Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	RWE	RWC	IR	HCFS		BLE	CLE	IE	PLE	CBSR	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 11	Reserved	R	R	All 0	This field shows a BCD encoding of the EHCI revision number supported by this host controller core. This host controller core supports EHCI v.1.1.
10	RWE	R/W	R	B'0	RemoteWakeupEnable This bit is used by software to enable or disable the remote wakeup feature upon the detection of upstream resume signaling. When this bit is set and the ResumeDetected bit in HcInterruptStatus is set, a remote wakeup is signaled to the host system. Setting this bit has no impact on the generation of hardware interrupt. 0: An interrupt due to remote wakeup is not generated. 1: An interrupt due to remote wakeup is generated.
9	RWC	R/W	RW	B'0	RemoteWakeupConnected This bit indicates whether the host controller supports remote wakeup signaling. Software should set this bit to 1 in the initialization sequence if it is required to support remote wakeup. The host controller clears this bit to 0 upon hardware reset but does not alter it upon software reset. 0: The remote wakeup is not supported. 1: The remote wakeup is supported.
8	IR	R/W	R	B'0	InterruptRouting This bit determines the routing of interrupts generated by events registered in HcInterruptStatus. If this bit is 0, all interrupts are routed to the normal host bus interrupt mechanism. If this bit is set to 1, interrupts are routed to the System Management Interrupt. Software clears this bit upon a hardware reset, but it does not alter this bit upon a software reset.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
7, 6	HCFS	R/W	R/W	B’00	HostControllerFunctionalState B’00: USB Reset B’01: USB Resume B’10: USB Operational B’11: USB Suspend. This field defines the functional state of the host controller. The transition to USB Operational state from another state causes SOF generation to show 1-ms frame boundary. Software controls this bit basically; this field may be changed by the host controller only when in the USB Suspend state. The host controller may move from the USB Suspend state to the USB Resume state after detecting the resume signaling from a downstream port. The host controller enters USB Suspend state after software reset, whereas it enters USB Reset state after hardware reset.
5	BLE	R/W	R	B’0	BulkListEnable This bit is set to 1 in order to enable the processing of the Bulk list in the next Frame. If this bit is 0, processing of the Bulk list does not occur after the next SOF. The host controller checks this bit whenever it determines to process the list. When software modifies the Bulk list, it should set this bit to 0 before modifying the list. 0: The processing of the Bulk list is disabled. 1: The processing of the Bulk list is enabled.
4	CLE	R/W	R	B’0	ControlListEnable This bit is set to 1 in order to enable the processing of the Control list in the next Frame. If this bit is 0, processing of the Control list does not occur after the next SOF. The host controller checks this bit whenever it determines to process the list. When software modifies the Control list, it should set this bit to 0 before modifying the list. 0: The processing of the Control list is disabled. 1: The processing of the Control list is enabled.
3	IE	R/W	R	B’0	IsochronousEnable This bit is set to 1 in order to enable the processing of isochronous EDs. While processing the periodic list in a Frame, the host controller checks the status of this bit when it finds an Isochronous ED (F = 1). If this bit is 1 (enabled), the host controller continues processing the EDs. If this bit is 0 (disabled), the host controller halts processing of the periodic list (which contains only isochronous EDs right now) and begins processing the Bulk/Control lists. Setting this bit is guaranteed to take effect in the next Frame (not the current Frame). 0: The processing of the isochronous ED is disabled. 1: The processing of the isochronous ED is enabled.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
2	PLE	R/W	R	B’0	PeriodicListEnable This bit is set to enable the processing of the periodic list in the next Frame. If cleared to 0 by software, processing of the periodic list does not occur after the next SOF. The host controller checks this bit before it starts processing the periodic list. 0: The processing of the periodic list is disabled. 1: The processing of the periodic list is enabled.
1, 0	CBSR	R/W	R	B’00	ControlBulkServiceRatio This field specifies the service ratio between Control and Bulk EDs. In case of reset, software should restore the value in this field. **CBSR No. of Control EDs Over Bulk EDs Served** B’00: 1:1 B’01: 2:1 B’10: 3:1 B’11: 4:1

60.2.1.3 HcCommandStatus Register (offset: H'008)

Register symbol: HcCommandStatus

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The HcCommandStatus register is used by the host controller to receive commands issued by software, as well as reflecting the current status of the host controller.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOC	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	OCR	BLF	CLF	HCR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	W	R/W	R/W	W

		R/W			
Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31 to 18	—	R	R	All 0	Reserved
17, 16	SOC	R	R/W	B’00	SchedulingOverrunCount This field is incremented on each scheduling overrun error. It is initialized to B'00 and wraps around at B'11. This field is incremented when a scheduling overrun is detected even if SchedulingOverrun in HcInterruptStatus register has already been set.
15 to 4	—	R	R	All 0	Reserved
3	OCR	W	R/W	B’0	OwnershipChangeRequest This bit is set by software to request a change of control of the host controller. When this bit is set to 1, the host controller sets the OwnershipChange bit in HcInterruptStatus register. After the changeover, this bit is cleared to 0. 0: The change of control of the host controller is not requested. 1: The change of control of the host controller is requested.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
2	BLF	R/W	R/W	B'0	BulkListFilled This bit is used to indicate whether there are any TDs on the Bulk list. It is set by software whenever it adds a TD to an ED in the Bulk list. When the host controller begins to process the head of the Bulk list, it checks BLF bit. As long as BLF bit is 0, the host controller does not start processing the Bulk list. If BLF bit is 1, the host controller starts processing the Bulk list and sets BLF bit to 0. If the host controller finds a TD on the list, then the host controller set BLF bit to 1 causing the Bulk list processing to continue. If no TD is found on the Bulk list, and if software does not set BLF bit, then BLF bit remains at 0 when the host controller completes processing the Bulk list and Bulk list processing will stop. 0: TD exists in the Bulk list. 1: TD does not exist in the Bulk list.
1	CLF	R/W	R/W	B'0	ControlListFilled This bit is used to indicate whether there are any TDs on the Control list. It is set by software whenever it adds a TD to an ED in the Control list. When the host controller begins to process the head of the Control list, it checks CLF bit. As long as CLF bit is 0, the host controller does not start processing the Control list. If CLF bit is 1, the host controller starts processing the Control list and sets CLF bit to 0. If the host controller finds a TD on the list, then the host controller set CLF bit to 1 causing the Control list processing to continue. If no TD is found on the Control list, and if software does not set CLF bit, then CLF bit remains at 0 when the host controller completes processing the Control list and Control list processing will stop. 0: TD exists in the Control list. 1: TD does not exist in the Control list.
0	HCR	W	R/W	B'0	HostControllerReset This bit is set by software to initiate software reset of the host controller. Regardless of the functional state of the host controller, it moves to the USB Suspend state. This bit is cleared to 0 by the host controller upon the completion of the reset operation. 0: The software reset of the host controller is not requested. 1: The software reset of the host controller is requested.

60.2.1.4 HcInterruptStatus Register (offset: H'00C)

Register symbol: HcInterruptStatus

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register provides status on various events that cause hardware interrupts. When an event occurs, the host controller sets the corresponding bit in this register. When a bit becomes set, an interrupt is generated if the interrupt is enabled in the HcInterruptEnable register and the MasterInterruptEnable bit is set.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	OC	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	RHSC	FNO	UE	RD	SF	WDH	SO
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31	—	R	R	B'0	Reserved
30	OC	R/W	R/W	B'0	OwnershipChange This bit is set by the host controller when software sets the OwnershipChangeRequest field in HcCommandStatus register. 0: The ownership change has not been requested. 1: The ownership change has been requested.
29 to 7	—	R	R	All 0	Reserved
6	RHSC	R/W	R/W	B'0	RootHubStatusChange This bit is set when the content of HcRhStatus or the content of any of HcRhPortStatus [NumberofDownstreamPort] has changed. 0: The status of root hub has not changed. 1: The status of root hub has changed.
5	FNO	R/W	R/W	B'0	FrameNumberOverflow This bit is set when the MSB of HcFmNumber (bit 15) changes value, from 0 to 1 or from 1 to 0, and after HccaFrameNumber has been updated. 0: The overflow of frame number has not occurred. 1: The overflow of frame number has occurred.
4	UE	R/W	R/W	B'0	UnrecoverableError This bit is set when the host controller detects a system error not related to USB (system bus error, for example). The host controller should not proceed with any processing nor signaling before the system error has been corrected. Software clears this bit after the host controller has been reset in that case. 0: The unrecoverable error has not occurred. 1: The unrecoverable error has occurred.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
3	RD	R/W	R/W	B'0	ResumeDetected This bit is set when the host controller detects that USB device is asserting resume signaling. This bit is not set when Software sets the USB Resume state. 0: The host controller has not detected resume signaling. 1: The host controller has detected resume signaling.
2	SF	R/W	R/W	B'0	StartofFrame This bit is set by the host controller at each start of a frame and after the update of HccaFrameNumber. The host controller also generates a SOF token at the same time. 0: The host controller has not started new frame. 1: The host controller has started new frame.
1	WDH	R/W	R/W	B'0	WritebackDoneHead This bit is set immediately after the host controller has written HcDoneHead to HccaDoneHead. Further updates of the HccaDoneHead will not occur until this bit has been cleared. Software should only clear this bit after it has saved the content of HccaDoneHead. 0: The write back to HccaDoneHead has not occurred. 1: The write back to HccaDoneHead has occurred.
0	SO	R/W	R/W	B'0	SchedulingOverrun This bit is set when the USB schedule for the current Frame overruns and after the update of HccaFrameNumber. A scheduling overrun also increments the SchedulingOverrunCount of HcCommandSttus register. 0: The scheduling overrun has not occurred. 1: The scheduling overrun has occurred.

60.2.1.5 HcInterruptEnable Register (offset: H'010)

Register symbol: HcInterruptEnable

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Each enable bit in the HcInterruptEnable register corresponds to an associated interrupt bit in the HcInterruptStatus register. The HcInterruptEnable register is used to control which events generate a hardware interrupt.

A hardware interrupt is generated when all conditions below are satisfied.

1. A bit is set in HcInterruptStatus register
2. The corresponding bit in HcInterruptEnable register is set
3. MIE (MasterInterruptEnable) bit in HcInterruptEnable register is set

Writing 1 to a bit in this register sets the corresponding bit, whereas writing 0 to a bit in this register leaves the corresponding bit unchanged. On read, the current value of this register is returned.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MIE	OCE	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31	MIE	R/W	R	B'0	MasterInterruptEnable Writing 1 to this bit enables an interrupt generation due to events specified in the other bits of this register. This bit is used by software as a Master interrupt Enable. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to events specified in the other bits of this register is disabled. 1: An interrupt generation due to events specified in the other bits of this register is enabled.
30	OCE	R/W	R	B'0	Writing 1 to this bit enables an interrupt generation due to the request of ownership change. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the request of ownership change is disabled. 1: An interrupt generation due to the request of ownership change is enabled. Write 1 to OC bit in HcInterruptDisable register in order to clear this bit.
29 to 7	—	R	R	All 0	Reserved

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
6	RHSCE	R/W	R	B'0	Writing 1 to this bit enables an interrupt generation due to the change of the status of root hub. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the change of the status of root hub is disabled. 1: An interrupt generation due to the change of the status of root hub is enabled. Write 1 to RHSC bit in HcInterruptDisable register in order to clear this bit.
5	FNOE	R/W	R	B'0	Writing 1 to this bit enables an interrupt generation due to the overflow of frame number. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the overflow of frame number is disabled. 1: An interrupt generation due to the overflow of frame number is enabled. Write 1 to FNO bit in HcInterruptDisable register in order to clear this bit.
4	UEE	R/W	R	B'0	Writing 1 to this bit enables an interrupt generation due to the unrecoverable error. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the unrecoverable error is disabled. 1: An interrupt generation due to the unrecoverable error is enabled. Write 1 to UE bit in HcInterruptDisable register in order to clear this bit.
3	RDE	R/W	R	B'0	Writing 1 to this bit enables an interrupt generation due to the detection of resume signaling. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the detection of resume signaling is disabled. 1: An interrupt generation due to the detection of resume signaling is enabled. Write 1 to RD bit in HcInterruptDisable register in order to clear this bit.
2	SFE	R/W	R	B'0	Writing 1 to this bit enables an interrupt generation due to the start of frame. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the start of frame is disabled. 1: An interrupt generation due to the start of frame is enabled. Write 1 to SF bit in HcInterruptDisable register in order to clear this bit.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
1	WDHE	R/W	R	B'0	Writing 1 to this bit enables an interrupt generation due to the write back to HccaDoneHead. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the write back to HccaDoneHead is disabled. 1: An interrupt generation due to the write back to HccaDoneHead is enabled. Write 1 to WDH bit in HcInterruptDisable register in order to clear this bit.
0	SOE	R/W	R	B'0	Writing 1 to this bit enables an interrupt generation due to the scheduling overrun. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the scheduling overrun is disabled. 1: An interrupt generation due to the scheduling overrun is enabled. Write 1 to SO bit in HcInterruptDisable register in order to clear this bit.

60.2.1.6 HcInterruptDisable Register (offset: H'014)

Register symbol: HcInterruptDisable

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Each disable bit in the HcInterruptDisable register corresponds to an associated interrupt bit in the HcInterruptStatus register. The HcInterruptDisable register is coupled with the HcInterruptEnable register. Thus, writing 1 to a bit in this register clears the corresponding bit in the HcInterruptEnable register, whereas writing 0 to a bit in this register leaves the corresponding bit in the HcInterruptEnable register unchanged.

When this register is read, the current value of the HcInterruptEnable register is returned.

60.2.1.13 HcDoneHead Register (offset: H'030)

Register symbol: HcDoneHead

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The HcDoneHead register contains the physical address of the last completed Transfer Descriptor that was added to the Done queue. In normal operation, software is not required to read this register as its content is periodically written to the HCCA.

		R/W			
Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31 to 4	DH	R	R/W	H'000_0000	DoneHead When a TD is completed, the host controller writes the content of HcDoneHead to the NextTD field of the TD. The host controller then overwrites the content of HcDoneHead with the address of this TD. This is set to zero whenever the host controller writes the content of this register to HCCA. It also sets the WritebackDoneHead of HcInterruptStatus.
3 to 0	—	R	R	All 0	Reserved

60.2.1.14 HcFmInterval Register (offset: H'034)

Register symbol: HcFmInterval

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The HcFmInterval register contains a 14-bit value which indicates the bit time interval in a Frame, (i.e., between two consecutive SOFs), and a 15-bit value indicating the Full Speed maximum packet size that the host controller may transmit or receive without causing scheduling overrun. Software can carry out minor adjustment on the FrameInterval by writing a new value over the present one at each SOF.

		R/W			
Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31	FIT	R/W	R	B’0	FrameIntervalToggle Software writes the toggled value to this bit whenever it writes a new value to FI field. The value in this bit is also loaded to FRT bit in HcFmRemaining register whenever the value in FI field is loaded to FR field of the same register. Software can confirm that the value in FI field is loaded to FR field in HcFmReamining register by seeing the toggled value in FRT field in the same register.
30 to 16	FSMPS	R/W	R	H'0000	FSLargestDataPacket The field specifies the largest amount of data in bits which can be sent or received by the HC in a single transaction at any given time without causing scheduling overrun. The host controller decides whether it can still continue the transfer by comparing the current position in frame with the value in this field. Software calculates the value and set it to this field.
15, 14	—	R	R	All 0	Reserved
13 to 0	FI	R/W	R	H'2EDF	FrameInterval This specifies the interval between two consecutive SOFs in bit times for full speed mode of USB. Use with the value “H'2EDF” (=11,999) to satisfy 1 ms length of frame.

60.2.1.15 HcFmRemaining Register (offset: H'038)

Register symbol: HcFmRemaining

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The HcFmRemaining register is a 14-bit down counter showing the bit time remaining in the current Frame.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31	FRT	R	R/W	B'0	FrameRemainingToggle When FR field reaches 0, the value in FI field in HcFmInterval register is loaded to FR field. At the same time, the value in FIT bit in HcFmInterval register is loaded to this bit. Software can use this bit to confirm that the value in FI field in HcFmInterval register is exactly copied to FR field.
30 to 14	—	R	R	All 0	Reserved
13 to 0	FR	R	R/W	H'2EDF	FrameRemaining This counter is decremented at each bit time. When it reaches 0, the value in FI field in HcFmInterval register is loaded to it at the next bit time boundary. When entering USB Operational state, the host controller re-loads the value in FI field in HcFmInterval register and uses the updated value from the next SOF.

60.2.1.16 HcFmNumber Register (offset: H'03C)

Register symbol: HcFmNumber

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The HcFmNumber register is a 16-bit counter. It provides a timing reference among events happening in the host controller and software.

		R/W			
Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31 to 16	—	R	R	All 0	Reserved
15 to 0	FN	R	R/W	H'0000	FrameNumber This field is incremented when HcFmRemaining register is re-loaded. It will be rolled over to H'0 after H'FFFF. When entering the USB Operational state, this will be incremented automatically. The content will be written to HCCA after the host controller has incremented the FrameNumber at each frame boundary and sent a SOF but before the host controller reads the first ED in that Frame. After writing to HCCA, the host controller will set SF bit in HcInterruptStatus register.

60.2.1.17 HcPeriodicStart Register (offset: H'040)

Register symbol: HcPeriodicStart

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The HcPeriodicStart register has a 14-bit programmable value which determines when is the earliest time the host controller should start processing the periodic list.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	PS[13:8]						PS[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 14	—	R	R	All 0	Reserved
13 to 0	PS	R/W	R	H'0000	PeriodicStart This field specifies when host controller starts processing the periodic list. Software calculates the adequate value and set it to this filed during initialization. The value is calculated roughly as 10% off from FI field in HcFmInterval register. When FR field in HcFmRemaining register reaches the value specified, processing of the periodic lists has priority over Control/Bulk processing. Therefore the host controller starts processing the Interrupt list after completing the current Control or Bulk transaction that is in progress.

60.2.1.18 HcLSThreshold Register (offset: H'044)

Register symbol: HcLSThreshold

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The HcLSThreshold register contains an 12-bit value used by the host controller to determine whether to commit to the transfer of a maximum of 8-byte LS packet before EOF. Neither the host controller nor software is allowed to change this value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31 to 24	POTPGT	R/W	R	H'0F	PowerOnToPowerGoodTime This byte specifies the duration the host controller has to wait before accessing a powered-on port of the Root Hub. The unit of time is 2 ms. The duration is calculated as POTPGT * 2 ms.
23 to 13	—	R	R	All 0	Reserved
12	NOCP	R/W	R	B'0	NoOverCurrentProtection This bit defines how the overcurrent status for the Root Hub ports is reported. When this bit is cleared, OCPM bit specifies global or per-port reporting. 0: Over-current status is reported collectively for all downstream ports 1: No overcurrent protection supported
11	OCPM	R/W	R	B'1	OverCurrentProtectionMode This bit defines how the overcurrent status for the Root Hub ports is reported. This bit shows the same mode as PSM bit when it is reset. This bit is valid only if NOCP bit is cleared. 0: over-current status is reported collectively for all downstream ports. 1: over-current status is reported on a per-port basis.
10	DT	R	R	B'0	DeviceType This bit is always 0 in order to show that the root hub is not a compound device.

Bit	Bit Name	R/W		Initial Value	Description
		HCD	HC		
9	NPS	R/W	R	B'0	NoPowerSwitching This bit is used to specify whether power switching is supported or port is always powered. When this bit is cleared, PSM bit specifies global or per-port switching. 0: Ports are power switched 1: Ports are always powered on when the HC is powered on
8	PSM	R/W	R	B'1	PowerSwitchingMode This bit is used to specify how the power switching of the Root Hub ports is controlled. This bit is only valid if the NPS bit is cleared. 0: all ports are powered at the same time. 1: each port is powered individually. This mode allows port power to be controlled by either the global switch or per-port switching. If the PPCM bit in HcRhDescriptorB register is set, the port responds only to port power commands (Set/ClearPortPower). If the port mask is cleared, then the port is controlled only by the global power switch (Set/ClearGlobalPower).
7 to 0	NDP	R/W	R	H'01	NumberDownstreamPorts This field specifies the number of downstream ports supported by the Root Hub.

60.2.1.20 HcRhDescriptorB Register (offset: H'04C)

Register symbol: HcRhDescriptorB

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The HcRhDescriptorB register is the second register of two describing the characteristics of the Root Hub.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PPCM[15:8]								PPCM[7:0]

		R/W			
Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31 to 16	PPCM	R/W	R	H'0002	PortPowerControlMask Each bit indicates if a port is affected by a global power control command when PSM bit in HcRhDescriptorA register is set. When set, the port's power state is only affected by per-port power control (Set/ClearPortPower). When cleared, the port is controlled by the global power switch (Set/ClearGlobalPower). If the device is configured to global switching mode (PSM bit = 0), this field is not valid. bit 0: Reserved bit 1: Ganged-power mask on Port #1 bit 15 to 2: Reserved
15 to 0	DR	R/W	R	H'0000	DeviceRemovable Each bit is dedicated to a port of the Root Hub. When cleared, the attached device is removable. When set, the attached device is not removable. bit 0: Reserved bit 1: Device attached to Port #1 bit 15 to 2: Reserved

60.2.1.21 HcRhStatus Register (offset: H'050)

Register symbol: HcRhStatus

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The HcRhStatus register is divided into two parts. The lower word of this dword represents the Hub Status field and the upper word represents the Hub Status Change field. Reserved bits should always be written 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31	CRWE	W	R	B’0	ClearRemoteWakeupEnable Writing 1 clears DRWE bit. Writing 0 has no effect.
30 to 18	—	R	R	All 0	Reserved
17	OCIC	R/W	R/W	B’0	OverCurrentIndicatorChange This bit is set by hardware when a change has occurred to the OCI bit. Writing 1 clears this bit when it is set. Writing 0 has no effect. 0: No change has occurred in over-current status. 1: A change has occurred in over-current status.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
16	LPSC	R/W	R	B'0	This bit has different meanings for read and write. (read) LocalPowerStatusChange This bit always returns 0 for read, since the Root Hub does not support the local power status feature. (write) SetGlobalPower In global power mode (PSM bit = 0 in HcRhDescriptorA register), this bit is written to 1 in order to turn on power to all ports (PPS bit in HcRhPortStatus[N] register is cleared). In per-port power mode, it sets PPS bit in HcRhPortStatus[N] register only on port whose PPCM bit in HcRhDescriptorB register is not set. Writing 0 has no effect.

written to this bit	PSM	PPCM[N]	description
0	—	—	no effect
1	0	—	PPS bit is set
	1	0	PPS bit is set
		1	no effect

15	DRWE	R/W	R	B'0	(read) DeviceRemoteWakeupEnable This bit enables a CCS bit in HcRhPortStatus[N] register as a resume event, causing the transition from USB Suspend state to USB Resume state and setting the ResumeDetected interrupt. 0: CCS bit does not show a remote wakeup event. 1: CCS bit shows a remote wakeup event. (write) SetRemoteWakeupEnable Writing 1 sets this bit. Writing 0 has no effect.
14 to 2	—	R	R	All 0	Reserved
1	OCI	R	R	B'0	OverCurrentIndicator This bit reports overcurrent conditions when the global reporting is implemented. When set, an overcurrent condition exists. When cleared, all power operations are normal. If per-port overcurrent protection is implemented this bit is always '0' 0: all power operations are normal 1: an overcurrent condition exists.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
0	LPS	R/W	R/W	B’0	This bit has different meanings for read and write. (read) LocalPowerStatus This bit always returns 0 for read, since the Root Hub does not support the local power status feature. (write) ClearGlobalPower In global power mode (PSM bit = 0 in HcRhDescriptorA register), this bit is written to 1 in order to turn off power to all ports (PPS bit in HcRhPortStatus[N] register is cleared). In per-port power mode, it clears PPS bit in HcRhPortStatus[N] register only on port whose PPCM bit in HcRhDescriptorB register is not set. Writing 0 has no effect.

written to this bit	PSM	PPCM[N]	description
0	—	—	no effect
1	0	—	PPS bit is set
	1	0	PPS bit is set
		1	no effect

60.2.1.22 HcRhPortStatus[1] Register (offset: H'054)

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 21	—	R	R	All 0	Reserved
20	PRSC	R/W	R/W	B'0	PortResetStatusChange This bit shows the port reset has been completed. This bit is set at the end of the 10-ms port reset signal. Writing 1 clears this bit. Writing 0 has no effect. 0: port reset has not been completed. 1: port reset has been completed
19	OCIC	R/W	R/W	B'0	PortOverCurrentIndicatorChange This bit shows that overcurrent condition has been detected, and is set when the host controller changes POCI bit. This bit is valid only if overcurrent conditions are reported on a per-port basis. Writing 1 clears this bit. Writing 0 has no effect. 0: no change has occurred in POCI bit. 1: change has occurred in POCI bit.
18	PSSC	R/W	R/W	B'0	PortSuspendStatusChange This bit is set when the full resume sequence has been completed. This sequence includes the 20-s resume pulse, LS EOP, and 3-ms resynchronization delay. Writing 1 clears this bit. Writing 0 has no effect. This bit is also cleared when PRSC bit is set. 0: resume sequence has not been completed. 1: resume sequence has been completed.
17	PESC	R/W	R/W	B'0	PortEnableStatusChange This bit is set when hardware events cause PES bit to be cleared. Writing 1 clears this bit. Writing 0 has no effect. 0: no change has occurred in PES bit 1: change has occurred in PES bit

Bit	Bit Name	R/W		Initial Value	Description
		HCD	HC		
16	CSC	R/W	R/W	B'0	ConnectStatusChange This bit is set whenever connect or disconnect event occurs. Writing 1 means to clear this bit. Writing 0 has no effect. If CCS bit is cleared and writing to SetPortReset, SetPortEnable, or SetPortSuspend occurs, this bit is set to force the driver to re-evaluate the connection status since these write should not occur if the port is disconnected. 0: no change has occurred in CCS bit 1: change has occurred in CCS bit
15 to 10	—	R	R	All 0	Reserved
9	LSDA	R/W	R/W	B'0	This bit has different meanings for read and write. (read) LowSpeedDeviceAttached This bit indicates the speed of the device attached to this port. When set, a Low Speed device is attached to this port. When cleared, a Full Speed device is attached to this port. This field is valid only when the CCS bit is set (which means device is connected). 0: full speed device attached 1: low speed device attached (write) ClearPortPower Writing 1 clears PPS bit. Writing 0 has no effect.
8	PPS	R/W	R/W	B'0	This bit has different meanings for read and write. (read) PortPowerStatus This bit reflects the port's power status. This bit is cleared if an overcurrent condition is detected. 0: port power is off. 1: port power is on. (write) SetPortPower Writing 1 sets PPS bit. Writing 0 has no effect. The HCD writes a 1 to set the PortPowerStatus bit. Writing 0 has no effect.
7 to 5	—	R	R	All 0	Reserved

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
4	PRS	R/W	R/W	B'0	This bit has different meanings for read and write. (read) PortResetStatus When this bit is set by writing to SetPortReset, port reset signaling is asserted. When reset is completed, this bit is cleared when PRSC bit is set. This bit cannot be set if CCS bit is cleared (which means no device is connected) 0: port reset signal is not active 1: port reset signal is active (write) SetPortReset Writing 1 asserts the port reset signaling. Writing 0 has no effect. When CCS bit is cleared (which means no device is connected), PRS bit is not set even with writing 1. But it causes CSC bit to be set instead. This informs that a disconnected port is attempted to be reset.
3	POCI	R/W	R/W	B'0	This bit has different meanings for read and write. (read) PortOverCurrentIndicator This bit is only valid when the host controller is configured in such a way that overcurrent conditions are reported on a per-port basis. If per-port overcurrent reporting is disabled, this bit always returns 0 for read. If cleared, all power operations are normal for this port. If set, an overcurrent condition exists on this port. 0: no overcurrent condition exists 1: overcurrent condition exists. (write) ClearSuspendStatus Writing 1 initiates the resume sequence. Writing 0 has no effect. A resume is initiated only if PSS bit is set.
2	PSS	R/W	R/W	B'0	This bit has different meanings for read and write. (read) PortSuspendStatus This bit indicates the port is suspended or in the resume sequence. This bit cannot be set when CCS bit is cleared (which means no device is connected). This bit is cleared with following conditions. The resume sequence is completed and PSSC bit is set. The port reset is completed and PRSC bit asset. The host controller is placed in USB Resume state. 0: Port is not suspended. 1: Port is suspended. (write) SetPortSuspend Writing 1 sets PSS bit. Writing 0 has no effect. When CCS bit is cleared (which means no device is connected), PSS bit is not set even with writing 1. But it causes CSC bit to be set instead. This informs that a disconnected port is attempted to be suspended.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
1	PES	R/W	R/W	B'0	This bit has different meanings for read and write. (read) PortEnableStatus This bit indicates whether the port is enabled or disabled. This host controller core clears this bit in case of an overcurrent condition, disconnect event, switched-off power, or operational bus error such as babble is detected. This change also sets PESC bit. This bit cannot be set when CCS bit is cleared (which means no device is connected). This bit is also set when port reset is completed and PRSC bit is set or when port is suspended and PSSC bit is set. 0: Port is disabled 1: Port is enabled. (write) SetPortEnable Writing 1 sets PES bit. Writing 0 has no effect. If CCS bit is cleared, this write does not set PES bit, but instead sets CSC bit. This informs the driver that it attempted to enable a disconnected port.
0	CCS	R/W	R/W	B'0	This bit has different meanings for read and write. (read) CurrentConnectStatus This bit reflects the current state of the downstream port. 0: no device is connected 1: device is connected (write) ClearPortEnable Writing 1 to this bit clears PES bit. Writing 0 has no effect.

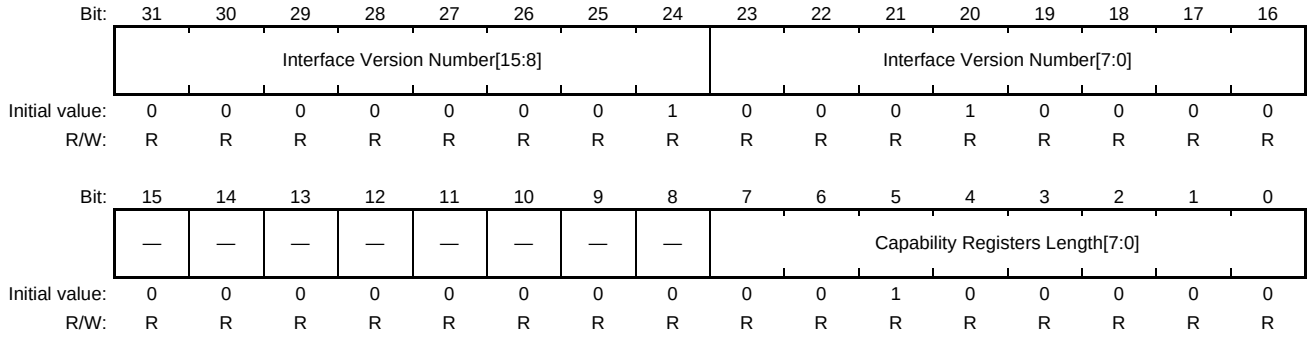
60.2.2 EHCI Controller Capability Registers

60.2.2.1 HCIVERSION/CAPLENGTH Register (offset: H'100)

Register symbol: CAPL_VERSION

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register is used as an offset to add to register base to find the beginning of the operational register space.



Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 16	Interface Version Number	R	R	H'0110	This field shows a BCD encoding of the EHCI revision number supported by this host controller core. This host controller core supports EHCI v.1.1.
15 to 8	—	R	R	All 0	Reserved
7 to 0	Capability Registers Length	R	R	H'20	This field is used as an offset to add to register base to find the beginning of the operational register space. This field is prepared considering the compatibility with EHCI specification. This field has the value of H'20 since the operational register starts from H'20 offset.

60.2.2.2 HCSPARAMS Register (offset: H'104)

Register symbol: HCSPARAMS

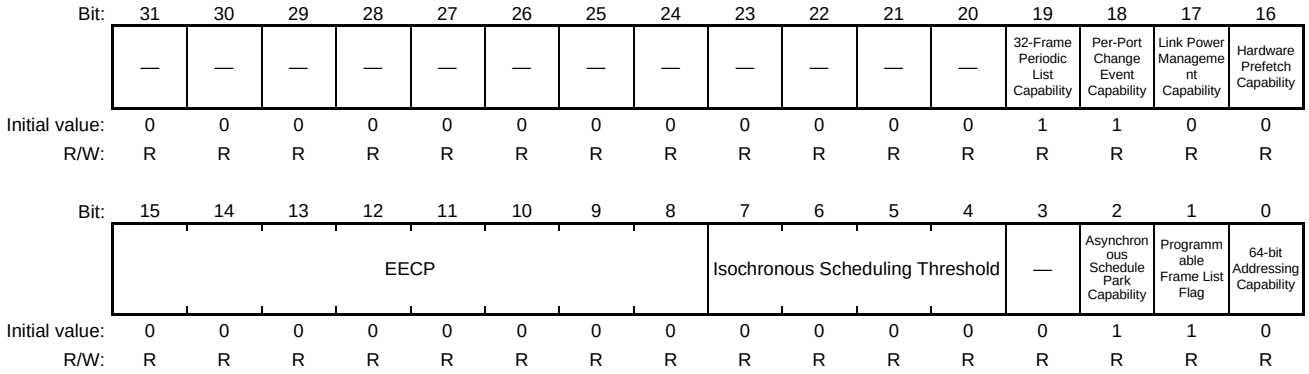
31 to 24	—	R	R	All 0	Reserved
23 to 20	Debug Port Number	R	R	H'0	This field always shows H'0 since this host controller core has no debug port.
19 to 17	—	R	R	All 0	Reserved
16	P_INDICATOR	R	R	B’0	Port Indicators (P_INDICATOR). This field always shows 0 since this host controller core does not have the function of port indicator.
15 to 12	N_CC	R	R	H’1	Number of Companion Controller This field indicates the number of companion controllers.
11 to 8	N_PCC	R	R	H’1	Number of Ports per Companion Controller (N_PCC). This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to software.
7	Port Routing Rules	R	R	B’1	Port Routing Rules. This field indicates the method used by this implementation for how all ports are mapped to companion controllers. 0: The first N_PCC ports are routed to the lowest numbered function companion host controller, the next N_PCC port are routed to the next lowest function companion controller, and so on. 1: The port routing is explicitly enumerated by the first N_PORTS elements of the HCSP-PORTROUTE array.
6, 5	—	R	R	All 0	Reserved
4	PPC	R	R	B’1	Port Power Control (PPC). This field indicates whether the host controller implementation includes port power control.
3 to 0	N_PORTS	R	R	H’1	This field specifies the number of physical downstream ports implemented as host controller

60.2.2.3 HCCPARAMS Register (offset: H'108)

Register symbol: HCCPARAMS

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 20	—	R	R	All 0	Reserved
19	32-Frame Periodic List Capability	R	R	B’1	This bit shows 1 since this host controller has 32-Frame Periodic List Capability. When set (1) this optional field indicates the host controller supports a 32 frame periodic schedule as specified by using the value B'11 in the USBCMD Frame List Size field. Software must treat a Flame List Size values (B'01 = 512 frames, B'10 = 256 frames) continues to be indicated through the Programmable Frame List Flag, where this bit only indicates programmability for a 32-frame list.
18	Per-Port Change Event Capability	R	R	B’1	This bit shows 1 since this host controller has Per-Port Change Event Capability. When set (1) this optional field indicates host controller support for pre-port change events and associated USBCMD Pre-Port Change Event Enable, USBSTS Port-n Change Detect, and USBINT Port-n Change Interrupt Enable fields. Note that software should treat those fields as reserved when this bit is cleared (0).
17	Link Power Management Capability	R	R	B’0	This bit shows 0 since this host controller doesn't have Link Power Management Capability. When set (1) this optional field indicates host controller support for this the Link Power Management L1 state and associated PORTSC Suspend using L1, Suspend Status, and Device Address field. Note that software should treat those fields as reserved then this bit is cleared (0).
16	Hardware Prefetch Capability	R	R	B’0	This bit shows 0 since this host controller does not have Hardware Prefetch Capability. This host controller doesn’t support this function.
15 to 8	EECP	R	R	H'00	EHCI Extended Capabilities Pointer (EECP).
7 to 4	Isochronous Scheduling Threshold	R	R	H'0	This field shows 0 since this host controller core does not support the function to cache the isochronous data structure.
3	—	R	R	B’0	Reserved

Bit	Bit Name	R/W		Initial Value	Description
		HCD	HC		
2	Asynchronous Schedule Park Capability	R	R	B’1	This bit shows 1 since this host controller core has Asynchronous Schedule Park Capability.
1	Programmable Frame List Flag	R	R	B’1	This bit shows 1 since this host controller core supports Programmable Frame List.
0	64-bit addressing Capability	R	R	B’0	This field shows 0 since this host controller core does not support 64-bit addressing.

60.2.2.4 HCSP-PORTROUTE Register (offset: H'10C)

Register symbol: HCSP_PORTROUTE

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This operational register is valid only if Port Routing Rules field in HCSPARAMs register.

In that case, this register shows how OHCI controller is routed to each port.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 28	—	R	R	All 0	Reserved
27 to 24	Host-Initiated Resume Duration	R/W	R	H'0	This field is used by software to specify the minimum amount of time the host controller will drive the K-state during a host-initiated resume from LPM (L1) state and is conveyed to each LPM-enabled device (via the HIRD bits within an LPM Token's bmAttributes field) upon entry into a low-power state. Encoding for this field is identical to the definition for the similarly named HIRD field within an LPM Token. Specifically, a value H'0 equals to 50 µs and each additional increment adds 75 µs. For example, the value H'1 equals 125 µs and H'F equals 1175 µs.
23 to 16	Interrupt Threshold Control	R/W	R	H'08	This field is used by system software to select the maximum rate at which the host controller core issue interrupts. If software writes an invalid value to this field, the results are undefined. **Value Maximum Interrupt Interval** H'00: Reserved H'01: 1 micro-frame H'02: 2 micro-frames H'04: 4 micro-frames H'08: 8 micro-frames (default, equals to 1 MS) H'10: 16 micro-frames (2 MS) H'20: 32 micro-frames (4 MS) H'40: 64 micro-frames (8 MS) Software should not set this bit to 0 while Halted bit is equal to 0.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
15	Per-Port Change Events Enable	R/W	R	B'0	This field is used by software to enable the per-port change event capability as defined by the Port-n Change Detect field in the USBSTS register and Port-n Change Detect Enable field in the USBINTR register. When this bit is set to 1, the per-port change event is enabled. When this bit is set to 0, the per-port change event is disabled.
14	Full Synchronized Prefetch	R	R	B'0	Since this host controller core does not have Hardware Prefetch Capability, this bit is fixed to 0.
13	Asynchronous Schedule Prefetch Enable	R	R	B'0	Since this host controller core does not have Hardware Prefetch Capability, this bit is fixed to 0.
12	Periodic Schedule Prefetch Enable	R	R	B'0	Since this host controller core does not have Hardware Prefetch Capability, this bit is fixed to 0.
11	Asynchronous Schedule Park Mode Enable	R/W	R	B'1	Software uses to enable or disable Asynchronous Schedule Park Mode. When this bit is set to 1, Park mode is enabled. When this bit is set to 0, Park mode is disabled.
10	—	R	R	B'0	Reserved
9, 8	Asynchronous Schedule Park Mode Count	R/W	R	B'11	This field defines a count of the number of successive transactions the host controller core is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. This function is enabled when Asynchronous Schedule Park Mode Enable is set to 1. Software should not write 0 to this bit.
7	Light Host Controller Reset	R	R	B'0	Since this host controller core does not support the function of Light Host Controller Reset, this bit is fixed to 0.
6	Interrupt on Async Advance Doorbell	R/W	R/W	B'0	This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule state, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Async Advance Enable bit in the USBINTR register is 1 then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to 0 after it has set the Interrupt on Async Advance status bit in the USBSTS register to 1. Software should not write 1 to this bit when the asynchronous schedule is disabled.
5	Asynchronous Schedule Enable	R/W	R	B'0	This bit controls whether the host controller skips processing the Asynchronous Schedule. 0: Do not process the Asynchronous Schedule 1: Use the ASYNCLISTADDR register to access the Asynchronous Schedule.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
4	Periodic Schedule Enable	R/W	R	B'0	This bit controls whether the host controller skips processing the Periodic Schedule. 0: Do not process the Periodic Schedule 1: Use the PERIODICLISTBASE register to access the Periodic Schedule.
3, 2	Frame List Size	R/W	R	B'00	This field specifies the size of the frame list. The size the frame list and controls which bits in the Frame Index Register should be used for the Frame List Current index. This host controller core has 32-Frame Periodic List Capability. Value the number of frames in Frame List B'00: 1024 frames (default) B'01: 512 frames B'10: 256 frames B'11: 32 frames
1	HCRESET	R/W	R/W	B'0	Host Controller Reset (HCRESET). This control bit is used by software to reset the host controller. When software writes 1 to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. All registers except EHCI operational registers are not affected by this reset. All operational registers, including port registers and port state machines are set to their initial values. Port ownership reverts to the companion host controller(s). Software must reinitialize the host controller in order to return the host controller to an operational state. This bit is set to 0 by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing 0 to this register. Software should not set this bit to 1 when the HCHalted bit in the USBSTS register is 0.
0	RS	R/W	R/W	B'0	Run/Stop (RS). When this bit is set to 1, the host controller proceeds with execution of the schedule. The host controller continues execution as long as this bit is set to 1. When this bit is set to 0, the host controller completes the current and any actively pipelined transactions on the USB and then halts. The HCHalted bit in the status register indicates when the host controller has finished its pending pipelined transactions and has entered the stopped state. Software should not write 1 to this field unless the host controller is in the Halted state (i.e. HCHalted in the USBSTS register is 1).

60.2.3.2 USBSTS Register (offset: H'124)

Register symbol: USBSTS

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register indicates pending interrupts and various states of the host controller. The status resulting from a transaction on the serial bus is not indicated in this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 16	Port-n Change Detect	R/W	R/W	H'0000	The definition of each bit is identical to the Port Change Detect field (bit 2 of this register) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set to 1 then a port change event was detected on Port 2, the N_PORTS field in HCSPARAMS specifies how many ports are exposed by the host controller and thus how many bits in this field are valid. The behavior of the Port Change Detect and related fields even when Per-Port Change Events are enabled. This field is only used by software when the Per-Port Change Events Enable bit within the USBCMD register is set to 1. bit 31 to 17: Reserved
15	Asynchronous Schedule Status	R	R/W	B'0	This bit reports the current real status of the Asynchronous Schedule. If this bit is 0 then the status of the Asynchronous Schedule is disabled. If this bit is 1 then the status of the Asynchronous Schedule is enabled. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0).
14	Periodic Schedule Status	R	R/W	B'0	This bit reports the current real status of the Periodic Schedule. If this bit is 0 then the status of the Periodic Schedule is disabled. If this bit is 1 then the status of the Periodic Schedule is enabled. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0).

Bit	Bit Name	R/W		Initial Value	Description
		HCD	HC		
13	Reclamation	R	R/W	B'0	This is a read-only status bit, which is used to detect an empty asynchronous schedule. When this bit is 1, asynchronous schedule is empty.
12	HCHalted	R	R/W	B'1	This bit is 0 whenever the Run/Stop bit is 1. The host controller sets this bit to 1 after it has stopped executing as a result of the Run/Stop bit being set to 0, either by software or by the host controller hardware (e.g. internal error).
11 to 6	—	R	R/W	All 0	Reserved
5	Interrupt on Async Advance	R/W	R/W	B'0	System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing 1 to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.
4	Host System Error	R/W	R/W	B'0	The host controller sets this bit to 1 when a serious error occurs. When this error occurs, the host controller clears the Run/Stop bit in the Command register to prevent further execution of the scheduled TDs. This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.
3	Frame List Rollover	R/W	R/W	B'0	The host controller sets this bit to 1 when a frame list rollover event occurs. The exact Frame List Index value at which the rollover occurs depends on the frame list size, nothing this generally occurs when FRINDEX rolls over from its maximum value to 0. For example, if the frame list size (as programmed in the Frame List Size field of the USBCMD register) is 1024 then a frame list rollover would occur every time FRINDEX[13] toggles. Similarly, a frame list rollover event would occur every time FRINDEX[12] toggles for a 512 frame list, and when FRINDEX[11] toggles for a 256 frame list. Note this behavior is different for a 32 frame list where a rollover event occurs every time FRINDEX[13] toggles (same as 1024). This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.
2	Port Change Detect	R/W	R/W	B'0	The host controller sets this bit to 1 when it detects any change of port status. The detailed conditions those set this bit to 1 are as follows. The connection or disconnection of device is detected and Connect Status Change bit (bit 1) of PORTSC[n] register is changed from 0 to 1. The enabled status of port is detected and Port Enable/Disable bit (bit 3) of PORTSC[n] register is changed from 0 to 1. The over current is detected and Over-current Change bit (bit 5) of PORTSC[n] register is changed from 0 to 1. J-K transition is detected on the suspended port and Force Port Resume bit (bit 6) of PORTSC[n] register is changed from 0 to 1. This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.

Bit	Bit Name	R/W		Initial Value	Description
		HCD	HC		
1	USBERRINT	R/W	R/W	B'0	USB Error Interrupt (USBERRINT). The host controller sets this bit to 1 when completion of a USB transaction results in an error condition. If the TD on which the error interrupt occurred also had its IOC bit set, both this bit and USBINT bit are set. This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.
0	USBINT	R/W	R/W	B'0	USB Interrupt (USBINT). The host controller sets this bit to 1 on the completion of a USB transaction, which results in the retirement of a Transfer Descriptor that had its IOC bit set. The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes). This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.

60.2.3.3 USBINTR Register (offset: H'128)

Register symbol: USBINTR

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register enables and disables reporting of the corresponding interrupt to the software. When a bit is set and the corresponding interrupt is active, an interrupt is generated to the host. Interrupt sources that are disabled in this register still appear in the USBSTS to allow the software to poll for events.

Each interrupt enable bit description indicates whether it is dependent on the interrupt threshold mechanism.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 16	Port-n Change Event Enable	R/W	R	H'0000	The definition for each bit in this field is identical to bit 2 of this register (Port Change Interrupt Enable bit) except these bits are specific to a given port, where bit 16 = Port 1, 17= Port 2, etc. For example, if bit 17 is set to 1 then a port change event was detected on Port 2. When a bit in this field is 1 and the corresponding Port-n Change Detect bit in the USBSTS register is 1, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port-n Change Detect bit. bit 31 to 17: Reserved
15 to 6	—	R	R	All 0	Reserved
5	Interrupt on Async Advance Enable	R/W	R	B’0	When this bit is a one, and the Interrupt on Async Advance bit in the USBSTS register is 1, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit.
4	Host System Error Enable	R/W	R	B’0	When this bit is 1, and the Host System Error Status bit in the USBSTS register is 1, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Host System Error bit.
3	Frame List Rollover Enable	R/W	R	B’0	When this bit is 1, and the Frame List Rollover bit in the USBSTS register is 1, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Frame List Rollover bit.
2	Port Change Detect Enable	R/W	R	B’0	When this bit is 1, and the Port Change Detect bit in the USBSTS register is 1, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port Change Detect bit.

Bit	Bit Name	R/W		Initial Value	Description
		HCD	HC		
1	USB Error Interrupt Enable	R/W	R	B'0	When this bit is 1, and the USBERRINT bit in the USBSTS register is 1, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the USBERRINT bit.
0	USB Interrupt Enable	R/W	R	B'0	When this bit is 1, and the USBINT bit in the USBSTS register is 1, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the USBINT bit.

60.2.3.4 FRINDEX Register (offset: H'12C)

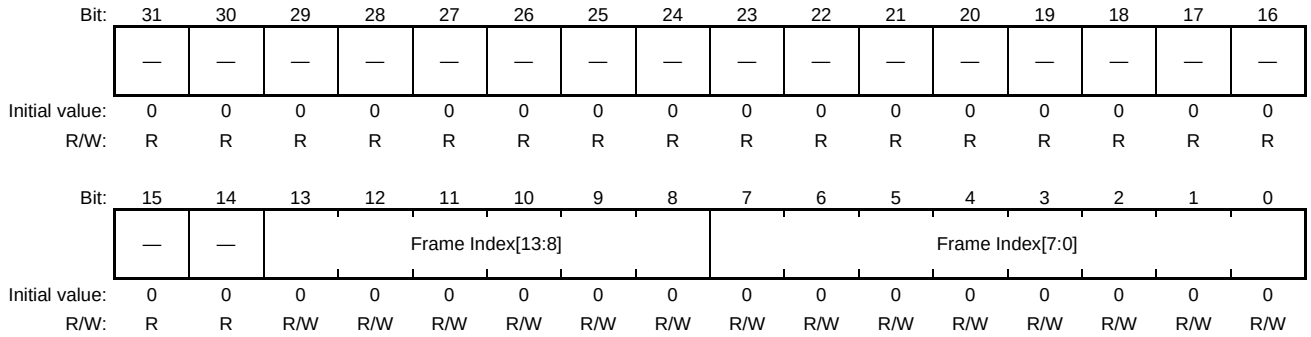
Register symbol: FRINDEX

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register is used by the host controller to index into the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N:3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the USBCMD register

This register can't be written unless the host controller is in the Halted state as indicated by HCHalted bit of USBSTS register. It is not allowed to write to this register while the Run/Stop bit is 1 either.

The host controller behaves slightly different when using a 32-frame Frame List Size, specifically it continues to count FRINDEX up to a full 1024 frames, transmit SOF values from 0 to 2047, and generate Frame List Rollover events (when enabled) every 1024 frames - exactly as if a 1024 frame list size was employed. The host controller will only reference 32 elements on the periodic schedule, however. This is accomplished by formulating the Periodic Frame List Element Address using {FRINDEX[N:3] modulo 32} rather than FRINDEX[N:3]. The same mapping should be done by system software whenever it needs to correlate the current FRINDEX value to a specific periodic schedule element. Note this new behavior only applies to a 32-frame list.



Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 14	—	R	R	All 0	Reserved
13 to 0	Frame Index[13:0]	R/W	R/W	H'0000	The value in this register increments at the end of each time frame (e.g. micro-frame). Bits [N:3] are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register. **Frame List Size** / **Number of Frames** / **N** B'00 / 1024 / 12 B'01 / 512 / 11 B'10 / 256 / 10 B'11 / 32 / 12

60.2.3.5 CTRLDSSEGMENT Register (offset: H'130)

Register symbol: CTRLDSSEGMENT

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Since this host controller does not have the 64-bit Addressing Capability and the 64-bit Addressing Capability bit in HCCPARAMS is 0, CTRLDSSEGMENT register is not used and fixed to H'0000_0000.

