data corresponding to the exp register as contents of the (H2D) Register FIS irrespective of the command code specified. Whether the data corresponding to the exp register is used or not is at the discretion of the command interpreter on the device side and the host side makes no intervention.

59.3.11 Signature of the Shadow Register (INFORMATIVE)

The Serial-ATA Specification stipulates that the device shall transmit a Register FIS*[1] immediately after a power-on reset, hardware reset, or software reset*[2] for the purpose of loading a shadow register with a value called the signature. This is also stipulated in the ATA/ATAPI-7 standard in the same way. Even when this SATA module reads out the shadow register for the purpose of receiving this register FIS and having its value reflected in the shadow register, for example, following the completion of OOB processing at power-on time, it cannot read the original initial value of the register because its value has already been modified.

For details on the signature, refer to the section on "Device command layer protocol" in the Serial-ATA Specification.

Notes: 1. There are commands such as EXECUTE DEVICE DIAGNOSTIC which take the signature as their return value. Their detailed description is omitted here. For details, refer to the Serial-ATA Specification.
2. This refers to the PHYRDY state, that is, immediately after bits 3-0 of the SCR SStatus register (SCRSSTS) are set to B'0011 for power-on reset and hardware reset, and to the time immediately after the reset processing is completed on the device side for software reset.

59.3.12 Reference Clock Source

Reference clock of SATA module is supplied from the external pin.

59.4 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

59.4.1 Host Termination

(1) Restriction

Immediately after host termination is executed in this IP, conduct a power-on reset or reset the hardware immediately.

(2) Fractional Data in DOUT Transfer

For host termination in DOUT transfer, the last DWORD is copied, including the end of the data management unit for the device. Zero padding is applied where data do not take up 16 bits.

59.4.2 Clock Input in the Partial and Slumber States

Do not stop input of the reference clock signal while the interface is in the Partial or Slumber state.

60.1 Overview

This module is a USB2.0 host controller conforming to the Enhanced Host Controller Interface (EHCI) Specification for USB Rev. 1.1.

Channel 0/3 can also be used as a dual-role device (DRD) or an OTG device in combination with a peripheral link module connected to the external UTMI+ interface.

60.1.1 Features

The descriptions in this section are compliant with the following USB 2.0 standards: "Universal Serial Bus Specification Revision 2.0" and "On-The-Go and Embedded Host Supplement to the USB Revision 2.0 Specification".

The following shows the features of this module.

Function	Description
Host function	• Supports High-speed (480 Mbps), Full-speed (12 Mbps), and Low-speed (1.5 Mbps) transfer. • Conforms to the Open Host Controller Interface (OHCI) Specification for USB Rev. 1.0a. • Conforms to the Enhanced Host Controller Interface (EHCI) Specification for USB Rev. 1.1.*1
Peripheral function	The peripheral function is available through a peripheral controller module connected to the external UTMI+ interface (only for channel 0).
Accessible memory space	32 bits
USB port count	Downstream port: 1 port for each channel Upstream port: 1 port
Other functions	• Battery charging function (supporting SDP and CDP conforming to Battery Charging Specification Rev. 1.2) • Dual-role device function (static switching between the USB host and peripheral functions) • OTG function*2 (supporting HNP and SRP conforming to Specification Rev. 2.0)

Notes: 1. Some functions (specifications) are not supported.
2. This function isn't supported RZ/G2E.

60.1.1.1 OTG Function

This module provides a function (registers) necessary to implement the OTG function using this module (host core) and the HS-USB module (peripheral). The registers necessary for OTG control are implemented in the UCOM module.

The OTG function can be used through appropriate control of these registers, EHCI registers, and HS-USB module registers by firmware according to the following policies.

[Basic policies of OTG control]

1. When this module is used for the OTG function, USB0SEL[1:0] in UGCTRL2 register of HS-USB should be set to B'11 and the host and peripheral modes should be switched through the UCOM registers.
2. The host function should be controlled through the EHCI registers and the peripheral function should be controlled through the HS-USB module registers in principle. The UCOM registers are used to control only the following.

- Host and peripheral mode switching
- VBUS supply control (A-device)
- Interrupt control (ID interrupt, VBUS interrupt, etc.)
- USB bus monitoring
- 15-kΩ pulldown resistor control

60.1.1.2 Battery Charging Function

The UCOM module in this module provides registers for controlling battery charging. The battery charging function of the UTMI+ PHY connected to this module is controlled by these registers of UCOM.

60.1.1.3 Core Setting

60.1.1.4 Host/Peripheral Switching Specifications

This module controls whether to use channel 0 as a downstream port (host function) or an upstream port (peripheral function) through a register setting. Control the OTG_PERI bit according to the user system specifications.

Switching between the host and peripheral functions is controlled through bit 31 (OTG_PERI) in the common control register in the UCOM when USB0SEL[1:0] in UGCTRL2 register of HS-USB be set to B'11. This control assumes the case where this module is used for OTG.

Channel	OTG_PERI (Register Bit)	Function
1	—	Fixed to host
0	0	Host
	1	Peripheral

60.1.2 External Pins

Table 60. 1 External Pins of USB

				Second Generation RZ/G Series Products			
Name	**Pin Name**	**I/O**	**Description**	**RZ/G2H**	**RZ/G2M V1.3 RZ/G2M V3.0**	**RZ/G2N**	**RZ/G2E**
Clock input for USB	USB_EXTAL	I	Used as an external clock input pin (50MHz)	√	√	√	—
	USB_XTAL	O	Outputs amplified negative feedback of EXTAL (50MHz)	√	√	√	—
USB D+ data	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] DPn [RZ/G2E] USB0_DP0	I/O	D+ Input/output of the on-chip transceiver Connect this pin to the D+ pin of the USB bus.	√	√	√	√
USB D- data	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] DMn [RZ/G2E] USB0_DM0	I/O	D- Input/output of the on-chip transceiver Connect this pin to the D- pin of the USB bus.	√	√	√	√
USB Identification	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] IDn [RZ/G2E] USB0_ID	I/O	Connect to the pin on the Micro connectors that is used to differentiate a Micro-A plug from a Micro-B plug.	√	√	√	√
USB VBUS	VBUSn	I/O	Connect to USB VBUS with external 30kΩ±1% series resistor.	√	√	√	—
USB external reference resistor	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] TXRTUNEn [RZ/G2E] USB0_RREF	I/O	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] Connect to external 200Ω±1% resistor. [RZ/G2E] Connect to external 1.8kΩ±1% resistor.	√	√	√	√

Notes: 1. The VBUS of USB connecter must not connect directly to VBUSn pin.
2. VBUSn pin must be isolated by an external 30kΩ±1% series resistor.
3. ‘n’ in Pin Name column are 0 or 1 for RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N, 0 for RZ/G2E.
4. A charge pump external to the USB PHY must provide power to VBUSn pin.

60.1.3 Register Configuration

60.1.3.1 Register Attributes

Table 60. 2 Register Bit-field types

Register Attribute	Description
R/W	Register bits can be read and written.
R/WC1	Register bits can be read. A clear bit may be set by writing “1”; writing 0 to R/WC1 bits has no effect.
R	Register bits can only be read.
W	Register bits can only be written.
Reserved	Reserved bits are Read Only field.

60.1.3.2 Address Mappings

Table 60.3 EHCI/OHCI Base Address