		R/W			
Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31 to 0	CTRLDS-SEGMENT	R	R	H'0000_0000	This host controller does not support 64-bit addressing.

60.2.3.6 PERIODICLISTBASE Register (offset: H'134)

Register symbol: PERIODICLISTBASE

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register contains the beginning address of the Periodic Frame List in the system memory.

Software loads this register prior to starting the schedule execution by the host controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

		R/W			
Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31 to 12	Base Address	R/W	R	H'0_0000	This field defines the beginning address of the Periodic Frame List in the system memory. The pointer contained in this field should be 4-Kbyte aligned.
11 to 0	—	R	R	All 0	Reserved

60.2.3.7 ASYNCLISTADDR Register (offset: H'138)

Register symbol: ASYNCLISTADDR

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register contains the address of the next asynchronous queue head to be executed.

Bits [4:0] of this register cannot be modified by software and will always return H'00 when read. The memory structure referenced by this physical memory pointer is assumed to be 32-byte (cache line) aligned.

R/W:	R	R	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R

		R/W			
Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31 to 25	Device Address	R/W	R/W	H'00	The 7-bit USB device address for the device attached to and immediately downstream of the associated root port. A value of zero indicates no device is present or support for this feature is not present.
24, 23	Suspend Status	R	R/W	B'00	These two bits are used by software to determine whether the most recent L1 suspend request was successful, specifically B'00: Success: State transition was successful (ACK) B'01: Not Yet: Device was unable to enter the L1 state at this time (NYET). B'10: Not Supported: Device does not support the L1 state (STALL) B'11: Timeout/Error: Device failed to respond or an error occurred This field is updated by hardware immediately following the completion of an L1 transition request (via an LPM token). To avoid any race conditions with hardware, software should only consume the contents of this field when Suspend = 0 (port no longer in L1).
22	WKOC_E	R/W	R/W	B'0	Wake on Over-current Enable. Writing 1 to this bit enables the port to detect the over-current conditions as wake-up events. Writing 0 to this bit has no effect. This bit is zero if PP bit is zero.
21	WKDSCNNT_E	R/W	R/W	B'0	Wake on Disconnect Enable. Writing 1 to this bit enables the port to detect the device disconnects as wake-up events. Writing 0 to this bit has no effect. This bit is zero if PP bit is zero.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
20	WKCNNT_E	R/W	R/W	B'0	Wake on Connect Enable. Writing 1 to this bit enables the port to detect the device connects as wake-up events. Writing 0 to this bit has no effect. This field is zero if PP bit is zero.
19 to 16	Port Test Control	R/W	R	B'0000	Port Test Control. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value. When this field is zero, the port is NOT operating in a test mode. Value test mode B'0000: Test mode not enabled B'0001: Test J_STATE B'0010: Test K_STATE B'0011: Test SE0_NAK B'0100: Test Packet B'0101: Test FORCE_ENABLE Other: Reserved
15, 14	Port Indicator Control	R	R	B'00	This field always shows B'00 since this host controller does not support Port Indicator Control.
13	Port Owner	R/W	R/W	B'1	This bit unconditionally goes to 0 when the Configured bit in the CONFIGFLAG register makes a transition from 0 to 1. This bit unconditionally goes to 1 whenever the Configured bit is zero. Software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes 1 to this bit when the attached device is not a high-speed device. 0: EHCI controller owns the port. 1: OHCI controller owns the port.
12	PP	R/W	R/W	B'0	Port Power (PP). The function of this bit depends on the value of PPC bit in HCSPARAMS register. The behavior is as follows: PPC PP Operation 0 1 RO – The host controller does not have port power control switches. Each port is hard-wired to power. 1 1/0 R/W – The host controller has port power control switches. This bit represents the current setting of the switch (0 = off, 1 = on). When power is not available on a port (i.e. PP equals to 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC bit is 1, the PP bit in each affected port may be transitioned by the host controller from 1 to 0 (which means removing power from the port).

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
11, 10	Line Status	R	R/W	B'00	This field reflects the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. This field is used for detection of low-speed USB devices prior to the port reset and enable sequence. This field is valid only when Port Enable/Disable bit is 0 and Current Connect Status bit is set to 1. {bit11, bit10} USB state description B'00 SE0 Not LS-device, perform EHCI reset. B'10 J-state Not LS-device, perform EHCI reset. B'01 K-state LS-device, change ownership from EHCI to OHCI. B'11 Undefined Not LS-device, perform EHCI reset. The value in this field is undefined if PP bit is 0.
9	Suspend using L1	R	R	B'0	0: Suspend using L2
8	Port Reset	R/W	R/W	B'0	This bit shows the reset status of the port. When software writes 1 to this bit (from a zero), the bus reset is started. Software is required to write 0 to this bit to terminate the bus reset sequence. Software should keep this bit at 1 long enough to ensure the reset sequence completes as specified in the USB Specification. Do not write 1 to this bit when HCHalted bit in USBSTS register is 0. This bit is 0 if PP bit is 0. 0: The port is not in reset. 1: The port is in reset.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
7	Suspend	R/W	R/W	B’0	P*ort Enabled* Bit and *Suspend* bit of this register define the port states as follows: {Port Enabled, Suspend} Port Status B’0x Disable B’10 Enable B’11 Suspend Software writes a one to this bit to transition a port to either the L1 or L2 suspend state. Which suspend state the host controller attempts depends on the value of the Suspend Using L1 field. When in suspend state, downstream propagation of data is blocked on this port, except for port reset. If this bit is set to a one when a transaction is in progress then the blocking will not occur until the end of the current transaction. In the suspend state, the port is sensitive to resume detection. Note that the status of this bit does not change until the port is fully suspended and there may be a delay in suspending a port if a transaction is currently in progress on the USB. Addition status for L1-based transitions is provided to software via the Suspend Status field. Software writes 1 to this bit in order to set it. Writing 0 to this bit has no effect. Software can writes to this bit only when PP bit is 1 and Port Owner bit is 0 and Current Connect Status bit is 1. The host controller unconditionally sets this bit to 0 when: Software sets Force Port Resume bit to 0 (from 1). Software sets Port Reset bit to 1 (from 0). Whenever Port Power is 0 This field is 0 if PP bit is 0.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
6	Force Port Resume	R/W	R/W	B'0	This bit indicates that the resume on the port is detected. 0: No resume signaling is detected or driven on the port. 1: The resume signaling is detected or driven on the port. The host controller set this bit to 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to 1 because a J-to-K transition is detected, the Port Change Detect and/or Port-n Changes Detect bits in the USBSTS register are also set to 1. If software sets this bit to 1, the host controller must not set the Port Change Detect and/or Port-n Change Detect bits. This functionality defined for manipulating this bit depends on the value of the Suspend and Suspend Using L1 bits. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. For legacy (L2) transitions, Software should set this bit to 0 when the appropriate amount of time has elapsed. Writing 0 (from 1) causes the port to return to high speed mode (forcing the bus below the port into a high-speed idle). This bit will remain 1 until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to 0. Software does not need to time resume signaling for L1 transactions as host controller hardware will automatically enforce the necessary timing and clear this bit when the port has fully resumed. Software can influence the amount of time hardware will drive resume signaling during L1 exit via the Host-Initiated Resume Duration field within the USBCMD register. This bit is 0 if PP bit is 0
5	Over-current Change	R/W	R/W	B'0	This bit indicates whether Over-current Active bit has been changed or not. Writing 1 to this bit clears it. Writing 0 to this bit has no effect. 0: Over-current Active bit has not changed. 1: Over-current Active bit has changed.
4	Over-current Active	R	R/W	B'0	This bit shows the over-current status of the port. When the host controller detects the over-current condition, it disables the port and then sets this bit to 1. The host controller automatically clears this bit when the over-current condition has been removed. 0: No over-current condition exists on the port. 1: The over-current condition exists on the port.
3	Port Enable/Disable Change	R/W	R/W	B'0	This bit indicates whether Port Enabled/Disabled bit has been changed or not. This bit is set 1 only when a port is disabled due to the appropriate conditions existing at EOF2 point. Writing 1 to this bit clears it. Writing 0 to this bit has no effect. This bit is 0 if PP bit is 0.

Bit	Bit Name	R/W		Initial Value	Description
		HCD	HC		
2	Port Enabled/ Disabled	R/W	R/W	B’0	Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing 1 to this field. The host controller will only set this bit to 1 the reset sequence determines that the attached device is a high-speed device. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by software. When the port is disabled (0) downstream propagation of data is blocked on this port, except for reset. When Port Test Control is B'0101, the port is always enabled and this bit is set to 1 independent of the port status. This bit is 0 if PP bit is 0. 0: The port is disabled 1: The port is enabled.
1	Connect Status Change	R/W	R/W	B’0	This bit indicates a change has occurred in the port’s Current Connect Status. The host controller sets this bit for all changes to the port device connect status, even if software has not cleared an existing connect status change. Writing 1 to this bit clears it. Writing 0 to this bit has no effect. This field is 0 if PP bit is 0.
0	Current Connect Status	R	R/W	B’0	This bit reflects the current state of the connection of the port. The host controller sets this bit to 1 when it detects the connection of device to the port. It also sets 1 to this bit with Port Test Control = B'0101, even when device is not connected. If it detects the device is disconnected, this bit is reset to 0. This bit is 0 if PP bit is 0 or if Port Owner bit is 0. 0: No device is present. 1: Device is present.

60.2.4 AHB Bridge Registers

60.2.4.1 INT_ENABLE Register (offset: H'200)

Register symbol: INT_ENABLE

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register enables or disables interrupt generation for each interrupt source bit in the INT_STATUS register. When a bit in this register is set to disabled, the interrupt signal is not asserted even when the interrupt condition for the corresponding source is satisfied and the corresponding source bit in the INT_STATUS register is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved The write value should be 0.
4	WAKEON_INT	B'0	R/W	This bit indicates the state of the WAKEON interrupt from the host core. Writing 1 clears this bit. 0: No WAKEON interrupt has occurred. 1: A WAKEON interrupt has occurred.
3	UCOM_INT	B'0	R	This bit indicates the state of the interrupt from the UCOM registers. Use the UCOM2 registers to clear the interrupt. 0: No external register interrupt has occurred. 1: An external register interrupt has occurred.
2	USBH_INTB	B'0	R	This bit indicates the state of the EHCI interrupt. Use the HcInterruptStatus register (an OHCI operational register) to clear the interrupt. 0: No INTB interrupt has occurred. 1: An INTB interrupt has occurred.
1	USBH_INTA	B'0	R	This bit indicates the state of the OHCI interrupt. Use the USBSTS register (an EHCI operational register) to clear the interrupt. 0: No INTA interrupt has occurred. 1: An INTA interrupt has occurred.
0	AHB_INT	B'0	R/W	This bit indicates occurrence of an AHB bus error. Writing 1 clears this bit. 0: No AHB bus error has occurred. 1: An AHB bus error has occurred.

60.2.4.3 AHB_BUS_CTR Register (offset: H'208)

Register symbol: AHB_BUS_CTR

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register specifies the AHB master and slave functions.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R/W	R	R	R/W	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The write value should be 0.
15 to 12	PROT_TYPE	B'0000	R/W	These bits specify the MHPROT[3:0] value for transfer from the AHB master interface. Bit [15] 0: Indicates a non-cacheable transfer. 1: Indicates a cacheable transfer. Bit [14] 0: Indicates a non-bufferable transfer. 1: Indicates a bufferable transfer. Bit [13] 0: Indicates user access. 1: Indicates privileged access. Bit [12] 0: Indicates an opcode. 1: Indicates data. For details of each bit meaning, refer to the AMBA AHB specifications
11 to 9	—	All 0	R	Reserved The write value should be 0.
8	PROT_MOD E	B'0	R/W	This bit selects the MHPROT[3:0] mode for transfer from the AHB master interface. 0: The PROT_TYPE value is output as MHPROT[3:0]. 1: During DMA transfer, H'0000 is output as MHPROT[3:0] in the last burst and the PROT_TYPE value is output in other burst transfers.
7, 6	—	All 0	R	Reserved The write value should be 0.

Bit	Bit Name	Initial Value	R/W	Description
5, 4	ALIGN_ADDRESS	B’00	R/W	These bits specify the address alignment for transfer from the AHB master interface. B’00: Burst transfer is issued so as not to extend beyond a 1-Kbyte boundary. B’01: Burst transfer is issued so as not to extend beyond a 64-byte boundary. B’10: Burst transfer is issued so as not to extend beyond a 32 -byte boundary. (The maximum burst length is limited to INCR8 because transfer goes beyond a 32-byte boundary if INCR16 is specified.) B’11: Burst transfer is issued so as not to extend beyond a 16-byte boundary. (The maximum burst length is limited to INCR4 because transfer goes beyond a 16-byte boundary if INCR8 or a longer length is specified.)
3, 2	—	All 0	R	Reserved The write value should be 0.
1, 0	MAX_BURST_LEN	B’00	R/W	These bits specify the maximum burst length for transfer from the AHB master interface. B’00: INCR16 B’01: INCR8 B’10: INCR4 B’11: SINGLE

60.2.4.4 USBCTR Register (offset: H'20C)

Register symbol: USBCTR

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register makes settings for the host core.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	DIRPD	PLL_RST	*Renesas Private*
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved The write value should be 0.
2	DIRPD	B'0	R/W	This bit controls the direct power-down (DIRPD) pin of the UTMI+ PHY developed by Renesas. Setting this bit to 1 places the PHY in the power-down state. Writing 0 to this bit while it is 1 releases the PHY from the direct power-down state. For setting and cancellation of direct power-down state, refer to the manual of the Renesas UTMI+ core. 0: Normal operation 1: Renesas UTMI+ PHY is placed in the power-down state.
1	PLL_RST	B'0	R/W	This bit controls the PLLRESET pin of the UTMI+ PHY developed by Renesas. 0: PLL reset is canceled. 1: PLL reset is issued.
0	*Renesas Private*	B'0	W	Do not write 1 to this bit.

60.2.5 Core Defined Registers

60.2.5.1 REVID Register (offset: H'300)

Register symbol: REVID

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Core ID	H'00	R	These bits indicate the ID of the host core.
23 to 16	—	All 0	R	Reserved The write value should be 0.
15 to 8	Major Version	H'02	R	These bits indicate the major version number of the host core.
7 to 0	Minor Version	H'01	R	These bits indicate the minor version number of the host core.

60.2.5.2 Register Enable/Clock Gating Control Register (offset: H'304)

Register symbol: REGEN_CG_CTRL

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Some registers are read-only in the initial state.

When such registers should be written to, set the corresponding bits in this register.

In addition, the clock can be gated for the unused sections in the host and peripheral function circuits.

Set the corresponding bits as necessary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

30	—	B'0	R	Reserved The write value should be 0.
29	HOST_CLK_MSK	B'0	R/W	This bit forcibly masks the clock to some circuits in the host core. 0: Not masked. 1: Masked.
28	PERI_CLK_MSK	B'0	R/W	This bit forcibly masks the clock to some circuits in the peripheral controller. 0: Not masked. 1: Masked.
27 to 25	—	All 0	R	Reserved The write value should be 0.
24	*Renesas Private*	B'0	R/W	Do not write 1 to this bit.
23 to 17	—	All 0	R	Reserved The write value should be 0.
16	*Renesas Private*	B'0	R/W	Do not write 1 to this bit.
15 to 1	—	All 0	R	Reserved The write value should be 0.
0	*Renesas Private*	B'0	R/W	Do not write 1 to this bit.

60.2.5.3 Suspend Control Register (offset: H'308)

Register symbol: SPD_CTRL

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register controls the SUSPENDM pin in the UTMI+ interface.

Through this register setting, SUSPENDM can be asserted when the Suspend state is entered, and UTMI+ interface SUSPENDM can be forcibly asserted.

The equivalent control is also applied to the SLEEPM pin.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SUSPENDM_ENABLE	*Renesas Private*	—	—	—	—	—	—	WKCNNT_ENABLE	*Renesas Private*	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R

	—	—	—	—	—	—	*Renesas Private*	*Renesas Private*	—	—	—	—	—	—	*Renesas Private*	GLOBAL_SUSPENDM_P1
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	SUSPENDM_ENABLE	B'0	R/W	This bit provides a function to assert the UTMI+ interface SUSPENDM signal when the Suspend bit in the related OHCI or EHCI operational register is asserted. Setting this bit to 1 asserts the UTMI+ interface SUSPENDM signal in the target port after the Suspend-related bit in the OHCI or EHCI operational register shown below is set. This function is intended to reduce the power consumption in the UTMI+ PHY when this module enters the Suspend state. [Target OHCI and EHCI operational registers of this function] OHCI: Bit [2] (PSS bit) in the HcRhPortStatus register EHCI: Bit [7] (Suspend bit) in the PORTSC register
30	*Renesas Private*	B'0	R/W	Do not write 1 to this bit.
29 to 24	—	All 0	R	Reserved The write value should be 0.
23	WKCNNT_ENABLE	B'0	R/W	Setting this bit to 1 deasserts SUSPENDM and SLEEPM when a change in the connection state is detected. This setting is valid when SUSPENDM_ENABLE or SLEEP_ENABLE is 1.
22	*Renesas Private*	B'0	R/W	Do not write 1 to this bit.
21 to 10	—	All 0	R	Reserved The write value should be 0.
9	*Renesas Private*	B'0	R/W	Do not write 1 to this bit.
8	*Renesas Private*	B'0	R/W	Do not write 1 to this bit.

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved The write value should be 0.
0	GLOBAL_SUSPENDM_P1	B’0	R/W	This bit provides a function to forcibly assert UTMI_P1SUSPENDM to 0. Setting this bit to 1 asserts the UTMI+ interface SUSPENDM pin (UTMI_P1SUSPENDM) for port 1. This function is intended to reduce the power consumption of the UTMI+ PHY by controlling this bit appropriately. [Note] Writing 1 to this bit is prohibited when the SUSPENDM_ENABLE bit is 1.

60.2.5.4 Suspend/Resume Timer Setting Register (offset: H'30C)

Register symbol: SPD_RSM_TIMSET

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register specifies the Connect/Disconnect detection time and Resume detection time when the clock from the UTMI+ PHY is stopped in the Suspend state.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	TIMER_CONNECT[15:0]	H'014E	R/W	These bits specify the timer value used to detect Device Connect or Disconnect while the UTMI+ interface SUSPENDM is asserted. Assuming that the clock from the UTMI+ PHY stops while SUSPENDM is asserted, whether Connect or Disconnect has occurred is checked using the AHB clock (HCLK). * Set this timer value so that the detection time is 2.5 µs or longer according to the AHB clock frequency used. A value of 1 specifies one cycle (µs). Reference setting values: AHB clock is 133 MHz: H'014E or a greater value AHB clock is 200 MHz: H'1F4 or a greater value
15 to 0	TIMER_RESUME[15:0]	H'029B	R/W	These bits specify the timer value used to detect the RemoteWakeup signal from the device while the UTMI+ interface SUSPENDM is asserted. Assuming that the clock from the UTMI+ PHY stops while SUSPENDM is asserted, whether the RemoteWakeup signal has been received is checked using the AHB clock (HCLK). Set this timer value so that the detection time is 5 µs or longer according to the AHB clock frequency used. A value of 1 specifies one cycle (µs). Reference setting values: AHB clock is 133 MHz: H'029B or a greater value

Note: Frequency of AHB clock (HCLK) is 133MHz (S3D2ϕ).

60.2.5.5 Overcurrent Detection Timer Setting Register (offset: H'310)

Register symbol: OC_TIMSET

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register specifies the overcurrent detection time.

When the overcurrent detection input signal (EXT_P1OCI) is asserted to 0 continuously for the time specified in this register, occurrence of an overcurrent is detected.

[Note]
This register setting is ignored when the OCISEL bit (bit [5]) in the host COMMON/OHCI extended register (offset: H'360) is 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	TIMER_OC[19:16]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TIMER_OC[15:0]															
Initial value:	0	0	0	0	1	0	0	1	1	0	1	0	1	0	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

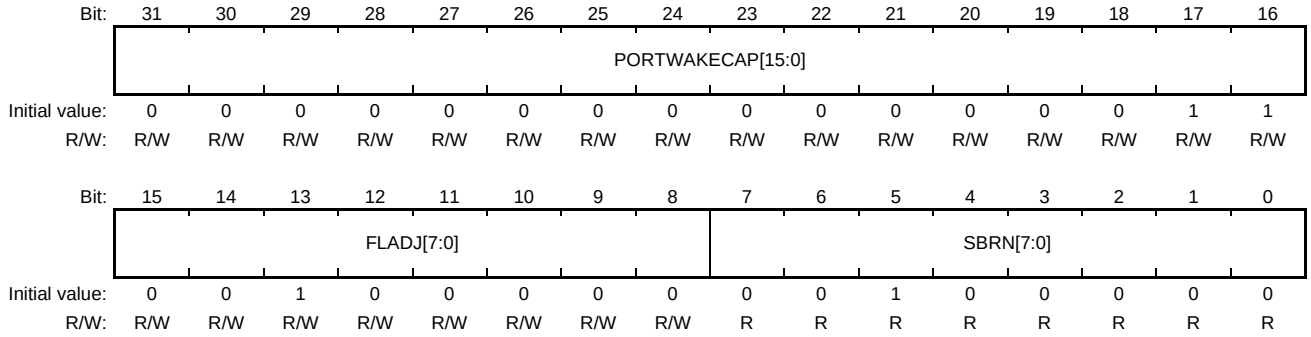
Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved The write value should be 0.
19 to 0	TIMER_OC [19:0]	H'2_09AB	R/W	These bits specify the timer value used to detect an overcurrent. When the overcurrent detection input signal (EXT_P1OCI) is asserted to 0 continuously for the time specified in this field, this module determines that an overcurrent has occurred. Set this timer value so that the detection time is 1 to 2 ms or longer according to the AHB clock frequency used. A value of 1 specifies one cycle (µs). Note that occurrence of an overcurrent is detected when EXT_P1OCI is asserted to 0 continuously over a certain period. Specify the period in these bits according to the AHB clock frequency. Reference setting values: To specify 1 ms when AHB clock (HCLK) is 133 MHz: H'2 09AB or a greater value.

Note: Frequency of AHB clock (HCLK) is 133MHz (S3D2ϕ).

60.2.5.6 SBRN, FLADJ, PORTWAKECAP Register (offset: H'314)

Register symbol: SBRN_FLADJ_PW

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PORTWAKECAP[15:0]	H'0003	R/W	The intended use of these bits are to establish a policy about which ports are to be used for wake events. This bit setting does not affect the operation of the host core.
15 to 8	FLADJ[7:0]	H'20	R/W	These bits adjust the length of one micro-frame in units of 16-HS-bit time. The initial value is H'20 (60000 HS-bit time).
7 to 0	SBRN[7:0]	H'20	R	These bits indicate the serial bus release number. This value is fixed to H'20.

60.2.6 UCOM Registers

60.2.6.1 Common Control Register (offset: H'800)

Register symbol: COMMCTRL

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register selects either the host or peripheral mode for each of the OTG and battery charging functions.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OTG_PERI	BC_PERI	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved
27	VGPICHG_STA3*	B'0	R/WC1	This bit is set when the input to the EXT_VGPI[3] pin changes. 0: EXT_VGPI[3] input has not changed. 1: EXT_VGPI[3] input has changed.
26	VGPICHG_STA2*	B'0	R/WC1	This bit is set when the input to the EXT_VGPI[2] pin changes. 0: EXT_VGPI[2] input has not changed. 1: EXT_VGPI[2] input has changed.
25	VGPICHG_STA1*	B'0	R/WC1	This bit is set when the input to the EXT_VGPI[1] pin changes. 0: EXT_VGPI[1] input has not changed. 1: EXT_VGPI[1] input has changed.
24	VGPICHG_STA0*	B'0	R/WC1	This bit is set when the input to the EXT_VGPI[0] pin changes. 0: EXT_VGPI[0] input has not changed. 1: EXT_VGPI[0] input has changed.
23 to 19	—	All 0	R	Reserved
18	DPMSTAINT_STA	B'0	R/WC1	This bit is set when D+ and D- in port 1 become equal to the value specified in LINECTRL1.DPMLVL[1:0]. However, if this bit was set when LINECTRL1.DMMON and DPMON became equal to LINECTRL1.DMPLVL[1:0] and then this bit was cleared but LINECTR1L.DMMON and DPMON have not changed, this bit is not set even if LINECTRL1.DPMON and DMMON are equal to LINECTRL.DPMLVL[1:0]. In this case, this bit is set only when LINECTRL1.DPMON or DMMON changes (a change in either of them will suffice in this case) and then LINECTRL1.DPMON and DMMON become equal to LINECTRL1.DPMLVL[1:0] again. 0: D+ and D- have not become equal to the value specified in LINECTRL1.DPMLVL[1:0]. 1: D+ and D- have become equal to the value specified in LINECTRL1.DPMLVL[1:0].

Bit	Bit Name	Initial Value	R/W	Description
17	DPMONCHG_STA	B'0	R/WC1	This bit is set when LINECTRL1.DPMON changes — that is, when the input to D+ in port 1 changes. 0: LINECTRL1.DPMON has not changed. 1: LINECTRL1.DPMON has changed.
16	DMMONCHG_STA	B'0	R/WC1	This bit is set when LINECTRL1.DMMON changes — that is, when the input to D- in port 1 changes. 0: LINECTRL1.DMMON has not changed. 1: LINECTRL1.DMMON has changed.
15 to 13	—	All 0	R	Reserved
12	SESSVLDCHG_STA*	B'0	R/WC1	This bit is set when ADPCTRL.OTGSESSVLD changes. 0: ADPCTRL.OTGSESSVLD has not changed. 1: ADPCTRL.OTGSESSVLD has changed.
11	IDDIGCHG_STA	B'0	R/WC1	This bit is set when ADPCTRL.IDDIG changes. 0: ADPCTRL.IDDIG has not changed. 1: ADPCTRL.IDDIG has changed.
10	VVLDCHG_STA*	B'0	R/WC1	This bit is set when ADPCTRL.VBUSVALID changes. 0: ADPCTRL.VBUSVALID has not changed. 1: ADPCTRL.VBUSVALID has changed.
9	APRBCHG_STA	B'0	R/WC1	This bit is set when ADPCTRL.ADPPRB changes. 0: ADPCTRL.ADPPRB has not changed. 1: ADPCTRL.ADPPRB has changed.
8	ASNSCHG_STA	B'0	R/WC1	This bit is set when ADPCTRL.ADPSNS changes. 0: ADPCTRL.ADPSNS has not changed. 1: ADPCTRL.ADPSNS has changed.
7, 6	—	All 0	R	Reserved
5	PDDETCHG2_STA	B'0	R/WC1	This bit is set when BCCTRL2.PDDETSTS changes from 0 to 1. 0: BCCTRL2.PDDETSTS has not changed from 0 to 1. 1: BCCTRL2.PDDETSTS has changed from 0 to 1.
4	PDDETCHG1_STA	B'0	R/WC1	This bit is set when BCCTRL1.PDDETSTS changes from 0 to 1. 0: BCCTRL1.PDDETSTS has not changed from 0 to 1. 1: BCCTRL1.PDDETSTS has changed from 0 to 1.
3	VBSTAINT_STA*	B'0	R/WC1	This bit is set when VBCTRL.VBSTA[3:0] becomes equal to the value specified in VBCTRL.VBLVL[3:0]. However, if this bit was set when VBCTRL.VBSTA[3:0] became equal to VBCTRL.VBLVL[3:0] and then this bit was cleared but VBCTRL.VBSTA[3:0] has not changed, this bit is not set even if VBCTRL.VBSTA[3:0] is equal to VBCTRL.VBLVL[3:0]. In this case, this bit is set only when VBCTRL.VBSTA[3:0] changes and then VBCTRL.VBSTA[3:0] becomes equal to VBCTRL.VBLVL[3:0] again. 0: VBCTRL.VBSTA[3:0] has not become equal to the value specified in VBCTRL.VBLVL[3:0]. 1: VBCTRL.VBSTA[3:0] has become equal to the value specified in VBCTRL.VBLVL[3:0].
2	VBSTACHG_STA*	B'0	R/WC1	This bit is set when the VBCTRL.VBSTA[3:0] state changes. 0: VBCTRL.VBSTA[3:0] has not changed. 1: VBCTRL.VBSTA[3:0] has changed.

Bit	Bit Name	Initial Value	R/W	Description
1	OCINT_STA	B'0	R/WC1	This bit is set when the input to the EXT_P1OCI pin is asserted. 0: EXT_P1OCI has not been asserted (remains at 1). 1: EXT_P1OCI has been asserted (has become 0).
0	—	B'0	R	Reserved

Note: * These bits are not supported RZ/G2E

60.2.6.3 OTG-BC Interrupt Enable Register (offset: H'808)

Register symbol: OBINTEN

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register enables or disables interrupts due to the status bits in the OBINTSTA register. When any of the bits in OBINTSTA is asserted and occurrence of the interrupt is enabled through the corresponding bit in the OBINTEN register, an OBINT interrupt occurs.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

60.2.6.4 VBUS Control Register (offset: H'80C)

Register symbol: VBCTRL

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	—

This register controls VBUS when this LSI works as an OTG device.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VBSTA[3:0]				—	—	—	—	VBLVL[3:0]				—	—	—	OCCLREN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	DRVVBUSSEL	VGPUO[3:0]				VGPLO[2:0]			VBOUT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	VBSTA[3:0]	H'0	R	These bits indicate the VBUS voltage level. The input to the EXT_VBSTA_IN[3:0] core pins is shown without change.
27 to 24	—	H'0	R	Reserved
23 to 20	VBLVL[3:0]	H'0	R/W	These bits are used to detect through an interrupt that VBUS reaches a specified level. When the value of the EXT_VBSTA_IN[3:0] core pins reaches the value specified in these bits, OBINTSTA.VBSTAINT_STA is set and a corresponding interrupt occurs if its occurrence is not masked.
19 to 17	—	All 0	R	Reserved
16	OCCLREN	B'0	R/W	This bit specifies whether to automatically clear VBCTRL.VBOUT and ADPCTRL.DRVVBUS when an overcurrent occurs. When an overcurrent occurs, OBINTSTA.OCINT_STA is set. 0: VBCTRL.VBOUT and ADPCTRL.DRVVBUS are not automatically cleared when an overcurrent occurs. 1: VBCTRL.VBOUT and ADPCTRL.DRVVBUS are automatically cleared when an overcurrent occurs.
15 to 9	—	All 0	R	Reserved
8	DRVVBUSSEL	B'0	R/W	This bit specifies whether to use VBCTRL.VBOUT or ADPCTRL.DRVVBUS to control the VBUS output control pin (EXT_VBOUT). 0: VBCTRL.VBOUT is used. 1: ADPCTRL.DRVVBUS is used. The output logic level can be specified through the EXT_VGPLO_INV core pin. EXT_VGPLO_INV = 0: The value is output without change. EXT_VGPLO_INV = 1: The inverted value is output.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	VGPUO[3:0]	H'0	R/W	The value in these bits is output through the EXT_VGPUO[3:0] core pins. This value is used to control the external power-supply IC. The output logic level can be specified through the EXT_VGPUO_INV core pin. EXT_VGPUO_INV = 0: The value is output without change. EXT_VGPUO_INV = 1: The inverted value is output.
3 to 1	VGPLO[3:1]	B'000	R/W	The value in these bits is output through the EXT_VGPLO[3:0] core pins. This value is used to control the external power-supply IC. The output logic level can be specified through the EXT_VGPLO_INV core pin. EXT_VGPLO_INV = 0: The value is output without change. EXT_VGPLO_INV = 1: The inverted value is output.
0	VBOUT	B'0	R/W	The VBOUT pin is one of the VBUS output control pins. It is used to control the external power-supply IC and assert VBUS. When VBCTRL.DRVVBUSSEL = 0, the EXT_VBOUT core pin reflects the value specified in this bit. 0: VBUS output is disabled. 1: VBUS output is enabled. Whether to output this bit value to the EXT_VBOUT core pin without change or invert it before output can be selected through the EXT_VGPLO_INV core pin. EXT_VGPLO_INV = 0: The value is output without change. EXT_VGPLO_INV = 1: The inverted value is output. Whether to automatically clear this bit when an overcurrent occurs can be specified in OCCLREN (bit 16).

60.2.6.5 Line Control Port1 Register (offset: H'810)

Register symbol: LINECTRL1

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register mainly controls D+ and D- in port 1.

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved
25, 24	DPMLVL[1:0]	B'00	R/W	These bits are used to detect through an interrupt that D+ and D- in port 1 change to specified states. Specify the state of D+ in port 1 in DPMLVL[1] and the state of D- in DPMLVL[0]; when both D+ and D- in port 1 become equal to the specified values (not when only either of the two is equal to the specified value), OBINTSTA.DPMINTSTA is set and a corresponding interrupt occurs if its occurrence is not masked. This function is used to detect a specified bus state such as J-state, K-state, or SE0.
23, 22	—	All 0	R	Reserved
21	DPRPU_EN	B'0	R/W	This bit enables the DP_RPU (bit 20) setting for pullup control of D+ in port 1. 0: DP_RPU (bit 20) setting for pullup control of D+ in port 1 is disabled. 1: DP_RPU (bit 20) setting for pullup control of D+ in port 1 is enabled.
20	DP_RPU	B'0	R/W	This bit controls pullup of D+ in port 1. This control is enabled only when DPRPU_EN (bit 21) = 1. Note that if this bit is cleared to 0 when DPRPU_EN (bit 21) = 1, D+ is in the floating state while no device drives the USB bus. Note also that setting DPRPD_EN (bit 19) and DP_RPD (bit 18) to enabled is prohibited while this bit is set to enabled — that is, enabling both pullup and pulldown of D+ together is prohibited. 0: Pullup of D+ in port 1 is disabled. 1: Pullup of D+ in port 1 is enabled.
19	DPRPD_EN	B'0	R/W	This bit enables the DP_RPD (bit 18) setting for pulldown control of D+ in port 1. 0: DP_RPD (bit 18) setting for pulldown control of D+ in port 1 is disabled. 1: DP_RPD (bit 18) setting for pulldown control of D+ in port 1 is enabled.

Bit	Bit Name	Initial Value	R/W	Description
18	DP_RPD	B'0	R/W	This bit controls pulldown of D+ in port 1. This control is enabled only when DPRPD_EN (bit 19) = 1. Note that if this bit is cleared to 0 when DPRPD_EN (bit 19) = 1, D+ is in the floating state while no device drives the USB bus. Note also that setting DPRPU_EN (bit 21) and DP_RPU (bit 20) to enabled is prohibited while this bit is set to enabled — that is, enabling both pullup and pulldown of D+ together is prohibited. 0: Pulldown of D+ in port 1 is turned off. 1: Pulldown of D+ in port 1 is turned on.
17	DMRPD_EN	B'0	R/W	This bit enables the DM_RPD (bit 16) setting for pulldown control of D- in port 1. 0: DM_RPD (bit 16) setting for pulldown control of D- in port 1 is disabled. 1: DM_RPD (bit 16) setting for pulldown control of D- in port 1 is enabled.
16	DM_RPD	B'0	R/W	This bit controls pulldown of D- in port 1. This control is enabled only when DMRPD_EN (bit 17) = 1. Note that if this bit is cleared to 0 when DMRPD_EN (bit 17) = 1, D- is in the floating state while no device drives the USB bus. 0: Pulldown of D- in port 1 is disabled. 1: Pulldown of D- in port 1 is enabled
15 to 10	—	All 0	R	Reserved
9	CNEN_EN	B'0	R/W	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] Not used. [RZ/G2E] Enable UTMI_P1CONNECT pin control by CNEN (bit 8). 0: UTMI_P1CONNECT pin control by CNEN is disable. 1: UTMI_P1CONNECT pin control by CNEN is enable.
8	CNEN	B'0	R/W	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] Not used. [RZ/G2E] This bit controls the single-end receiver in port 1. This control is valid only when CNEN_EN (bit 9) = 1. When this module is used in the peripheral mode, this function is used to prevent the USB signals from becoming Hi-Z and entering the floating state if nothing is connected through USB. Set this bit to 0 when nothing is connected in the peripheral mode. 0: Single-end receiver in port 1 is disabled. (The value of the UTMI_P1CONNECT core pin becomes 0.) 1: Single-end receiver in port 1 is enabled. (The value of the UTMI_P1CONNECT core pin becomes 1.)
7	—	B'0	R	Reserved
6	OPMODE_NODRV	B'0	R/W	This pin controls OPMODE[1:0] in port 1 (UTMI_P1OPMODE) in the UTMI+ interface. Set this bit to 1 when OPMODE should be set to the non-driving state (B'01). 0: UTMI_P1OPMODE[1:0] is controlled by the host or peripheral device. 1: UTMI_P1OPMODE[1:0] is fixed to B'01 (non-driving state)
5, 4	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
3	DPMON	B'0	R	This bit indicates the state of the D+ signal in port 1. The value of the UTMI_P1LINESTATE[0] core pin is shown without change.
2	DMMON	B'0	R	This bit indicates the state of the D- signal in port 1. The value of the UTMI_P1LINESTATE[1] core pin is shown without change.
1	—	B'0	R	Reserved
0	—	B'0	R	Reserved

60.2.6.6 BC Control Port1 Register (offset: H'820)

Register symbol: BCCTRL1

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register controls battery charging for port 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved
25	BCPWRDWNB	B'1	R/W	Not used. This value should be left at 1.
24	PWRDWNB	B'1	R/W	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] Not used. [RZ/G2E] This bit controls the PHY_P1PWRDWNB pin in port 1. 0: Power down state 1: Power on state
23 to 10	—	All 0	R	Reserved
9	PDDETSTS	B'0	R	This bit indicates the result of portable device detection in port 1. The value input to the PHY_P1PRTBLDET core pin is shown. (The CHGET value output from the PHY is shown.)
8	CHGDETSTS	B'0	R	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] Not used. [RZ/G2E] This bit indicates the result of Charging Port detection in port 1. The value input to the PHY_P1CHGDET core pin is shown. (The CHGDET value output from PHY is shown)

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved
5	DCPMODE	B'0	R/W	Not used. This value should be left at 0.
4	VDMSRCE (VDATSRCENB)	B'0	R/W	This bit controls the PHY VDATSRCENB pin in port 1. This setting is valid when COMMCTRL.BC_PERI (bit 30) = 0. When BC_PERI = 0, this bit value is output to PHY_P1VDMSRCEN to control VDATSRCENB in the PHY. 0: VDAT_SRC is disabled. 1: VDAT_SRC is enabled.
3	IDPSINKE (VDATDETENB)	B'0	R/W	This bit enables detection of Attach or Connect for port 1 in PHY battery charging. This setting is valid when COMMCTRL.BC_PERI (bit 30) = 0. When BC_PERI = 0, this bit value is output to PHY_P1PRTBLDETEN to control whether to enable or disable detection by CGDETSTS in the PHY. 0: Detection by CHDGETSTS is disabled. 1: Detection by CHDGETSTS is enabled.
2	VDPSRCE (DCDENB)	B'0	R/W	This bit enables or disables the data contact detection for port 1 in the PHY. This setting is valid when COMMCTRL.BC_PERI (bit 30) = 0. When BC_PERI = 0, this bit value is output to PHY_P1VDPSRCEN to control the DCDENB pin in the PHY. 0: Data contact detection is disabled. 1: Data contact detection is enabled.
1	IDMSINKE (VDATDETENB)	B'0	R/W	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] Not used. [RZ/G2E] This bit enables detection of Attach or Connect for port 1 in PHY battery charging when this module is Portable Device mode. This setting is valid when COMMCTRL.BC_PERI (bit 30) = 0. When BC_PERI = 0, this bit value is output to PHY_P1CHGDETEN to control whether to enable or disable detection by CHGDET in the PHY. 0: Detection by CHGDETSTS is disabled. 1: Detection by CHGDETSTS is enabled.
0	IDPSRCE (CHARGSEL)	B'0	R/W	This bit selects the battery charging source for port 1 in the PHY. This setting is valid when COMMCTRL.BC_PERI (bit 30) = 0. This bit selects whether to apply the VDAT_SRC voltage to D+ or D-. In the CDP mode, set this bit to 1 because the voltage should be applied to D-. 0: VDAT_SRC is applied to D+ and SINK for D+ is enabled. 1: VDAT_SRC is applied to D- and SINK for D- is enabled.

60.2.6.7 ADP Control Register (offset: H'830)

Register symbol: ADPCTRL

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register controls the ADP function.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	OTGSESSVLD	IDDIG	VBUSVALID	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	VBUSVLDEXT	VBUSVLDEXTSEL	—	—	IDPULLUP	DRVVBUS	OTGDISABLE	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved
20	OTGSESSVLD	B'0	R	This bit indicates the result from the OTG device session valid comparator. 0: The voltage on VBUS is below the OTG Device Session Valid threshold. 1: The voltage on VBUS is above the OTG Device Session Valid threshold.
19	IDDIG	B'0	R	This bit indicates the result of ID pin sampling. 0: A mini-A plug is connected. 1: A mini-B plug is connected.
18	VBUSVALID	B'0	R	This bit indicates the result from the VBUS valid comparator in the PHY. 0: VBUS is not valid. 1: VBUS is valid.
17 to 10	—	All 0	R	Reserved
9	VBUSVLDEXT	B'0	R/W	This bit controls the PHY_P1VBUSVLDEXT pin of this module and the VBUSVLDEXT pin of the PHY. The VBUSVLDEXT signal is valid and used for DP pullup control when VBUSVLDEXTSEL = 1. 0: DP pullup resistor is disabled when VBUSVDLEXTSEL = 1. 1: DP pullup resistor is enabled when VBUSVDLEXTSEL = 1. When this module is used for OTG, the VBUS supply is turned off. Therefore, to execute SRP as a B-device, set both this bit and VBUSVLDEXTSEL to 1. DP can be pulled up only when the UTMI+ interface is controlled (XCVRSELECT == 01, TERMSELECT == 1, and OPMODE != 01).

Bit	Bit Name	Initial Value	R/W	Description
8	VBUSVLDEXTSEL	B'0	R/W	This bit controls the PHY_P1VBUSVLDEXTSEL pin of this module and the VBUSVLDEXTSEL pin of the PHY. The VBUSVLDEXTSEL signal is used to detect VBUS in the PHY and to select whether to control DP pullup by the session valid comparator in the PHY or through an external pin (PHY_P1 VBUSVLDEXT) of the core. 0: Controlled by the session valid comparator in the PHY. 1: Controlled through the PHY_P1 VBUSVLDEXT core pin (VBUSVLDEXT pin of the PHY). When this module is used for OTG, the VBUS supply is turned off. Therefore, to execute SRP as a B-device, set both this bit and VBUSVLDEXT to 1. DP can be pulled up only when the UTMI+ interface is controlled (XCVRSELECT == 01, TERMSELECT == 1, and OPMODE != 01).
7, 6	—	All 0	R	Reserved
5	IDPULLUP	B'0	R/W	This bit controls the PHY_P1IDPULLUP pin of this module and the IDPULLUP pin of the PHY. Set this bit to 1 when the ID signal of a mini-AB plug is connected to ID0 of the PHY and sampling of the ID value should be enabled. The sampling result is indicated in ADPCTRL.IDDIG. 0: ID sampling is disabled. 1: ID sampling is enabled.
4	DRVVBUS	B'0	R/W	This bit controls the PHY_P1DRVVBUS pin of this module and the DRVVBUS pin of the PHY. This signal is input to the PHY and is also used to enable or disable VBUS control in the external charge pump. For the PHY, this signal enables or disables the VBUS valid comparator. 0: DRVVBUS is set to 0. 1: DRVVBUS is set to 1.
3	OTGDISABLE	B'0	R/W	This bit works as the VBUS valid comparator disable signal and controls the PHY_P1OTGDISABLE pin of this module and the OTGDISABLE pin of the PHY. Setting this bit to 1 turns off the power to the VBUS valid comparator. However, this bit does not affect the session valid comparator, ADP probing or sensing, or ID detection. When not using the OTG function, set this bit to 1 to reduce the power consumed by the VBUS valid comparator. 0: VBUS valid comparator is enabled. 1: VBUS valid comparator is disabled.
2 to 0	—	All 0	R/W	Reserved

60.3 Clock Specifications

60.3.1 Clock Gating Specifications

60.3.1.1 Overview

This module has a function for switching between the host and peripheral modes. In some case, no clock supply is needed for the unused circuits (stopping the clock causes no problem).

To reduce the power consumption through clock gating for the circuits that do not need clock supply, this module provides three clock control gating bits in the register enable/clock gating control register.

Control these bits of REGEN_CG_CTRL appropriately to gate the clock supply to some circuits in the host core and peripheral controller.

Bit	Symbol
[31]	NONUSE_CLK_MSK
[29]	HOST_CLK_MSK
[28]	PERI_CLK_MSK

It is the outside targeted of clock gating for the common function part (UCOM register and so on) in this core which has no dependence of core operation.

60.3.1.2 NONUSE_CLK_MSK Function Specifications

This bit is intended to reduce the power consumption when the function of this module is fixed to either the host or the peripheral and no clock needs to be supplied to the unused function or when no clock needs to be supplied to a function that is not assigned as the role of this module in OTG operation. After this bit is set, the clock is automatically gated for the host or peripheral function that is not assigned as the role.

The clock is gated as follows according to the target USB channel, USB0SEL[1:0] in UGCTRL2 register of HS-USB and the OTG_PERI bit setting.

Table 60.7 NONUSE_CLK_MSK Function

Clock Gating Register Bit Settings			Host/Peripheral Switch Setting			Clock to be Gated	
				Register Bit			
NONUSE_CLK_MSK	HOST_CLK_MSK	PERI_CLK_MSK	Channel	USB0SEL[1:0]*	OTG_PERI	Host	Peripheral
B’1	B’0	B’0	Channel 1/2	—	—	Gated	—
			Channel 0/3	2’b00	—	Gated	Gated
				2’b01	—	Not Gated	Gated
				2’b10	—	Not Gated	Not Gated
				2’b11	B’0	Not Gated	Gated
					B’1	Gated	Not Gated

[Note on Using the NONUSE_CLK_MSK Bit]

When using the NONUSE_CLK_MSK bit, the HOST_CLK_MSK and PERI_CLK_MSK bits should be cleared to 0 in principle. If either of them is set to 1, the effect of clock gating is determined by a logical OR of all these bit settings.

Note: USB0SEL[1:0] is in UGCTRL2 register of HS-USB

60.3.1.3 PERI_CLK_MSK and HOST_CLK_MSK Function Specifications

The PERI_CLK_MSK and HOST_CLK_MSK bits respectively provide functions for forcibly gating the 60-MHz clock to the peripheral controller and the internal clock for the host core.

Their purposes and prerequisites are the same as those of NONUSE_CLK_MSK, but they provide manual gating functions that do not depend on the settings through the USB0SEL[1:0] in UGCTRL2 register of HS-USB and the OTG_PERI bit.

Table 60.8 PERI_CLK_MSK and HOST_CLK_MSK Function

Clock Gating Register Bit Settings			Host/Peripheral Switch Setting			Clock to be Gated	
				Register Bit			
NONUSE _CLK_MSK	HOST _CLK_MSK	PERI_ CLK_MSK	Channel	USB0SEL [1:0]*	OTG_PERI	Host	Peripheral
B’0	B’1	B’0	Channel 1/2	—	—	Gated	—
			Channel 0/3	—	—	Gated	—
	B’0	B’1	Channel 1/2	—	—	—	—
			Channel 0/3	—	—	—	Gated
	B’1	B’1	Channel 1/2	—	—	Gated	—
			Channel 0/3	—	—	Gated	Gated

[Note on Using the HOST_CLK_MSK and PERI_CLK_MSK Bits]

When using the HOST_CLK_MSK and PERI_CLK_MSK bits, the NONUSE_CLK_MSK bit should be cleared to 0 in principle. If it is set to 1, the effect of clock gating is determined by a logical OR of all these bit settings.

Note: USB0SEL[1:0] is in UGCTRL2 register of HS-USB

60.4 Reset Specifications

60.4.1 Input Reset Specifications

This module has a software reset input from CPG module. Asserting this reset signal initializes all FFs in this module.

60.5 Interrupt Specifications

60.5.1 Interrupt Signal List

This module has the following six interrupt signal lines.
Use all of them as level interrupts.

Interrupt Pin Name	Interrupt Type	Pulse/ Level	Minimum Pulse Width	Active Level	Synchro-nized with
U2H_INT	An interrupt signal output from the AHB_IF module. This is generated when a bus error occurs in the AHB master. It is controlled through the related AHB bridge register.	Level	—	H	AHB clock (HCLK)*
U2H_OHCI_INT	An interrupt signal output from OHCI. This is generated when data transfer is completed or a change in the USB bus state is detected in the FS or LS transfer. It is controlled through the related OHCI operational register.	Level	—	H	AHB clock (HCLK)*
U2H_EHCI_INT	An interrupt signal output from EHCI. This is generated when data transfer is completed or a change in the USB bus state is detected in the HS transfer. It is controlled through the related EHCI operational register.	Level	—	H	AHB clock (HCLK)*
U2H_WAKEON_INT	An interrupt signal output from EHCI. This is generated due to an EHCI wakeup event. It is controlled through the related EHCI operational register.	Level	—	H	AHB clock (HCLK)*
U2H_OBINT	An interrupt signal output from the UCOM2 module. This is generated due to an event related to OTG or battery charging. It is controlled through the related UCOM2 register.	Level	—	H	AHB clock (HCLK)*
U2H_BIND_INT	Logical OR of the interrupt signals. (U2H_INT + U2H_OHCI_INT + U2H_EHCI_INT + U2H_WAKEON_INT + U2H_OBINT)	Level	—	H	AHB clock (HCLK)*

Note: Frequency of AHB clock (HCLK) is 133MHz (S3D2ϕ).

60.5.2 Interrupt Sources and Control

60.5.2.1 U2H_INT Assertion Source and Control

Interrupt Enable Control in Register:

This interrupt signal is asserted when an interrupt source event occurs while the interrupt enable bit in the following register is set to enabled (1).

AHB bridge register: INT_ENABLE register (offset: H'200) Bit [0] (AHB_INTEN)

Interrupt Source:

A bus error occurs (MHRESP = 1) in the AHB bridge.

Clearing Interrupt:

To clear the interrupt, write 1 to the following register bit.

AHB bridge register: INT_STATUS register (offset: H'204) Bit [0] (AHB_INT)

60.5.2.2 U2H_OHCI_INT Assertion Sources and Control

Interrupt Enable Control in Registers:

This interrupt signal is asserted when an interrupt source event occurs while the interrupt enable bits in the following registers are set to enabled (1).

AHB bridge register: INT_ENABLE register (offset: H'200) Bit [1] (USBH_INTAEN)
OHCI operational register: HcInterruptEnable Register (offset: H'010) Bit [31] and Bits [6:0]*

Note: * Set the necessary bits enabled as interrupt assertion source bits.

Interrupt Sources:

		Necessary Enable Settings in Register Bits							
			HcInterruptEnable

19	USB schedule overrun occurs for a frame.	√	√	—	—	—	—	—	√

√: Necessary

Clearing Interrupt:

To clear the interrupt, write 1 to one of the following register bits that corresponds to the interrupt source.

OHCI operational register: HcInterruptStatus register (offset: H'00C) Bits [6:0]

60.5.2.3 U2H_EHCI_INT Assertion Sources and Control

Interrupt Enable Control in Registers:

This interrupt signal is asserted when an interrupt source event occurs while the interrupt enable bits in the following registers are set to enabled (1).

AHB bridge register: INT_ENABLE register (offset: H'200) Bit [2] (USBH_INTBEN)
EHCI operational register: USBINTR register (offset: H'128) Bits [17:16] and Bits [5:0]*

Note: * Set the necessary bits enabled as interrupt assertion source bits.

In addition, control the following register bits as necessary.

EHCI operational register: USBCMD register (offset: H'120) Bit [15] and Bit [6]

Interrupt Sources:

		Necessary Enable Settings in Register Bits								
			USBCMD		USBINTR

4	RemoteWakeup signal (Resume signal) from a device is detected.	√	—	—	—	—	—	—	√	—	—
5	Babble state is detected on the USB bus.	√	—	—	—	—	—	—	√	—	—
6	USB transfer with qTD IOC = 1 is successfully completed.	√	—	—	—	—	—	—	—	—	√
7	Short packet is received.	√	—	—	—	—	—	—	—	—	√
8	USB transfer ends with an error. (Retry fails three times, a babble error is detected, or STALL is received.)	√	—	—	—	—	—	—	—	√	—
9	QH processing with bit [6] (Interrupt on Async Advance Doorbell) in the USBCMD register set to 1 is successfully completed.	√	—	√	—	—	√	—	—	—	—
10	FrameIndex bit in the FRINDEX register returns from the maximum value to H'000 (rollover is detected).	√	—	—	—	—	—	√	—	—	—
11	Port Change Detect event (interrupt sources 1 to 5) is detected in USB port 1.	√	√	—	—	√	—	—	—	—	—

√: Necessary

Clearing Interrupt:

To clear the interrupt, write 1 to one of the following register bits that corresponds to the interrupt source.

EHCI operational register: USBSTS register (offset: H'124) Bits [17:16] and Bits [5:0]

60.5.2.4 U2H_WAKEON_INT Assertion Sources and Control

Interrupt Enable Control in Registers:

This interrupt signal is asserted when an interrupt source event occurs while the interrupt enable bits in the following registers are set to enabled (1).

AHB bridge register: INT_ENABLE register (offset: H'200) Bit [4] (WAKEON_INTEN)
EHCI operational register: PORTSC[1:2] registers (offset: H'164 and H'168) Bits [22:20]*

Note: * Set the necessary bits enabled as interrupt assertion source bits.

Interrupt Sources:

		Necessary Enable Settings in Register Bits			
			PORTSC		
			Bit[22]	Bit[21]	Bit[20]
	Interrupt Source	WAKEON_INTEN	WKOC_E	WKDSCNNT_E	WKCNNT_E
1	Device connection is detected.	√	—	—	√
2	Device disconnection is detected.	√	—	√	—
3	Overcurrent is detected.	√	√	—	—
4	RemoteWakeup signal (Resume signal) from a device is detected.	√	—	—	—

√: Necessary

Clearing Interrupt:

To clear the interrupt, write 1 to the following register bit.

AHB bridge register: INT_STATUS register (offset: H'204) Bit [4] (WAKEON_INT)

60.5.2.5 U2H_OBINT Assertion Sources and Control

Interrupt Enable Control in Registers:

This interrupt signal is asserted when an interrupt source event occurs while the interrupt enable bits in the following registers are set to enabled (1).

AHB bridge register: INT_ENABLE register (offset: H'200) Bit [3] (UCOM_INTEN)
UCOM register*[1]: OTG-BC interrupt enable register (offset: H'808) Bits [27:24], Bits [18:16], Bits [12:8], and Bits [3:0]*[2]

Notes: 1. Bits [27:24], Bits [12:8], and Bits [3:2] are not supported RZ/G2E
2. Set the necessary bits enabled as interrupt assertion source bits.

Interrupt Sources:

		Necessary Enable Settings in Register Bits				
			OTG-BC Interrupt Enable			
			Bit[27]	Bit[26]	Bit[25]	Bit[24]

4	Value of the EXT_OTG_ID input pin changes. *1	√	—	—	—	√

√: Necessary

Note: These bits are not supported RZ/G2E

Clearing Interrupt:

To clear the interrupt, write 1 to one of the following register bits that corresponds to the interrupt source.

UCOM register*1: OTG-BC interrupt status register (offset: H'804) Bits [27:24], Bits [18:16], Bits [12:8], and Bits [3:0]

Note: Bits [27:24], Bits [12:8], and Bits [3:2] are not supported RZ/G2E

60.5.3 Interrupt Signal Deassertion Timing

After a register is accessed to clear an interrupt source, it may take a certain period of time until the corresponding interrupt is actually cleared. Therefore, a measure should be taken to prevent misdetection of the previous interrupt between register access for clearing and correct detection of the next interrupt.

60.5.3.1 Connection of Interrupt Signal Lines

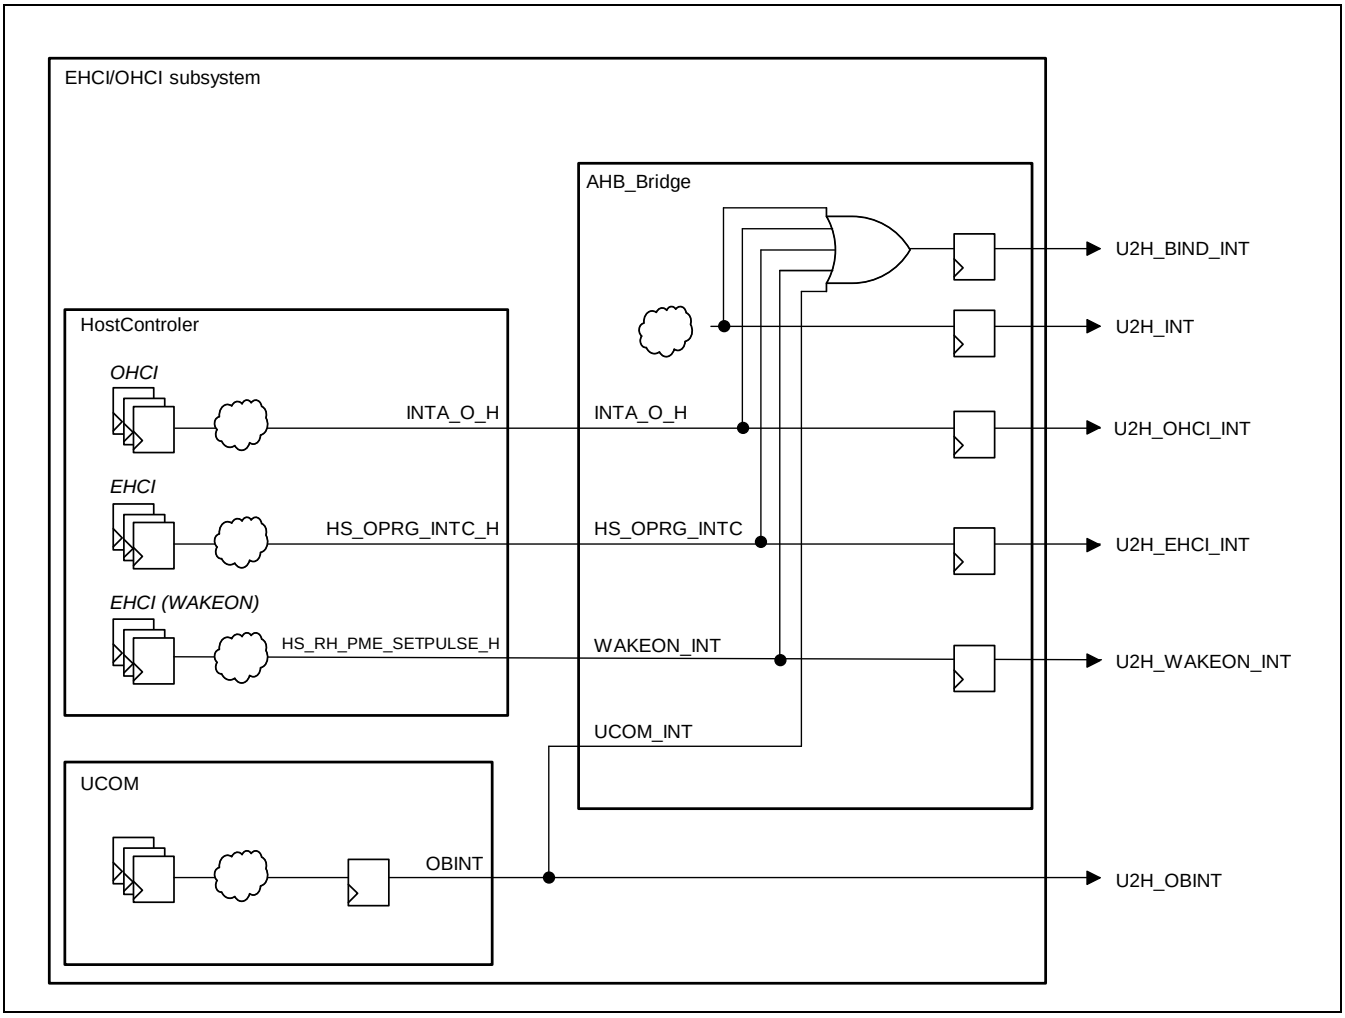

Figure 60.2 Connection diagram of Interrupt Signal Lines

60.6 Power Management

The system implementing this module provides the following two types of low-power control for the USB 2.0 core (including the UTMI+ PHY).

1. Controls the SUSPENDM and SLEEPM pins of the UTMI+ PHY.
2. Stops unnecessary clock supply to the host core internal circuits and the peripheral core through clock gating.

60.6.1 Controlling SUSPENDM and SLEEPM Pins of UTMI+ PHY

The following power-reducing effects are expected from assertion of the SUSPENDM and SLEEPM pins of the UTMI+ PHY.

- The power consumption in the UTMI+ PHY can be reduced.
- The power consumption in the host core can be reduced because the clock from the PHY is stopped.

The SUSPENDM and SLEEPM pins of the UTMI+ PHY are not asserted in the default settings even when the EHCI or OHCI is placed in the Suspend state as described earlier.

See section 60.2.5.3, Suspend Control Register (offset: H'308), and set up the register appropriately.

60.6.2 Controlling Clock Gating Function

The clock supply to the unused one of the host and peripheral functions can be gated through register settings.

See section 60.2.5.2, Register Enable/Clock Gating Control Register (offset: H'304), and set up the register appropriately.

60.7 OTG Control

60.7.1 Conditions for Using This Module for OTG

60.7.1.1 Core Pin and define Item Settings

Make the following settings and define items shown below when using this module for OTG.

1. Set the USB0SEL[1:0] in UGCTRL2 register of HS-USB module to B'11.

60.7.1.2 ID Pin Connections

This module has an ID detection pin; use this pin to detect ID.

60.7.1.3 Port Power (VBUS) Control and Connection with External Power-Supply IC

The following describes how to control the port power (VBUS) when using this module for OTG.

1. Control the port power through the related UCOM register.
   An example for connection is described later.
2. Connect the external power-supply IC and the corresponding pins of this module as follows.

LSI Pin Name	I/O	Connection
[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] USB*_PWEN [RZ/G2E] USB0_PWEN_A/B	O	Connect this as output to the power-supply IC.
[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] USB*_OVC [RZ/G2E] USB0_OVC_A/B	I	Connect this as input from the power-supply IC.

Notes: OTG function isn't supported RZ/G2E
'*' in LSI Pin Name column are 0 or 1 for RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N.

60.7.1.4 OTG System Configuration Example

The following shows an example of connections to support the OTG function[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N].

This configuration includes an external power-supply IC and a peripheral controller (HS-USB module).

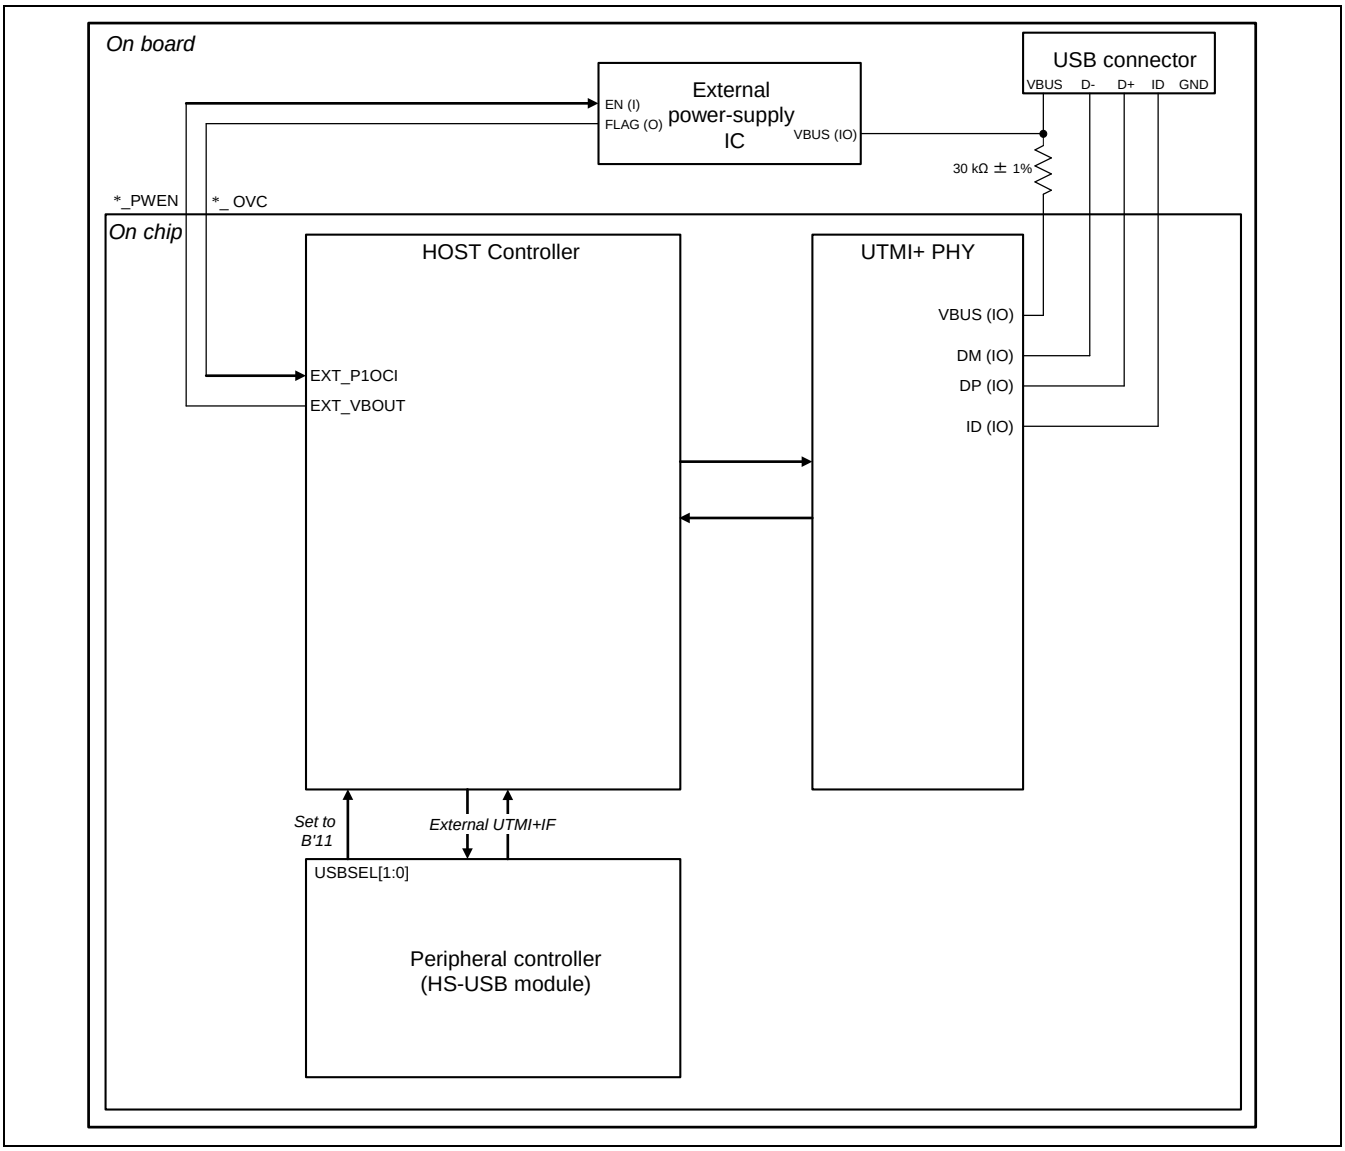

Figure 60.3 OTG System Configuration Example

60.7.2 Initial Setting Procedure

The following shows the initial setting procedure when this module is used for OTG.

This shows the steps before detection of A-plug or B-plug connection through the ID or VBUS pin.

60.7.2.1 OTG Initial Setting Procedure

Assumed control of ID and VBUS: VBUS control: ADPCTRL.DRVVBUS
ID detection: PHY

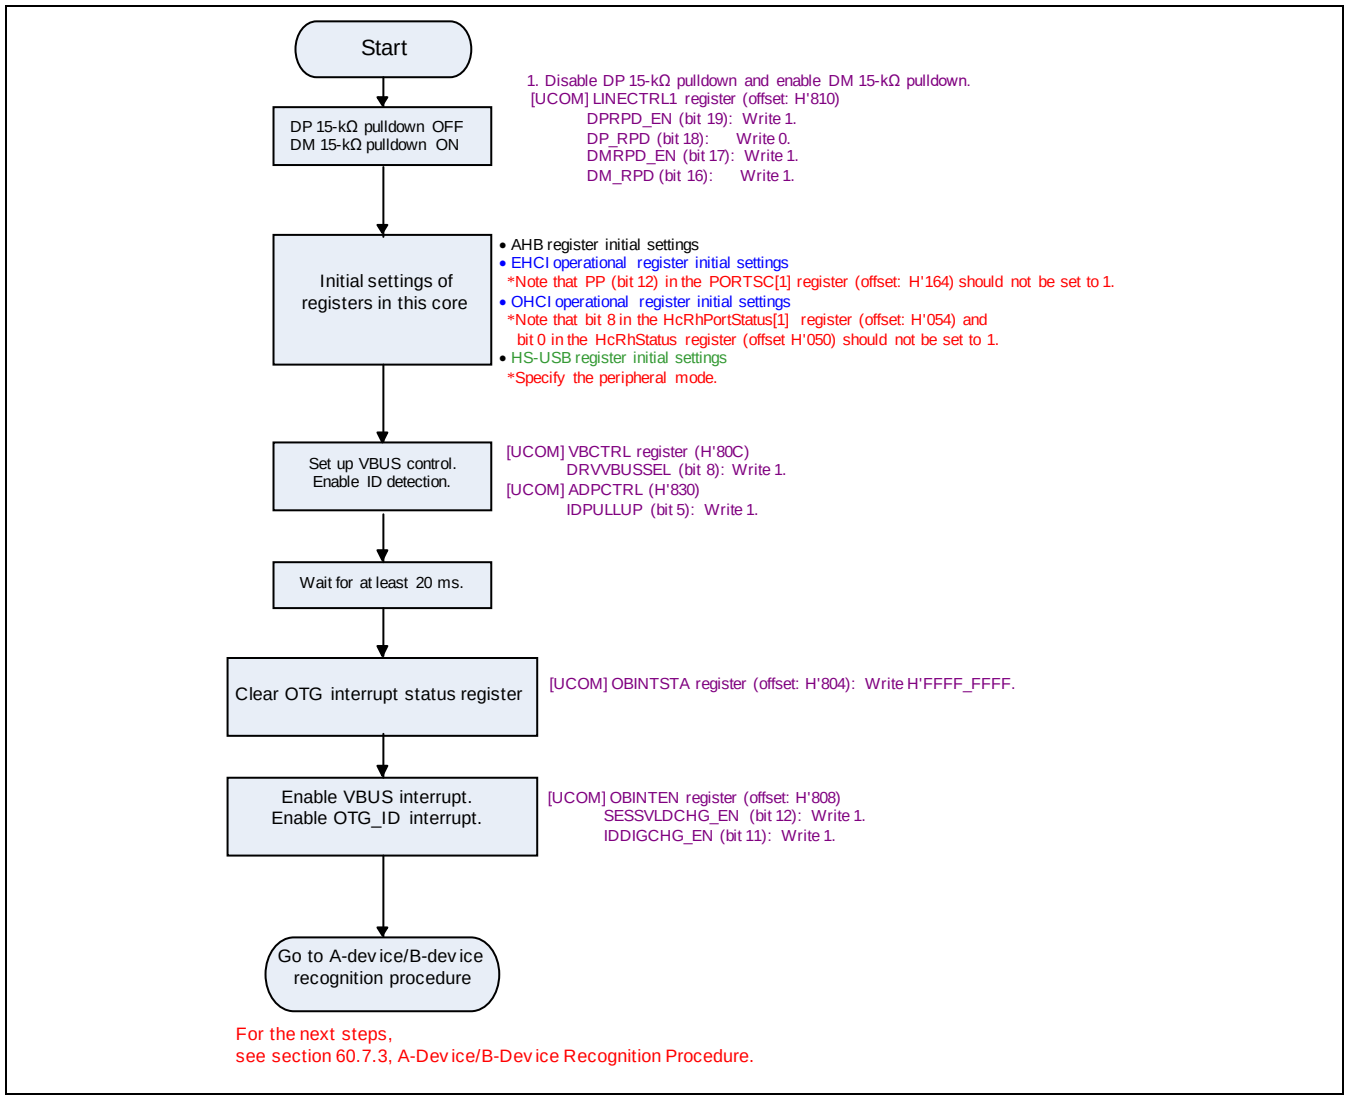

Figure 60.4 OTG Initial Setting Procedure

60.7.3 A-Device/B-Device Recognition Procedure

The following shows the control procedure for operating this module as an A-device or a B-device through A-plug or B-plug connection after the steps described in section 60.7.2, Initial Setting Procedure, or section 60.7.4, Disconnect Detection Procedure.

60.7.3.1 A-Device/B-Device Recognition Procedure

Assumed control of ID and VBUS: VBUS control: ADPCTRL.DRVVBUS
ID detection: PHY

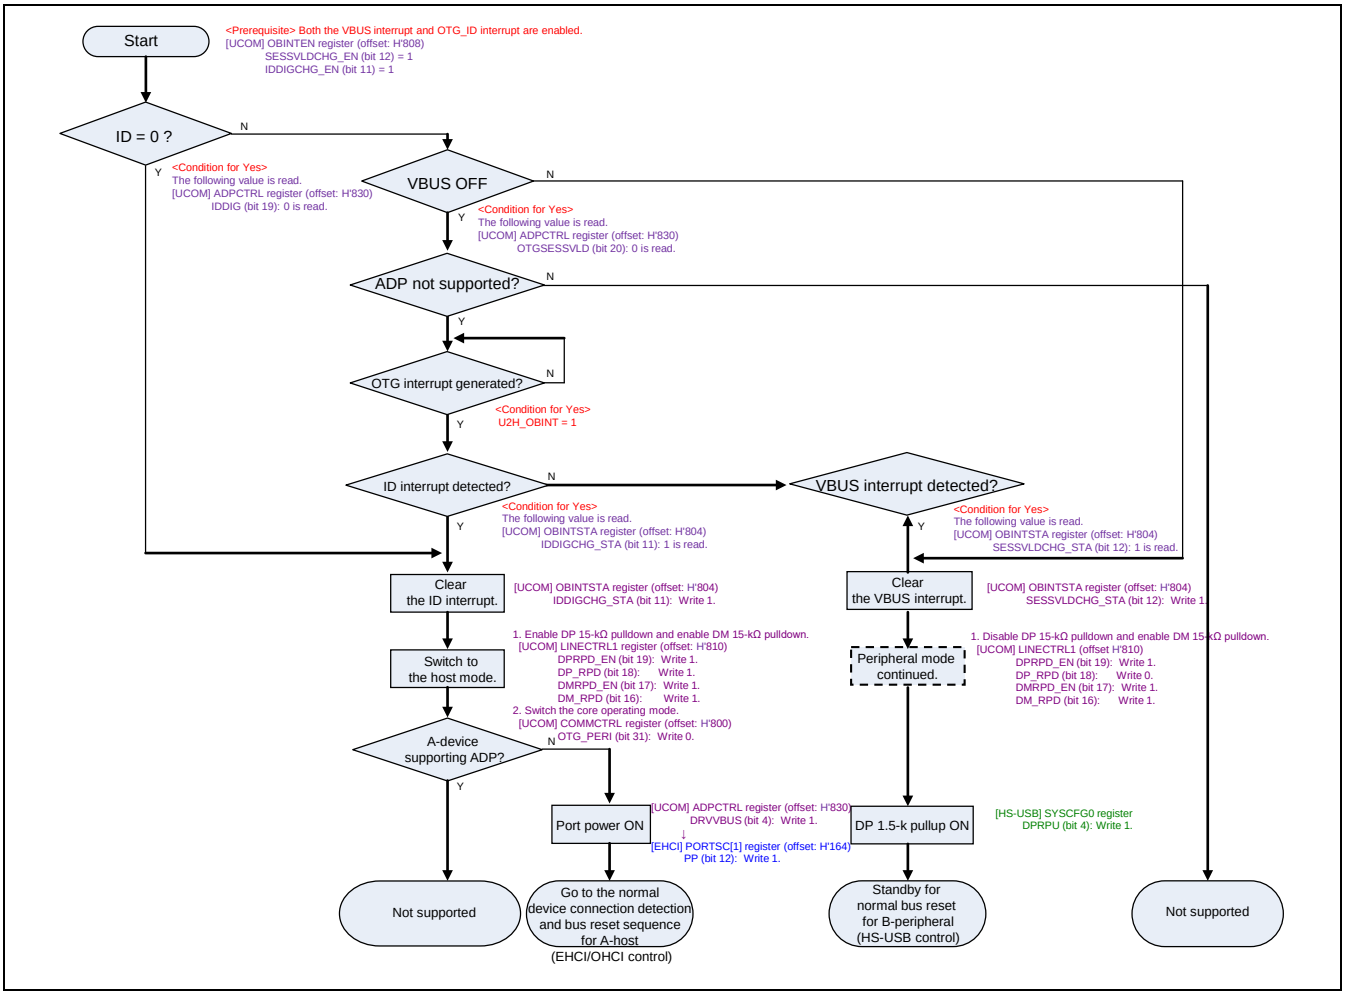

Figure 60.5 A-Device/B-Device Recognition Procedure

60.7.4 Disconnect Detection Procedure

The following shows the Disconnect detection procedure.

Here, "Disconnect detection" means detection of physical disconnection of an A-plug or B-plug from a USB port.

60.7.4.1 Disconnect Detection Procedure

Assumed control of ID and VBUS: VBUS control: ADPCTRL.DRVVBUS
ID detection: PHY

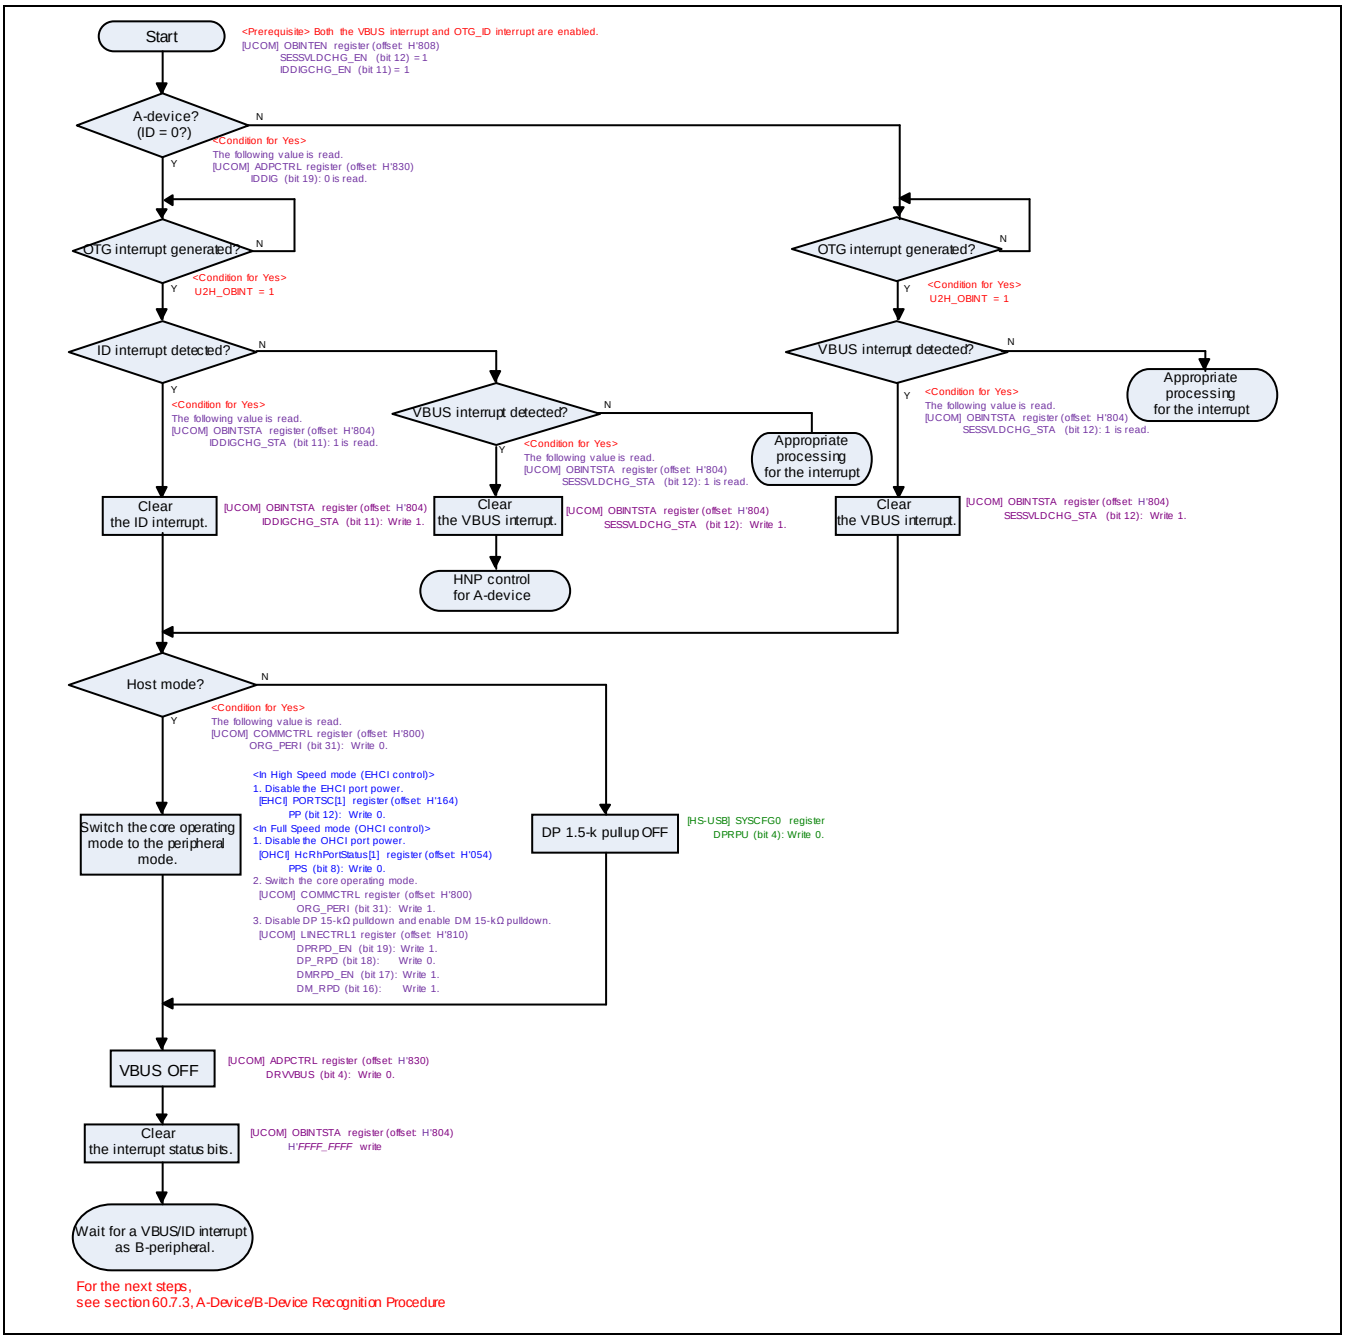

Figure 60.6 Disconnect Detection Procedure

60.7.5 HNP Control Procedure (Conforming to OTG Revision 2.0)

60.7.5.1 HNP Control Procedure for A-Device (Switching from A-Host to A-Peripheral)

The following shows the control procedure after a B-device's request for the host role is detected from the result of HNP polling for the B-device.

For HNP Control in High Speed Mode (Controlled by EHCI):

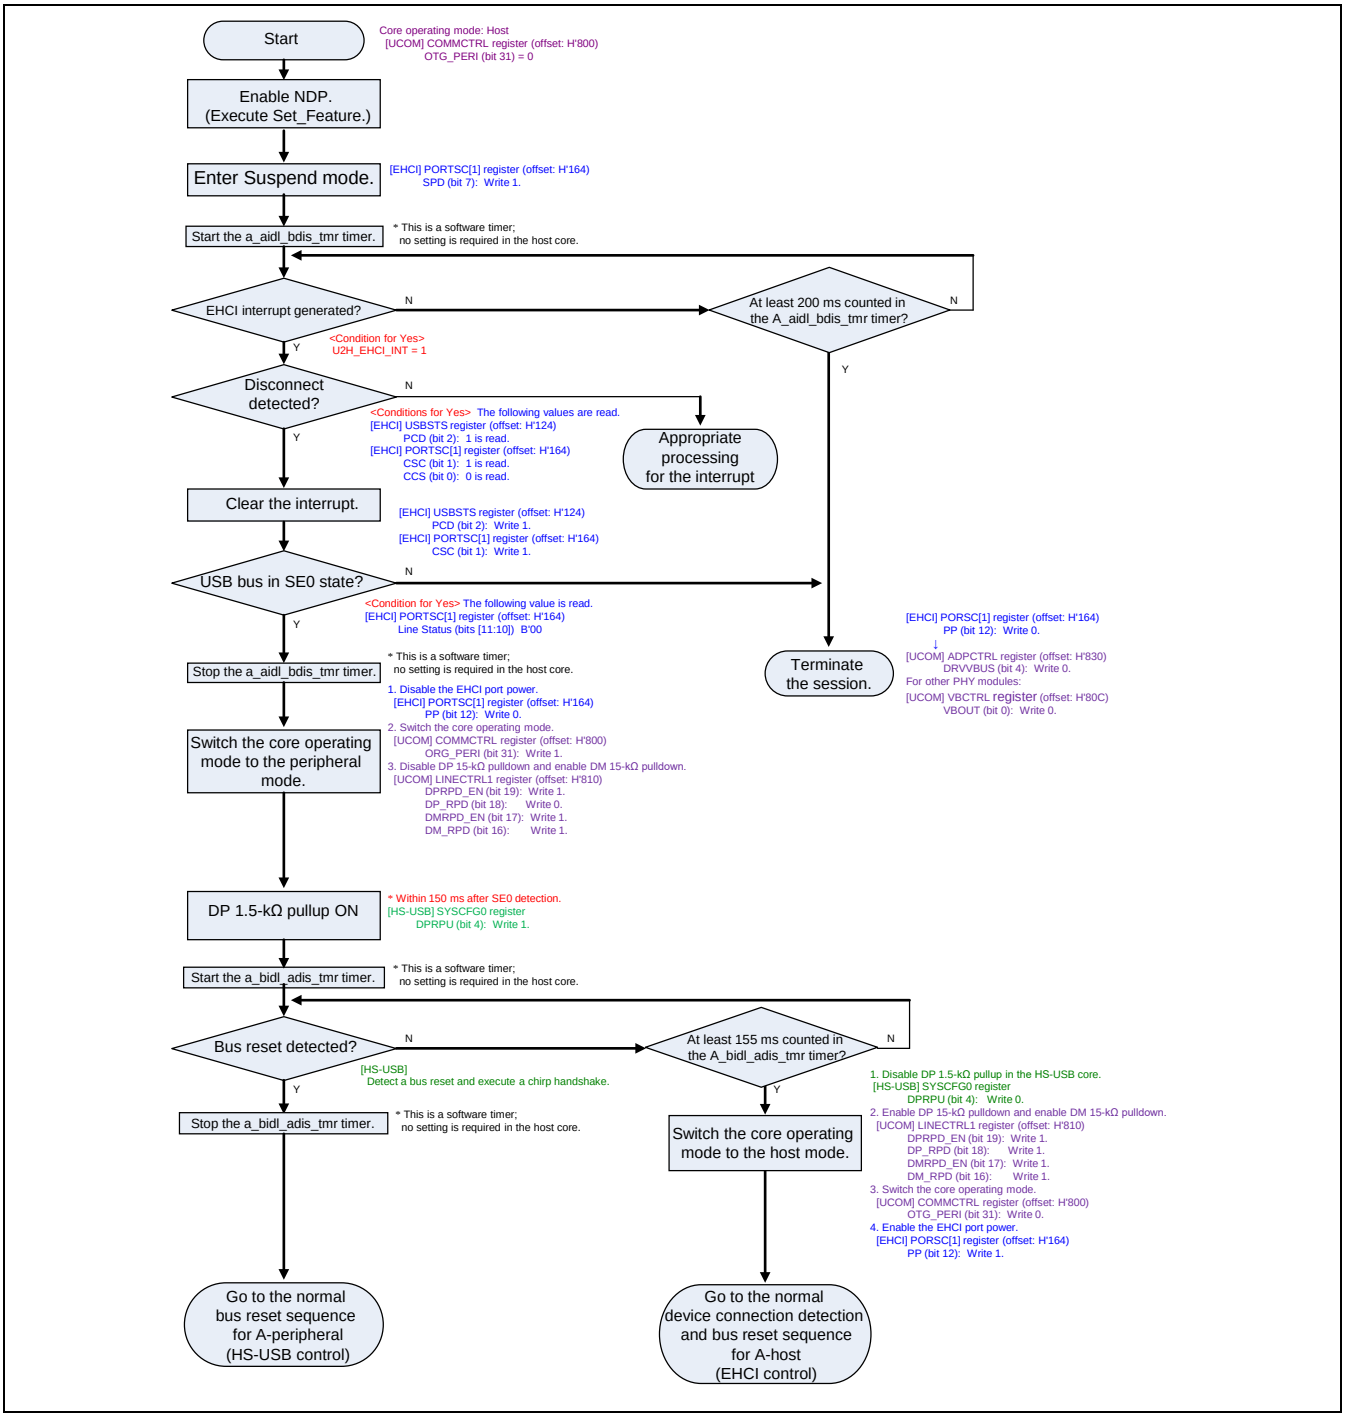

Figure 60.7 HNP Control Procedure for A-Device (Switching from A-Host to A-Peripheral in High Speed Mode)

For HNP Control in Full Speed Mode (Controlled by OHCI):

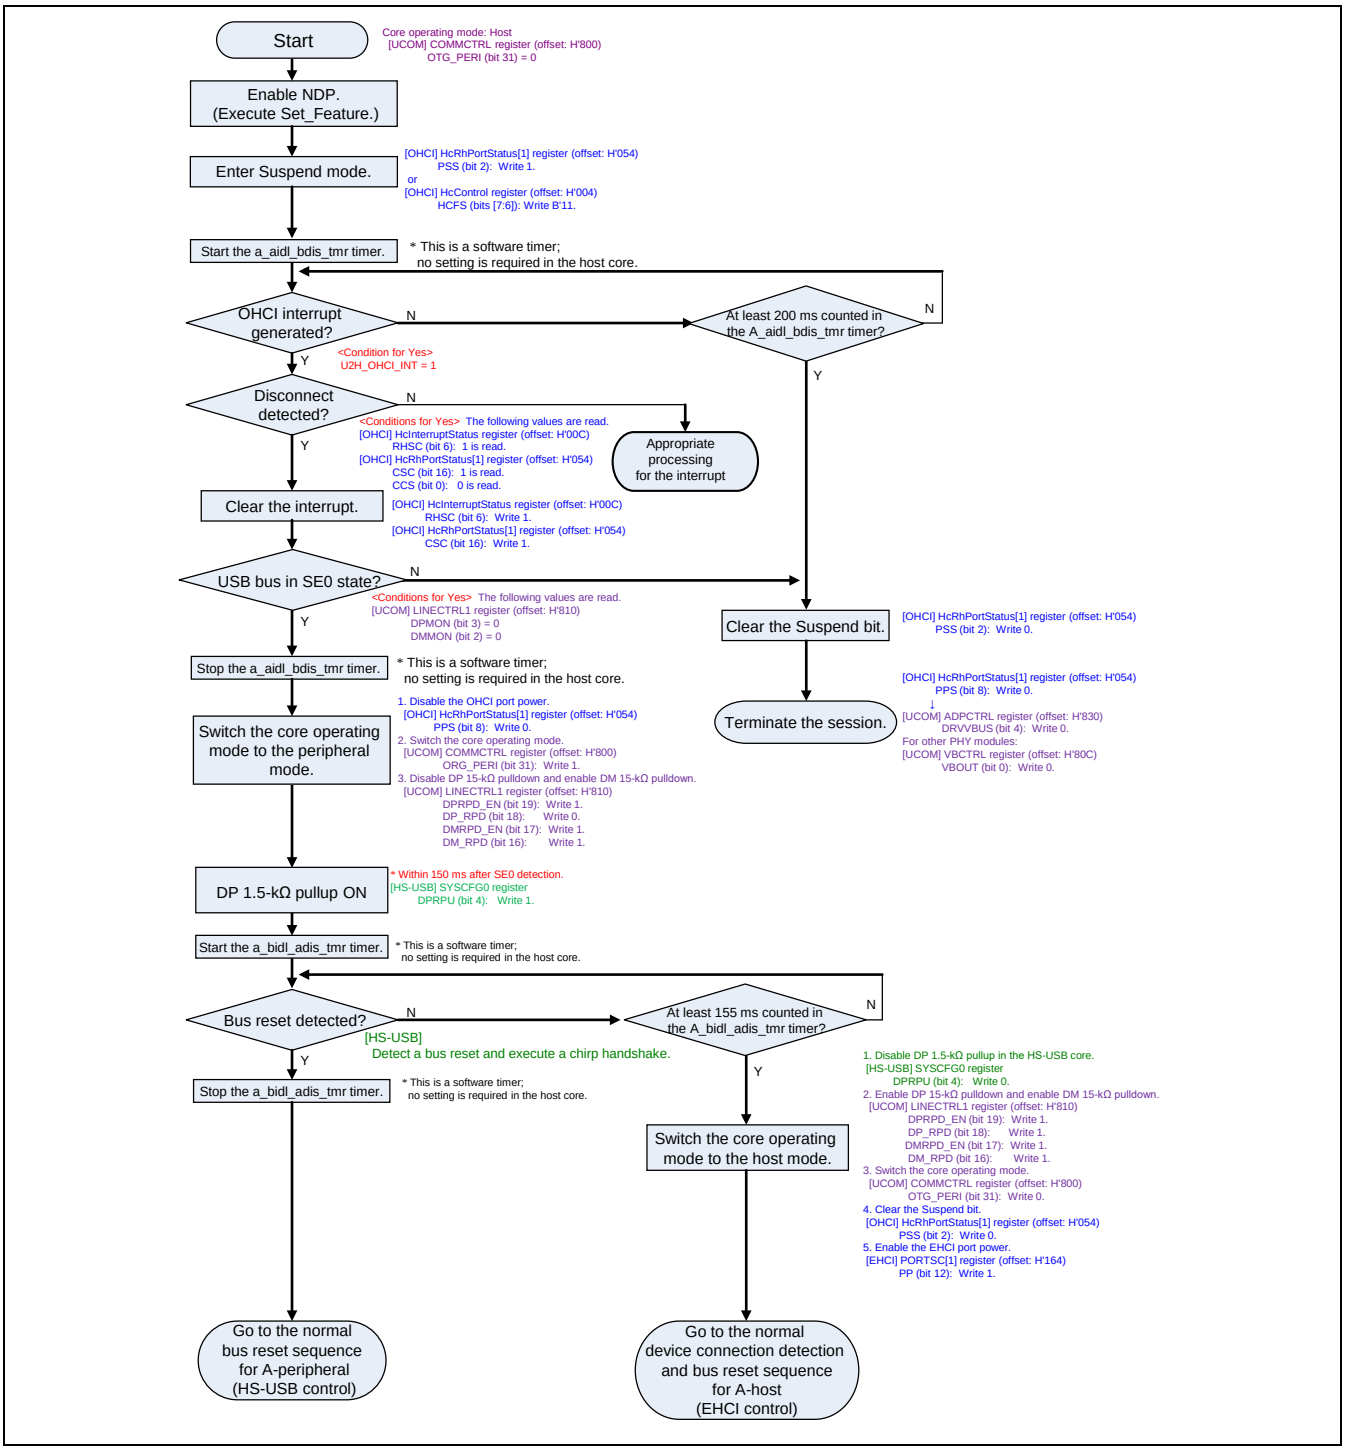

Figure 60.8 HNP Control Procedure for A-Device
(Switching from A-Host to A-Peripheral in Full Speed Mode)

60.7.5.2 HNP Control Procedure for A-Device (Switching from A-Peripheral to A-Host)

<Assumed Conditions>

Even for FS OTG, EHCI is assumed to be the port owner after switching of the role from the peripheral to the host. Therefore, the procedure for switching from the A-peripheral to the A-host is not separately prepared for each of OHCI and EHCI.

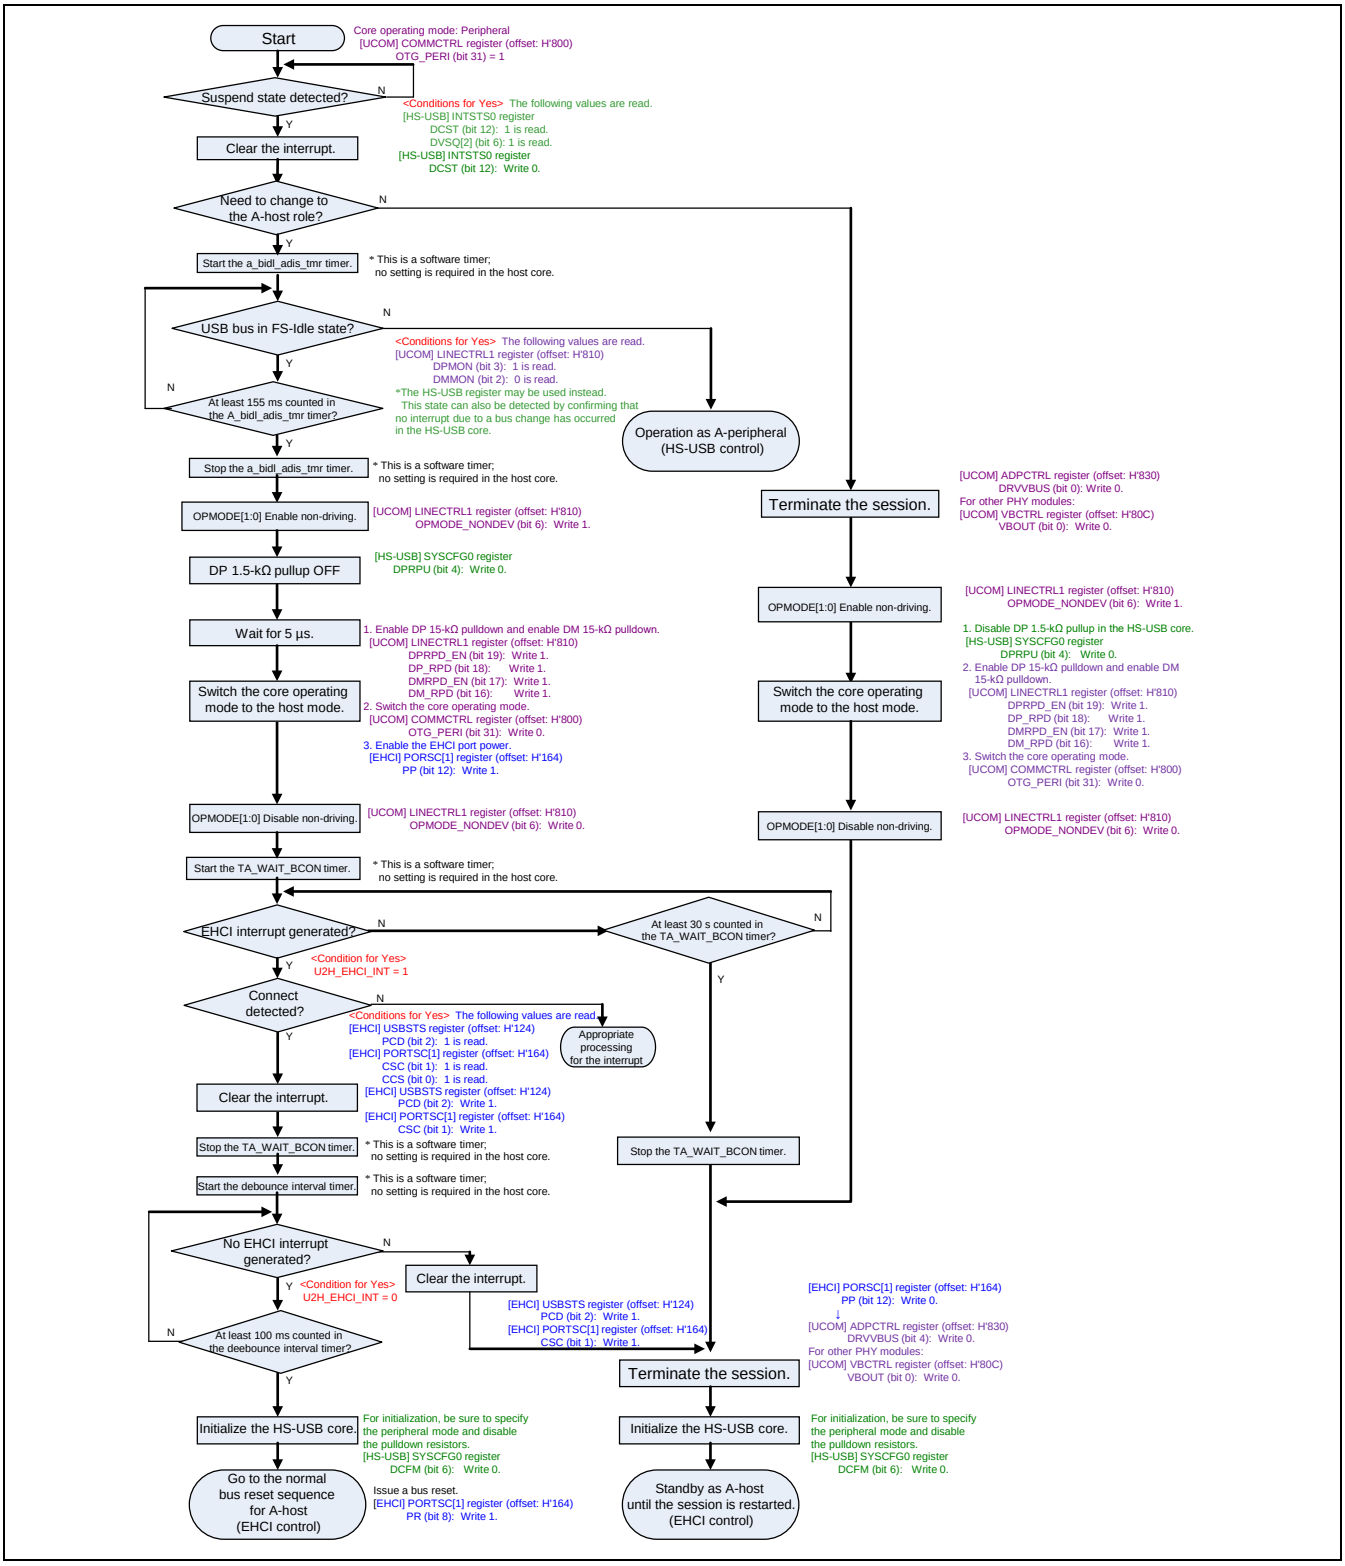

Figure 60.9 HNP Control Procedure for A-Device (Switching from A-Peripheral to A-Host)

60.7.5.3 HNP Control Procedure for B-Device (Switching from B-Peripheral to B-Host)

The following shows the procedure after the A-device issues Set Feature.

<Assumed conditions>

Even for FS OTG, EHCI is assumed to be the port owner after switching of the role from the peripheral to the host. Therefore, the procedure for switching from the B-peripheral to the B-host is not separately prepared for each of OHCI and EHCI.

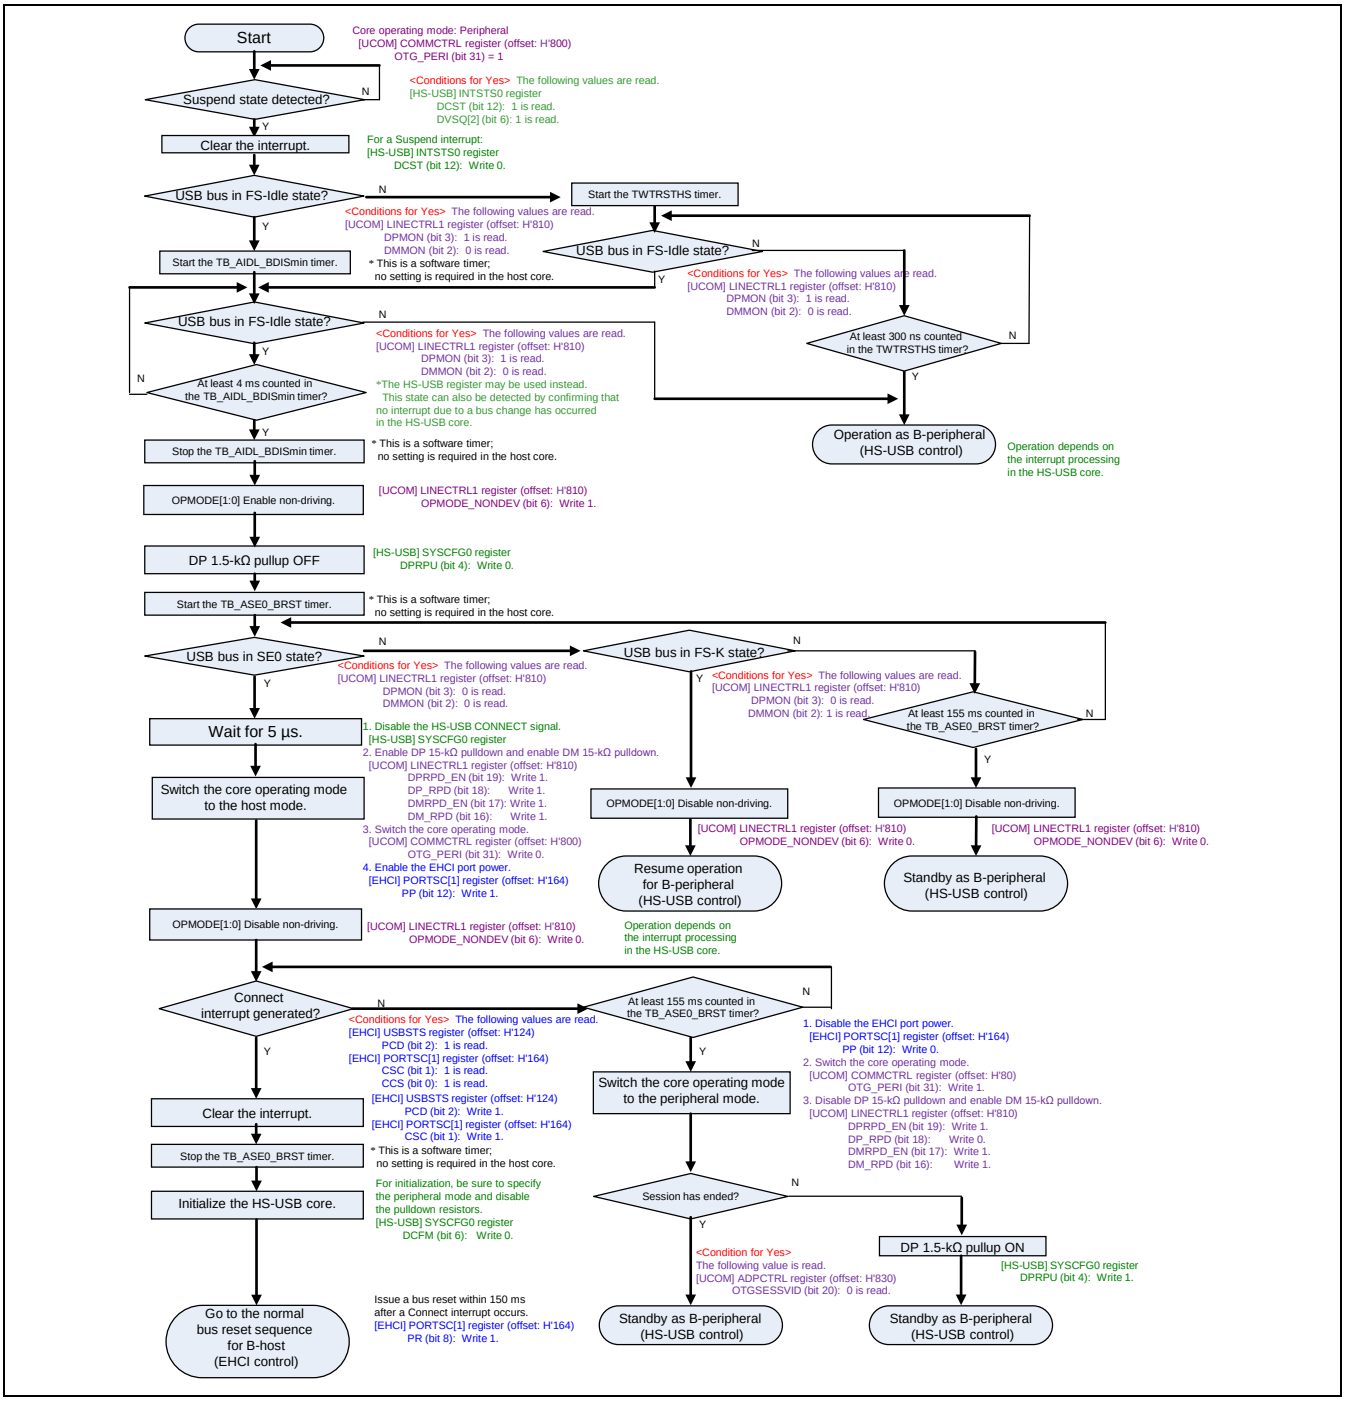

Figure 60.10 HNP Control Procedure for B-Device (Switching from B-Peripheral to B-Host)

60.7.5.4 HNP Control Procedure for B-Device (Switching from B-Host to B-Peripheral)

The following shows the procedure after no transfer is done by the B-Host.

<VBUS control: ADPCTRL.DRVVBUS; ID detection: PHY>

For HNP Control in High Speed Mode (Controlled by EHCI):

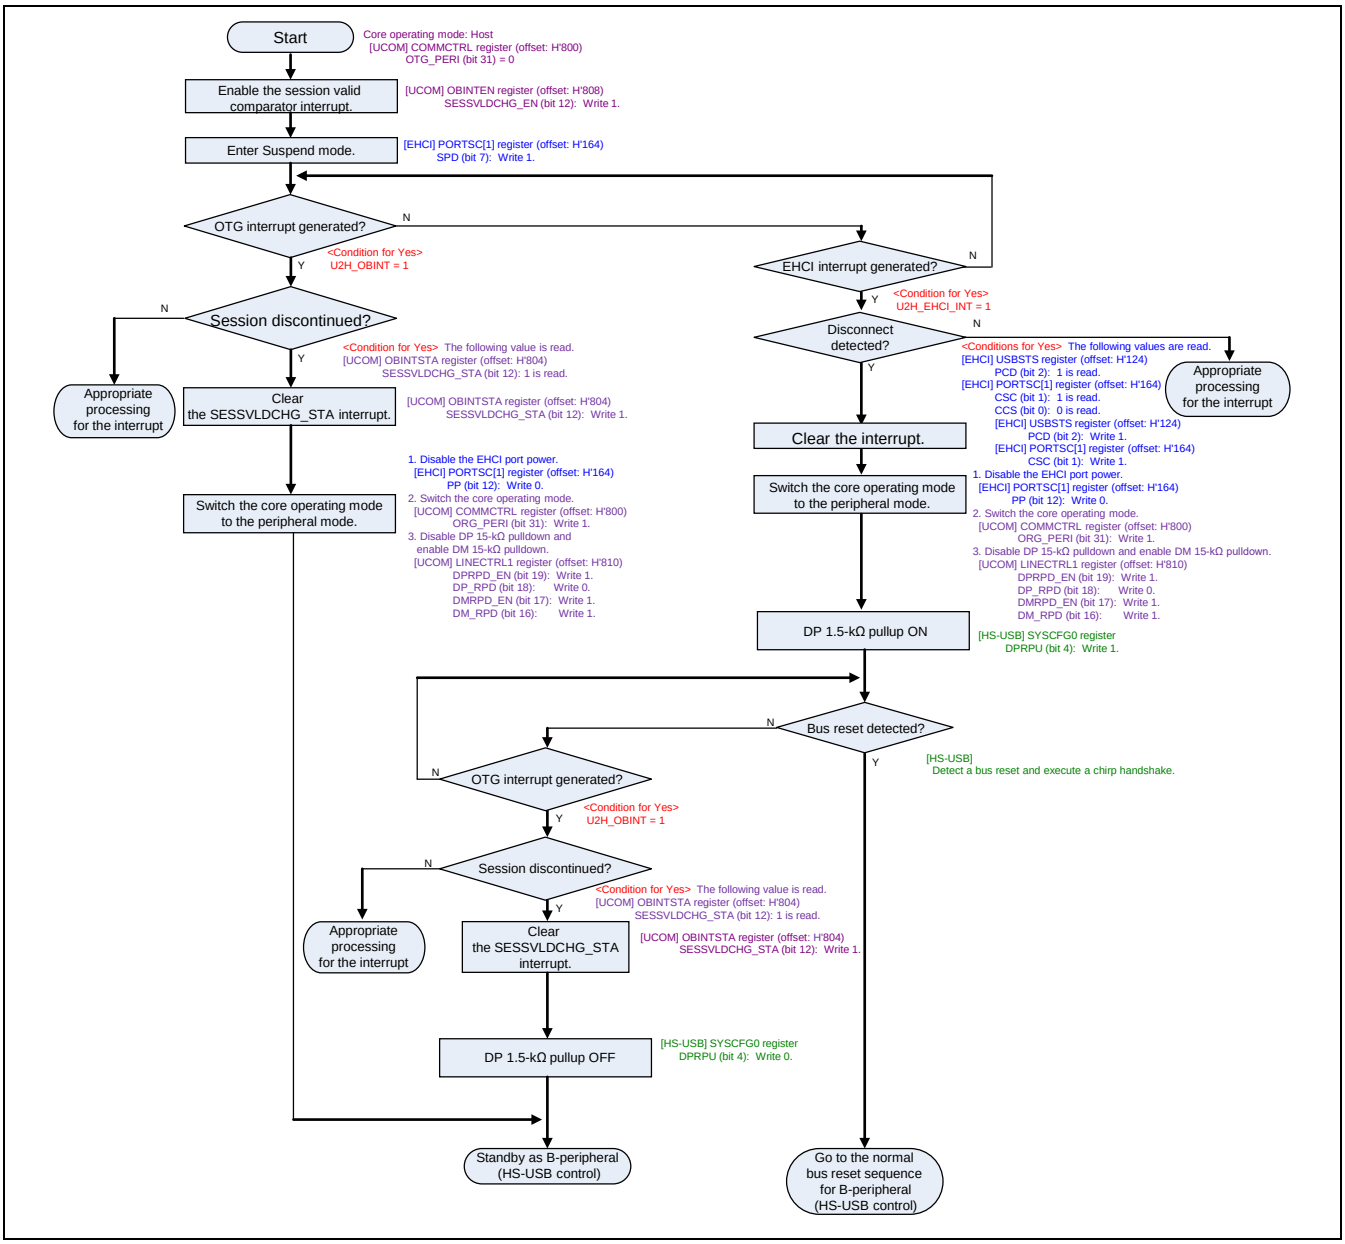

Figure 60.11 HNP Control Procedure for B-Device (Switching from B-Host to B-Peripheral in High Speed Mode)

For HNP Control in Full Speed Mode (Controlled by OHCI):

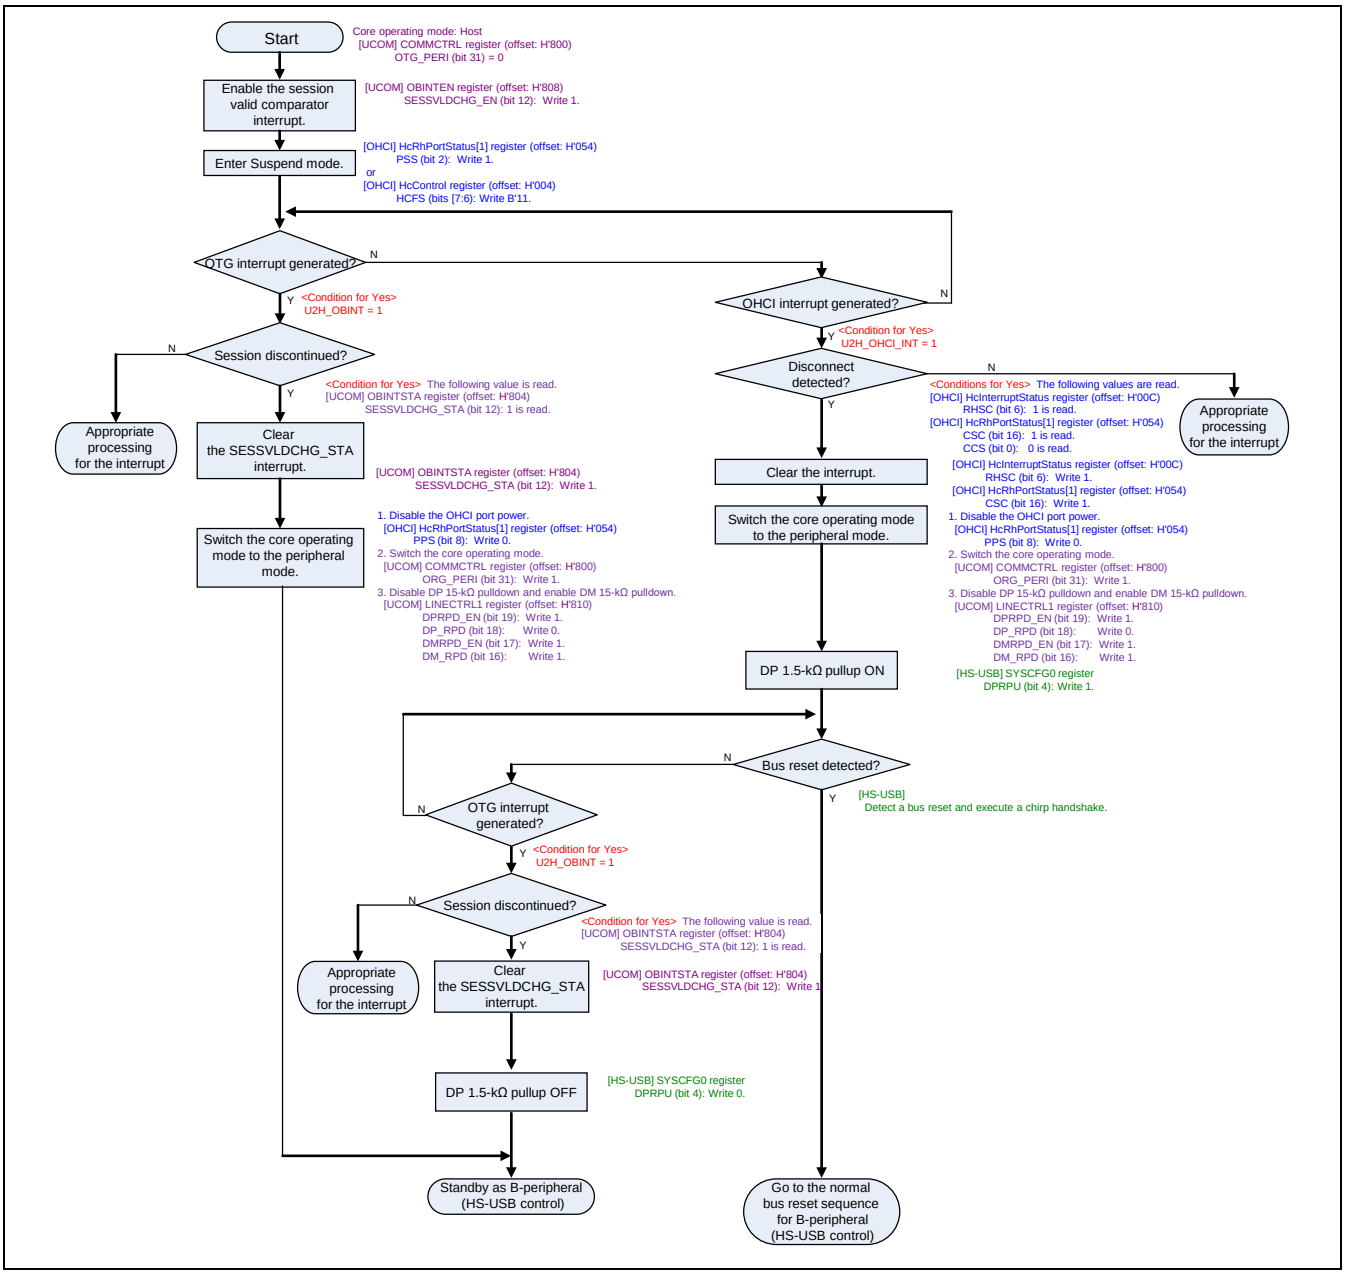

Figure 60.12 HNP Control Procedure for B-Device
(Switching from B-Host to B-Peripheral in Full Speed Mode)

60.7.6 SRP Control Procedure (Conforming to OTG Revision 2.0)

60.7.6.1 SRP Control Procedure for A-Device

The following shows the procedure starting with the step for terminating a session because the B-device issues no request for the host role and the A-device does not need to transfer data.

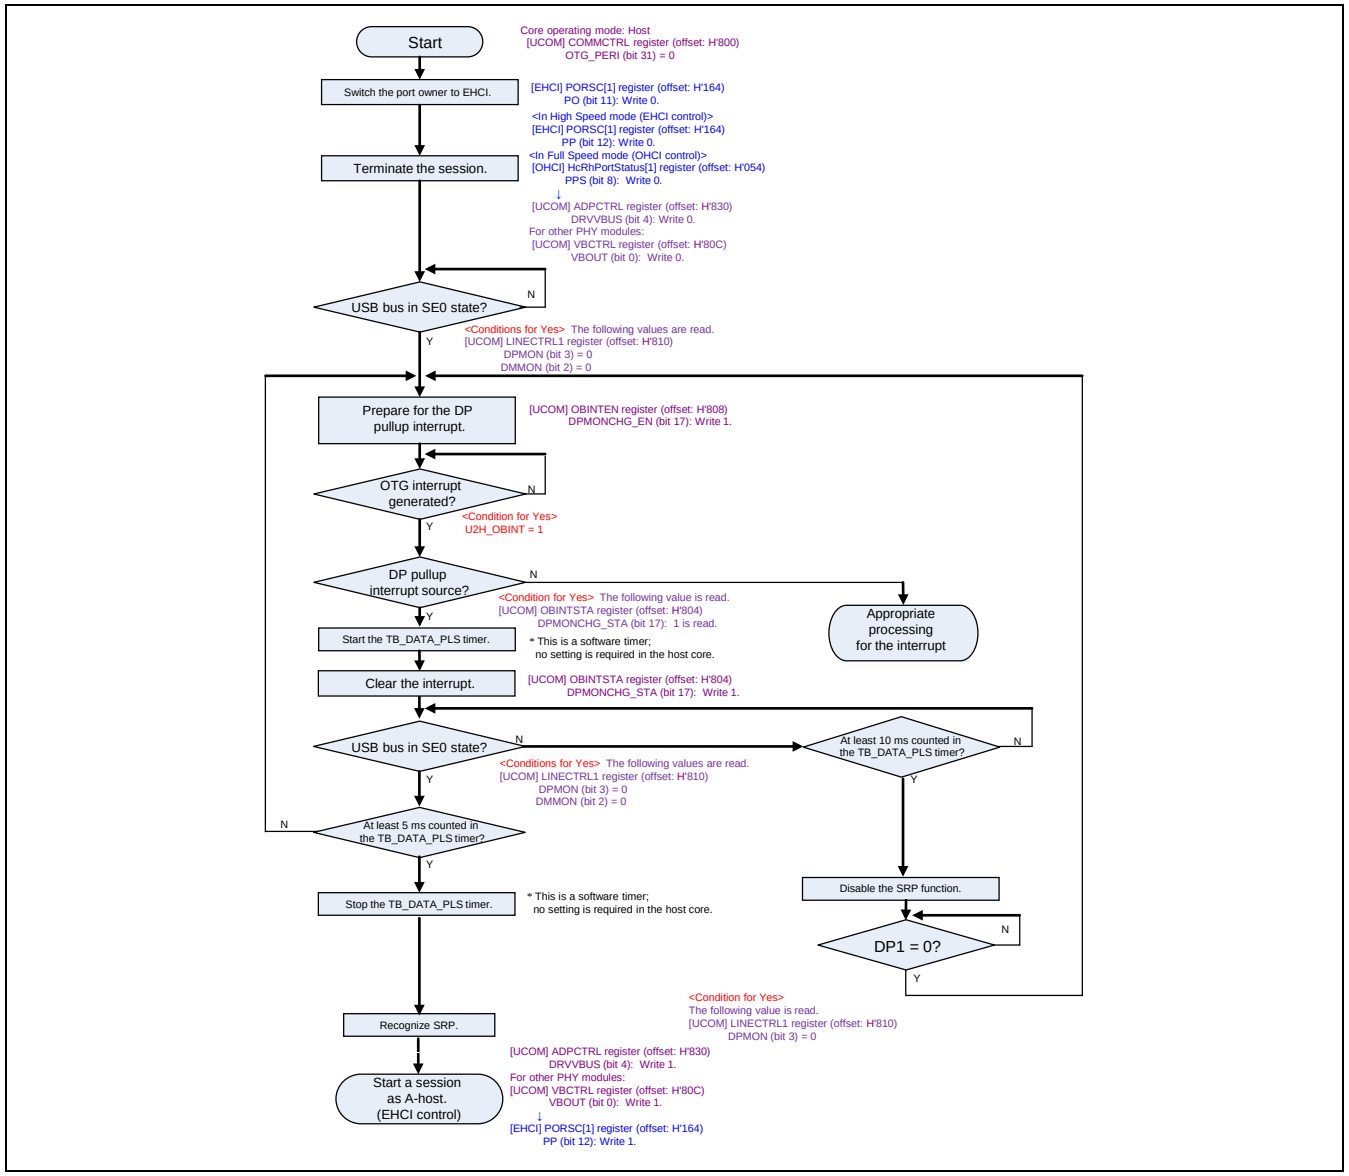

Figure 60.13 SRP Control Procedure for A-Device

60.7.6.2 SRP Control Procedure for B-Device

The following shows the procedure starting from the state of standby for a session termination request from the A-device.

<VBUS control: ADPCTRL.DRVVBUS; ID detection: PHY>

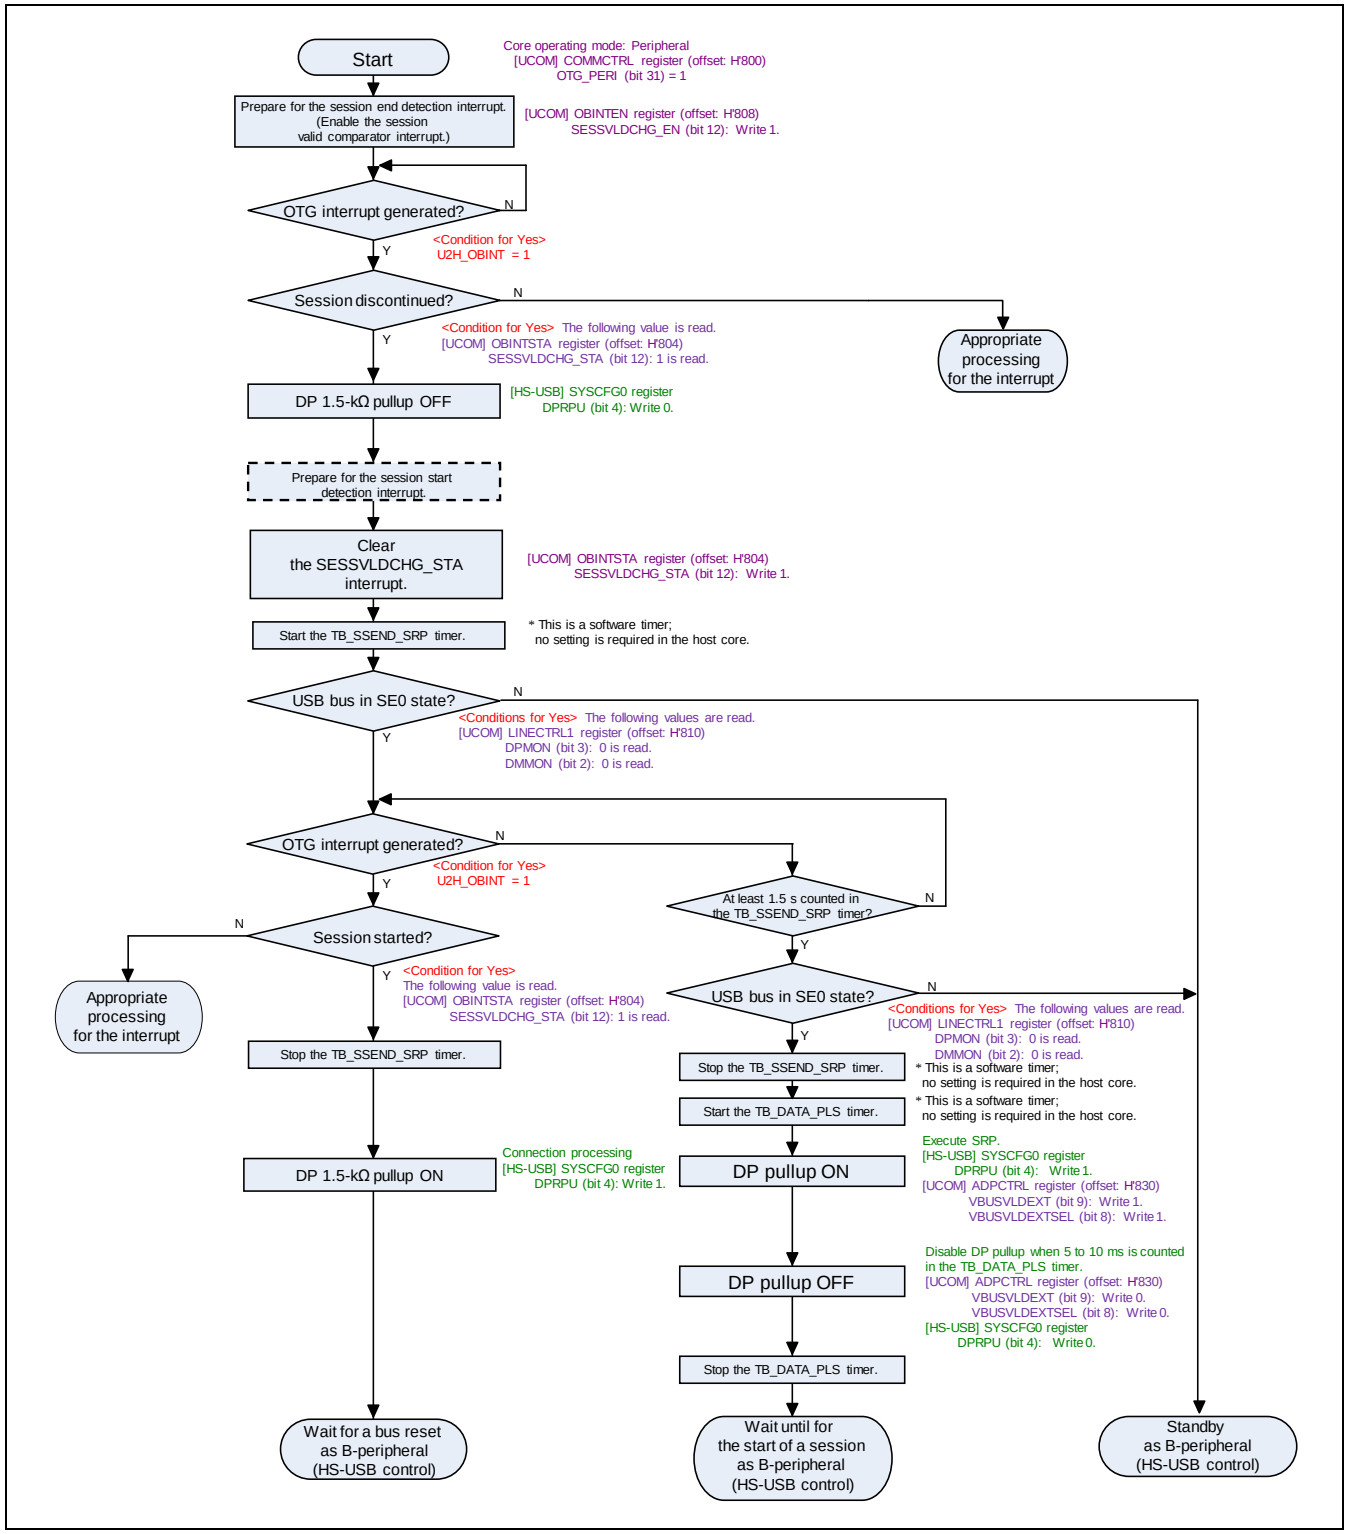

Figure 60.14 SRP Control Procedure for B-Device

60.8 Battery Charging Control

60.8.1 Conditions for Using Battery Charging Function in this Module

60.8.1.1 Limitations on Support of Charging Ports

A port that supplies power conforming to the Battery Charging Specification is called a charging port, and it is implemented in the host side in most cases.

Charging Ports are classified into the following types according to the function.

Type	Function	Support in This Module
CDP (Charging Downstream Port)	This is a downstream port that supplies power conforming to the Battery Charging Specification. After a portable device is detected and a handshake for battery charging is completed, the normal device connect sequence is entered (the port works as a normal host).	Supported
DCP (Dedicated Charging Port)	This is a port dedicated to the power supply function conforming to the Battery Charging Specification. This port does not perform normal host operation.	—
SDP (Standard Downstream Port)	This is a normal downstream port that does not conform to the Battery Charging specification. It supplies power within the conventional power range prescribed in the USB 2.0 specification. It works as a normal host.	Supported

60.8.1.2 Portable Device Control

A device that receives (requests) power supply conforming to the Battery Charging Specification is called a portable device, and it is implemented in the peripheral side in most cases.

This module assumes the Renesas HS-USB module as the peripheral controller.

A portable device can be controlled through either the HS-USB module or the registers of this module (UCOM registers).

Select a controller in accordance with the target system.

60.8.2 Controlling Method

The following describes control procedure for the Battery Charging function.

60.8.2.1 How to Control

(1) Notes on CDP Mode

Note the following two points in the CDP mode.

1. Use the following UCOM register bits to control the OPMODE[1:0] in the UTMI+ interface and 15-kΩ pulldown resistors for DP and DM as shown below.

Register		Setting	Function
[UCOM]	LINECTRLx.OPMODE_NODRV (bit 6)	B’1	Set UTMI_PxOPMODE[1:0] to output B'01 and set the USB bus control in the PHY to the non-driving state (actually, to the weak pulldown state). This bit is not supported RZ/G2E.
	LINECTRLx.DPRPD_EN (bit 19)	B’1	Disable the 1.5-kΩ pulldown resistor for DP.
	LINECTRLx.DP_RPD (bit 18)	B’0	
	LINECTRLx.DMRPD_EN (bit 17)	B’1	Disable the 1.5-kΩ pulldown resistor for DM.
	LINECTRLx.DM_RPD (bit 16)	B’0	

2. Use the Global Suspend function to forcibly assert UTMI_PxSUSPENDM to 0.

Register		Setting
[Core Defined]	Port 1: SPD_CTRL.GLOBAL_SUSPENDM_P1 (bit 0)	B’1

(2) CDP Mode Control

The following shows control on the port 1 side.

[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N]

Port 1: UTMI+ PHY SUSPENDM is Asserted in CDP Mode:

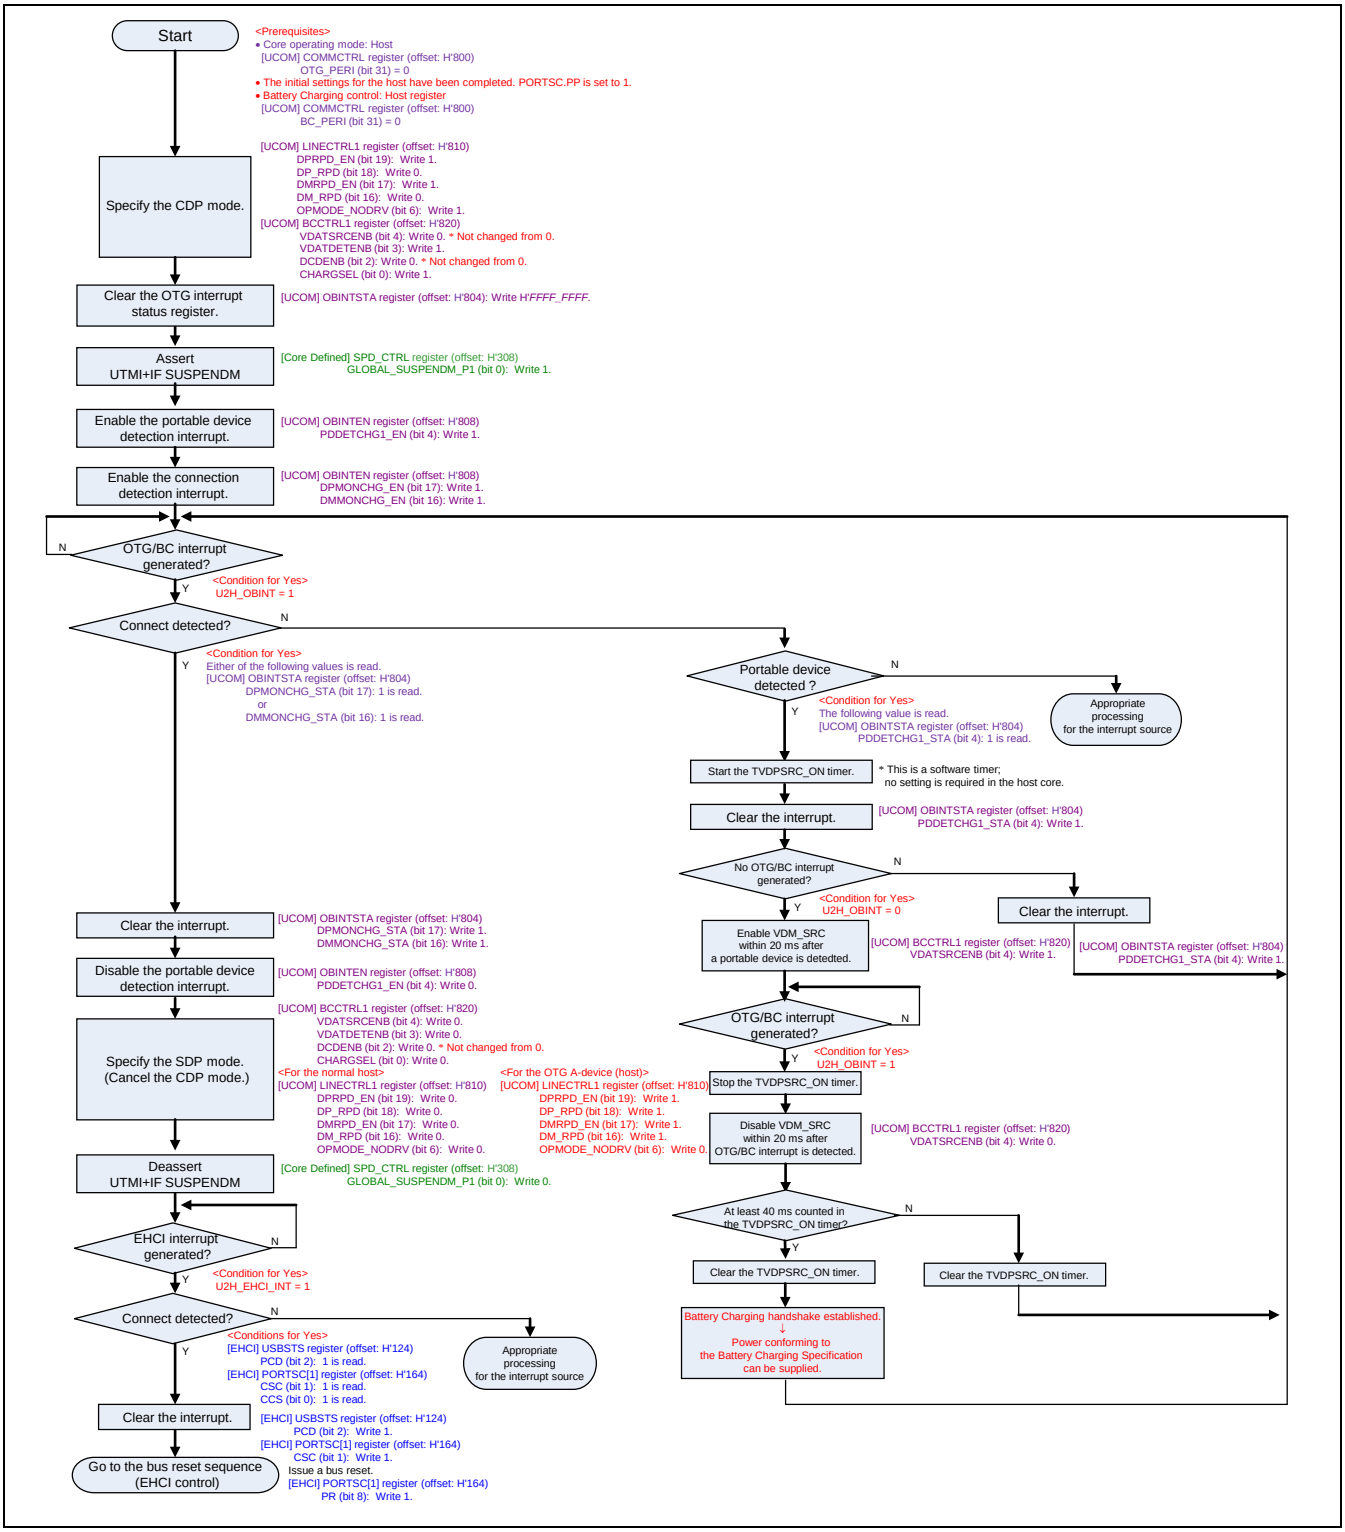

Figure 60.15 CDP Mode Control (UTMI+ PHY SUSPENDM is Asserted in CDP Mode)

Port 1: UTMI+ PHY SUSPENDM is Not Asserted in CDP Mode:

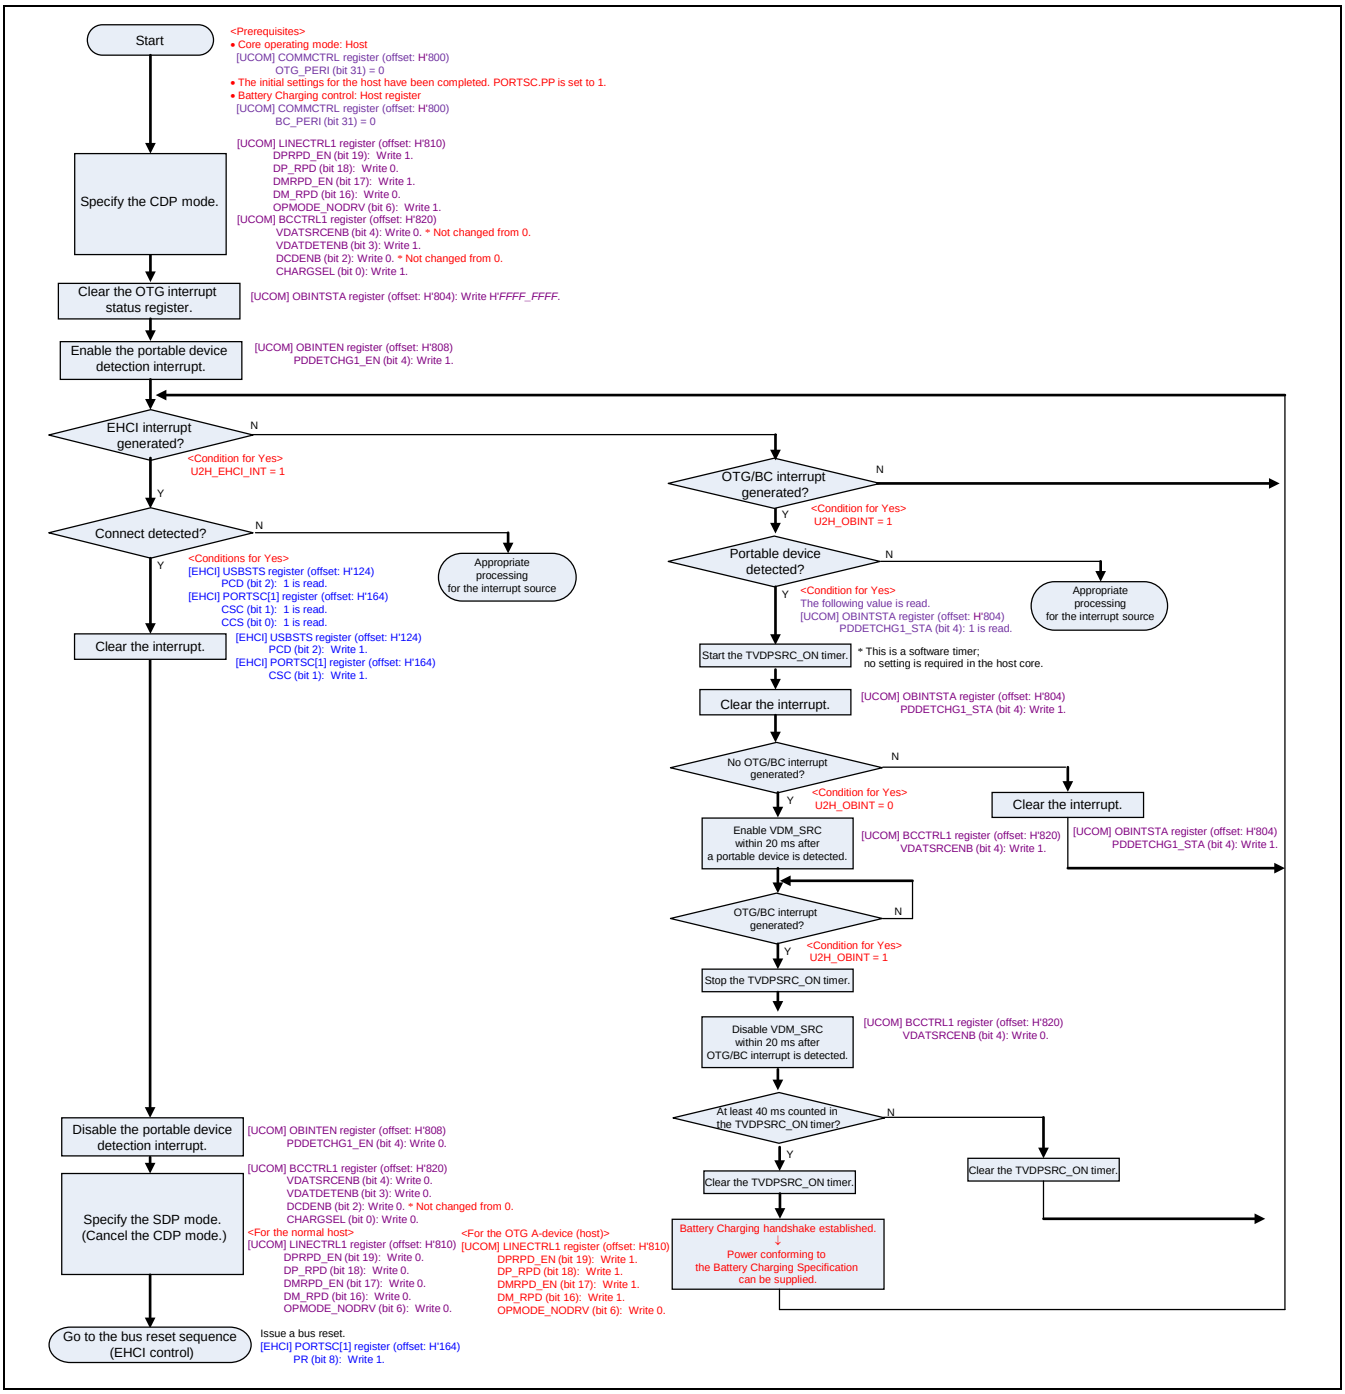

Figure 60.16 CDP Mode Control (UTMI+ PHY SUSPENDM is Not Asserted in CDP Mode)

[RZ/G2E]

Port 1: UTMI+ PHY SUSPENDM is Asserted in CDP Mode:

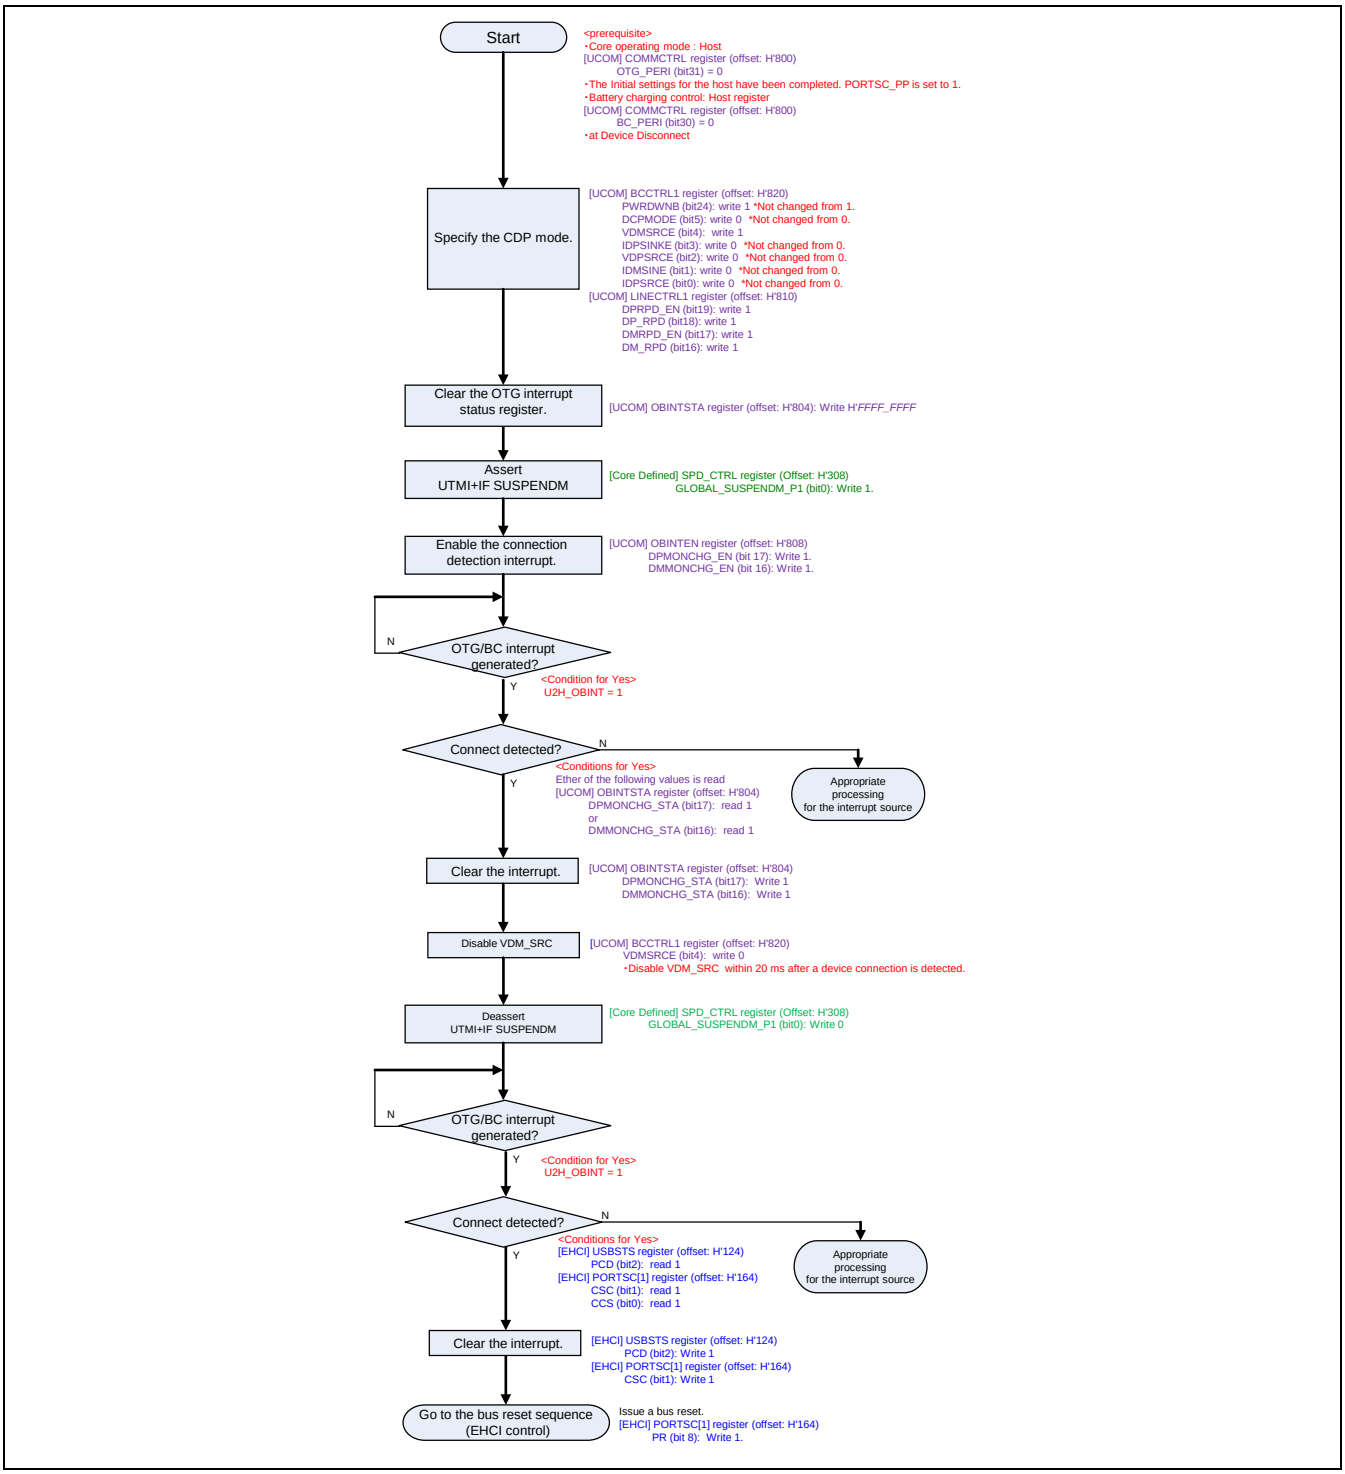

Figure 60.17 CDP Mode Control (UTMI+ PHY SUSPENDM is Asserted in CDP Mode)

Port 1: UTMI+ PHY SUSPENDM is Not Asserted in CDP Mode:

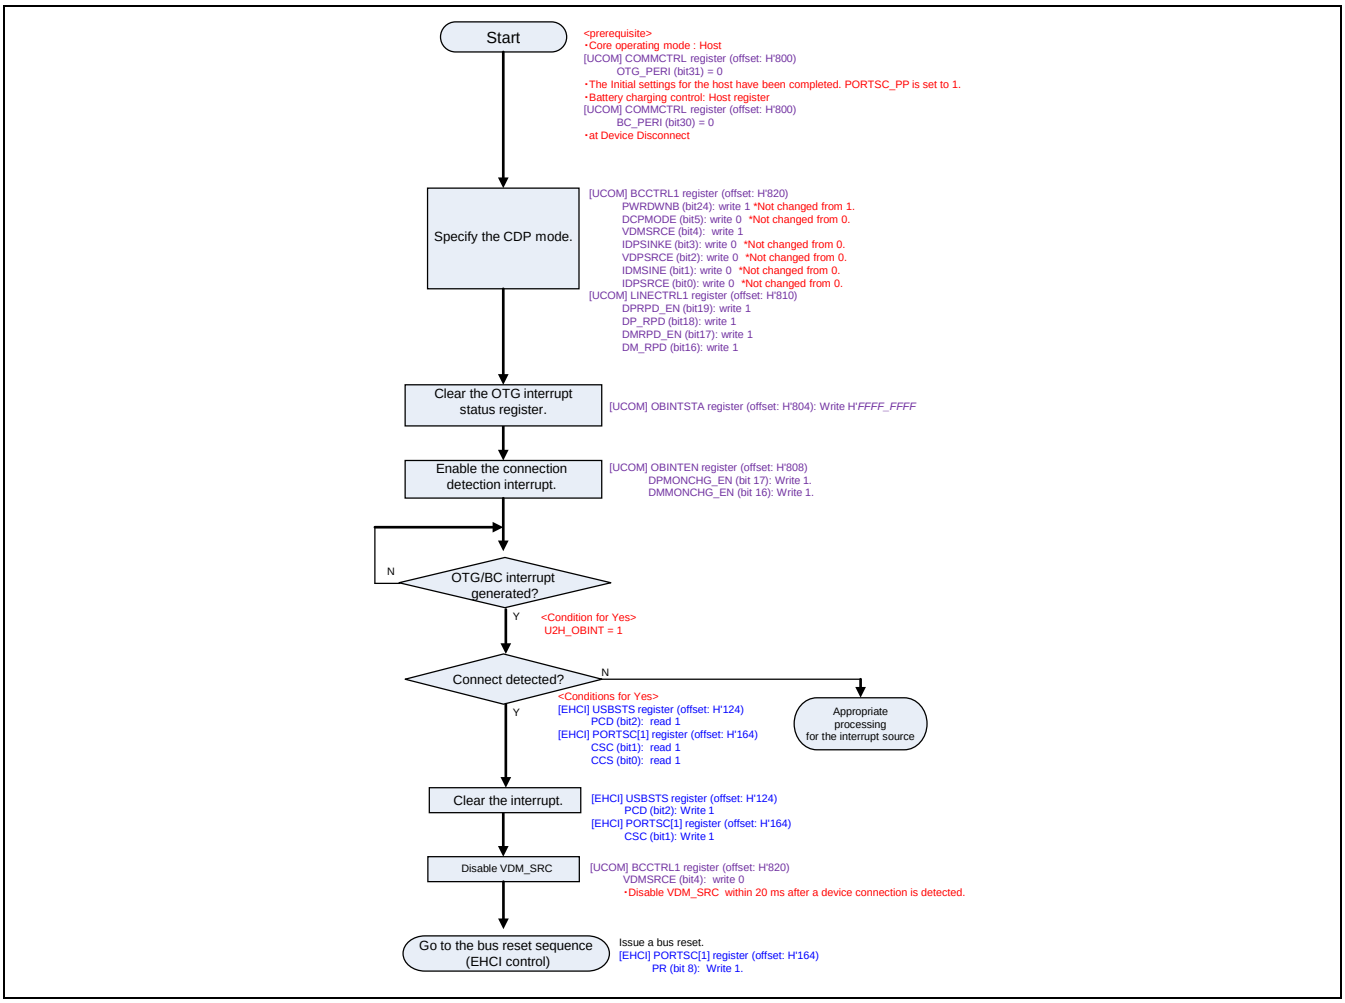

Figure 60.18 CDP Mode Control (UTMI+ PHY SUSPENDM is Asserted in CDP Mode)

(3) Portable Device Control

The following figures respectively show the procedures when a portable device is controlled through the register in this module (UCOM register) and when it is controlled through the peripheral controller (HS-USB module).

[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N]

Portable Device Control through UCOM Register:

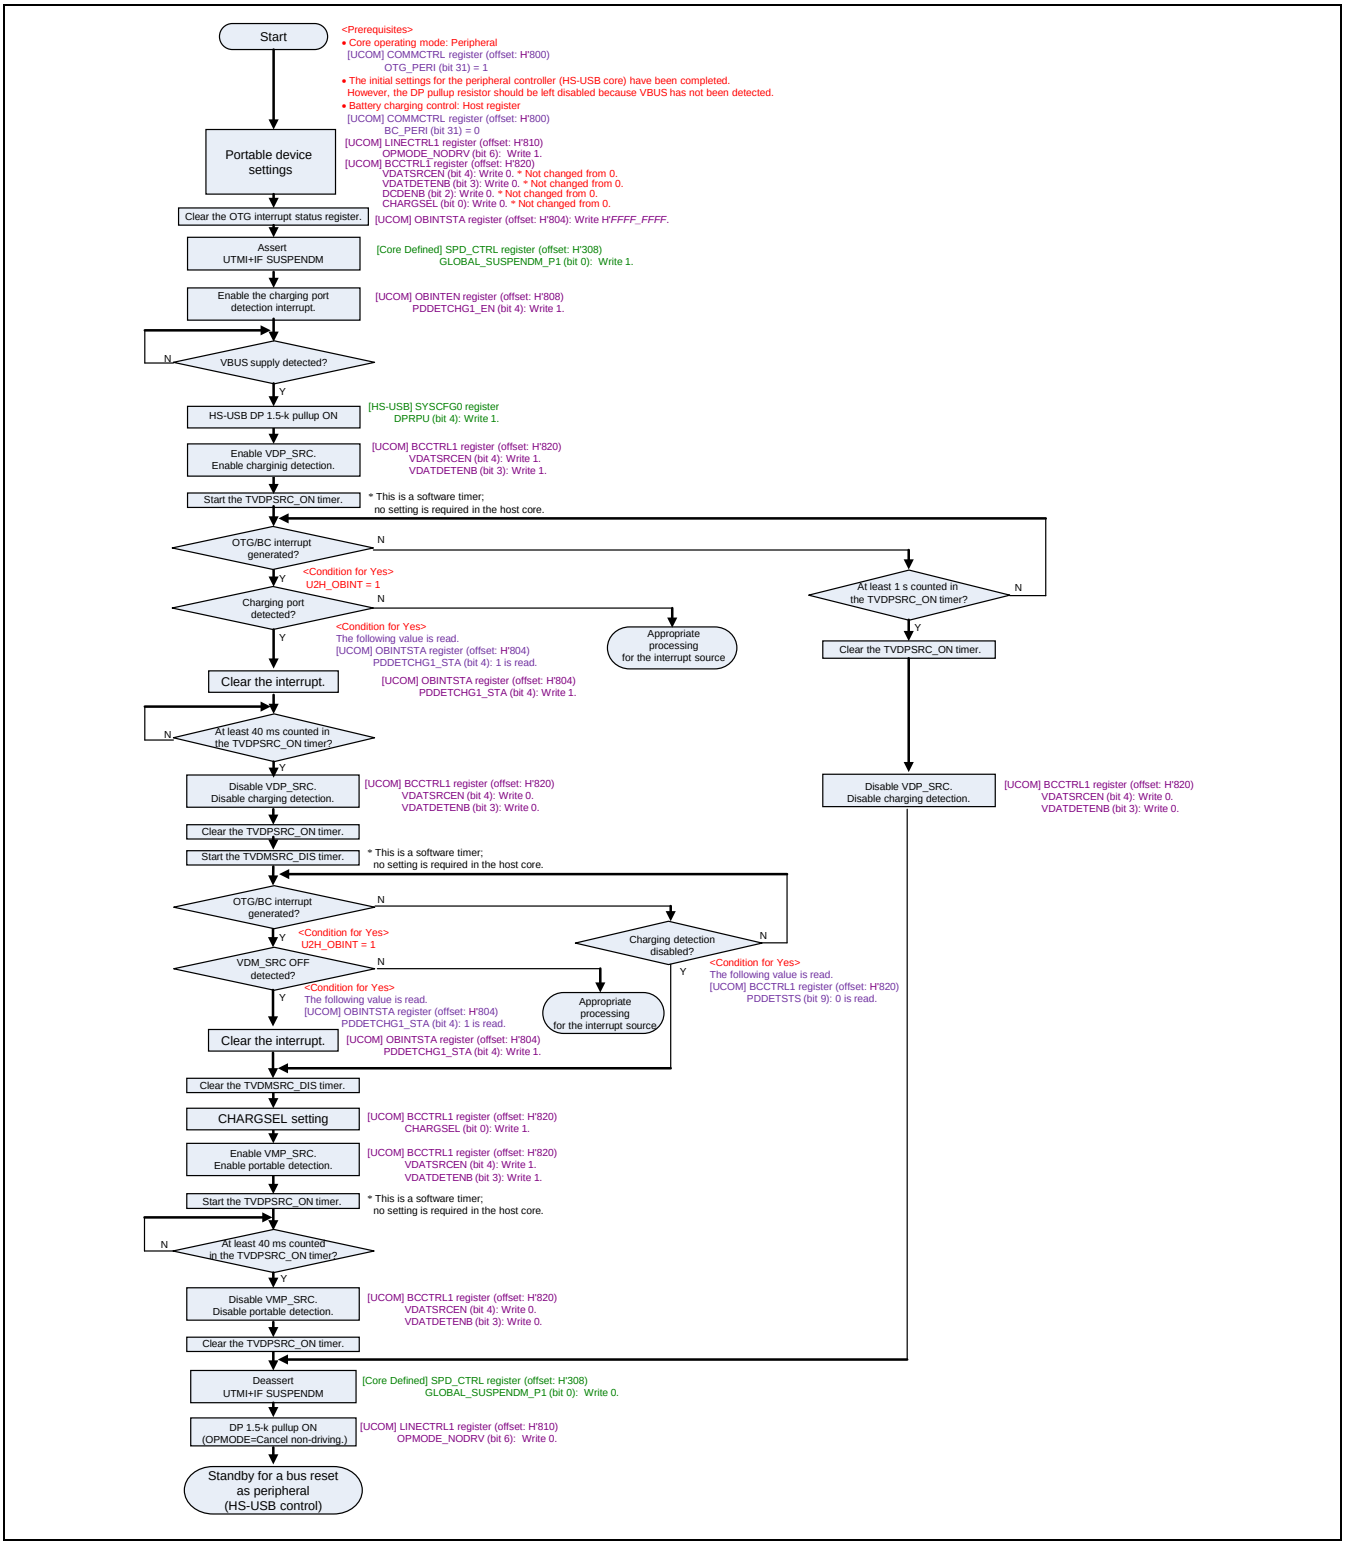

Figure 60.19 Portable Device Control through UCOM Register

Portable Device Control through Peripheral Controller (HS-USB module):

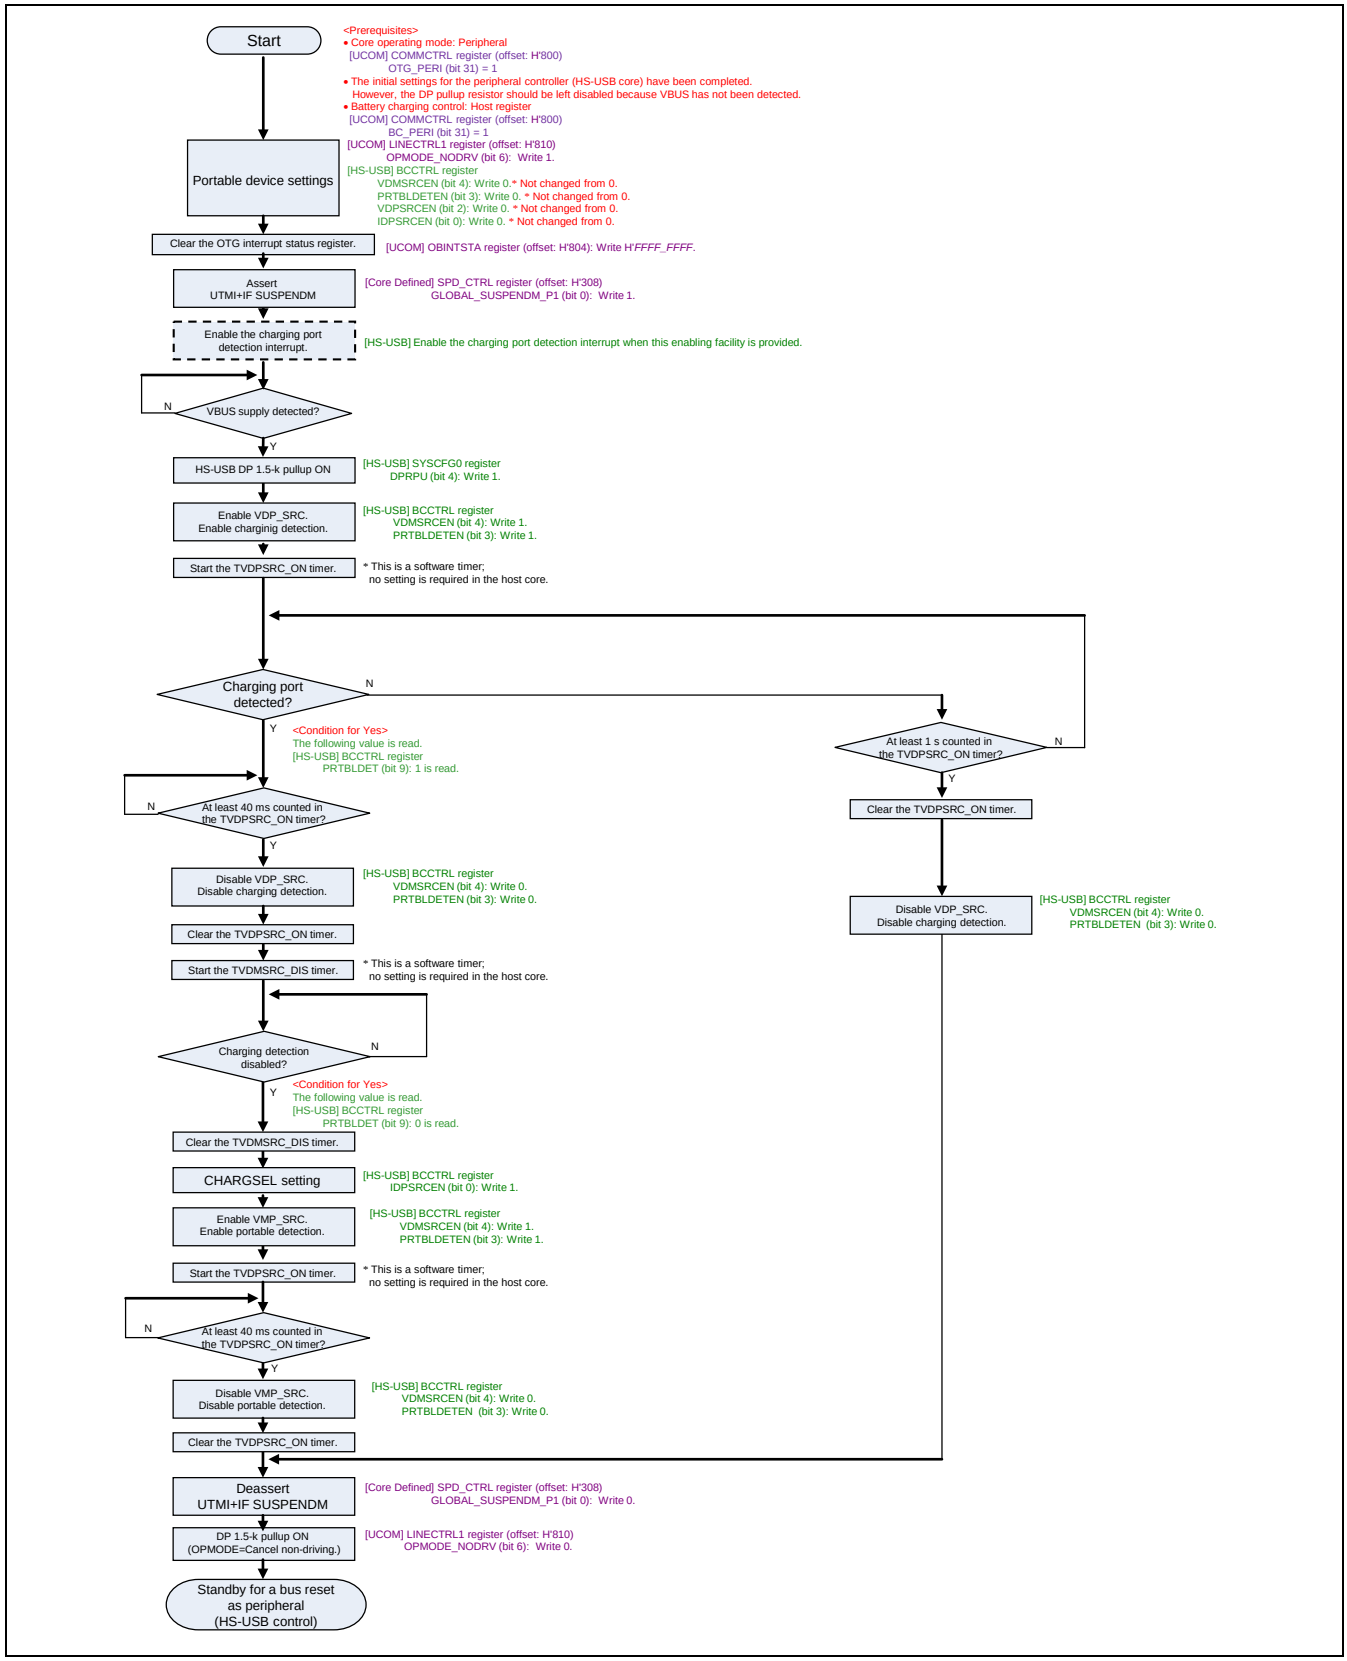

Figure 60.20 Portable Device Control through Peripheral Controller (HS-USB module)

[RZ/G2E]

Portable Device Control through UCOM Register:

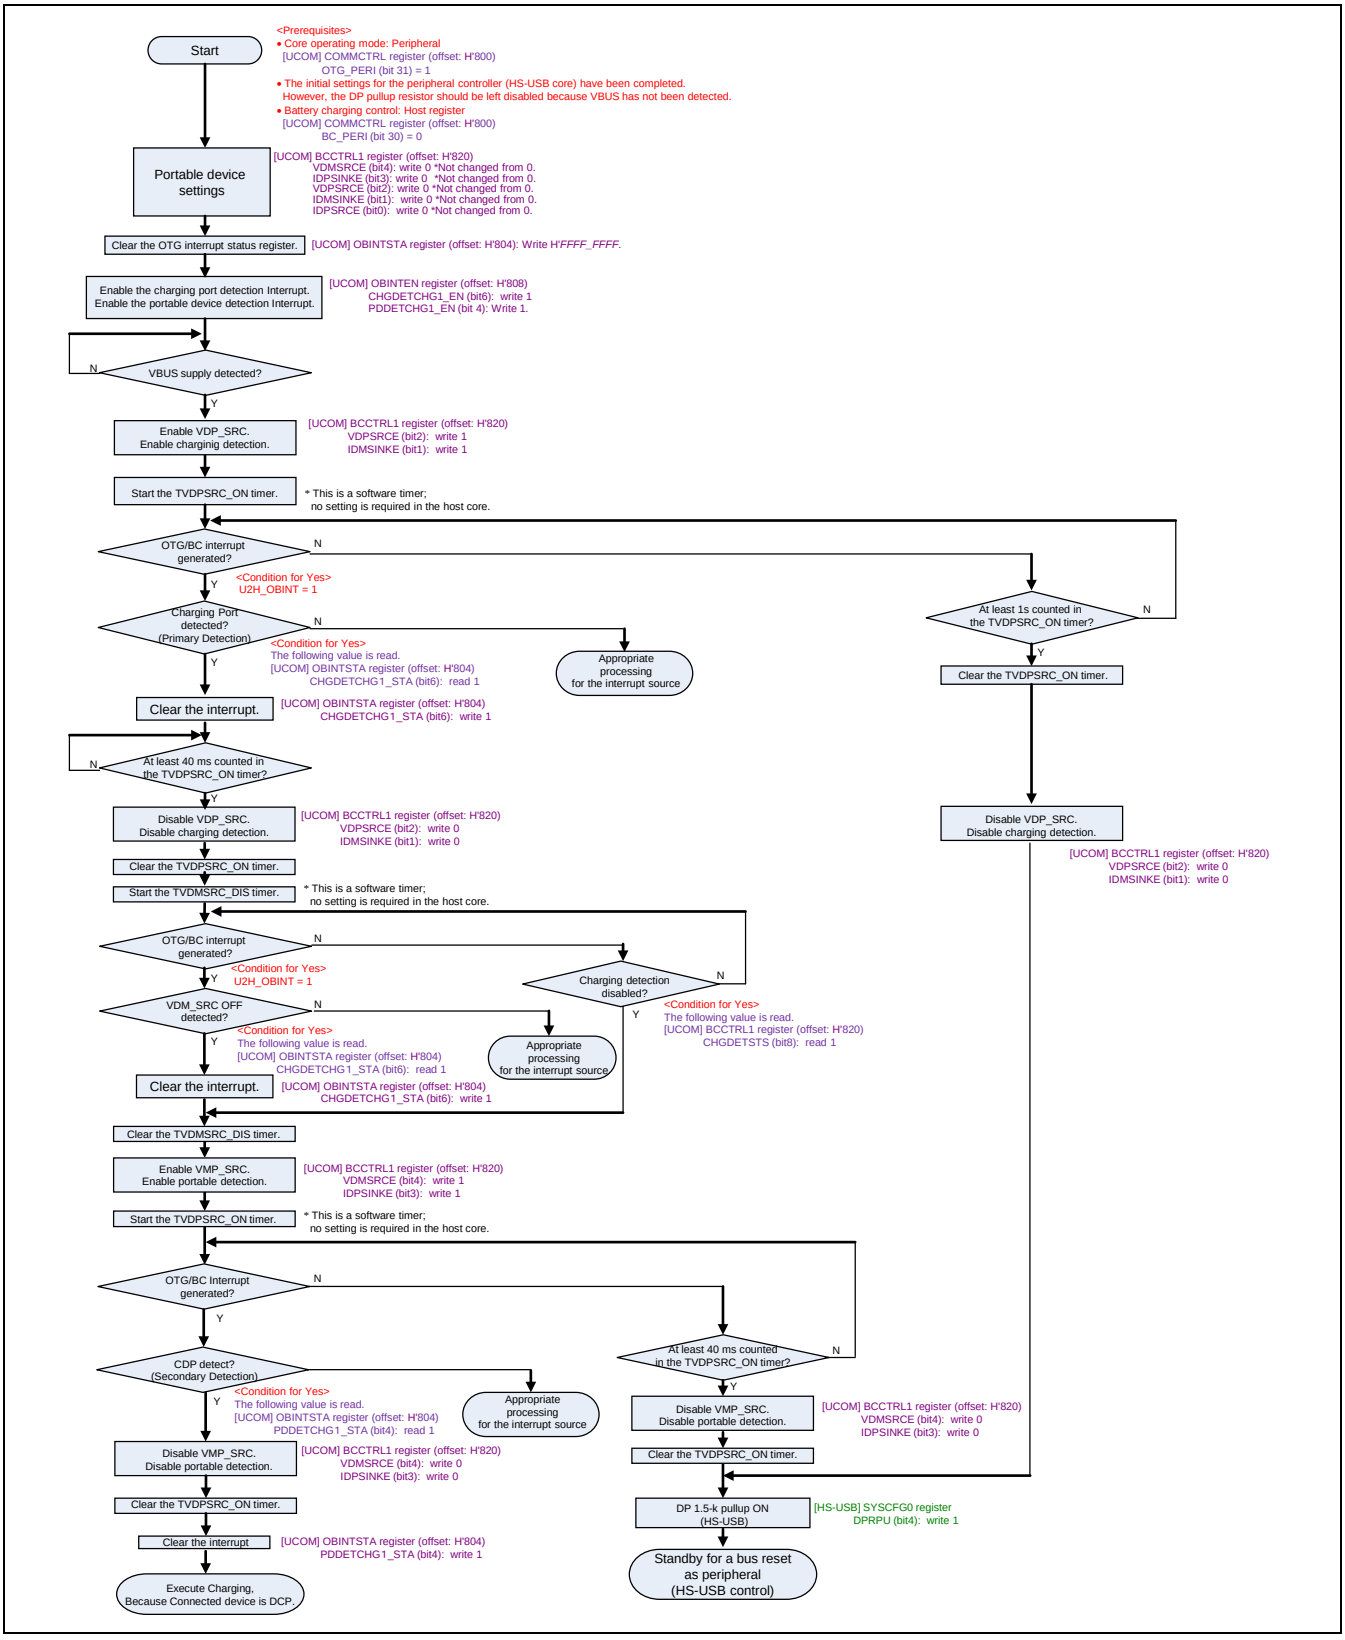

Figure 60.21 Portable Device Control through UCOM Register

Portable Device Control through Peripheral Controller (HS-USB module):

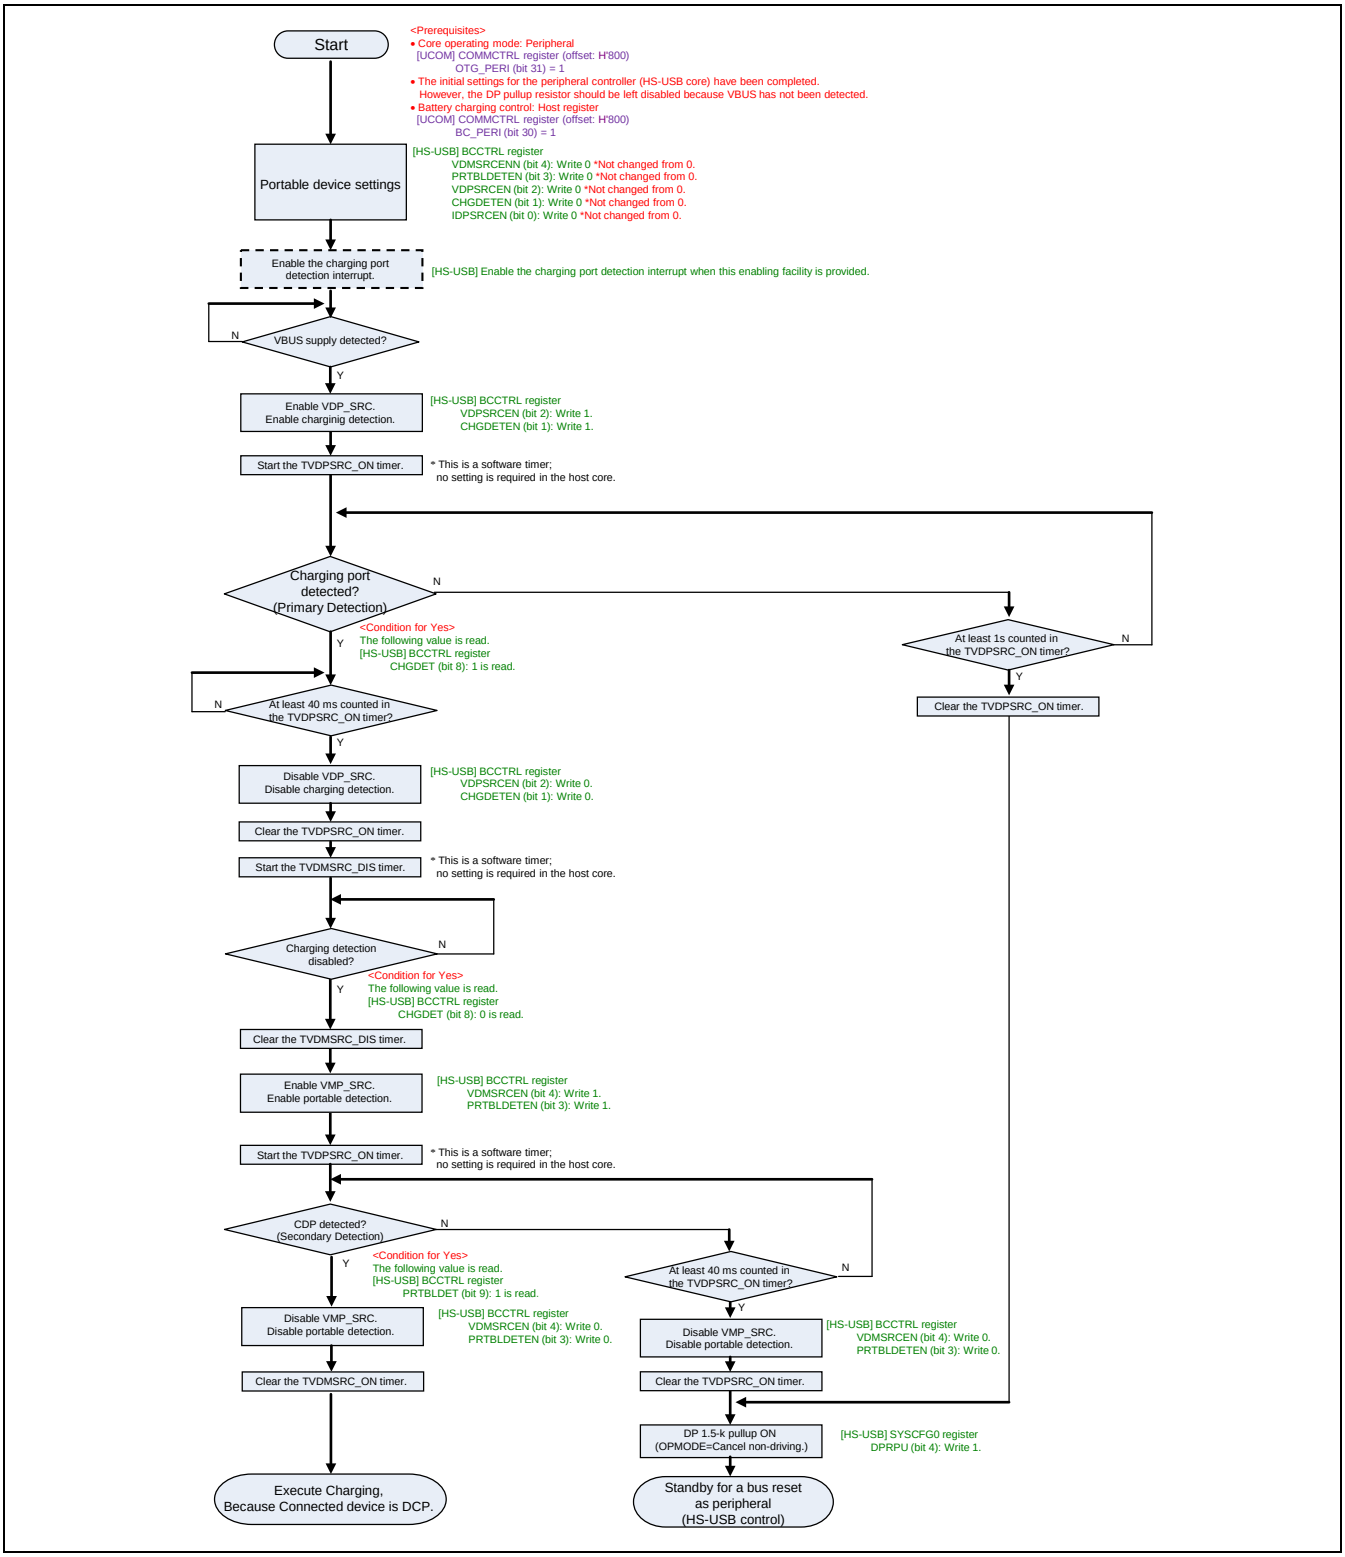

Figure 60.22 Portable Device Control through Peripheral Controller (HS-USB module)

60.9 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

This section describes register operations required for the initial settings of this module and the registers required for the power consumption control.

60.9.1 Power control and Initialization

[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N]

1. EHCI/OHCI and HS-USB module stop release and module reset assert.
2. USB0SEL[1:0] in UGCTRL2 register of HS-USB should be set to B'01 for EHCI/OHCI (Host function). In case of OTG function, it should be set to B’11.
3. Starting normal operation.

[RZ/G2E]

1. EHCI/OHCI and HS-USB module stop release and module reset assert.
2. PLLRESET release.
3. USB0SEL[1:0] in UGCTRL2 register of HS-USB should be set to B'01 for EHCI/OHCI (Host function).
4. LPSTS.SUSPM set to normal mode.
5. Check PLL Lock status by UGSTS.PLLRESET.
6. Starting normal operation after PLL Lock status enabled.
7. UGCTRL.CONNECT bit set to 1

60.9.2 Transfer Overview

Transfer by the host controller must be performed in compliance with the following OHCI and EHCI specifications.

Open Host Controller Interface Specification for USB Rev 1.0a

Enhanced Host Controller Interface Specification for Universal Serial Bus Revision 1.0

61. USB High-Speed Module (HS-USB)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

61.1 Overview

This module is a USB controller provided with the function controller function, and high-speed transfer and full-speed transfer are available. Provided with an on-chip USB transceiver, this module also supports all transfer types defined by the USB Specification.

This module can use up to twelve pipes when the function controller is selected. Furthermore, for pipes 1 to F, arbitrary endpoint numbers can be allocated according to peripheral devices to be communicated and user systems.

61.1.1 Features

(1) On-chip USB transceiver

(2) Achieves space-saving mount with less external elements

- On-chip D+ pull-up resistor (function operation mode)
- On-chip D+/D- terminating resistors (high-speed operation mode)
- On-chip D+/D- output resistors (full-speed operation mode)

(3) All Types of USB Transfers Supported

- Control transfer
- Bulk transfer
- Interrupt transfer (except for high bandwidth)
- Isochronous transfer (except for high bandwidth)

(4) Dedicated DMA interface

- On-chip 4-channel DMA interface

(5) Pipe configuration

- Up to sixteen pipes are selectable (including the default control pipe)
- Programmable pipe configuration
- Arbitrary endpoint numbers can be allocated to pipes 1 to F.
- Settable transfer conditions for each pipe are as follows:

Pipe 0:	A pipe only for control transfer with a 64-byte (fixed) single buffer
Pipes 1 and 2:	Bulk transfers/isochronous transfer, continuous transfer mode, programmable buffer size (up to 2-Kbytes: double buffer can be specified)
Pipes 3 to 5 and B to F:	Bulk transfer, continuous transfer mode, programmable buffer size (up to 2-Kbytes: double buffer can be specified)
Pipes 6 to 8:	Interrupt transfer, 64-byte fixed single buffer
Pipes 9:	Bulk transfer, programmable buffer size (up to 512-bytes: double buffer can be specified)
Pipes A:	Bulk transfer, continuous transfer mode, programmable buffer size (up to 64-bytes: double buffer can be specified)/Interrupt transfer, 64-byte fixed single buffer

(6) Other functions

- Transfer ending function using transaction count
- DMA transfer ending function using external triggers (TEND or WREND signal)
- SOF pulse output function
- BRDY interrupt event notification timing change function (BFRE)
- Function that automatically clears the buffer memory after the data for the pipe specified at the DnFIFO (n = 0 to 3) port has been read (DCLRM)
- NAK setting function (SHTNAK) for the response PID due to the transfer end
- The suspend and resume of whole LSI can be done by using USBHS.

(7) Embedded USB PHY

[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N]

The embedded USB PHY consists of the following features.

- Contains the USB functions drivers and receivers for D+ and D- signaling
- Supports battery charger detection (Battery Charging Specification revision 1.2)
- Supports On-The-Go function (On-The-Go Specification revision 2.0)

This USB subsystem support external device interface for external device control. These signals inform the vbus status, vbus valid and the OTG SRP, HNP

[RZ/G2E]

The embedded USB PHY consists of the following features.

- Contains the USB functions drivers and receivers for D+ and D- signaling
- Supports battery charger detection (Battery Charging Specification revision 1.2)

The embedded USB PHY does not support ID pin detection and VBUS detection. This function is exported to the external device (for example, MAX3355E). This product support only OVC signals for vbus detection.

This USB subsystem support external device interface for external device control. These signals inform the vbus status, vbus valid and the OTG SRP

61.1.2 External Pins

Table 61.1 lists the input and output pins of the USB.

Table 61.1 Pin Configuration of USB

				Second Generation RZ/G Series Products			
Name	**Pin Name**	**I/O**	**Description**	**RZ/G2H**	**RZ/G2M V1.3 RZ/G2M V3.0**	**RZ/G2N**	**RZ/G2E**
Clock input for USB	USB_EXTAL	I	Used as an external clock input pin(50MHz)	√	√	√	—
	USB_XTAL	O	Outputs amplified negative feedback of EXTAL (50MHz)	√	√	√	—
USB D+ data	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] DPn/USB2_CH3_DP [RZ/G2E] USB0_DP0	I/O	D+ Input/output of the on-chip transceiver Connect this pin to the D+ pin of the USB bus.	√	√	√	√
USB D- data	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] DMn/USB2_CH3_DM [RZ/G2E] USB0_DM0	I/O	D- Input/output of the on-chip transceiver Connect this pin to the D- pin of the USB bus.	√	√	√	√
USB Identification	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] IDn/USB2_CH3_ID [RZ/G2E] USB0_ID	I/O	Connect to the pin on the Micro connectors that is used to differentiate a Micro-A plug from a Micro-B plug.	√	√	√	√
USB VBUS	VBUSn	I/O	Connect to USB VBUS with external 30kΩ±1% series resistor.	√	√	√	—
USB external reference resistor	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] TXRTUNEn [RZ/G2E] USB0_RREF	I/O	[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] Connect to external 200Ω±1% resistor. [RZ/G2E] Connect to external 1.8kΩ±1% resistor.	√	√	√	√

Notes: 1. The VBUS of USB connecter must not connect directly to VBUSn pin.
2. VBUSn pin must be isolated by an external 30kΩ±1% series resistor.
3. Suffix "n" of pin names is 0 for RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N, RZ/G2E.

61.1.3 Register Configuration

Table 61.2 HS-USB Base Address

61.1.4 Connected Module

Table 61.5 The connected modules to the HS-USB

Module name	Connected module name	Function of connected module
HS-USB	AP-System Core	Access the Register
	CPG	Output Clocks
	PFC	Select External pins
	Module Standby, Software Reset	Control to stop clocks, Execute software reset
	INTC, INTC-AP	Control to interrupt
	EHCI/OHCI	USB2.0 Host (EHCI/OHCI)

61.2 Register Description

[Legend for the Register Description]

A bit assignment figure is shown for each register. The initial value and R/W attribute are indicated for each bit.

Bit:	Bit number or bit range
Bit Name:	Bit name or field name
Initial value:	Register value after a reset
—:	Undefined value
R/W:	Readable/writable. The written value can be read.
RW0C:	Readable/writable. The bit is initialized when 0 is written. Writing 1 is ignored.
RW1C:	Readable/writable. The bit is initialized when 1 is written. Writing 0 is ignored.
R:	Read-only. The write value should always be 0. (If there is a direction on a read or write value in the Description column, set the bit as directed.)

61.2.1 System Configuration Control Register (SYSCFG)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SYSCFG enables or disables high-speed operation, controls the DPn/USB_DP pin, and enables or disables the operation of this module.

Note: "n" of pin names is 0 for RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N, RZ/G2E

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	HSE	—	—	DPRPU	—	—	—	USBE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	—	B'0	R	Reserved This bit is always read as 0. Writes have no effect.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	HSE	B'0	R/W	High-Speed Operation Enable 0: High-speed operation is disabled. Full-speed operation only 1: High-speed operation is enabled. (This module detects the transmission rate.) When HSE is 0, this module performs full-speed operation. When HSE is 1, this module executes the reset handshake protocol, and according to the result, this module automatically performs high-speed or full-speed operation. Change this bit while the DPRPU bit is 0.
6, 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	DPRPU	B'0	R/W	D+ Line Resistance Control Enables or disables pull-up of the D+ line. 0: Pull-up is disabled. 1: Pull-up is enabled. When this bit is set to 1, this module pulls up the D+ line at 3.3V, and informs the USB host of ATTACH. Clearing this bit to 0 cancels the pull-up of the D+ line, and informs the USB host of DETACH. Set this bit to 1 before using this module. Set this bit to 0 when this module is not used. (when EHCI/OHCI Host function is used or USB is not used).
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	USBE	B'0	R/W	USB Module Operation Enable Enables or disables the USB module operation. 0: The USB module operation is disabled. 1: The USB module operation is enabled. Table 61.6 list the registers and bit names initialized when this bit is cleared to 0.

Table 61.6 Registers Initialized by Writing 0 in the USBE Bit

Register Name	Bit Name
SYSSTS	LNST
DVSTCTR	RHST
INTSTS0	DVSQ
USBADDR	USBADDR
USBREQ	BRequest, bmRequestType
USBVAL	wValue
USBINDX	wIndex
USBLENG	wLength

61.2.2 CPU Bus Wait Register (BUSWAIT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

BUSWAIT specifies the number of access waits from the CPU to this module.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	BWAIT[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	BWAIT[3:0]	B’1111	R/W	CPU Bus Wait Specify the number of access waits to this module. 0000: 0 waits (2 access cycles) 0001: 1 wait (3 access cycles) 0010 to 1110: 2 to 14 waits (4 to 16 access cycles) 1111: 15 waits (17 access cycles) initial value The following restriction is provided for access cycles to the registers of addresses beginning with H'04 of this controller. Restriction for wait: The cycle of continuous accesses to the registers of this controller must be 80 ns or more. To satisfy this restriction, control waits using the frequency of system clock S3D2ϕ. Choose the best value within the initial value of 17 clock cycles (maximum). This setting is the same as the waits in accesses to the FIFO port register. The maximum speed of accesses to the FIFO port is as follows: MBW = B'10 (32-bit width): Max. 48 Mbytes/s MBW = B'01 (16-bit width): Max. 24 Mbytes/s MBW = B'00 (8-bit width) : Max. 12 Mbytes/s

61.2.3 System Configuration Status Register (SYSSTS)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SYSSTS monitors the USB data bus line status (D+ and D- lines).

This register is initialized by a power-on reset or a USB reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LNST[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	LNST[1:0]	Undefined*	R	USB Data Line Status Monitor Indicate the USB data bus line (D+ and D- lines) status. Table 61.7 shows the USB data bus line status. Read these bits after the attach processing (DPRPU = 1).

Note: * These bits depend on the state of the DPn/USB_DP and DMn/USB_DM pins.
"n" of pin name is 0 for RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N, RZ/G2E

Table 61.7 USB Data Bus Line Status

LNST[1]	LNST[0]	Full-Speed Operation	High-Speed Operation	Chirp Operation
0	0	SE0	Squelch	Squelch
0	1	J-State	UnSquelch	Chirp J
1	0	K-State	Invalid	Chirp K
1	1	SE1	Invalid	Invalid

Legend:
Chirp: The reset handshake protocol (RHSP) is being executed with high-speed operation is enabled (HSE = 1 in SYSCFG).
Squelch: SE0 or idle state
UnSquelch: High-speed J-State or high-speed K-State
Chirp J: Chirp J-State
Chirp K: Chirp K-State
Invalid: Invalid

61.2.4 Device State Control Register (DVSTCTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

DVSTCTR controls and monitors the USB data bus state.

This register is initialized by a power-on reset. The WKUP bit is initialized and the RESUME bit becomes undefined by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	WKUP	—	—	—	—	—	RHST[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	WKUP	B’0	R/W	Wakeup Output Enables or disables the remote wakeup (resume signal output) to the USB bus. 0: The remote wakeup signal is not output. 1: The remote wakeup signal is output. This module controls the remote wakeup signal output time. When this bit is set to 1, this module outputs 10 ms K-State and then clears this bit. The USB Specification requires the USB bus idle state to be maintained for at least 5 ms before transmitting the remote wakeup signal. For this reason, this module outputs K-State after waiting for 2 ms even if 1 is written in this bit immediately after the suspended state is detected. Write 1 in this bit only when the device is in the suspended state (DVSQ = 1xx in INTSTS0) and remote wakeup is enabled by the USB host. When setting this bit to 1, do not stop the internal clock even in the suspended state (Write 1 in this bit with SUSPM set to 1).
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	RHST[2:0]	B’000	R	Reset Handshake Indicate the reset handshake state. B’000: Transmission rate is undefined. B’100: The reset handshake processing is in progress. B’010: Full-speed connection B’011: High-speed connection When this module detects a USB bus reset with the HSE bit set to 1 for the port, these bits become B'100. After that, when this module outputs ChirpK and detects ChirpJK from the USB host three times, these bits become B'011. Unless high-speed mode is fixed within 2.5 ms after the ChirpK output, these bits become B'010. When this module detects a USB bus reset with the HSE bit set to 0 for the port, these bits become B'010. When the RHST bits are fixed to B'010 or B'011 after this module detected a USB bus reset, the DVST interrupt occurs.

61.2.5 Test Mode Register (TESTMODE)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TESTMODE controls the USB test signal output in high-speed operation mode.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	UTST[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	UTST[3:0]	B'0000	R/W	Test Mode Table 61.8 shows the test mode operation of this module. Control the USB test signal output in high-speed operation mode. These bits are valid only in high-speed operation mode. Use this test mode when the RHST bits in DVSTCTR are B'011. After the test with these bits, cancel this test mode by a power-on reset. Set these bits according to the SetFeature request from the USB host during high-speed communication. While these bits are B'0001 to B'0100, this module does not enter the suspended state.

Table 61.8 Test Mode Operation

Test Mode	UTST Bits Setting
Normal operation	B'0000
Test_J	B'0001
Test_K	B'0010
Test_SE0_NAK	B'0011
Test_Packet	B'0100
Test_Force_Enable	—
Reserved	B'0101 to B'0111

61.2.6 CFIFO Port Register (CFIFO)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

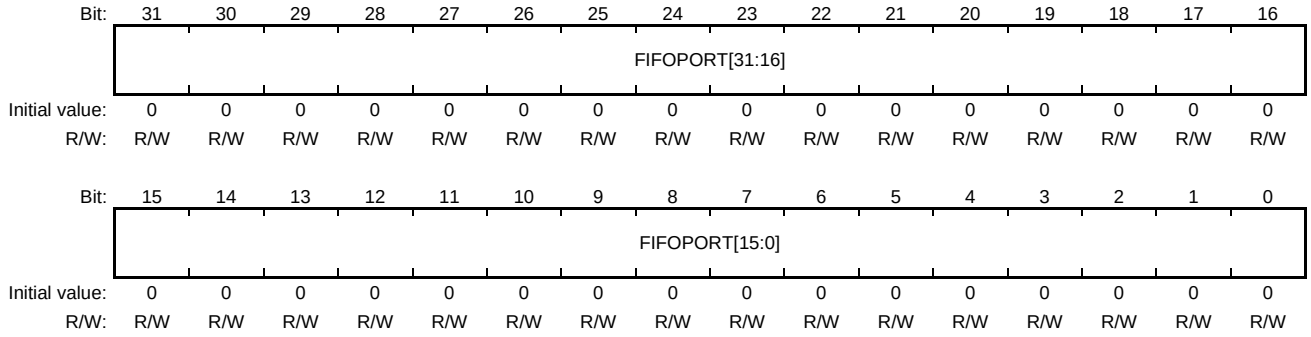
CFIFO is a port register to read data from or write data to the FIFO buffer memory.

Each FIFO port consists of this register (CFIFO) for data read/write from/to the FIFO buffer memory, the select registers (CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL) to select pipes to be allocated to a FIFO port, and the control registers (CFIFOCTR, D0FIFOCTR, D1FIFOCTR, D2FIFOCTR and D3FIFOCTR).

Each FIFO port provides the following features.

- Make accesses to the FIFO buffer for DCP through the CFIFO port.
- Make accesses to the FIFO buffer with DMA transfers through the DMAC module for USB high-speed only.
- When using a function specific to FIFO ports (DMA transfer function, etc.), the pipe number (selected pipe) specified by the CURPIPE bits cannot be changed.
- Register groups of a FIFO port do not affect other FIFO ports.
- Do not allocate the same pipe number to different FIFO ports.
- There are two FIFO buffer states where the access mastership is on the CPU side and on the SIE side. When the FIFO buffer access mastership is on the SIE side, the CPU cannot make an access to the FIFO buffer.

This register is initialized by a power-on reset.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	FIFOPORT [31:0]	H'0000_0000	R/W	FIFO Port Read receive data from the FIFO buffer or write transmit data to the FIFO buffer using these bits. Access to this register is enabled only when the FRDY bit in each control register (CFIFOCTR, D0FIFOCTR, D1FIFOCTR, D2FIFOCTR and D3FIFOCTR) is set to 1. Valid bits in this register vary with the value of the MBW bits. Table 61.9 shows the valid bits in this register.

Table 61.9 Operation of This Register when Accessed

Access Size	Bits 31 to 24	Bits 23 to 16	Bits 15 to 8	Bits 7 to 0
32 bits	N + 3 address	N + 2 address	N + 1 address	N + 0 address
16 bits	Write: Invalid, Read: Prohibited*		N + 1 address	N + 0 address
8 bits	Write: Invalid, Read: Prohibited*			N + 0 address

Note: * Reading an invalid register with word access or byte access is prohibited.

61.2.7 FIFO Port Select Registers (CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL, D3FIFOSEL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL select pipes to be allocated to FIFO ports and control accesses to each FIFO port.

Do not specify the same pipe number for the CURPIPE bits in CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL When the CURPIPE bits in D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL are set to B'000, no pipe is specified.

Do not change any pipe number when DMA transfer is enabled.

This register is initialized by a power-on reset.

(1) CFIFOSEL

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCNT	REW	—	—	MBW[1:0]		—	—	—	—	ISEL	—	CURPIPE[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	RCNT	B’0	R/W	Read Count Mode Specifies read mode of the DTLN bits in CFIFOCTR. 0: Clears the DTLN bits after reading all receive data in the CFIFO (or after reading receive data of one side of the double buffer). 1: Counts down the DTLN bits at each reading of CFIFO receive data.
14	REW	B’0	R/W*	Buffer Pointer Rewind Specifies whether to rewind the buffer pointer or not. 0: The buffer pointer is not rewound. 1: The buffer pointer is rewound. When the selected pipe is in the receive direction and this bit is set to 1 during FIFO buffer reading, the FIFO buffer can be read from the first data. (In the case of a double buffer, the first data of one side that is being read can be read again.) Do not set this bit to 1 concurrently with the CURPIPE setting change. Be sure to confirm that the FRDY bit is 1 when setting this bit to 1. To rewrite the FIFO buffer data from the first data for a pipe in the transmit direction, use the BCLR bit.
13, 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
11, 10	MBW[1:0]	B’00	R/W	CFIFO Port Access Bit Width Specify the bit width for accesses to the CFIFO port. B’00: 8 bits B’01: 16 bits B’10: 32 bits B’11: Setting prohibited When the selected pipe is in the receive direction and data read is started after these bits are set, do not change these bits until all data is completely read. When the selected pipe is in the receive direction, set the CURPIPE and MBW bits at the same time. When the selected pipe is in the transmit direction, no bit width can be changed (from 8 bits to 16/32 bits or from 16 bits to 32 bits) during data write to the buffer memory. When 8-bit width or 16-bit width is selected, data of odd bytes can also be written by controlling the byte access.
9 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	ISEL	B’0	R/W	CFIFO Port Access Direction when DCP is Selected 0: Buffer memory read is selected. 1: Buffer memory write is selected. To change this bit when the selected pipe is DCP, write 1 or 0 in this bit, read the value of this bit, confirm that the write value equals the read value, and then proceed with the next processing. If this bit is changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of this bit is rewritten, and then further access is enabled. Set this bit concurrently with the CURPIPE bits.
4	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	CURPIPE [3:0]	B’0000	R/W	CFIFO Port Access Pipe Select Set the number of pipe to be used for data read or write through the CFIFO port. B’0000: DCP B’0001: Pipe 1 B’0010: Pipe 2 B’0011: Pipe 3 B’0100: Pipe 4 B’0101: Pipe 5 B’0110: Pipe 6 B’0111: Pipe 7 B’1000: Pipe 8 B’1001: Pipe 9 B’1010: Pipe A B’1011: Pipe B B’1100: Pipe C B’1101: Pipe D B’1110: Pipe E B’1111: Pipe F To change these bits, write a value in these bits, read the value of these bits, confirm that the write value equals the read value, and then proceed with the next processing. Do not write the same pipe number in the CURPIPE bits in CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL. If these bits are changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of these bits is rewritten, and then further access is enabled.

Note: * Only reading 0 is enabled.

(2) D0FIFOSEL, D1FIFOSEL, D2FIFOSEL, D3FIFOSEL

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCNT	REW	DCLRM	DREQE	MBW[1:0]		—	—	DEZPM	—	—	—	CURPIPE[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	RCNT	B'0	R/W	Read Count Mode Specifies read mode of the DTLN bits in DnFIFOCTR. 0: Clears the DTLN bits after reading all receive data in the DnFIFO (or after reading receive data of one side of the double buffer). 1: Counts down the DTLN bits at each reading of DnFIFO receive data. When making an access to the DnFIFO with the BFRE bit set to 1, set this bit to 0.
14	REW	B'0	R/W*	Buffer Pointer Rewind Specifies whether to rewind the buffer pointer or not. 0: The buffer pointer is not rewound. 1: The buffer pointer is rewound. When the selected pipe is in the receive direction and this bit is set to 1 during FIFO buffer reading, the FIFO buffer can be read from the first data. (In the case of a double buffer, the first data of one side that is being read can be read again.) Do not set this bit to 1 concurrently with the CURPIPE setting change. Be sure to confirm that the FRDY bit is 1 when setting this bit to 1. To rewrite the FIFO buffer data from the first data for a pipe in the transmit direction, use the BCLR bit.
13	DCLRM	B'0	R/W	Buffer Memory Auto-Clear Mode after Reading Data of Selected Pipe Enables or disables buffer memory auto-clear mode after reading data of the selected pipe. 0: Buffer memory auto-clear mode is disabled. 1: Buffer memory auto-clear mode is enabled. When this bit is 1 and a Zero-Length packet is received while the FIFO buffer allocated to the selected pipe is empty or when a short packet is received with the BFRE bit set to 1 and the packet data is completely read, this module performs buffer clear (BCLR = 1 processing) of the FIFO buffer. When using this module with the BRDYM bit set to 1, be sure to set this bit to 0.
12	DREQE	B'0	R/W	DMA Transfer Request Enable Enables or disables making a DMA transfer request. 0: DMA transfer request is disabled. 1: DMA transfer request is enabled. To enable a DMA transfer request, set the CURPIPE bits and then set this bit to 1. Set this bit to 0 before changing the CURPIPE setting.

Bit	Bit Name	Initial Value	R/W	Description
11, 10	MBW[1:0]	B'00	R/W	FIFO Port Access Bit Width Specify the bit width for accesses to the DnFIFO port. B'00: 8 bits B'01: 16 bits B'10: 32 bits B'11: Setting prohibited When the selected pipe is in the receive direction and data read is started after these bits are set, do not change these bits until all data is completely read. When the selected pipe is in the receive direction, set the CURPIPE and MBW bits at the same time. When the selected pipe is in the transmit direction, no bit width can be changed (from 8 bits to 16/32 bits or from 16 bits to 32 bits) during data write to the buffer memory. When 8-bit width or 16-bit width is selected, data of odd bytes can also be written by controlling the byte access.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	DEZPM	B'0	R/W	DEZPM: Zero-Length Packet Addition Mode If the DMA transfer size that is set for the USB-DMAC modules is an integral multiple of the maximum packet size, a null packet is added after all of the data has been sent. 0: Disables addition of packets. 1: Enables addition of packets. This bit is applied to pipes used to write to the FIFO buffer. DEZPM must be set before starting DMA transfers. If the DEZPM bit is set after DMA transfers complete, no null packets are added. Note: This mode depends on the buffer size (PIPEBUF.BUFSIZE[4:0]). A null packet is added after transferring data up to buffer size which is defined by PIPEBUF.BUFSIZE[4:0]. When transfer data size is over 2Kbytes, this mode must not be used because max size of buffer is 2Kbytes. In that case, add the null packet by SW with BVAL bit of FIFO Port Control Registers.
6 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	CURPIPE [3:0]	B'0000	R/W	FIFO Port Access Pipe Select Set the number of pipe to be used for data read or write through the DnFIFO ports. B'0000: No pipe B'0001: Pipe 1 B'0010: Pipe 2 B'0011: Pipe 3 B'0100: Pipe 4 B'0101: Pipe 5 B'0110: Pipe 6 B'0111: Pipe 7 B'1000: Pipe 8 B'1001: Pipe 9 B'1010: Pipe A B'1011: Pipe B B'1100: Pipe C B'1101: Pipe D B'1110: Pipe E B'1111: Pipe F To change these bits, write a value in these bits, read the value of these bits, confirm that the write value equals the read value, and then proceed with the next processing. Do not write the same pipe number in the CURPIPE bits in CFIFOSEL, DnFIFOSEL (n = 0 to 3). If these bits are changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of these bits is rewritten, and then further access is enabled.

Note: * Only reading 0 is enabled.

61.2.8 FIFO Port Control Registers (CFIFOCTR, D0FIFOCTR, D1FIFOCTR, D2FIFOCTR, D3FIFOCTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CFIFOCTR and D0FIFOCTR, D1FIFOCTR, D2FIFOCTR and D3FIFOCTR specify buffer memory write end and CPU buffer clear, as well as indicate whether the FIFO port is accessible or not. These registers correspond to each FIFO port.

These registers are initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BVAL	BCLR	FRDY	—	DTLN[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	BVAL	B'0	R/W*1	Buffer Memory Enable Flag This flag is set to 1 upon completion of data write in the FIFO buffer of the CPU of the pipe selected by the CURPIPE bits. 0: Invalid 1: Write end When the selected pipe is in the transmit direction, set this bit to 1 in the following cases. This module sets the FIFO buffer of the CPU to the SIE side to enable data transmission. To send a short packet, set this bit to 1 upon completion of data write. To send a Zero-Length packet, set this bit to 1 before writing data to the FIFO buffer. For pipes of continuous transfer mode, set this bit to 1 after writing data that is a positive integer multiple of MaxPacketSize and less than the BufferSize value. When data with the size specified by MaxPacketSize is written to a pipe of continuous transfer mode, this module writes 1 in this bit and sets the FIFO buffer of the CPU to the SIE side to enable data transmission. Set this bit to 1 when this module shows FRDY = 1. When the selected pipe is in the receive direction, do not set this bit to 1.
14	BCLR	B'0	R/W*2	CPU buffer clear Clears the CPU side FIFO buffer of the selected pipe. 0: Invalid 1: Clears the CPU side FIFO buffer. When the FIFO buffer assigned to the selected pipe is set to a double buffer, and even when both sides of the buffer are readable, this module clears only one side of the FIFO buffer. When the selected pipe is DCP, this module clears the FIFO buffer when this bit is set to 1 irrespective of whether the FIFO buffer is on the CPU side or SIE side. When clearing the SIE side FIFO buffer, be sure to set the PID bits in DCP to NAK and then set the BCLR bit to 1. When the selected pipe is in the transmit direction, and if 1 is written in the BVAL and BCLR bits at the same time, this module clears the previously written data, and makes a Zero-Length packet transmittable. When the selected pipe is not DCP, write 1 in this bit while the FRDY flag indicates 1.

Bit	Bit Name	Initial Value	R/W	Description
13	FRDY	B'0	R	FIFO Port Ready Indicates whether the CPU (DMAC) can access the FIFO port. 0: The FIFO port is not accessible. 1: The FIFO port is accessible. This module indicates FRDY = 1 in the following cases. However, since there is no data to read, no data can be read from the FIFO port. In these cases, set the BCLR bit to 1 to clear the FIFO buffer to make transmission/reception of the next data available. When a Zero-Length packet is received with the FIFO buffer assigned to the selected pipe empty When a short packet is received with BFRE set to 1 and the packet data is completely read
12	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
11 to 0	DTLN[11:0]	H'000	R	Receive Data Length Indicate the receive data length. The value of these bits during FIFO buffer reading varies as follows depending on the setting of the RCNT bit. When RCNT = 0: This module indicates the receive data length with these bits until the CPU (DMAC) finishes reading one side of the FIFO buffer. When BFRE is 1, this module retains the receive data length until the BCLR bit is set to 1 after the FIFO buffer read is completed. When RCNT = 1: This module decrements the value of the DTLN bits in each read cycle (-1 when MBW = 0, and -2 when MBW = 1) When reading out from a single FIFO buffer is complete, DTLN = 0 for this module. However, the behavior is different when double-buffering has been specified. If reading out of data from one side is not finished before the other side is full of received data, when all data have been read out from the first side, the DTLN bits reflect the amount of data received in the other side. When reading these bits during FIFO buffer reading while the RCNT bit is 1, note that this module updates the value in these bits within 150 ns after each FIFO port read cycle.

Notes: 1. Only writing 1 is enabled.
2. Only reading 0 and writing 1 are enabled.

61.2.9 Interrupt Enable Register 0 (INTENB0)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

INTENB0 specifies masking of each interrupt when selection for function controller. When this module detects an interrupt for which 1 is written in the corresponding bit in this register by the software, this module generates a USB interrupt.

When interrupt source detection conditions are satisfied irrespective of the register setting (interrupt enable/disable), this module sets the corresponding status bit in INTSTS0.

When the software changes an interrupt enable bit (0 to 1) whose interrupt source status bit in INTSTS0 is set to 1, this module generates a USB interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

8	BRDYE	B'0	R/W	Buffer Ready Interrupt Enable Enables or disables USB interrupt outputs when the BRDY interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

61.2.10 BRDY Interrupt Enable Register (BRDYENB)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

BRDYENB enables or disables the BRDY bit to be set to 1 when the BRDY interrupt of a pipe is detected.

When this module detects the BRDY interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPEBRDY bit of the pipe in BRDYSTS and also sets the BRDY bit in INTSTS0 and generates the BRDY interrupt.

When one or more PIPEBRDY bits in BRDYSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates the BRDY interrupt.

This register is initialized by a power-on reset.

61.2.11 NRDY Interrupt Enable Register (NRDYENB)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

NRDYENB enables or disables the NRDY bit to be set to 1 when the NRDY interrupt of a pipe is detected.

When this module detects the NRDY interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPENRDY bit of the pipe in NRDYSTS and also sets the NRDY bit in INTSTS0and generates an NRDY interrupt.

When one or more PIPENRDY bits in NRDYSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates an NRDY interrupt.

This register is initialized by a power-on reset.

61.2.12 BEMP Interrupt Enable Register (BEMPENB)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

BEMPENB enables or disables the BEMP bit to be set to 1 when the BEMP interrupt of a pipe is detected.

When this module detects the BEMP interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPEBEMP bit of the pipe in BEMPSTS and the BEMP bit in INTSTS0 and generates the BEMP interrupt.

When one or more PIPEBEMP bits in BEMPSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates the BEMP interrupt.

This register is initialized by a power-on reset.

0	PIPE0 BEMPE	B'0	R/W	Pipe 0 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

61.2.13 SOF Output Configuration Register (SOFCFG)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SOFCFG specifies an effective period of transactions, the BRDY interrupt status clear timing, and others.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	BRDYM	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	BRDYM	B'0	R/W	Status Clear Timing of Each Pipe BRDY Interrupt Specifies the timing to clear the BRDY interrupt status of each pipe. 0: The software clears the status. 1: This module clears the status by reading or writing the FIFO buffer.
5 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

61.2.14 Interrupt Status Register 0 (INTSTS0)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

INTSTS0 can know the interrupt generation by referring to the register when the function controller is selected.

Permit interrupt by the status change that each bit of this register shows only when you select the function.

This register is initialized by a power-on reset. The DVSQ2 to DVSQ0 bits are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VBINT	RESM	SOFR	DVST	CTRT	BEMP	NRDY	BRDY	VBSTS	DVSQ[2:0]			VALID	CTSQ[2:0]		
Initial value:	0	0	0	0/1	0	0	0	0	0/1	0	0	0/1	0	0	0	0
R/W:	RW0C	RW0C	RW0C	RW0C	RW0C	R	R	R	R	R	R	R	RW0C	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	VBINT	B'0	RW0C	VBUSn [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] / OVC signal status [RZ/G2E] Interrupt Status*4*5 0: No VBUS interrupt is generated. 1: A VBUS interrupt is generated. This bit indicates 1 when this module detects a change in the VBUSn [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] /OVC signal status [RZ/G2E] pin input level (high to low or low to high level). This module indicates the VBUSn [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] /OVC signal status [RZ/G2E] pin input value using the VBSTS bit. When a VBINT interrupt occurs, read the VBSTS bit several times by the software and confirm that the read value is equal each time to eliminate chattering.
14	RESM	B'0	RW0C	Resume Interrupt Status*4*5 0: No resume interrupt is generated. 1: A resume interrupt is generated. This bit indicates 1 when this module detects a falling of the DP_0 pin level in the suspended state (DVSQ = 1XX).
13	SOFR	B'0	RW0C	Frame Number Update Interrupt Status*4 0: No SOF interrupt is generated. 1: An SOF interrupt is generated. This module indicates SOFR = 1 at the frame number update timing. (This interrupt is detected every millisecond.) Even when an SOF packet from the USB host is corrupted, this module detects an SOFR interrupt using the internal interpolation.
12	DVST	B'0/B'1 *1	RW0C	Device State Transition Interrupt Status*4 0: No device state transition interrupt is generated. 1: A device state transition interrupt is generated. When this module detects a change in device state, this module updates the DVSQ value and set this bit to 1. When this interrupt occurred, clear the status before this module detects the next device state transition.

Bit	Bit Name	Initial Value	R/W	Description
11	CTRT	B'0	RW0C	Control Transfer Stage Transition Interrupt Status*4 0: No control transfer stage transition interrupt is generated. 1: A control transfer stage transition interrupt is generated. When this module detects a control transfer stage transition, this module updates the CTSQ value and set this bit to 1. When this interrupt occurred, clear the status before this module detects the next stage transition in control transfers.
10	BEMP	B'0	R	Buffer Empty Interrupt Status 0: No BEMP interrupt is generated. 1: A BEMP interrupt is generated. This module indicates BEMP = 1 when at least one of the PIPEBEMP bits in BEMPSTS corresponding to the pipes for which 1 is set in the PIPEBEMPE bits in BEMPENB is set to 1 (when this module detects a BEMP interrupt of one or more pipes for which BEMP interrupts are enabled by the software). For PIPEBEMP status assertion conditions, see section 61.3.2 (3), BEMP Interrupt. When the software writes 0 to all PIPEBEMP bits corresponding to the pipes for which interrupts are enabled by the PIPEBEMPE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.
9	NRDY	B'0	R	Buffer Not Ready Interrupt Status 0: No NRDY interrupt is generated. 1: An NRDY interrupt is generated. This module indicates NRDY = 1 when at least one of the PIPENRDY bits in NRDYSTS corresponding to the pipes for which 1 is set in the PIPENRDYE bits in NRDYENB is set to 1 (when this module detects an NRDY interrupt of one or more pipes for which NRDY interrupts are enabled by the software). For PIPENRDY status assertion conditions, see section 61.3.2 (2), NRDY Interrupt. When the software writes 0 to all PIPENRDY bits corresponding to the pipes for which interrupts are enabled by the PIPENRDYE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.
8	BRDY	B'0	R	Buffer Ready Interrupt Status Indicates the BRDY interrupt status. 0: No BRDY interrupt is generated. 1: A BRDY interrupt is generated. This module indicates BRDY = 1 when at least one of the PIPEBRDY bits in BRDYSTS corresponding to the pipes for which 1 is set in the PIPEBRDYE bits in BRDYENB is set to 1 (when this module detects a BRDY interrupt of one or more pipes for which BRDY interrupts are enabled by the software). For PIPEBRDY status assertion conditions, see section 61.3.2 (1), BRDY Interrupt. When the software writes 0 to all PIPEBRDY bits corresponding to the pipes for which interrupts are enabled by the PIPEBRDYE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.

Bit	Bit Name	Initial Value	R/W	Description
7	VBSTS	B’0/B’1 *3	R	VBUS Input Status 0: The VBUS pin is low level. 1: The VBUS pin is high level. [RZ/G2E] This value is 1, when USB0_OVC function is not selected by PFC.
6 to 4	DVSQ[2:0]	B’000/B’001*2	R	Device State B’000: Powered state B’001: Default state B’010: Address state B’011: Configuration state B’1xx: Suspended state
3	VALID	B’0	RW0C	USB Request Receive 0: Not detected 1: A setup packet is received.
2 to 0	CTSQ[2:0]	B’000	R	Control Transfer Stage B’000: Idle stage or setup stage B’001: Control read data stage B’010: Control read status stage B’011: Control write data stage B’100: Control write status stage B’101: Control write (NoData) status stage B’110: Control transfer sequence error B’111: Setting prohibited

Notes:
1. The initial value is B'0 after a power-on reset, and B'1 after a USB bus reset.
2. The initial value is B'000 after a power-on reset, and B'001 after a USB bus reset.
3. The initial value is 1 when the VBUS pin is high level, and is 0 when the VBUS pin is low level.
4. To clear the VBINT, RESM, SOFR, DVST, or CTRT bit, write 0 only to bits to be cleared and write 1 to the other bits. Do not write 0 to status bits that indicate 0.
5. When a status change shown in the VBINT or RESM bit is detected while the clock is halted (SUSPM = 0) and the corresponding interrupt is enabled, the interrupt is output. Clear the interrupt status of these bits by the software after the clock is enabled.

61.2.15 BRDY Interrupt Status Register (BRDYSTS)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

BRDYSTS indicates the BRDY interrupt status of each pipe.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPEF BRDY	PIPEE BRDY	PIPED BRDY	PIPEC BRDY	PIPEB BRDY	PIPEA BRDY	PIPE9 BRDY	PIPE8 BRDY	PIPE7 BRDY	PIPE6 BRDY	PIPE5 BRDY	PIPE4 BRDY	PIPE3 BRDY	PIPE2 BRDY	PIPE1 BRDY	PIPE0 BRDY
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEFBRDY	B'0	R/W*1	Pipe F BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
14	PIPEEBRDY	B'0	R/W*1	Pipe E BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
13	PIPEDBRDY	B'0	R/W*1	Pipe D BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
12	PIPECBRDY	B'0	R/W*1	Pipe C BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
11	PIPEBBRDY	B'0	R/W*1	Pipe B BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
10	PIPEABRDY	B'0	R/W*1	Pipe A BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
9	PIPE9BRDY	B'0	R/W*1	Pipe 9 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
8	PIPE8BRDY	B'0	R/W*1	Pipe 8 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7BRDY	B'0	R/W*1	Pipe 7 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6BRDY	B'0	R/W*1	Pipe 6 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5BRDY	B'0	R/W*1	Pipe 5 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
4	PIPE4BRDY	B'0	R/W*1	Pipe 4 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
3	PIPE3BRDY	B'0	R/W*1	Pipe 3 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2BRDY	B'0	R/W*1	Pipe 2 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1BRDY	B'0	R/W*1	Pipe 1 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0BRDY	B'0	R/W*1	Pipe 0 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.

Notes: 1. To clear the status of each bit in this register when BRDYM is 0, write 0 only to bits to be cleared and write 1 to the other bits.
2. When BRDYM is 0, be sure to clear this interrupt before making an access to the FIFO.

61.2.16 NRDY Interrupt Status Register (NRDYSTS)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

NRDYSTS indicates the NRDY interrupt status of each pipe.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPEF NRDY	PIPEE NRDY	PIPED NRDY	PIPEC NRDY	PIPEB NRDY	PIPEA NRDY	PIPE9 NRDY	PIPE8 NRDY	PIPE7 NRDY	PIPE6 NRDY	PIPE5 NRDY	PIPE4 NRDY	PIPE3 NRDY	PIPE2 NRDY	PIPE1 NRDY	PIPE0 NRDY
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEFNRDY	B'0	R/W*	Pipe F NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
14	PIPEENRDY	B'0	R/W*	Pipe E NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
13	PIPEDNRDY	B'0	R/W*	Pipe D NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
12	PIPECNRDY	B'0	R/W*	Pipe C NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
11	PIPEBNRDY	B'0	R/W*	Pipe B NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
10	PIPEANRDY	B'0	R/W*	Pipe A NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
9	PIPE9NRDY	B'0	R/W*	Pipe 9 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
8	PIPE8NRDY	B'0	R/W*	Pipe 8 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7NRDY	B'0	R/W*	Pipe 7 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6NRDY	B'0	R/W*	Pipe 6 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5NRDY	B'0	R/W*	Pipe 5 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
4	PIPE4NRDY	B'0	R/W*	Pipe 4 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
3	PIPE3NRDY	B'0	R/W*	Pipe 3 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2NRDY	B'0	R/W*	Pipe 2 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1NRDY	B'0	R/W*	Pipe 1 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0NRDY	B'0	R/W*	Pipe 0 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Note: * To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

61.2.17 BEMP Interrupt Status Register (BEMPSTS)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

BEMPSTS indicates the BEMP interrupt status of each pipe.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPEF BEMP	PIPEE BEMP	PIPED BEMP	PIPEC BEMP	PIPEB BEMP	PIPEA BEMP	PIPE9 BEMP	PIPE8 BEMP	PIPE7 BEMP	PIPE6 BEMP	PIPE5 BEMP	PIPE4 BEMP	PIPE3 BEMP	PIPE2 BEMP	PIPE1 BEMP	PIPE0 BEMP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEFBEMP	B'0	R/W*	Pipe F BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
14	PIPEEBEMP	B'0	R/W*	Pipe E BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
13	PIPEDBEMP	B'0	R/W*	Pipe D BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
12	PIPECBEMP	B'0	R/W*	Pipe C BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
11	PIPEBBEMP	B'0	R/W*	Pipe B BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
10	PIPEABEMP	B'0	R/W*	Pipe A BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
9	PIPE9BEMP	B'0	R/W*	Pipe 9 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
8	PIPE8BEMP	B'0	R/W*	Pipe 8 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7BEMP	B'0	R/W*	Pipe 7 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6BEMP	B'0	R/W*	Pipe 6 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5BEMP	B'0	R/W*	Pipe 5 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
4	PIPE4BEMP	B'0	R/W*	Pipe 4 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
3	PIPE3BEMP	B'0	R/W*	Pipe 3 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2BEMP	B'0	R/W*	Pipe 2 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1BEMP	B'0	R/W*	Pipe 1 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0BEMP	B'0	R/W*	Pipe 0 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Note: * To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

61.2.18 Frame Number Register (FRMNUM)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

FRMNUM indicates the sources of isochronous errors and a frame number.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OVRN	CRCE	—	—	—	FRNM[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	RW0C	RW0C	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	OVRN	B'0	RW0C	Overrun/Underrun Detect Status Indicates whether an overrun or underrun error is detected or not in a pipe that is performing isochronous transfer. 0: No error is detected. 1: An error is detected. Writing 0 to this bit by the software clears this bit to 0. At this time, write 1 to the other bits in this register. This module indicates OVRN =1 in any of the following cases. When the IN token is received when transmit data write to the FIFO buffer is not completed in a transmit direction pipe of isochronous transfer type When the OUT token is received with no side of the FIFO buffer empty in a receive direction pipe of isochronous transfer type
14	CRCE	B'0	RW0C	Receive Data Error Indicates whether a CRC error or bit stuffing error is detected or not in a pipe that is performing isochronous transfer. 0: No error is detected. 1: An error is detected. Writing 0 to this bit by the software clears this bit to 0. At this time, write 1 to the other bits in this register. When a CRC error is detected, this module does not generate an internal NRDY interrupt request.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	FRNM [10:0]	H'000	R	Frame Number This module modifies this bit when an SOF is received and indicates the latest frame number. Read these bits twice and confirm that the read value is equal each time.

61.2.19 µ Frame Number Register (UFRMNUM)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

UFRMNUM indicates a µ frame number.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	UFRNM[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	UFRNM[2:0]	B'000	R	µ Frame Indicate a µ frame number. In high-speed operating mode, these bits indicate a µ frame number. In other operating modes, these bits indicate B'000. Read these bits twice and confirm that the read value is equal each time.

61.2.20 USB Address Register (USBADDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

USBADDR indicates a USB address.

This register is initialized by a power-on reset or USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	USBADDR[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	USBADDR[6:0]	H'00	R	USB Address Indicate the USB address allocated by the host when the SET_ADRESS request is successfully processed. When this module detects a USB reset, these bits indicate H'00.

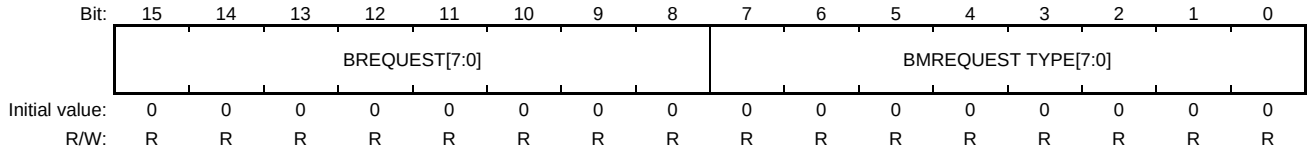
61.2.21 USB Request Type Register (USBREQ)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

USBREQ stores the setup request for control transfers.

USBREQ stores the values of received bRequest and bmRequestType.

This register is initialized by a power-on reset or USB bus reset.



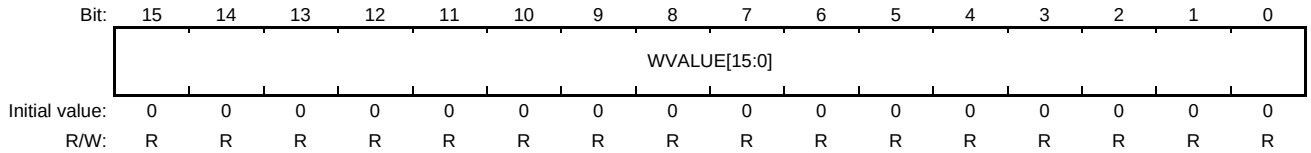
Bit	Bit Name	Initial Value	R/W	Description
15 to 8	BREQUEST [7:0]	H'00	R	Request Store the value of USB request bRequest. Indicate the USB request data received in the SETUP transaction. These bits cannot be modified.
7 to 0	BMREQUEST TYPE[7:0]	H'00	R	Request Type Store the value of USB request bmRequestType. Indicate the USB request data received in the SETUP transaction. These bits cannot be modified.

61.2.22 USB Request Value Register (USBVAL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

USBVAL stores the value of received wValue.

This register is initialized by a power-on reset or USB bus reset.



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WVALUE [15:0]	H'0000	R	Value Store the value of USB request wValue. Indicate the value of USB request wValue received in the SETUP transaction. These bits cannot be modified.

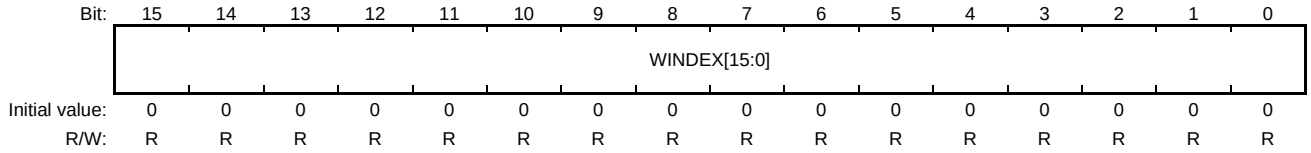
61.2.23 USB Request Index Register (USBINDX)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

USBINDX stores the setup request for control transfers.

USBINDX stores the value of received wIndex.

This register is initialized by a power-on reset or USB bus reset.



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WINDEX [15:0]	H'0000	R	Index Store the value of USB request wIndex. Indicate the value of USB request wIndex received in the SETUP transaction. These bits cannot be modified.

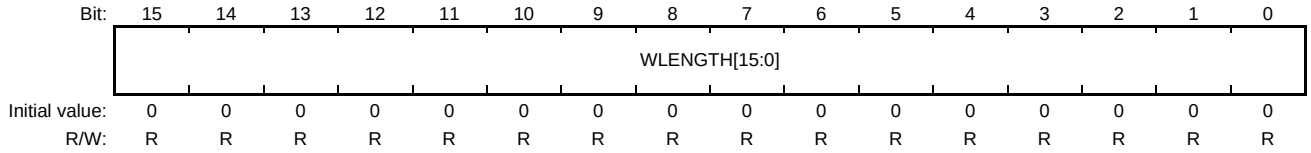
61.2.24 USB Request Length Register (USBLENG)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

USBLENG stores the setup request of control transfers.

USBLENG stores the value of received wLength.

This register is initialized by a power-on reset or USB bus reset.



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WLENGTH [15:0]	H'0000	R	Length Store the value of USB request wLength. Indicate the value of USB request wLength received in the SETUP transaction. These bits cannot be modified.

61.2.25 DCP Maximum Packet Size Register (DCPMAXP)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

DCPMAXP specifies the maximum packet size of the DCP.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	MXPS[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	MXPS [6:0]	H'40	R/W	Maximum Packet Size Set the payload of DCP data (maximum DCP packet size) in these bits. The initial value of these bits is H'40 (64 bytes). Set a value in the MXPS bits based on the USB Specification. Set the MXPS bits when PID = NAK, and the CURPIPE bits are not set. When setting these bits to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Do not write the FIFO buffer when the MXPS bits are 0 or set the PID bits to BUF.

61.2.26 DCP Control Register (DCPCTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

DCPCTR is used to monitor the buffer memory status, change/check the data PID sequence bit, and set the response PID for a DCP.

This register is initialized by a power-on reset. The PID2 to PID0 bits in CCPL are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSTS	—	—	—	—	—	—	SQCLR	SQSET	SQMON	PBUSY	—	—	CCPL	PID[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	B'0	R	Buffer Status Indicates whether the DCP FIFO buffer is accessible or not. 0: The buffer is not accessible. 1: The buffer is accessible. This bit indicates as follows depending on the ISEL value. When ISEL = 0, this bit indicates whether the buffer is ready to read receive data. When ISEL = 1, this bit indicates whether the buffer is ready to write transmit data.
14 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	SQCLR	B'0	R/W*	Toggle Bit Clear The expected value of the sequence toggle bit for the next transaction in DCP transfer can be set in DATA0. 0: Invalid 1: The expected value is set in DATA0. This bit always indicates 0. Do not set the SQCLR and SQSET bits to 1 at the same time. Set this bit to 1 when PID = NAK, and the CURPIPE bits are not set. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
7	SQSET	B'0	R/W*	Toggle Bit Set The expected value of the sequence toggle bit for the next transaction in DCP transfer can be set in DATA1. 0: Invalid 1: The expected value is set in DATA1. Do not set the SQCLR and SQSET bits to 1 at the same time. Set this bit to 1 when PID = NAK, and the CURPIPE bits are not set. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
6	SQMON	B'1	R	Sequence Toggle Bit Monitor Indicates the expected value of the sequence toggle bit for the next transaction in DCP transfer. 0: DATA0 1: DATA1 When the transaction is successfully completed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled. This module sets this bit to 1 (sets the expected value in DATA1) when the setup packet is successfully received. This module does not read this bit in IN transactions or OUT transactions in the status stage.
5	PBUSY	B'0	R	Pipe Busy Indicates whether the DCP communication state is shifted to the NAK state or not when the DCP changed the PID bits from BUF to NAK. 0: Transition to the NAC state is not completed. 1: Transition to the NAC state is completed. When this module starts the USB transaction for the corresponding pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to check whether changing the pipe setting is enabled or not.
4, 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	CCPL	B'0	R/W*	Control Transfer End Enable 0: Invalid 1: The control transfer end is enabled. When the software sets this bit to 1 while the corresponding PID bits are set to BUF, this module finishes the control transfer stage. That is, this module sends an ACK handshake in response to OUT transactions from the USB host in the control read transfer, and sends a Zero-Length packet in response to IN transactions from the USB host in control write and no-data control transfers. However, a SET_ADDRESS request is detected, this module automatically sends responses from the SETUP stage until the end of the status stage irrespective of the setting of this bit. When this module receives the next setup packet, this module clears this bit to 0. When VALID = 1, the software cannot write 1 to this bit.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	B’00	R/W	Response PID Control responses of this module in control transfers. B’00: NAK response B’01: BUF response (depending on buffer state) B’10: STALL response B’11: STALL response This module modifies these bits in the following cases. This module changes these bits to NAK upon receiving a SETUP packet. At this time, this module indicates VALID = 1. The software cannot modify these bits until the software sets VALID = 0. When this module receives data with a size exceeding the MaxPacketSize value while these bits are set to BUF by the software, this module indicates PID = STALL (11). When this module detects a control transfer sequence error, this module indicates PID = STALL (1x). When this module detects a USB bus reset, this module indicates PID = NAK. This module does not read the value of these bits during the SET_ADDRESS request processing (auto processing).

Note: * These bits are always read as 0. Only writing 1 is enabled.

61.2.27 Pipe Window Select Register (PIPESEL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Make settings for pipes 1 to F using PIPESEL, PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN.

Specify a pipe to be used with PIPESEL, and then make function settings for each pipe in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI. The PIPEnCTR, PIPEnTRE, and PIPEnTRN registers can be set independently from pipe selection using PIPESEL.

Not only the selected pipe but also the corresponding bits in registers for all pipes are initialized by a power-on reset or USB bus reset.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	PIPESEL [3:0]	B’0000	R/W	Pipe Window Select Specify a pipe number corresponding to PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI to be read or written. B’0000: No pipe is selected. B’0001: Pipe 1 B’0010: Pipe 2 B’0011: Pipe 3 B’0100: Pipe 4 B’0101: Pipe 5 B’0110: Pipe 6 B’0111: Pipe 7 B’1000: Pipe 8 B’1001: Pipe 9 B’1010: Pipe A B’1011: Pipe B B’1100: Pipe C B’1101: Pipe D B’1110: Pipe E B’1111: Pipe F PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI corresponding to the pipe number specified by these bits can be read and written. When these bits are set to B'0000, all bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI are read as 0 and cannot be modified.

61.2.28 Pipe Configuration Register (PIPECFG)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

PIPECFG specifies the transfer type, buffer memory access direction, and endpoint number for pipes 1 to F, selects continuous transfer mode or discontinuous transfer mode, and single buffer or double buffer, and also specifies whether to disable the operation of each pipe when data transfer finishes.

This register is initialized by a power-on reset. The TYPE1 and TYPE0 bits are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TYPE[1:0]		—	—	—	BFRE	DBLB	CNTMD	SHTNAK	—	—	DIR	EPNUM[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15, 14	TYPE[1:0]	B’00	R/W	Transfer Type Select the transfer type of the pipe specified by the PIPESEL bits (selected pipe). Pipes 1 and 2 B’00: No pipe is used. B’01: Bulk transfer B’10: Setting prohibited B’11: Isochronous transfer Pipes 3 to 5, 9 to F B’00: No pipe is used. B’01: Bulk transfer B’10: Setting prohibited B’11: Setting prohibited Pipes 6 to 8 B’00: No pipe is used. B’01: Setting prohibited B’10: Interrupt transfer B’11: Setting prohibited Before setting the selected pipe for PID = BUF (before starting USB communication using the selected pipe), be sure to set these bits to a value other than B'00. Modify these bits when the PID bits of the selected pipe are set to NAK. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10	BFRE	B'0	R/W	BRDY Interrupt Operation Specifies the BRDY interrupt output timing from this module to the CPU for the selected pipe. 0: At a BRDY interrupt timing during data transmission or reception 1: At a BRDY interrupt timing after reading data When this bit is set to 1 by the software and the selected pipe is used in the receive direction, this module detects the transfer end and outputs a BRDY interrupt when the packet is completely read. When a BRDY interrupt occurs with this setting, the software must set BCLR = 1. Unless BCLR = 1 is set, the FIFO buffer allocated to the selected pipe does not enter the receive ready state. When this bit is set to 1 by the software and the selected pipe is used in the transmit direction, this module generates no BRDY interrupt. For details, see section 61.3.2 (1), BRDY Interrupt. Modify this bit when PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
9	DBLB	B'0	R/W	Double Buffer Mode Specifies a single buffer or double buffer for the FIFO buffer used in the selected pipe. 0: Single buffer 1: Double buffer This bit is valid when pipes 1 to 5, 9 to F are selected. When this bit is set to 1 by the software, this module allocates the FIFO buffer size specified by the BUFSIZE bits in PIPEBUF to the selected pipe for two sides. Thus the size of the FIFO buffer that this module allocates to the selected pipe is as follows: (BUFSIZE + 1) × 64 × (DBLB + 1) [bytes] When this bit is set to 1 by the software and the selected pipe is used in the transmit direction, this module generates no BRDY interrupt. For details, see section 61.3.2 (1), BRDY Interrupt. Modify this bit when PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
8	CNTMD	B'0	R/W	Continuous Transfer Mode Selects continuous transfer mode or discontinuous transfer mode to be used in communication for the selected pipe. 0: Discontinuous transfer mode 1: Continuous transfer mode This bit is valid when pipes 1 to 5, 9 to F are selected by the PIPESEL bits and bulk transfer is selected (TYPE = 01). Modify this bit when PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
7	SHTNAK	B'0	R/W	Pipe Disable at the Time of Transfer End Specifies whether to change the setting of the PID bits to NAK at the end of transfer when the selected pipe is in the receive direction. 0: The pipe is continued at the end of transfer. 1: The pipe is disabled at the end of transfer. This bit is valid when the selected pipe is either of pipes 1 to 5, 9 to F and is in the receive direction. When the software sets this bit to 1 for a receive direction pipe, this module changes the setting of the PID bits corresponding to the selected pipe to NAK for the selected pipe when this module determines the transfer end. When the following conditions are satisfied, this module determines the transfer end. When short packet data (including a Zero-Length packet) is correctly received. When the transaction counter is used and packets with a size of the transaction counter are correctly received. Modify this bit when PID = NAK. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. For transmit direction pipes, set this bit to 0.
6, 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	DIR	B’0	R/W	Transfer Direction Selects the transfer direction of the selected pipe. 0: Receive direction 1: Transmit direction When this bit is set to 0 by the software, this module uses the selected pipe in the receive direction. When this bit is set to 1, this module uses the selected pipe in the transmit direction. Modify this bit when PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
3 to 0	EPNUM [3:0]	B’0000	R/W	Endpoint Number Specify the endpoint number of the selected pipe. The setting of B'0000 means an unused pipe. Modify these bits when PID = NAK. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Set these bits so that the combination of the DIR setting and the EPNUM setting does not overlap the setting of other pipes (EPNUM = B'0000 is allowed in this case.)

61.2.29 Pipe Buffer Register (PIPEBUF)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

PIPEBUF specifies the buffer size and buffer number for pipes 1 to F.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	BUFSIZE[4:0]					—	—	BUFNMB[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 10	BUFSIZE [4:0]	H'00	R/W	Buffer Size Specify the buffer size of the pipe specified by the PIPESEL bits (selected pipe) in units of blocks. One block is 64 bytes. B’0_0000 (H'00): 64 bytes B’0_0001 (H'01): 128 bytes : B’1_1111 (H'1F): 2 Kbytes When DBLB = 1 is set by the software, this module allocates the FIFO buffer size specified by these bits to the selected pipe for two sides. Thus the size of the FIFO buffer that this module allocates to the selected pipe is as follows: (BUFSIZE + 1) × 64 × (DBLB + 1) [bytes] A value that can be set in these bits varies depending on pipes selected. For pipes 1 to 5, 9 to F: Set BUFSIZE to H'00 to H'1F. For pipes 6 to 8: Set BUFSIZE to H'00. When using the buffer with CNTMD = 1, set a value in multiples of MaxPacketSize in these bits. Modify these bits when PID = NAK, and no pipe number is specified by the CURPIPE bits. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	BUFNMB [7:0]	H'00	R/W	Buffer Number Specify the FIFO buffer number of the selected pipe with a value from H'04 to H'FF. When the selected pipe is either of pipes 1 to 5, 9 to F, these bits can be set to a value according to user systems. Set BUFNMB to H'06 to H'4F. BUFNMB = 0 to 3 are for DCP only. BUFNMB = 4 is for pipe 6 only. However, when pipe 6 is not used, this is available for other pipes. When pipe 6 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 4. BUFNMB = 5 is for pipe 7 only. However, when pipe 7 is not used, this is available for other pipes. When pipe 7 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 5. BUFNMB = 6 is for pipe 8 only. However, when pipe 8 is not used, this is available for other pipes. When pipe 8 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 6. Modify these bits when PID = NAK, and no pipe number is set in the CURPIPE bits. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

61.2.30 Pipe Maximum Packet Size Register (PIPEMAXP)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

PIPEMAXP specifies the maximum packet size for pipes 1 to F.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	MXPS[10:0]										
Initial value:	0	0	0	0	0	*	*	*	*	*	*	*	*	*	*	*
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	MXPS[10:0]	*	R/W	Maximum Packet Size Specify the payload of data (maximum packet size) of the selected pipe. The settable value range for each pipe is as follows: Pipes 1 and 2: 1 byte (H'001) to 1024 bytes (H'400) Pipes 3 to 5, 9 to F: 8 (H'008), 16 (H'010), 32 (H'020), 64 (H'040), or 512 bytes (H'200) (MXPS2 to MXPS0 bits are not provided.) Pipes 6 to 8: 1 byte (H'001) to 64 bytes (H'040) Set a value in the MXPS bits based on the USB Specification for each transfer type. To transmit an isochronous pipe in split transactions, set a value of 188 bytes or less in the MXPS bits. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Do not write the FIFO buffer when the MXPS = 0 or set the PID bits to BUF.

Note: * The initial value is H'000 (when no pipe is selected by the PIPESEL bits in PIPESEL) or H'040 (when a pipe is selected).

61.2.31 Pipe Cycle Control Register (PIPEPERI)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

PIPEPERI specifies whether to activate the buffer flush function or not at the time of an interval error during the isochronous IN transfer, and also specifies the interval error detection interval for pipes 1 to F.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	IFIS	B’0	R/W	Isochronous IN Buffer Flush Specifies whether to flush the FIFO buffer when the pipe specified by the PIPESEL bits (selected pipe) is isochronous IN transfer type. 0: The FIFO buffer is not flushed. 1: The FIFO buffer is flushed. Buffer flush is a function that this module automatically clears the FIFO buffer when this module does not receive IN-Token from the USB host in a (μ) frame for each interval specified in the IITV bits when the selected pipe is isochronous IN transfer type. When double buffer is selected (DBLB = 1), this module clears data of only the older side. The FIFO buffer is cleared when an SOF packet is received immediately after the (μ) frame where IN-Token is to be received. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time when the SOF packet is to be received using the internal interpolation. When the selected pipe is not isochronous transfer type, set this bit to 0.
11 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	IITV[2:0]	B’000	R/W	Interval Error Detection Interval Specify the interval error detection interval of the selected pipe with a value of 2's n-th power of the frame timing. Set these bits when PID = NAK, and no pipe number is specified by the CURPIPE bits. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. To change the setting of these bits after USB communication, set PID = NAK and then set ACLRM = 1 to initialize the interval timer. These bits are not provided for pipes 3 to F. Set B'000 in the position of these bits corresponding to pipes 3 to F.

61.2.32 Pipe n Control Register (PIPEnCTR) (n = 1 to F)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

PIPEnCTR monitors the buffer memory status, changes/checks the data PID sequence bits, selects whether to use auto-response mode and buffer auto-clear mode, and specifies a response PID for pipes 1 to F. This register can be set independently of the pipe selection using PIPESEL.

This register is initialized by a power-on reset. The PID1 and PID0 bits are also initialized by a USB bus reset.

(1) PIPEnCTR (n = 1 to 5, 9 to F)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSTS	INBUFM	—	—	—	ATREPM	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	B'0	R	Buffer Status Indicates the FIFO buffer status of the pipe. 0: The buffer is not accessible from the CPU. 1: The buffer is accessible from the CPU. The meaning of this bit differs depending on the settings of the DIR, BFRE, and DCLRM bits as shown in Table 61.10.
14	INBUFM	B'0	R	Transmit Buffer Monitor Indicates the FIFO buffer status of the selected pipe in the transmit direction. 0: The buffer memory contains no transmittable data. 1: The buffer memory contains transmittable data. When transmit direction (DIR = 1) is set for the pipe, this module sets this bit to 1 when the software (or DMAC) finishes writing data to the FIFO buffer for at least one register set. When this module finishes sending all data on the register set (writing is completed) of the FIFO buffer, this bit indicates 0. In the case of a double buffer (DBLB = 1), when this module finishes sending all data on both register sets and the software (or DMAC) has not completed writing of data for one register set, this bit indicates 0. When receive direction (DIR = 0) is set for the selected pipe, this bit indicates the same value as the BSTS bit.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10	ATREPM	B'0	R/W	Auto-Response Mode Enables or disables auto-response for the selected pipe. 0: Auto-response is disabled. 1: Auto-response is enabled. When the transfer type of the selected pipe is set to bulk transfer, this bit can be set to 1. When this bit is 1, this module sends responses to tokens from the USB host as follows: (1) When the selected pipe is set for Bulk-IN transfer (TYPE = B'01 and DIR = 1) When ATREPM = 1 and PID = BUF, this module sends a Zero-Length packet in response to the IN-Token. Each time this module receives ACK from the USB host (flow of one transaction: receiving IN-Token -> sending Zero Length packet -> receiving ACK), this module updates the sequence toggle bit (DATA-PID) by toggling it. No BRDY interrupt or BEMP interrupt is generated. (2) When the selected pipe is set for Bulk-OUT transfer (TYPE = B'01 and DIR = 0) When ATREPM = 1 and PID = BUF, this module sends NAK in response to the OUT-Token (or PING-Token) and generates an NRDY interrupt. Modify this bit when PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Be sure to set this bit to 1 for USB communication when the FIFO buffer is empty. Do not write data to the FIFO buffer during USB communication with this bit set to 1. When the selected pipe is set for isochronous transfer, be sure to set this bit to 0.
9	ACLRM	B'0	R/W	Buffer Auto-Clear Mode Enables or disables buffer auto-clear mode for the selected pipe. 0: Buffer auto-clear mode is disabled. 1: Buffer auto-clear mode is enabled. (All buffers are initialized.) To completely delete the data in the FIFO buffer allocated to the pipe, write 1 and then 0 continuously to the ACLRM bit. Table 61.11 shows data cleared by this module when this bit is set to 1 and then 0 and cases where such data is cleared. Modify this bit when PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
8	SQCLR	B'0	R/W*	Toggle Bit Clear Set this bit to 1 to clear the expected value (in DATA0) of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is cleared in DATA0. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA0. This module always indicates SQCLR = 0. Set the SQCLR bit to 1 when PID = NAK. When setting this bit to 1 after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
7	SQSET	B'0	R/W*	Toggle Bit Set Set this bit to 1 to set the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is set in DATA1. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA1. This module always indicates SQSET = 0. Set the SQSET bit to 1 when PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
6	SQMON	B'0	R	Toggle Bit Check Indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: DATA0 1: DATA1 If the pipe is not the isochronous transfer type, when a transaction is successfully processed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled.
5	PBUSY	B'0	R	Pipe Busy Indicates whether the pipe is currently used in the USB bus or not. 0: The selected pipe is not used in the USB bus. 1: The selected pipe is being used in the USB bus. When this module starts the USB transaction for the selected pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to see if changing the pipe setting is enabled or not.
4 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	B’00	R/W	Response PID Specify a response used in the next transaction for the selected pipe. B’00: NAK response B’01: BUF response (depending on buffer state) B’10: STALL response B’11: STALL response These bits are set to NAK by default. To perform USB transfer with the selected pipe, change the setting of these bits to BUF. Table 61.12 shows the basic operation (with no error in packets) of this module in each setting of the PID bits. When changing these bits from BUF to NAK by the software while the pipe is in USB communication, write 00 (NAK) to these bits and then check PBUSY = 1 to confirm that the USB transfer of the pipe entered the NAK state. However, when this module changed these bits to NAK, the software does not have to check the PBUSY bit. This module modifies these bits in the following cases. • When the pipe is in the receive direction and the software sets the SHTNAK bit of the selected pipe to 1, this module indicates PID = NAK when this module recognizes the transfer end. • When this module receives data with a payload exceeding the MaxPacketSize value for the pipe, this module indicates PID = STALL (11). • When this module detects a USB bus reset, this module indicates PID = NAK. Set these bits as follows: • To change the state from NAK (00) to STALL, write B'10. • To change the state from BUF (01) to STALL, write B'11. • To change the state from STALL (11) to NAK, write B'10 then B'00. • To change the state from STALL to BUF, set these bits to NAK and then to BUF.

Note: * Only reading 0 and writing 1 are enabled.

Table 61.10 Operations of BSTS Bit

DIR Bit	BFRE Bit	DCLRM Bit	Meaning of BSTS Bit
B’0	B’0	B’0	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 upon completion of the data read.
		B’1	Setting prohibited
	B’1	B’0	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 when the software sets BCLR = 1 after the buffer data read.
		B’1	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 upon completion of the data read.
B’1	B’0	B’0	Indicates 1 when the FIFO buffer becomes ready to write transmit data to the buffer, and indicates 0 upon completion of the data write.
		B’1	Setting prohibited
	B’1	B’0	Setting prohibited
		B’1	Setting prohibited

Table 61.11 Data Cleared by This Module when ACLRM = 1

No.	Data Cleared by the ACLRM Bit	Clearing Timing
1	All data in the FIFO buffer (both sides for double FIFO buffer) allocated to the pipe	—
2	Interval count value when the pipe is isochronous transfer type	When resetting the interval count value
3	Internal flags related to the BFRE bit	When changing the BFRE setting
4	FIFO buffer toggle control	When changing the DBLB setting
5	Internal flags related to the transaction count	When forcibly terminating the transaction count function

Table 61.12 Operations of This Module in Each Setting of PID Bits

PID Bits	Transfer Type	Transfer Direction (DIR Bit)	Operation of This Module
B'00 (NAK)	Bulk or interrupt	Independent of the setting	Sends a NAK response to a token from the USB host.
	Isochronous	Independent of the setting	Sends no response to a token from the USB host.
B'01 (BUF)	Bulk	Receive direction (DIR = 0)	Receives data and sends an ACK response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, sends a NAK response. Sends an ACK response to the PING token from the USB host when the FIFO buffer for the selected pipe is ready to receive. Otherwise, sends a NYET response.
	Interrupt	Receive direction (DIR = 0)	Receives data and sends an ACK response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, sends a NAK response.
	Bulk or interrupt	Transmit direction (DIR = 1)	Sends data in response to a token from the USB host when the FIFO buffer for the pipe is ready to transmit. Otherwise, sends a NAK response.
	Isochronous	Receive direction (DIR = 0)	Receives data in response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, ignores the data.
		Transmit direction (DIR = 1)	Sends data in response to a token from the USB host when the FIFO buffer for the pipe is ready to transmit. Otherwise, sends a Zero-Length packet.
B'10 (STALL) or B'11 (STALL)	Bulk or interrupt	Independent of the setting	Sends a STALL response to a token from the USB host.
	Isochronous	Independent of the setting	Sends no response to a token from the USB host.

(2) PIPEnCTR (n = 6 to 8)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	B'0	R	Buffer Status Indicates the state of the FIFO buffer of the selected pipe. 0: The buffer is not accessible. 1: The buffer is accessible. The meaning of this bit differs as shown in Table 61.10 depending on the settings of the DIR, BFRE, and DCLRM bits.
14 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	ACLRM	B'0	R/W	Buffer Auto-Clear Mode*2*3 Enables or disables buffer auto-clear mode for the selected pipe. 0: Buffer auto-clear mode is disabled. 1: Buffer auto-clear mode is enabled. (All buffers are initialized.) To completely delete the data in the FIFO buffer allocated to the pipe, write 1 and then 0 continuously to the ACLRM bit. Table 61.13 shows data cleared by this module when this bit is set to 1 and then 0 and cases where such data is cleared. Modify this bit when PID = NAK, and the pipe is not set in the CURPIPE bits. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
8	SQCLR	B'0	R/W*1	Toggle Bit Clear*2*3 Set this bit to 1 to clear the expected value (in DATA0) of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is cleared in DATA0. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA0. This module always indicates SQCLR = 0. When this bit is set to 1 for a Bulk-Out transfer pipe with the host controller function selected, this module starts the next transfer with the PING-token for the pipe. Set the SQCLR bit to 1 when PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
7	SQSET	B'0	R/W*1	Toggle Bit Set*2*3 Set this bit to 1 to set the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is set in DATA1. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the selected pipe in DATA1. This module always indicates SQSET = 0. Set the SQSET bit to 1 when PID = NAK. When setting this bit to 1 after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
6	SQMON	B'0	R	Toggle Bit Check Indicates the expected value of the sequence toggle bit for the next transaction of the pipe. 0: DATA0 1: DATA1 If the selected pipe that is not the isochronous transfer type, when a transaction is successfully processed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled.
5	PBUSY	B'0	R	Pipe Busy Indicates whether the selected pipe is currently used in the USB bus or not. 0: The selected pipe is not used in the USB bus. 1: The selected pipe is being used in the USB bus. When this module starts the USB transaction for the selected pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to see if changing the pipe setting is enabled or not.
4 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	B'00	R/W	Response PID Specify a response used in the next transaction for the selected pipe. B'00: NAK response B'01: BUF response (depending on buffer state) B'10: STALL response B'11: STALL response These bits are set to NAK by default. To perform USB transfer with the selected pipe, change the setting of these bits to BUF. Table 61.12 shows the basic operation (with no error in packets) of this module in each setting of the PID bits. When changing these bits from BUF to NAK by the software while the pipe is in USB communication, write 00 (NAK) to these bits and then check PBUSY = 1 to confirm that the USB transfer of the selected pipe entered the NAK state. However, when this module changed these bits to NAK, the software needs not check the PBUSY bit. This module modifies these bits in the following cases. • When the selected pipe is in the receive direction and the software sets the SHTNAK bit of the selected pipe to 1, this module indicates PID = NAK when this module recognizes the transfer end. • When this module receives data with a payload exceeding the MaxPacketSize value for the pipe, this module indicates PID = STALL (11). • When this module detects a USB bus reset, this module indicates PID = NAK. Set these bits as follows: • To change the state from NAK (00) to STALL, write B'10. • To change the state from BUF (01) to STALL, write B'11. • To change the state from STALL (11) to NAK, write B'10 then B'00. • To change the state from STALL to BUF, set these bits to NAK and then to BUF.

Notes: 1. Only reading 0 and writing 1 are enabled.
2. Set the ACLRM, SQCLR, or SQSET bit when PID = NAK, and the selected pipe is not set in the CURPIPE bits.
3. When setting the ACLRM, SQCLR, or SQSET bit after changing the PID bits from BUF to NAK, check that PBUSY = 0 for the pipe. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Table 61.13 Data Cleared by This Module when ACLRM = 1

No.	Data Cleared by the ACLRM Bit	Clearing Timing
1	All data in the FIFO buffer allocated to the selected pipe	—
2	Not Support	—
3	Internal flags related to the BFRE bit	When changing the BFRE setting
4	Internal flags related to the transaction count	When forcibly terminating the transaction count function

61.2.33 Pipe n Transaction Counter Enable Register (PIPEnTRE) (n = 1 to 5, 9 to F)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

PIPEnTRE enables or disables the transaction counter function and clears the counter for pipes 1 to 5, 9 to F.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	TRENB	B'0	R/W	Transaction Counter Enable Enables or disables the transaction counter function. 0: The transaction counter function is disabled. 1: The transaction counter function is enabled. When the software sets the number of total packets in the TRNCNT bits in PIPEnTRN for the receive pipe and then sets this bit to 1, this module controls the following when it received the same number of packets as the setting of the TRNCNT bits. When continuous communication mode is used (CNTMD = 1), this module toggles the received data to the CPU even if the FIFO buffer is not full at the end of reception. When SHTNAK = 1, this module changes the PID bits for the corresponding pipe to NAK when this module received the same number of packets as the setting of the TRNCNT bits. When BFRE = 1, this module asserts the BRDY interrupt when this module received the same number of packets as the setting of the TRNCNT bits and read the receive data completely. For transmit pipes, set this bit to 0. When the transaction counter function is not used, set this bit to 0. When using the transaction counter function, set the TRNCNT bits and then set this bit to 1. Furthermore, set this bit to 1 before receiving the first packet that is included in the transaction count range.
8	TRCLR	B'0	R/W	Transaction Counter Clear Clears the current count value of the transaction counter for the pipe and indicates TRCLR = 0. 0: Invalid 1: The current count value is cleared.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: Change the bits in this register when PID = NAK.
When changing the bits in this register after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

61.2.34 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5, 9 to F)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

PIPEnTRN is a transaction counter for pipes 1 to 5, 9 to F.

This register is initialized by a power-on reset, but the setting of this register is retained through a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TRNCNT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TRNCNT [15:0]	All 0	R/W	Transaction Counter Writing: Specify the number of transactions of DMA transfer. Reading: When TRENB = 0, the set number of transactions is indicated. When TRENB = 1, the number of current transactions is indicated. This module increments (+1) the value of these bits when the following conditions are all satisfied. TRENB = 1 TRCNT value ≠ current count value +1 when a packet is received. The payload of the received packet equals the value of the MXPS bits. This module clears these bits to 0 when any of the following is satisfied. When the following conditions are all satisfied — TRENB = 1 — TRCNT value = current count value +1 when a packet is received. — The payload of the received packet equals the value of the MXPS bits. When the following conditions are all satisfied — TRENB = 1 — A short packet is received. When the following conditions are all satisfied — TRENB = 1 — The software sets the TRCLR bit to 1. For transmit pipes, set these bits to all 0. When the transaction counter function is not used, set these bits to all 0. Change these bits when PID = NAK and TRENB = 0. When setting these bits to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. When changing these bits, set TRCNT = 1 and then set TRENB = 1.

61.2.35 Low Power Status register (LPSTS)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register provides low power management control.

11	INCLK_SEL	B'0	R/W	USB_XTAL/USB_EXTAL to USB3 path control 0: Connects the crystal oscillator to the USB_EXTAL and USB_XTAL 1: Inputs an external oscillator to the USB_EXTAL
10 to 0	—	H'001	R	Reserved The write value should always be same value.

Note: This register is only in Channel 0.

61.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

61.3.1 System Control and Oscillation Control

This section describes register operations required for the initial settings of this module.

(1) Power control and Initialization

The following is the initialize power on procedure of USB subsystem.

[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N]

1. Supply 3.3 V
2. Release HS-USB and EHCI/OHCI module stop and assert HS-USB and EHCI/OHCI module reset.
3. Set LPSTS.SUSPM to normal mode.
4. Set UGCTRL2.USB0SEL bits to B’10 to select HS USB module.
5. Wait 45 µs for USB PHY to stabilize, and then start normal operation.

[RZ/G2E]

1. Supply 1.8 V
2. Supply 3.3 V (Note: Do not supply 3.3 V when 1.8 V is not supplied.)
3. Wait 100 µs for USB PHY power stable.
4. Release HS-USB and EHCI/OHCI module stop and assert HS-USB and EHCI/OHCI module reset.
5. UGCTRL.PLLRESET release
6. UGCTRL2.USB0SEL[1:0] should be set to B’10 for HS-USB.
7. LPSTS.SUSPM set to normal mode.
8. Check PLL Lock status by USB General status register (UGSTS)
9. Starting normal operation after PLL Lock status enabled.
10. UGCTRL.CONNECT bit set to 1

The following is the power off procedure of USB subsystem

[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N]

1. Normal operation finished
2. Module stop enable.
3. Shut off powers.

[RZ/G2E]

1. Normal operation finished
2. UGCTRL.CONNECT bit set to 0
3. PLL disable by UGCTRL.PLLRESET assert
4. Shut off 3.3V (VD331)
5. Shut off 1.8V (VD181) (Note: Do not shut off 1.8 V while 3.3 V is being supplied.)
6. Module stop enable.

(2) Enabling High-Speed Operation

This module can set the USB transmission rate (communication bit rate) by the software.

High-speed operation or full-speed operation is selectable. To enable high-speed operation with this module, set the HSE bit in SYSCFG to 1. When high-speed operation is enabled, this module executes the reset handshake protocol and automatically sets the USB transmission rate. The reset handshake result can be checked by the RHST bits in DVSTCTR.

When high-speed operation is disabled, this module operates only in full speed when the function controller function is selected.

(3) USB Data Bus Resistor Control

Figure 61.1 shows the connection between this module and the USB connector.

This module incorporates a pull-up resistor of the D+ signal. Specify pull-up using the DPRPU bits in SYSCFG.

Furthermore, this module controls the terminating resistors of the D+ and D- signals in high-speed operation, and the output resistors in full-speed operation. This module automatically switches the on-chip resistors after connection to the host controller detecting a reset handshake, suspended state, or resume.

When the DPRPU bit in SYSCFG is set to 0 during communication with the host controller, this module disables the pull-up resistors (or terminating resistors) of the USB data line. Therefore, the USB host can be notified of a disconnection from the device.

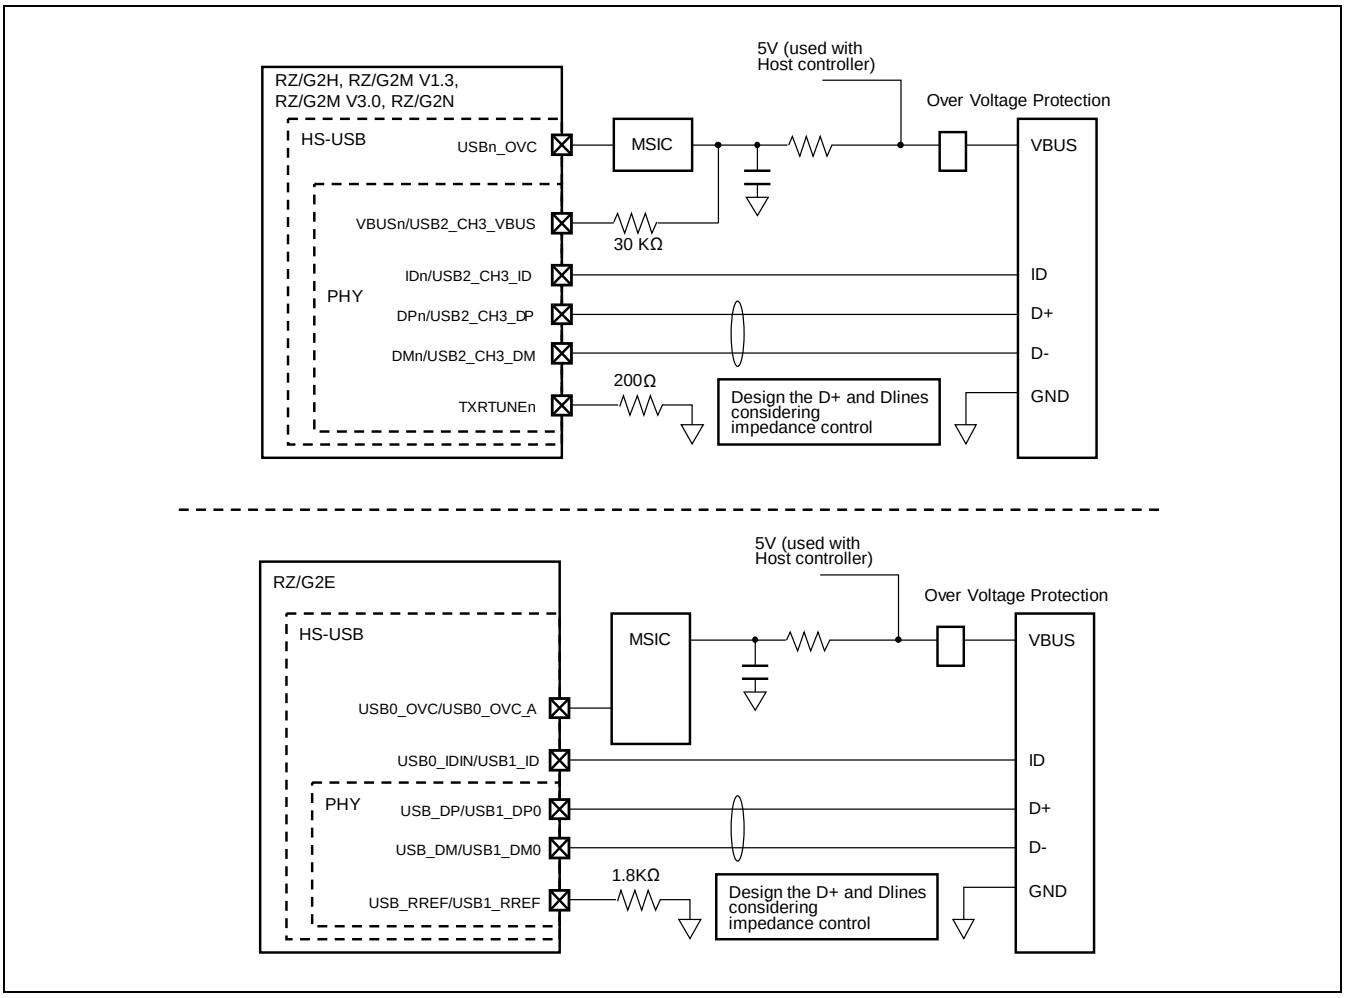

Figure 61.1 Connection to the USB Connector

(4) Software reset when the USB disconnection is detected

Issue a software reset of the USBHS module when the USB disconnection is detected. If the DMA interface is being used, issue a software reset of the USB-DMAC module as well. A software reset can be issued via a register in the CPG

Whether or not the USB disconnection is detected can be determined by the VBSTS in the INTSTS0 register.

Note: USB-PHY might become inoperable to use by the instantaneous interruption of VBUS. As a result S/W on the LSI side (driver) becomes a state of the connection, and USB-PHY becomes a state of power cutoff. It's possible to cancel this state by putting the next way into effect by software.

1) When detecting a bus reset or cutoff of VBUS, refer to the state bit of USB - PHY (USB_OFF bit of USBCR2 register in GPIO) and in case of USB_OFF = 1, set USB_START bit.
2) When 1) is performed and USB - PHY is started, USB_PHY_ON interrupt occurs, so perform a soft reset to USBHS,USB-DMAC and do the setting by which USBHS,USB-DMAC is initialization and DP pull up --, etc. by this timing.

61.3.2 Interrupt Function

Table 61.14 lists the interrupt generating conditions of this module.

When any of the following interrupt generating conditions are satisfied and the interrupt output is enabled by the corresponding interrupt enable register, this module outputs a USB interrupt request to the interrupt controller (INTC).

Table 61.14 Interrupt Generating Conditions

Bit	Interrupt Name	Interrupt Generating Conditions	Related Status
VBINT	VBUS interrupt	When VBUS input pin state change is detected (both L to H and H to L)	VBSTS
RESM	Resume interrupt	When a USB bus state change is detected in the suspended state (J-State to K-State or J-State to SE0)	—
SOFR	Frame number update interrupt	SOFRM = 0: When an SOF packet with a different frame number is received	—
		SOFRM = 1: When an SOF packet with a μ frame number of 0 cannot be received due to damage, etc.	
DVST	Device state transition interrupt	When a device state transition is detected	DVSQ
		USB bus reset detected	
		Suspended state detected	
		SET_ADDRESS request received	
		SET_CONFIGURATION request received	
CTRT	Control transfer stage transition interrupt	When a control transfer stage transition is detected	CTSQ
		Setup stage completed	
		Control write transfer status stage shifted	
		Control read transfer status stage shifted	
		Control transfer completed	
		Control transfer sequence error occurred	
BEMP	Buffer empty interrupt	When the buffer becomes empty after sending all buffer memory data	BEMPSTS.PIPEBEMP
		When a packet with a size exceeding the maximum packet size is received	
NRDY	Buffer not ready interrupt	When NAK is sent in response to IN token, OUTtoken, or PING token	NRDYSTS.PIPENRDY
		When a CRC error or bit stuffing error occurred during data reception in isochronous transfer	
		When an overrun or underrun error occurred during data reception in isochronous transfer	
BRDY	Buffer ready interrupt	When the buffer becomes ready for reading or writing	BRDYSTS.PIPEBRDY
OVRCR	OVRCR interrupt	When an OVC input pin state change is detected	OVCMON

Note: These bits in this table are those of INTSTS0 if any register's name is not indicated.

Figure 61.2 shows a block diagram of the interrupt circuit of this module.

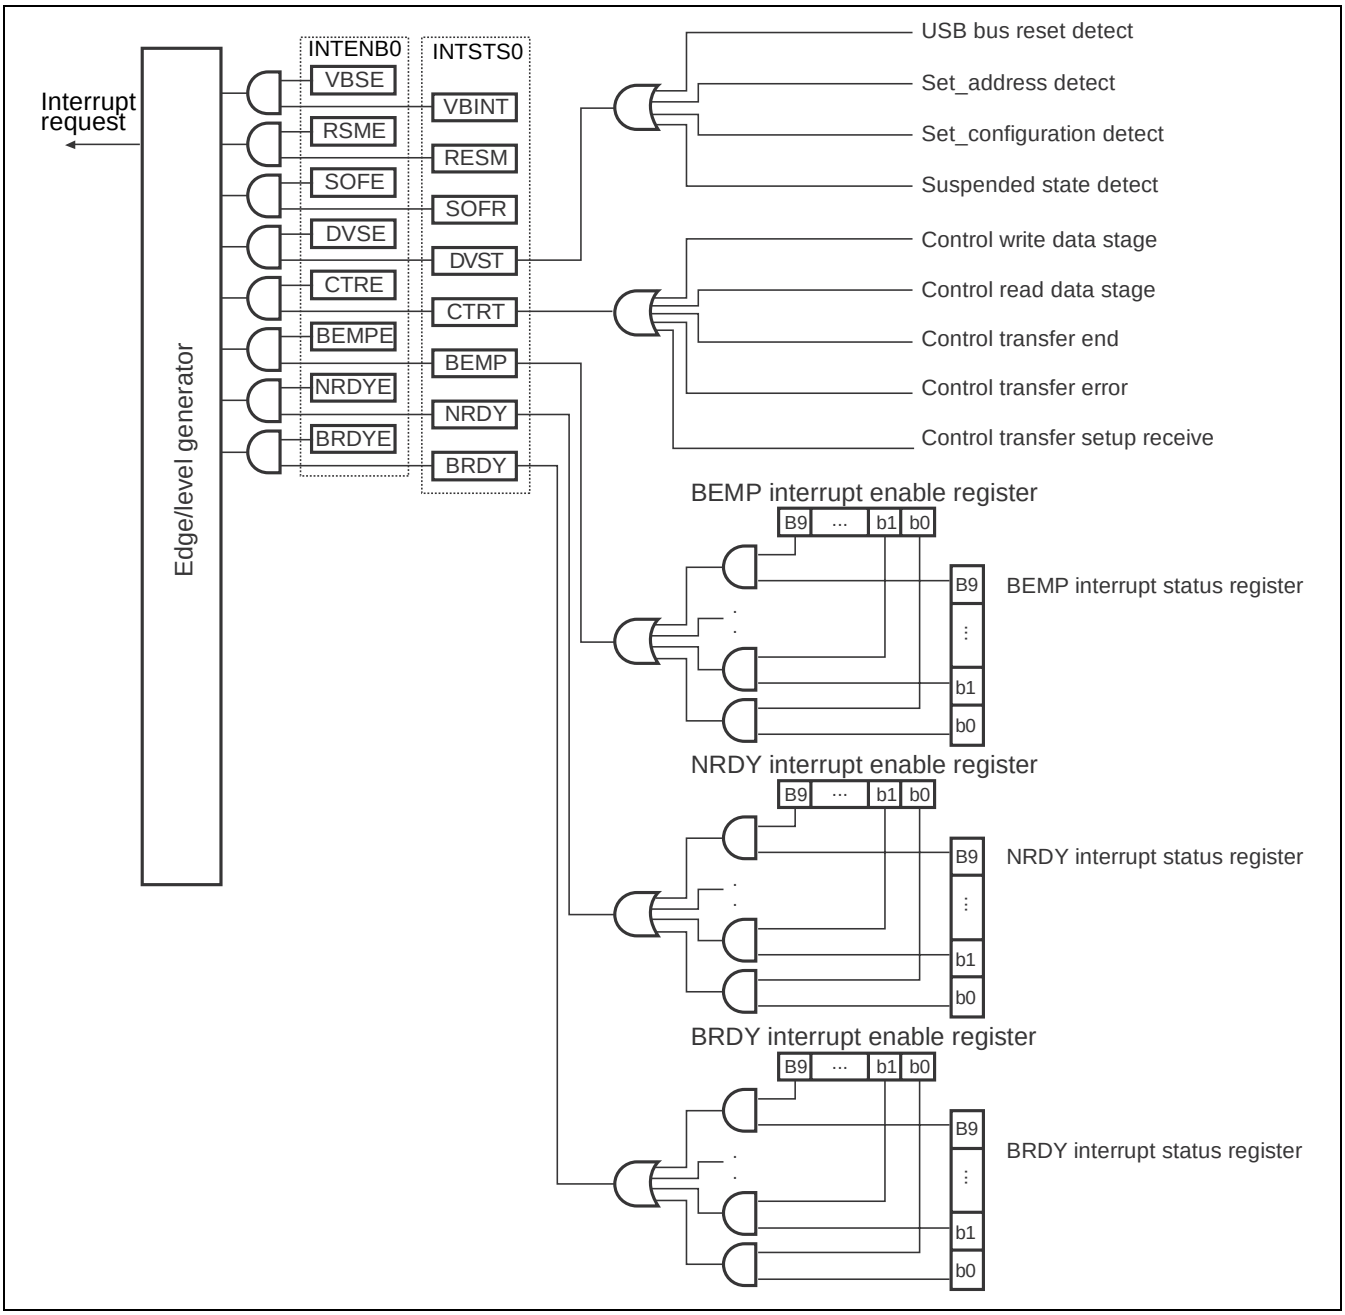

Figure 61.2 Block Diagram of Interrupt Circuit

(1) BRDY Interrupt

A BRDY interrupt can be generated. When the following conditions in each pipe are satisfied, this module sets the corresponding bit in BRDYSTS to 1. At this time, when the PIPEBRDYE bit for the pipe in BRDYENB is set to 1 and the BRDYE bit in INTENB0 is set to 1 by the software, this module generates a BRDY interrupt.

BRDY interrupt generating conditions and clearing method depend on the settings of the BRDYM bit and the BFRE bit for each pipe.

(a) When BRDY interrupt disable (BRDYM = 0) and BRDY interrupt output enable (BFRE = 0) at data reception/transmission are specified

With this setting, a BRDY interrupt indicates that the FIFO port is accessible.

This module generates an internal BRDY interrupt request trigger when the following conditions are satisfied, and sets the PIPEBRDY bit corresponding to the request trigger pipe to 1.

1. Pipes set for the transmit direction
   - When the software changes the DIR bit from 0 to 1
   - When this module finishes sending a packet of the pipe while data write from the CPU to the FIFO buffer allocated to the pipe is disabled (BSTS = 0)
   - When continuous communication mode is selected, this module generates a BRDY interrupt request trigger upon completion of sending data for one side of the FIFO buffer.
   - When a double FIFO buffer is specified and one side of the FIFO buffer is empty when data write to the other side of the FIFO buffer is completed.

     Even if one side of the FIFO buffer becomes empty while the other side is in data write processing, no BRDY interrupt is generated until the ongoing data write finishes.
   - When this module generates a buffer flush for a pipe of isochronous transfer type
   - When the FIFO buffer becomes write enable state by writing 1 to the ACLRM bit

No BRDY interrupt request trigger is generated for the DCP (in data transmission of control transfer).

2. Pipes set for the receive direction
   - When this module receives a packet successfully and the FIFO buffer becomes ready for reading while data read access from the CPU to the FIFO buffer allocated to the pipe is disabled (BSTS = 0)
   - No BRDY interrupt request trigger is generated in transactions with incorrect data PID.
   - When continuous communication mode is selected, no BRDY interrupt request trigger is generated for packets with a MaxPacketSize data size and when the FIFO buffer still has available space.
   - When this module receives a short packet, this module generates a BRDY interrupt request trigger even if the buffer has available space.
   - When a transaction counter is used, this module generates a BRDY interrupt request trigger when this module receives a packet with a size of the set value even if the FIFO buffer still has available space.
   - When a double FIFO buffer is specified and one side of the FIFO buffer is ready for reading when data read from the other side of the FIFO buffer is completed

     Even if data read for one side of the FIFO buffer is completed while the other side is undergoing data read, no BRDY interrupt request trigger is generated until the ongoing data read finishes.

This interrupt is not generated in communication in the control transfer status stage.

The software can clear the PIPEBRDY interrupt status of the pipe by writing 0 to the PIPEBRDY bit for the pipe in BRDYSTS. At this time, write 1 to the bits corresponding to other pipes.

Be sure to clear the BRDY interrupt status before accessing the FIFO buffer.

(b) When BRDY interrupt disable (BRDYM = 0) and BRDY interrupt output enable (BFRE = 1) at the end of data read are specified

With this setting, this module determines that a BRDY interrupt is generated upon completion of reading all data of one transfer in a receive pipe, and sets the bit for the pipe in this register to 1.

This module determines that the last data of a transfer was received in either of the following cases.

- A Zero-Length packet or another short packet is received.
- A transaction counter (TRNCNT bits) is used and a packet with a size of the value of the TRNCNT bits is received.

When either of these conditions is satisfied and the data read is completed, this module determines that reading all data for one transfer is completed.

When this module receives a Zero-Length packet with the FIFO buffer empty, this module determines that reading all data for one transfer is completed when the Zero-Length packet data is toggled to the CPU. In this case, write 1 to the BCLR bit in the corresponding FIFOCTR register by the software to start the next transfer.

With this setting, this module generates no BRDY interrupt for transmit pipes.

The software can clear the PIPEBRDY interrupt status of the pipe to 0 by writing 0 to the PIPEBRDY bit for the pipe. At this time, write 1 to the bits corresponding to other pipes.

When using this mode, do not change the BFRE setting until the processing for one transfer is completed.

To change the BFRE bit during processing, clear all FIFO buffers for the pipe by the ACLRM bit.

(c) When BRDY interrupt enable (BRDYM = 1) and BRDY interrupt output enable (BFRE = 0) at data reception/transmission are specified

With this setting, the value of the PIPEBRDY bit varies with the value of the BSTS bit for each pipe. That is, this module indicates 1 or 0 of the BRDY interrupt status according to the FIFO buffer status.

1. Pipes set for the transmit direction

   When the FIFO port is ready to write data, the PIPEBRDY bit indicates 1. When the FIFO port is not ready to write data, the PIPEBRDY bit indicates 0.

   However, even if the transmit pipe of the DCP is ready to write data, no BRDY interrupt is asserted.

2. Pipes set for the receive direction

   When the FIFO port is ready to read data, the PIPEBRDY bit indicates 1. When all data is read from the FIFO port (reading disabled), the PIPEBRDY bit indicates 0.

   When this module receives a Zero-Length packet with the FIFO buffer empty, this module indicates 1 with the corresponding bit until 1 is written to BCLR by the software, and continues to assert the BRDY interrupt.

   With this setting, the software cannot clear the PIPEBRDY bit to 0.

   When BRDYM = 1, set the BFRE bit to 0 for all pipes.

Figure 61.3 shows the BRDY interrupt generation timing.

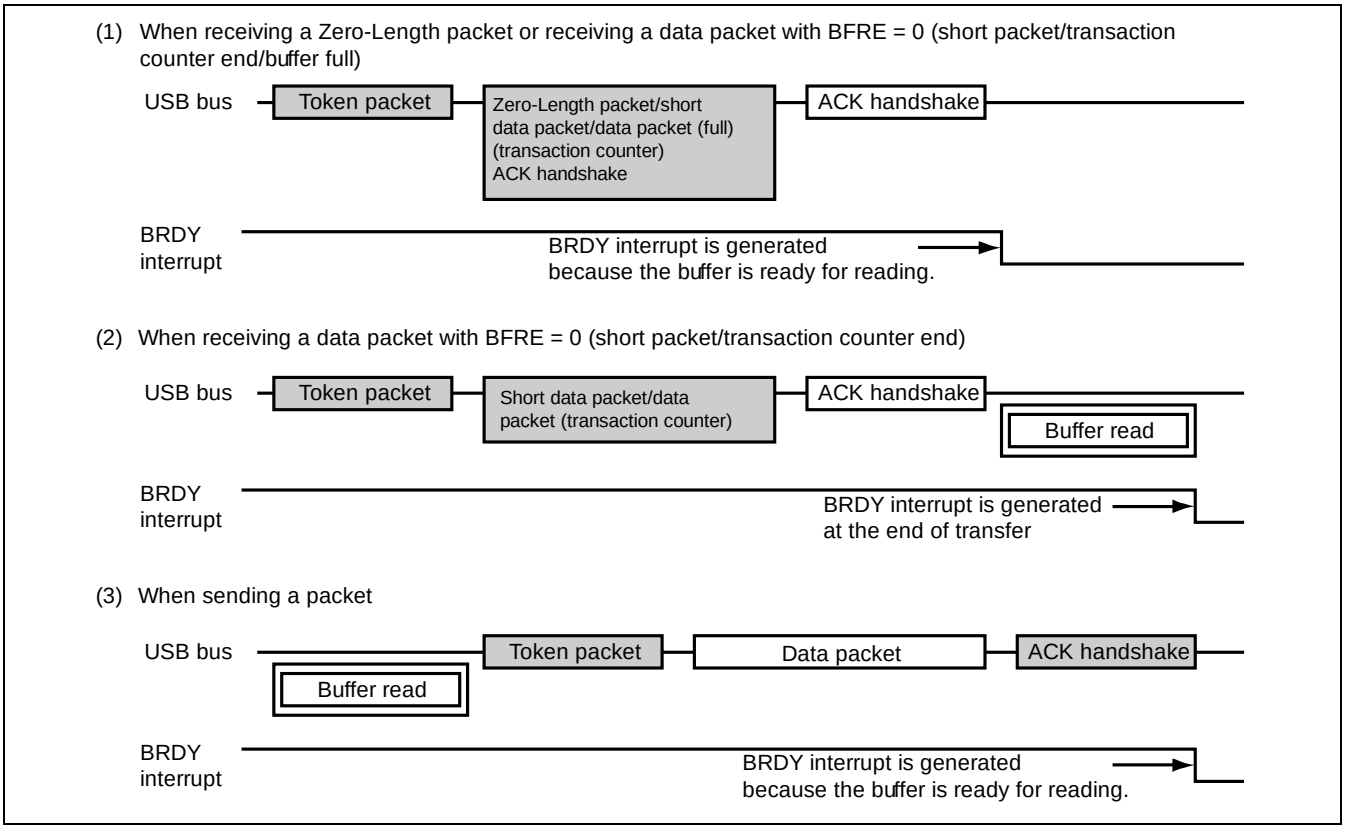

Figure 61.3 BRDY Interrupt Generation Timing

(2) NRDY Interrupt

When this module generates an internal NRDY interrupt request for the pipe in which PID = BUF is set by the software, this module indicates PIPENRDY = 1 for the pipe in NRDYSTS. At this time, when 1 is set in the corresponding bit in NRDYENB by the software, this module indicates NRDY = 1 in INTSTS0 and generates a USB interrupt.

The following shows the conditions for this module to generate an internal NRDY interrupt request for a pipe.

Furthermore, when executing the control transfer status stage, this module generates no interrupt request.

1. Pipes in the transmit direction
   - When this module receives an IN token with no transmit data in the FIFO buffer
     This module generates an NRDY interrupt request and indicates PIPENRDY = 1.
   - When the pipe in which the interrupt is generated is isochronous transfer type, this module sends a Zero-Length packet and indicates OVRN = 1.
2. Pipes in the receive direction pipe
   - When this module receives an OUT token with the FIFO buffer occupied
   - When the pipe in which the interrupt is generated is isochronous transfer type, this module generates an NRDY interrupt request when this module receives an OUT token, and indicates PIPENRDY = 1 and OVRN = 1.
   - When the pipe in which the interrupt is generated is not isochroous transfer type, this module generates an NRDY interrupt request when this module sends an NAK handshake response after receiving data following the OUT token, and indicates PIPENRDY = 1.
     However, this module generates no NRDY interrupt when resending data (in the case of DATA-PID mismatch) or when an error occurs in a data packet.
   - When this module receives a PING token with the FIFO buffer occupied
     This module generates an NRDY interrupt request when this module receives a PING token and indicates PIPENRDY = 1.
   - When a packet is not received correctly within the interval frame in an isochroous transfer-type pipe
     This module generates an NRDY interrupt request when this module receives SOF and indicates PIPENRDY = 1.

Figure 61.4 shows the NRDY interrupt generation timing.

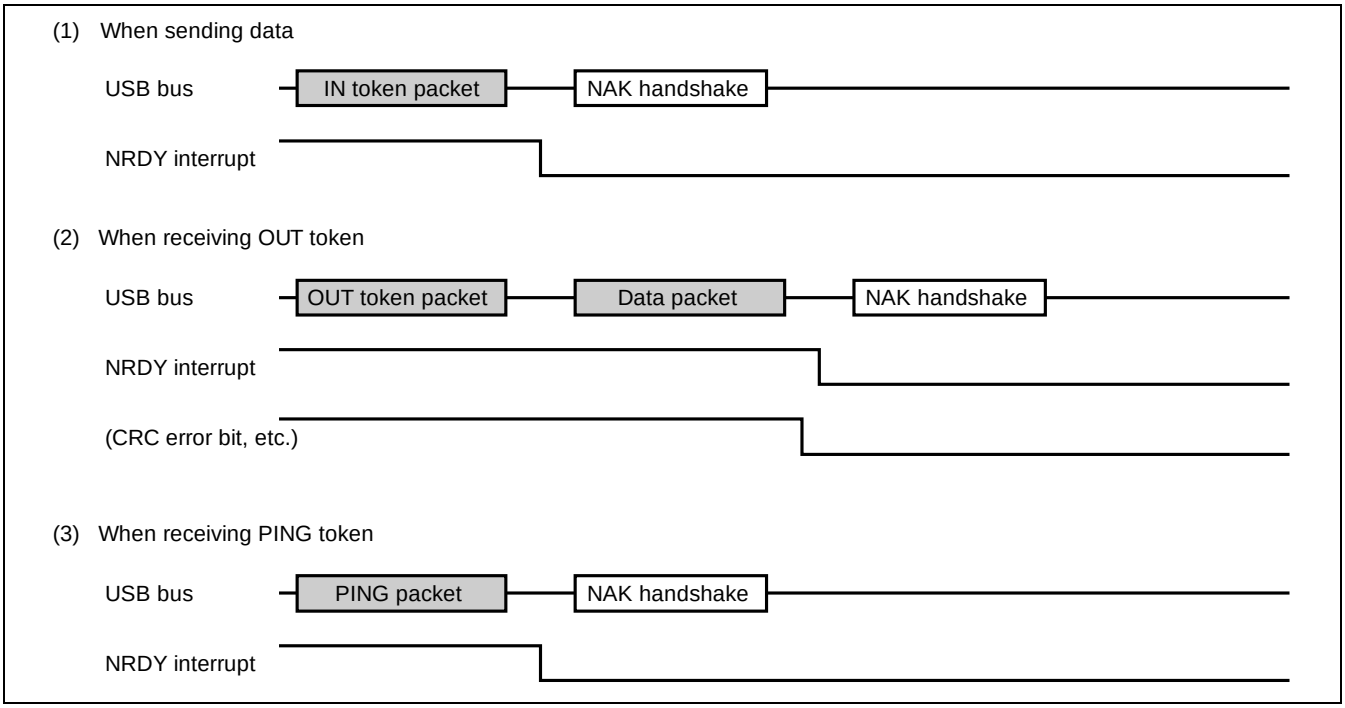

Figure 61.4 NRDY Interrupt Generation Timing

(3) BEMP Interrupt

When this module detects a BEMP interrupt for the pipe in which PID = BUF is set by the software, this module indicates PIPEBEMP = 1 for the pipe in BEMPSTS. At this time, when 1 is set in the corresponding bit in BEMPENB by the software, this module indicates BEMP = 1 in INTSTS0 and generates a USB interrupt.

This module generates an internal BEMP interrupt request in the following cases.

1. Transmit direction pipes
   — When the FIFO buffer for the pipe is empty at the end of transmission (including transmission of a Zero-Length packet)
   — When single buffer is set for the FIFO buffer, this module generates an internal BEMP interrupt request concurrently with a BRDY interrupt for pipes other than DCP.
   However, this module generates no internal BEMP interrupt request in the following cases.
   - In the case of double buffer, when the software (DMAC) already started writing data to the FIFO buffer of the CPU at the end of transmission for one-side data
   - When the buffer is cleared (empty) by writing 1 to the ACLRM or BCLR bit.
   - When sending a Zero-Length packet (IN transfer) of the control transfer status stage

2. Receive direction pipes
   — When this module receives a packet with a data size exceeding the MaxPacketSize value
   In this case, this module generates a BEMP interrupt request and indicates the PIPEBEMP = 1 for the pipe, ignores the received data, and changes the PID bits for the pipe to STALL (11).
   At this time, this module sends a STALL response.
   However, this module generates no BEMP interrupt request in the following cases.
   - When this module detects a CRC error or bit stuffing error in the receive data
   - When executing the SETUP transaction
     Writing 0 to the PIPEBEMP bits clears the status.
     Writing 0 to the PIPEBEMP bits has no effect on the operation of this module.

Figure 61.5 shows the BEMP interrupt generation timing.

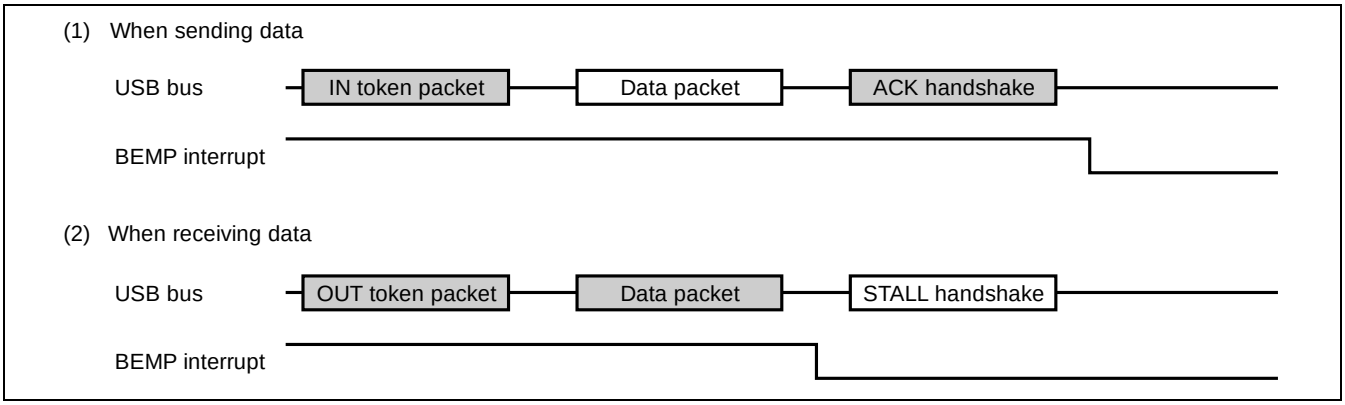

Figure 61.5 BEMP Interrupt Generation Timing

(4) Device State Transition Interrupt

Figure 61.6 shows the device state transitions of this module. This module controls device states and generates device state transition interrupts. However, when returning from the suspended state (detecting the resume signal), this module detects the transition with a resume interrupt. The device state transition interrupt is enabled or disabled by setting INTENB0. The current device state can be monitored using the DVSQ bits in INTSTS0.

When this module shifts to the default state, a device state transition interrupt occurs after executing the reset handshake protocol.

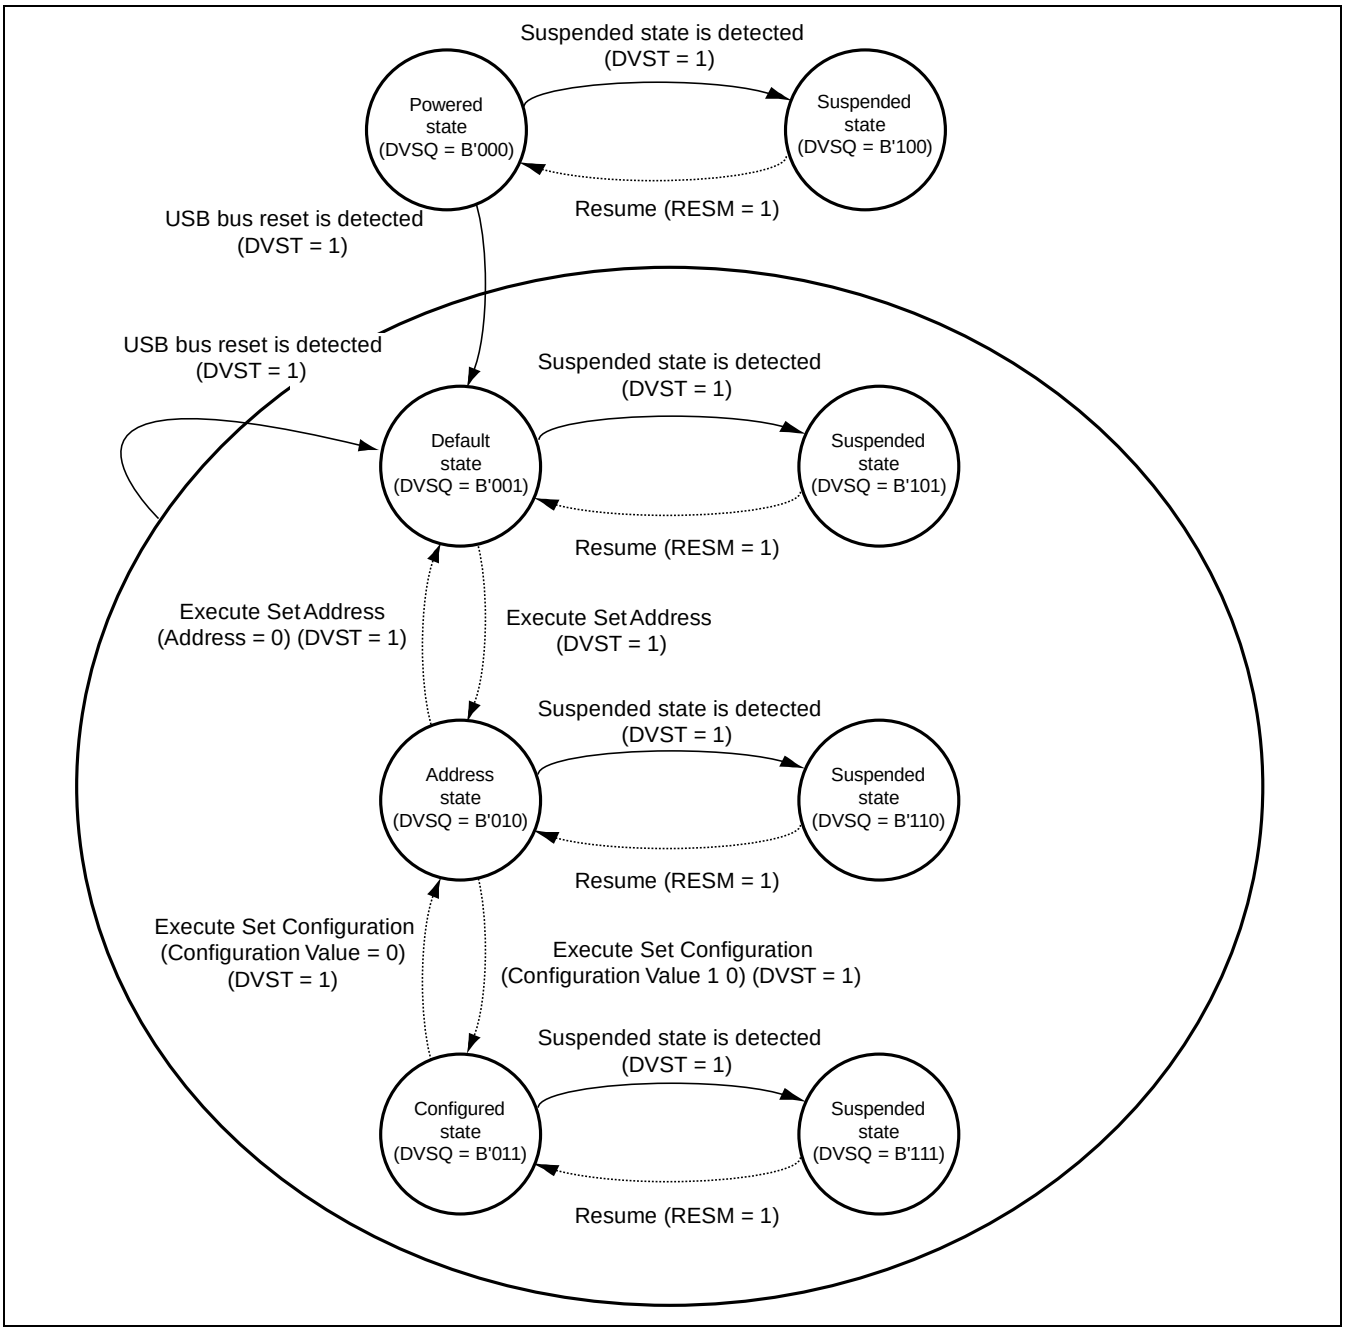

Figure 61.6 Device State Transitions

(5) Control Transfer Stage Transition Interrupt

Figure 61.7 shows control transfer stage transitions of this module. This module manages the sequence of control transfers and generates control transfer stage transition interrupts. Enabling or disabling each control transfer stage transition interrupt can be set by INTENB0. The current transfer stage after transition can be checked by the CTSQ bits in INTSTS0.

The following describes control transfer sequence errors. When an error occurs, the PID bits in DCPCTR indicate B'1x (STALL response).

1. Control read transfer
   - This module receives an OUT or PING token in response to the IN token in the data stage before starting data transfer.
   - This module receives an IN token in the status stage.
   - This module receives a packet with a data packet of DATAPID = DATA0 in the status stage.
2. Control write transfer
   - This module receives an IN token in response to the OUT token in the data stage before sending an ACK response.
   - This module receives a packet with the first data packet of DATAPID = DATA0.
   - This module receives an OUT or PING token in the status stage.
3. Control write no-data control transfer
   - This module receives an OUT or PING token in the status stage.

If the size of the receive data exceeds the wLength value of the USB request in the control write transfer data stage, this is not treated as a control transfer sequence error. This module sends ACK for normal end in response to a packet other than Zero-Length packet in the control read transfer status stage.

When a CTRT interrupt is generated (SERR = 1) due to a sequence error, CTSQ = B'110 is retained until the interrupt status is cleared (CTRT = 0) by the system. For this reason, while CTSQ = B'110, even if a new USB request is received, a CTRT interrupt at the end of the setup stage is not generated. (This module retains the setup stage end status and generates a setup stage end interrupt after the interrupt status is cleared by the software.)

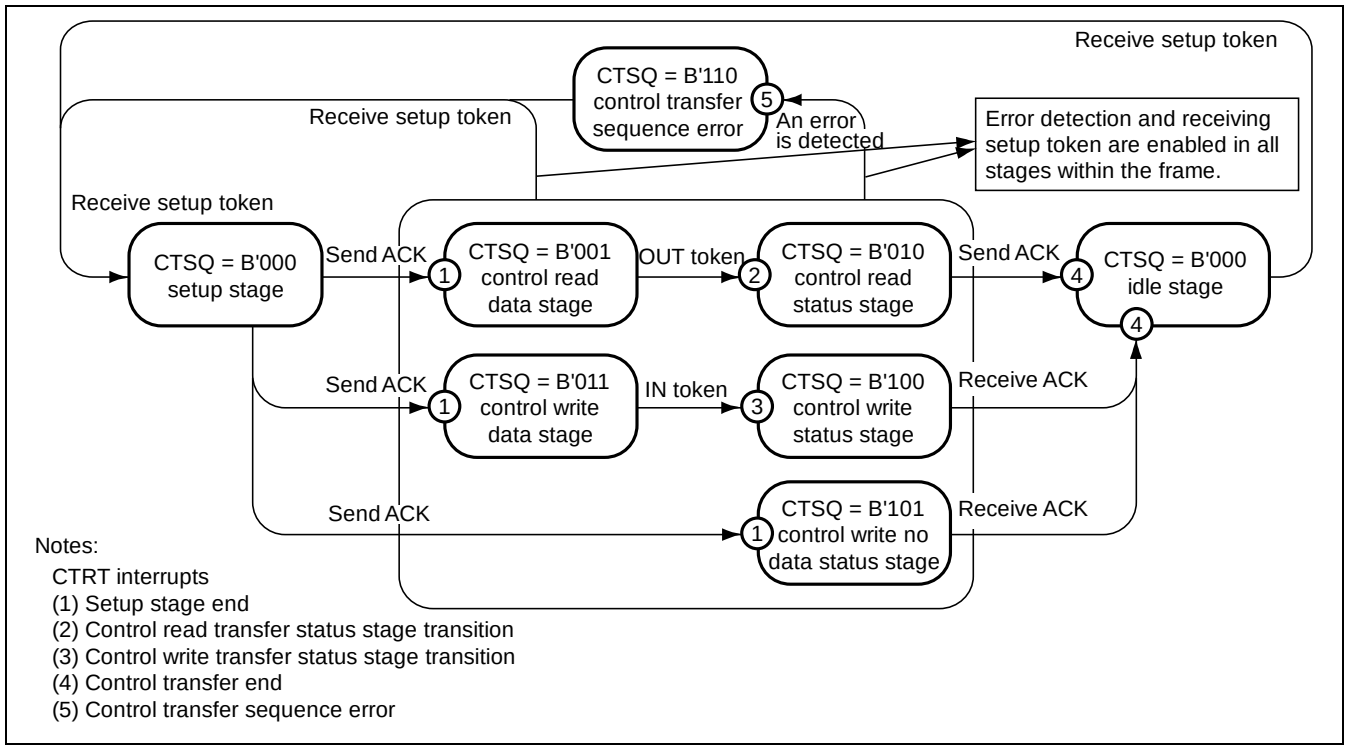

Figure 61.7 Control Transfer Stage Transitions

(6) Frame Update Interrupt

Figure 61.8 shows an example of the SOFR interrupt output timing of this module.

An SOFR interrupt is generated immediately after the frame number is updated.

When this module detects a new SOF packet during the full-speed operation, this module updates the frame number and generates an SOFR interrupt. In the high-speed operation, however, the frame number is not updated or no SOFR interrupt is generated unless the module enters the µ SOF lock state. Furthermore, the SOF interpolation function is not activated. The µ SOF lock state occurs when this module receives a µ SOF packet twice in a row with different frame numbers without an error.

The µ SOF lock monitoring start and stop conditions are as follows:

1. µ SOF lock monitoring start conditions
   USBE = 1
2. µ SOF lock monitoring stop conditions
   USBE = 0, receiving USB bus reset, or detection of suspended state

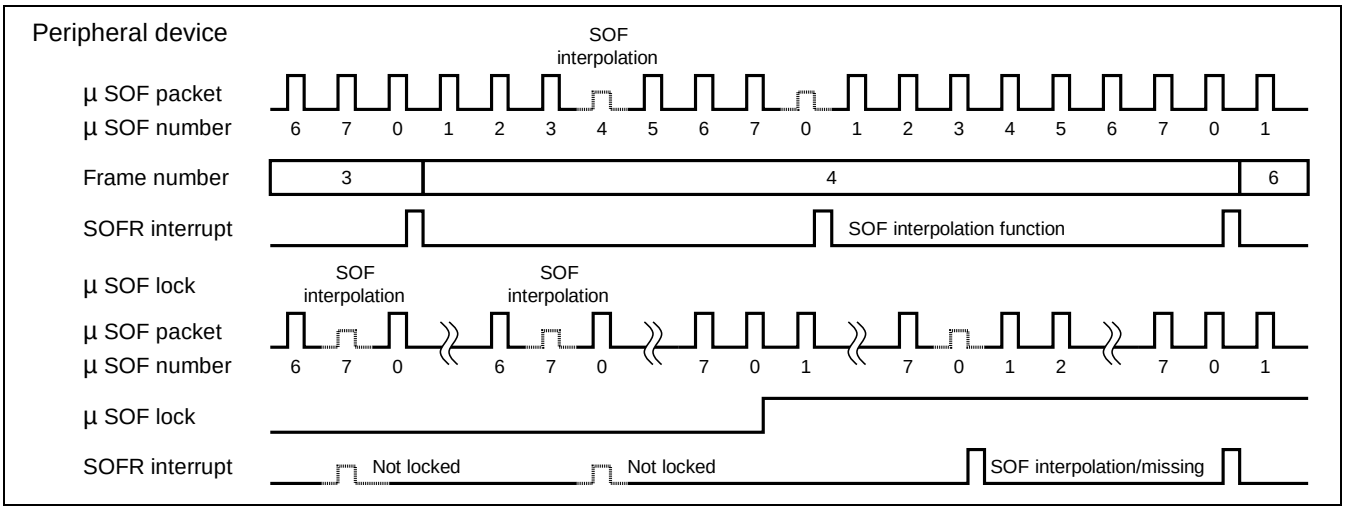

Figure 61.8 Example of SOFR Interrupt Output Timing

(7) VBUS Interrupt

When the VBUSn [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] /OVC signal status [RZ/G2E] pin state changes, a VBUS interrupt is generated. The VBUSn [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] /OVC signal status [RZ/G2E] pin level can be checked by the VBSTS bit in INTSTS0. The VBUS interrupt is used to check connection or disconnection to/from the host controller. However, when the system starts up with the host controller connected, the VBUSn [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] /OVC signal status [RZ/G2E] pin state remains unchanged, and therefore the first VBUS interrupt is not generated.

(8) Resume Interrupt

When the USB bus state changes (J-State to K-State or J-State to SE0) with the device state suspended, a resume interrupt is generated. The resume interrupt is used to detect the return from the suspended state.

When the host controller function is selected, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

61.3.3 Pipe Control

Table 61.15 lists the pipe settings of this module. In the USB data transfer, data must be transmitted or received using virtual pipes called “endpoint.” This module is provided with ten pipes for data transfer. Set each pipe according to system specifications.

Table 61.15 Pipe Settings

Register Name	Bit Name	Setting	Remarks
DCPCFG PIPECFG	TYPE	Transfer type	Pipes 1 to F: Setting allowed
	BFRE	BRDY interrupt mode	Pipes 1 to 5, B to F: Setting allowed
	DBLB	Double buffer	Pipes 1 to 5, B to F: Setting allowed Pipes 9, A: Setting allowed only when bulk transfer is selected
	CNTMD	Continuous transfer or discontinuous transfer	Pipes 1 to 2, 9 to A: Setting allowed only when bulk transfer is selected Pipes 3 to 5, B to F: Setting allowed
	DIR	Transfer direction	IN or OUT selectable
	EPNUM	Endpoint number	Pipes 1 to F: Setting allowed Set a value other than 0000 when using pipes
	SHTNAK	Disabling pipes at the end of transfer	Pipes 1 to 2, 9 to A: Setting allowed only when bulk transfer is selected Pipes 3 to 5, B to F: Setting allowed
PIPEBUF	BUFSIZE	Buffer memory size	DCP: Setting disallowed (256 bytes fixed) Pipes 1 to 5, 9 to F: Setting allowed (up to 2 Kbytes) Pipes 6 to 8: Setting disallowed (64 bytes fixed)
	BUFNMB	Buffer memory number	DCP: Setting disallowed (H'0 to H'3 fixed) Pipes 1 to 5, 9 to F: Setting allowed (H'8 to H'87) Pipes 6 to 8: Setting disallowed (H'4 to H'7 fixed)
DCPMAXP PIPEMAXP	MXPS	Maximum packet size	Setting conforming to the USB Specification
PIPEPERI	IFIS	Buffer flush	Pipes 1, 2: Setting allowed only when isochronous transfer is selected Pipes 3 to F: Setting disallowed
	IITV	Interval counter	Pipes 1, 2: Setting allowed only when isochronous transfer is selected Pipes 3 to F: Setting disallowed
DCPCTR PIPEnCTR	BSTS	Buffer status	For DCP, receive buffer status and transmit buffer status are switched by the ISEL bit.
	INBUFM	IN buffer monitor	Provided only for pipes 3 to 5, 9 to F.
	ATREPM	Auto-response mode	Pipes 1 to 5, 9 to F Setting allowed.
	ACLRM	Buffer auto-clear	Pipes 1 to F Setting allowed
	SQCLR	Sequence clear	Data toggle bit clear
	SQSET	Sequence setting	Data toggle bit setting
	SQMON	Sequence check	Data toggle bit check
	PBUSY	Pipe busy check	
	PID	Response PID	See section 61.3.3 (6), Response PID.
PIPEnTRE	TRENB	Transaction count enable	Pipes 1 to 5, 9 to F: Setting allowed
	TRCLR	Current transaction counter clear	Pipes 1 to 5, 9 to F: Setting allowed
PIPEnTRN	TRNCNT	Transaction counter	Pipes 1 to 5, 9 to F: Setting allowed

(1) Pipe Control Registers Switching Procedure

The following bits in the pipe control registers can be modified only when USB communication is set to disabled (PID = NAK).

Bits/registers that cannot be modified when USB communication is set to enabled (PID = BUF)

- SQCLR and SQSET bits in DCPCTR
- Each bit in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPExCTR
- Each bit in PIPExTRE and PIPExTRN

When changing these bits from the state where USB communication is enabled (PID = BUF), follow the steps below.

1. Generate a pipe control register bit change request.
2. Change the PID bits for the pipe to NAK.
3. Wait until the PBUSY bit for the pipe is cleared to 0.
4. Change the bits in the pipe control registers.

The following bits in the pipe control registers can be modified only for pipe information that is not set in any of the CURPIPE bits in CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL.

Bits/registers that cannot be modified while the CURPIPE bits in FIFO-PORT are being set

- Each bit in DCPCFG and DCPMAXP
- Each bit in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI

Before changing the pipe information, set the CURPIPE bits to a pipe other than that to be changed. For the DCP, clear the buffer by the BCLR bit after modifying the pipe information.

(2) Transfer Type

Specify the transfer type of each pipe by the TYPE bits in PIPEPCFG as follows:

- DCP: Setting is not required (fixed to control transfer).
- Pipes 1, 2: Set bulk transfer or isochronous transfer.
- Pipes 3 to 5, 9 to F: Set bulk transfer.
- Pipes 6 to 8: Set interrupt transfer.

(3) Endpoint Number

Specify the endpoint number of each pipe by the EPNUM bits in PIPEPCFG. The endpoint number of the DCP is always 0. For other pipes, endpoint 1 to endpoint 15 are selectable.

- DCP: Setting is not required (fixed to endpoint 0).
- Pipes 1 to F Set an endpoint number by selecting a number 1 to 15.
  However, set an endpoint number so that combinations of the DIR bit and the EPNUM bits do not overlap.

(4) Maximum Packet Size

Specify the maximum packet size of each pipe by the MXPS bits in DCPMAXP and PIPEMAXP. For the DCP and pipes 1 to 5, 9 to F, any of the maximum packet sizes defined in the USB Specification can be set. For pipes 6 to 8 a maximum packet size up to 64 bytes can be set. Specify a maximum packet size as follows before starting transfer (PID = BUF):

- DCP: Set 64 for high-speed operation.
- DCP: Set 8, 16, 32, or 64 for full-speed operation.
- Pipes 1 to 5, B to F: Set 512 for high-speed bulk transfer.
- Pipes 1 to 5, B to F: Set 8, 16, 32, or 64 for full-speed bulk transfer.
- Pipes 1, 2: Set a value from 1 to 1024 for high-speed isochronous transfer.
- Pipes 1, 2: Set a value from 1 to 1023 for full-speed isochronous transfer.
- Pipes 6 to 8: Set a value from 1 to 64.
- Pipe 9: Set 512 for high-speed bulk transfer.
- Pipe 9: Set 8, 16, 32, or 64 for full-speed bulk transfer.
- Pipe A: Set a value from 1 to 64.

High Bandwidth in interrupt and isochronous transfers is not supported.

(5) Transaction Counter (Pipes 1 to 5, 9 to F: Read Direction)

When the specified number of transactions with data packet in the receive direction are completed, this module recognizes this as a transfer end. The transaction counter works when the pipe selected for the D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL ports is set for the data read (from the buffer memory) direction. The transaction counter is provided with the TRNCNT register to specify the number of transactions and the current counter to count transactions internally. When the current counter reaches the specified value, the buffer memory becomes ready for reading. The current counter of the transaction counter function can be initialized by the TRCLR bit to count transactions again from the beginning. The TRNCNT read data varies depending on the TRENB setting.

- TRENB = 0: The set transaction counter value is read.
- TRENB = 1: The internally counted current counter value is read.
- Change the CURPIPE bits according to the following.
- Do not change the CURPIPE bits until the transaction for the specified pipe finishes.
- Change the CURPIPE bits when the current counter is cleared.
- Control the TRCLR bit according to the following.
- Do not clear the current counter during transaction count and PID = BUF.
- Do not clear the current counter while data is remaining in the buffer.

(6) Response PID

Specify the response PID for each pipe by the PID bits in DCPCTR and PIPEnCTR.

This module operates as follows according to the response PID setting.

The response PID specifies a response to transactions from the host.
- NAK setting: NAK is always sent in response to a transaction.
- BUF setting: A response is sent to a transaction according to the buffer memory status.
- STALL setting: STALL is always sent in response to a transaction.

Note: This module always sends ACK in response to a setup transaction irrespective of the PID setting, and stores a USB request in the register.

This module modifies the PID bits in the following cases depending on transaction results.

- When the response PID is set by the hardware
  - NAK setting: This module sets PID to NAK in the following cases and always sends NAK in response to a transaction.
- When a SETUP token is successfully received (DCP only)
- When the SHTNAK bit in PIPECFG is set to 1 in a bulk transfer and the transaction counter stops counting or this module receives a short packet
  - BUF setting: This module does not set the PID bits to BUF.
  - STALL setting: This module sets PID to STALL in the following cases and always sends STALL in response to a transaction.
- When a maximum packet size exceeded error is detected in a receive data packet
- When a control transfer sequence error is detected (DCP only)

(7) Data PID Sequence Bit

When data is successfully transferred in the control transfer data stage, bulk transfer, or interrupt transfer, this module automatically toggles the data PID sequence bit. The sequence bit of the data PID transmitted next can be monitored by the SQMON bit in DCPCTR and PIPEnCTR. In a data transmission period, the sequence bit switches at the ACK handshake receive timing. In a data reception period, the sequence bit switches at the ACK handshake transmit timing. The data PID sequence bit can also be changed by the SQCLR and SQSET bits in DCPCTR and PIPEnCTR.

In control transfers when the function controller function is selected, this module automatically sets the sequence bit during a stage transition. DATA0 is indicated at the end of the setup stage, and DATA1 is used for responses in the status stage. This does not require the setting of the sequence bit by the software.

Note that, the software must also set the data PID sequence bit when sending or receiving a ClearFeature request.

The sequence bit cannot be modified by the SQSET bit for isochronous transfer pipes.

(8) Response PID = NAK Function

This module has a function to disable the pipe operation (Response PID = NAK) at the last data packet receive timing in a transfer (this module automatically identifies the last data packet receive timing at the short packet receive timing or using the transaction counter) by setting the SHTNAK bit in PIPECFG to 1.

This function allows reception of data packets in transfer units when the buffer memory is used as a double buffer. Furthermore, when the pipe operation is disabled, the software must set the response PID to BUF to enable the pipe operation.

This function is available only for bulk transfers.

(9) Auto-Response Mode

When the ATREPM bit in PIPEnCTR is set to 1 in a bulk transfer pipe (pipes 1 to 5, 9 to F), this module enters auto-response mode: OUT-NAK mode in OUT transfers (DIR = 0) or null auto-response mode in IN transfers (DIR = 1).

1. OUT-NAK mode

   When the ATREPM bit is set to 1 in a bulk OUT transfer pipe, this module sends NAK in response to an OUT token or PING token and outputs an NRDY interrupt. To change response mode from normal mode to OUT-NAK mode, specify OUT-NAK mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). After that, OUT-NAK mode is enabled. However, if an OUT token is received immediately before the pipe operation is disabled, this module receives the data of the token correctly and sends ACK to the host.

   To change response mode from OUT-NAK mode to normal mode, reset OUT-NAK mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). In normal mode, this module can receive OUT data and sends ACK in response to a PING token when the buffer is ready for receiving.

2. Null auto-response mode

   When the ATREPM bit is set to 1 in a bulk IN transfer pipe, this module continues to send Zero-Length packets. To change response mode from normal mode to null auto-response mode, specify null auto-response mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). After that, null auto-response mode is enabled. However, specify null auto-response mode while the buffer is empty. Verify this by checking INBUFM = 0. Since INBUFM = 1 indicates that the buffer contains data, clear the buffer by setting the ACLRM bit. Do not write data to the buffer from the FIFO port during setting to null auto-response mode.

To change response mode from null auto-response mode to normal mode, delay the pipe operation disabled state (Response PID = NAK) for a time period for sending a Zero-Length packet (full-speed: 10 μs, high-speed: 3 μs), and then reset null auto-response mode. Normal mode allows writing from the FIFO port, and also allows sending packets to the host by enabling the pipe operation (Response PID = BUF).

61.3.4 FIFO Buffer Memory

(1) Allocating FIFO Buffer Memory

Figure 61.9 shows an example of the FIFO buffer memory map of this module. The FIFO buffer memory is an area shared by the CPU and this module. There are two FIFO buffer memory states where the access right is given to the system (CPU) or to this module (SIE).

The FIFO buffer memory provides independent areas for each pipe. A memory area is set with the block start number and the number of blocks (BUFNMB and BUFSIZE bits in PIPEBUF) in 64-byte units as one block.

When continuous transfer mode is selected by the CNTMD bit in PIPEnCFG, be sure to set the BUFSIZE bits to a value in integral multiples of the maximum packet size. When double buffer is selected by the DBLB bit in PIPEnCFG, two sides of the memory area specified by the BUFSIZE bits in PIPEBUF are provided for the same pipe.

Furthermore, three FIFO ports are used for accesses (data read/write) to the buffer memory. The number of a pipe to be allocated to the FIFO ports is specified by the CURPIPE bits in CFIFOSEL and DnFIFOSEL.

The buffer status of each pipe can be monitored by the BSTS and INBUFM bits in DCPCTR and PIPEnCTR. The access right to the FIFO ports can be checked by the FRDY bit in CFIFOCTR and DnFIFOCTR.

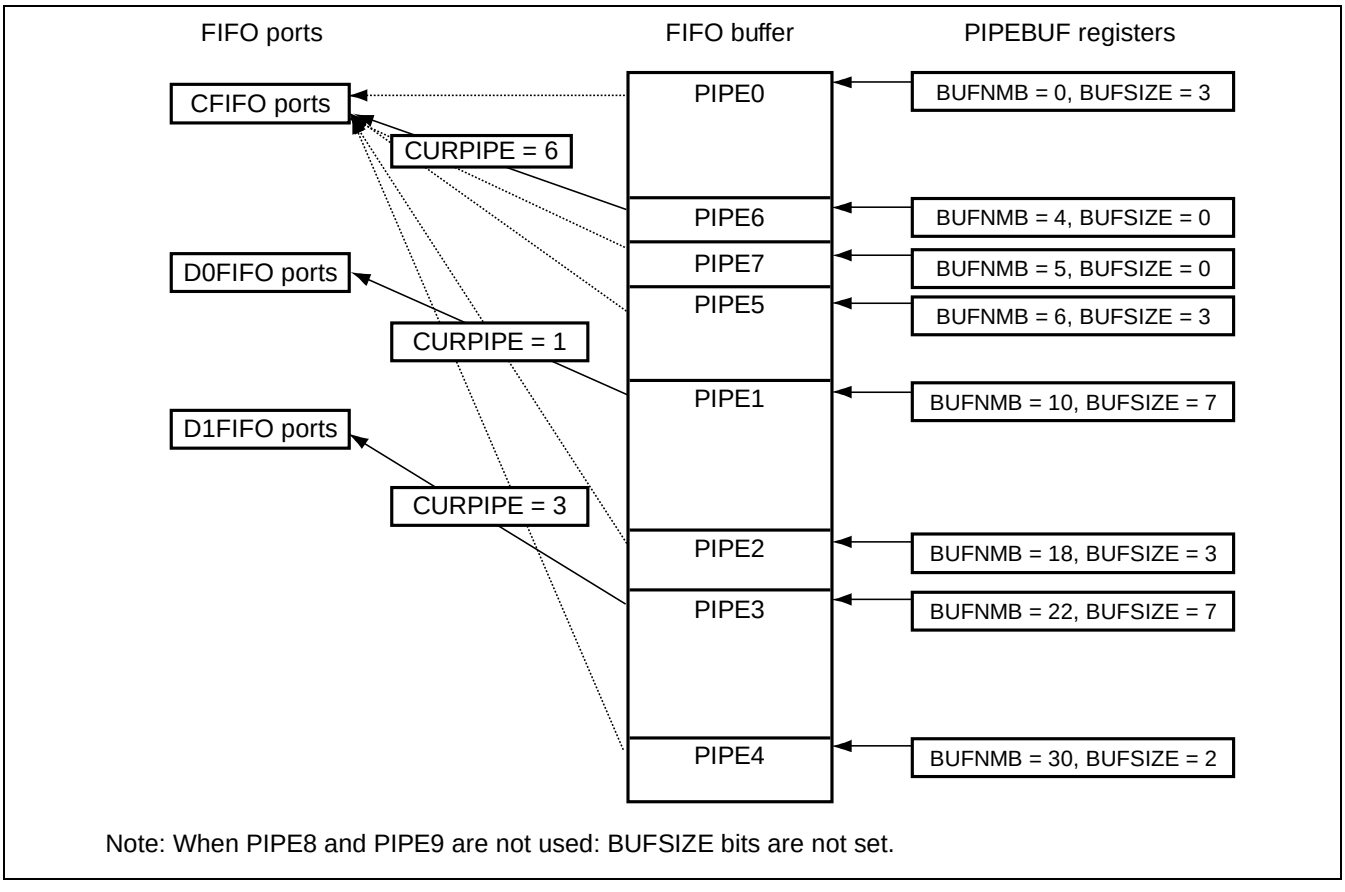

Figure 61.9 Example of Buffer Memory Map

- Buffer status

  Tables 61.16 and 61.17 show the buffer memory status of this module. The buffer memory status can be monitored by the BSTS bit in DCPCTR and the INBUFM bit in PIPEnCTR. The buffer memory access direction is specified by the DIR bit in PIPEnCFG or the ISEL bit in CFIFOSEL (when DCP is selected).

  The INBUFM bit is valid only for pipes 1 to 5, 9 to F in the transmit direction.

  When a transfer pipe in the transmit direction is set to double buffer, the BSTS bit is used to monitor the buffer status on the CPU side, and the INBUFM bit is used to monitor the buffer status on the SIE side. When data write to the FIFO port by the CPU (DMAC) takes time and buffer empty cannot be checked by the BEMP interrupt, the INBUFM bit is available to check completion of transmission.

Table 61.16 Buffer Memory Status That Varies Depending on the BSTS Bit

ISEL or DIR	BSTS	Buffer Memory Status
0 (receive direction)	0	No receive data in the buffer memory or data is being received. Data cannot be read from the FIFO port.
0 (receive direction)	1	Receive data in the buffer memory or a Zero-Length packet is received. Data can be read from the FIFO port. However, the buffer must be cleared because the FIFO port cannot be read when this module receives a Zero-Length packet.
1 (transmit direction)	0	Transmission of data is not completed. Data cannot be written to the FIFO port.
1 (transmit direction)	1	Transmission of data is completed. The CPU can write data to the buffer memory.

Table 61.17 Buffer Memory Status That Varies Depending on the INBUFM Bit

DIR	INBUFM	Buffer Memory Status
0 (receive direction)	Invalid	Invalid
1 (transmit direction)	0	Transmittable data is completely sent. No transmittable data is in the buffer memory.
1 (transmit direction)	1	Transmittable data is written from the FIFO port. The buffer memory contains transmittable data.

- FIFO buffer clear

  Table 61.18 shows clearing of the FIFO buffer memory of this module. The buffer memory can be cleared by the BCLR, DCLRM, and ACLRM bits.

Table 61.18 Buffer Clear

Bit Name	BCLR	DCLRM	ACLRM
Register	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Function	Clears the buffer memory of the CPU.	Automatically clears the buffer memory after reading data of the specified pipe.	Automatically clears the buffer memory by ignoring all received packets.
Clearing method	Writing 1 to this bit clears the buffer memory.	1: This mode is enabled. 0: This mode is disabled.	1: This mode is enabled. 0: This mode is disabled.

- Buffer area

  Table 61.19 shows a buffer memory map of this module. The buffer memory includes a dedicated areas reserved beforehand for pipes and user areas provided for user settings.

  The buffer for DCP is a dedicated area commonly used in control read transfers and control write transfers.

  Areas for pipes 6 to 8are allocated respectively in advance. However, when none of pipes 6 to 9 is used, the areas are available for pipes 1 to 5, 9 to F as user areas.

  Allocate different areas of the buffer memory to each pipe. Note that, when double buffer is specified, the size of an area is twice of the set value.

  Do not set the buffer size to a value smaller than the maximum packet size.

Table 61.19 Buffer Memory Map

Buffer Memory Number	Buffer Size	Pipe Setting	Remarks
H'0	64 bytes	Fixed only for DCP	Single buffer
H'1 to H'3	—	Unavailable	—
H'4	64 bytes	Fixed only for pipe 6	Single buffer
H'5	64 bytes	Fixed only for pipe 7	Single buffer
H'6	64 bytes	Fixed only for pipe 8	Single buffer
H'7 to H'7F	Max. 7616 bytes	User area for pipes 1 to 5, 9 to F	Double buffer and continuous transfer can be set

- Buffer auto-clear mode function

  When the ACLRM bit PIPEnCTR is set to 1, this module discards all data packets received. However, when this module receives a data packet successfully, it sends ACK to the host controller. This function is available only for the buffer memory read direction.

  Writing 1 and then 0 continuously to the ACLRM bit clears the buffer memory of the selected pipe irrespective of the access direction.

  Take at least 100 ns between writing 1 and writing 0 for the sequence execution time of the hardware.

- Buffer memory specifications (single buffer/double buffer setting)

  Single buffer or double buffer is selectable for pipes 1 to 5, 9 to F with the DBLB bit in PIPEnCFG. Double buffer is a function to provide two sides of the memory area specified by the BUFSIZE bits in PIPEBUF for the same pipe. Figure 61.10 shows an example of setting for the buffer memory of this module.

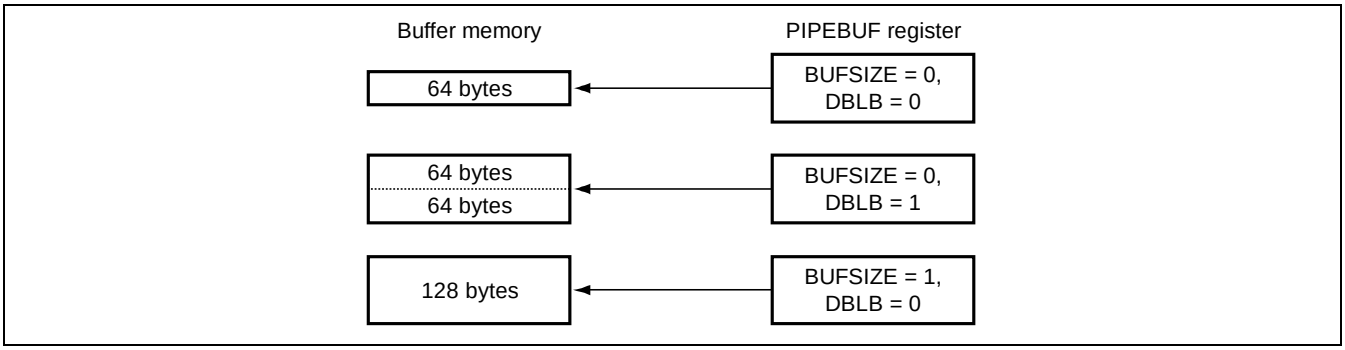

Figure 61.10 Example of Buffer Memory Setting

- Buffer memory operation (continuous transfer setting)

  Continuous transfer mode or discontinuous transfer mode is selectable with the CNTMD bit in PIPEnCFG. This selection is enabled for pipes 1 to 5, 9 to F.

  The continuous transfer mode function allows continuous transmission/reception of multiple transactions. When continuous transfer mode is selected, data up to the buffer size allocated to each pipe can be transferred without outputting an interrupt to the CPU.

  In continuous transmission mode, data in the buffer is divided by the maximum packet size and is then transmitted. To send data less than the buffer size (a short packet or a packet with a size of integral multiples of the maximum packet size and less than the buffer size), set BVAL = 1 after writing transmit data to the buffer.

  In continuous reception mode, no interrupt is generated until this module receives packets to the buffer size, the transaction count ends, or this module receives a short packet.

Table 61.20 shows the relationship between the CNTMD setting and determination of transmission/reception end of the FIFO buffer.

Table 61.20 Relationship between CNTMD Setting and Determination of Transmission/Reception End of FIFO Buffer

Transfer Mode	Determination of Buffer Readable State and Data Transmittable State
Discontinuous transfer (CNTMD = 0)	Conditions for FIFO buffer readable state when data receive direction is selected (DIR = 0): When this module receives one packet
	Conditions for FIFO buffer data transmittable state when data transmit direction is selected (DIR = 1): Any of the following cases: The software (or DMAC) writes data of the maximum packet size to the FIFO buffer. The software (or DMAC) writes data of a short packet (including 0 bytes) to the FIFO buffer, and then sets BVAL = 1.
Continuous transfer (CNTMD = 1)	Conditions for FIFO buffer readable state when data receive direction is selected (DIR = 0): When the bytes of data received in the FIFO buffer for the selected pipe equals the allocated bytes ((BUFSIZE + 1) × 64) When this module receives a short packet other than a Zero-Length packet When this module receives a Zero-Length packet when data is already stored in the FIFO buffer for the selected pipe When this module receives packets as large as the transaction counter value specified for the selected pipe by the software
	Conditions for FIFO buffer data transmittable state when data transmit direction is selected (DIR = 1): Any of the following cases: The volume of data written by the software (or DMAC) equals the size of one side of the FIFO buffer for the selected pipe. The software (or DMAC) writes data less than the size of one side of the FIFO buffer for the selected pipe to the FIFO buffer, and then sets BVAL = 1.

Figure 61.11 shows an example of buffer memory operation of this module.

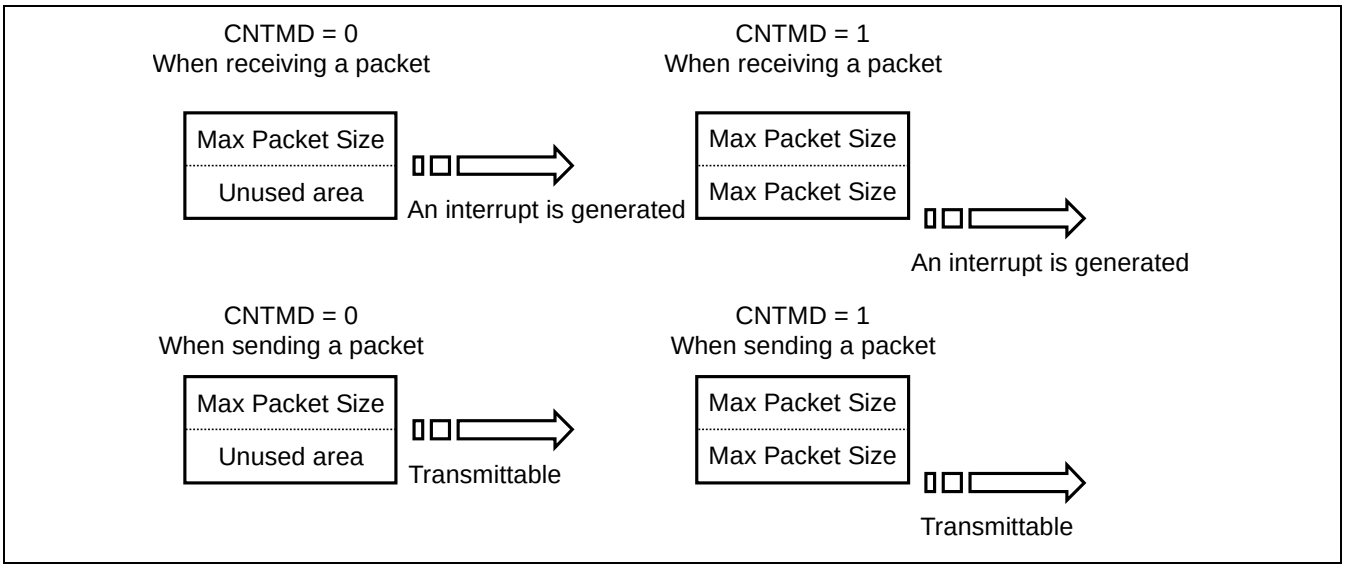

Figure 61.11 Example of Buffer Memory Operation

(2) FIFO Port Function

Table 61.21 lists the settings for the FIFO port functions of this module. During a data write access, when data up to buffer full (or up to the maximum packet size in discontinuous transfer) is written, the FIFO port automatically enters the data transmittable state. To make data less than buffer full (or the maximum packet size in discontinuous transfer) transmittable, set the BVAL bit in CFIFOCTR and DnFIFOCTR to 1 to set write end (DMA transfer: **TEND** signal). For transmission of a Zero-Length packet, clear the buffer using the BCLR bit in these registers and then set the BVAL bit to 1.

During a data read access, when all data is read, the FIFO port automatically enters the new packet receivable state. However, when receiving a Zero-Length packet (DTLN = 0), no data can be read. Therefore, clear the buffer using the BCLR bit in these registers. The receive data length can be checked by the DTLN bits in CFIFOCTR and DnFIFOCTR.

Table 61.21 FIFO Port Function Settings

Register Name	Bit Name	Function	Remarks
CFIFOSEL DnFIFOSEL	RCNT	Selects DTLN read mode.	
	REW	Rewinds the buffer memory (reread/rewrite).	
	DCLRM	Reads and clears receive data of the specified pipe.	DnFIFO only
	DREQE	Enables DMA transfer.	DnFIFO only
	MBW	Specify FIFO port access bit width.	
	BIGEND	Selects FIFO port endian.	
	ISEL	Selects FIFO port access direction.	DCP only
	CURPIPE	Select the current pipe.	
CFIFOCTR DnFIFOCTR	BVAL	Specifies buffer memory write end.	
	BCLR	Clears the buffer memory of the CPU.	
	DTLN	Check receive data length.	

(a) FIFO Port Selection

Table 61.22 shows pipes that can be selected in each FIFO port. Select a pipe to be accessed by the CURPIPE bits in CFIFOSEL and DnFIFOSEL. After selecting a pipe, confirm that the set CURPIPE value is read correctly, check FRDY = 1, and then make an access to the FIFO port. (If the previous pipe number is read, this controller is changing a pipe.)

Also select the bus width to be accessed by the MBW bits. The buffer memory access direction is specified by the DIR bit in PIPEnCFG. However, only the access direction of DCP is determined by the ISEL bit.

Table 61.22 FIFO Port Access

Pipe	Access	Available port
DCP	CPU access	CFIFO port register
Pipes 1 to F	CPU access	CFIFO port register
	DMA access	D0FIFO, D1FIFO, D2FIFO and D3FIFO port

(b) REW Bit

The current access to a pipe can be suspended temporarily, and it is also possible to make an access to another pipe to continue the ongoing pipe processing. This processing is allowed by using the REW bit in CFIFOSEL and DnFIFOSEL.

When the REW bit is set to 1 together with the CURPIPE bits in CFIFOSEL and DnFIFOSEL and a pipe is selected, the reading or writing pointer of the buffer memory is reset, which allows reading or writing data from the first byte. Furthermore, when a pipe is selected with the REW bit set to 0, data can be read or written following the data at the previous selection without resetting the reading or writing pointer of the buffer memory.

To make accesses to the FIFO port, select a pipe and check FRDY = 1.

(3) DMA Transfer (Dedicated DMA Interface)

(a) Overview of DMA Transfer

The FIFO port can be accessed by the DMAC for pipes 1 to F When the buffer of a pipe specified for DMA transfer becomes accessible, this module outputs a DMA transfer request.

Specify the data transfer unit to the FIFO port by the MBW bits in DnFIFOSEL, and select a pipe used for DMA transfer by the CURPIPE bits in DnFIFOSEL. Do not change the selected pipe during a DMA transfer.

(b) DMA Transfer End Auto-Recognition

This module can terminate writing of data by DMA transfer to the FIFO buffer by controlling the DMA transfer end signal input. After sampling the transfer end signal, this module drives the buffer memory into the transmittable state (same state as BVAL = 1).

(c) DnFIFO Auto-Clear Mode (D0FIFO, D1FIFO, D2FIFO and D3FIFO Port Read Direction)

By setting the DCLRM bit in DnFIFOSEL to 1, this module automatically clears the buffer memory for the selected pipe upon completion of data read from the buffer memory.

Table 61.23 shows the relationship between packet reception and buffer memory clear by the software. As shown in the table, buffer clearing conditions vary with the BFRE setting. However, in any state that needs clearing, using the DCLRM bit makes buffer clearing by the software unnecessary. Thus DMA transfer is enabled without requiring any software control.

- This function is available only for the buffer memory read direction.

Table 61.23 Relationship between Packet Reception and Buffer Memory Clear by the Software

Buffer Status When Receiving a Packet	Register Setting			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	Clearing not required	Clearing not required	Clearing not required	Clearing not required
Zero-Length packet reception	Clearing required	Clearing required	Clearing not required	Clearing not required
Normal short packet reception	Clearing not required	Clearing required	Clearing not required	Clearing not required
Transaction count end	Clearing not required	Clearing required	Clearing not required	Clearing not required

61.3.5 Control Transfer (DCP)

The default control pipe (DCP) is used for data transfer in the control transfer data stage. The buffer memory for the DCP is a 64-byte single buffer of a fixed area used for both control read and control write. The buffer memory can be accessed only by the CFIFO ports.

(1) Setup Stage

1. This module always sends ACK in response to a normal setup packet to this module. The following describes the operation of this module in the setup stage.
   When this module receives a new setup packet, this module sets the following bits.
   — The VALID bit in INTSTS0 to 1
   — The PID bits in DCPCTR to NAK
   — The CCPL bit in DCPCTR to 0
2. When this module receives a data packet following a setup packet, this module stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Be sure to process responses to control transfers while VALID = 0. The PID bits cannot be set to BUF when VALID = 1, and therefore the data stage cannot be completed.

With the VALID bit function, this module can suspend the ongoing request processing if this module receives a new USB request during a control transfer, and send a response to the latest request.

This module also determines the direction bit (bit 8 of bmRequestType) of the received USB request and the request data length (wLength), identifies a control read transfer, control write transfer, and control write no-data transfer, and controls stage transitions. For an incorrect sequence, a sequence error of the control transfer stage transition interrupt occurs, and the error is reported to the software. For the stage control of this module, see Figure 61.7.

(2) Data Stage

Transfer data in response to the received USB request using the DCP. Before making an access to the DCP buffer memory, specify the access direction by the ISEL bit in CFIFOSEL.

When the transfer data size is larger than the DCP buffer memory size, use a BRDY interrupt for control write transfers and a BEMP interrupt for control read transfers.

In the high-speed control write transfer, this module sends responses using the NYET handshake according to the buffer memory status.

(3) Status Stage

Setting the CCPL bit to 1 with the PID bits in DCPCTR set to BUF finishes a control transfer.

After these settings, this module executes the status stage as follows according to the data transfer direction determined in the setup stage:

- Control read transfer
  This module sends a Zero-Length packet and receives an ACK response from the USB host.
- Control write transfer, no-data control transfer
  This module receives a Zero-Length packet from the USB host and sends an ACK response.

(4) Control Transfer Auto-Response Function

This module automatically responds to a correct SET_ADDRESS request. If any of the following errors occurs in the SET_ADDRESS request, the software must respond to the error.

- Other than control read transfer: bmRequestType ≠ H'00
- Request errors: wIndex ≠ H'00
- Other than no-data control transfer: wLength ≠ H'00
- Request errors: wValue > H'7F
- Control transfer of device state errors: DVSQ = B'011 (configured)

All requests other than SET_ADDRESS require a response made by the software.

61.3.6 Bulk Transfer (Pipes 1 to 5, 9 to F)

The buffer memory usage (single buffer/double buffer setting or continuous/discontinuous transfer mode setting) can be selected for bulk transfers. The buffer memory size can be set to up to 2 Kbytes. This module manages the buffer memory status and automatically responds to a PING packet and an NYET handshake.

(1) NYET Handshake Control

Table 61.24 lists NYET handshake responses of this module. This module sends a NYET response under the following conditions. However, when this module receives a short packet, this module sends ACK instead of NYET. The same is true of the control write transfer data stage.

Table 61.24 NYET Handshake Responses

Setting of PID Bits in DCPCTR	Buffer Memory Status	Token	Response	Remarks
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY1	OUT/PING	ACK	Receives a data packet when receiving an OUT token.
	RCV-BRDY2	OUT	NYET	Receives a data packet. Sends a “reception disable” response.
	RCV-BRDY2	OUT (Short)	ACK	Receives a data packet. Sends a “reception enable” response.
	RCV-BRDY2	PING	ACK	Sends a “reception enable” response.
	RCV-NRDY	OUT/PING	NAK	Sends a “reception disable” response.
	TRN-BRDY	IN	DATA0/1	Sends a data packet.
	TRN-NRDY	IN	NAK	TRN-NRDY

[Legend]
RCV-BRDY1: The buffer memory has available space for two packets or more when receiving an OUT or PING token.
RCV-BRDY2: The buffer memory has available space for only one packet when receiving an OUT token.
RCV-NRDY: The buffer memory is occupied when receiving an PING token.
TRN-BRDY: The buffer memory contains transmit data when receiving an IN token.
TRN-NRDY: The buffer memory contains no transmit data when receiving an IN token.

61.3.7 Interrupt Transfer (Pipes 6 to 8)

This module performs interrupt transfer following the cycles controlled by the host controller. In interrupt transfers, this module ignores PING packets (no response), sends no NYET handshake, and sends ACK, NAK, and STALL responses.

This module does not support the High-Bandwidth interrupt transfer.

61.3.8 Isochronous Transfer (Pipes 1, 2)

This module is provided with the following functions for isochronous transfers.

- Reporting isochronous transfer error information
- Interval counter (IITV bits)
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function (IFIS bit)

This module does not support the isochronous High-Bandwidth transfer.

(1) Isochronous Transfer Error Detection

This module is provided with a function to detect the following error information so that the software can manage isochronous transfer errors. Table 61.25 and 61.26 show the error detection priority of this module and interrupts generated as a result of error detection.

1. PID error
   — When the PID in a receive packet is invalid
2. CRC error, bit stuffing error
   — When a CRC error is found in a receive packet or bit stuffing is invalid
3. Maximum packet size exceeded error
   — When the data size of a receive packet is over the maximum packet size setting
4. Overrun/underrun error
   — When the buffer memory contains no data when this module receives an IN token in the IN direction (transmission) transfer
   — When the buffer memory is occupied when this module receives an OUT token in the OUT direction (reception) transfer
5. Interval error
   This module generates an interval error in the following cases.
   — When no IN token can be received in interval frames in the isochronous IN transfer
   — When this module receives an OUT token other than interval frames in the isochronous OUT transfer

Table 61.25 Error Detection when Receiving Tokens

Priority for Error Detection	Error	Interrupt and Status
1	PID error	This module generates no interrupt (ignores as a damaged packet).
2	CRC error, bit stuffing error	This module generates no interrupt (ignores as a damaged packet).
3	Overrun error, underrun error	This module generates an NRDY interrupt and sets the OVRN bit. This module sends a Zero-Length packet in response to the IN token. This module receives no data packet in response to the OUT token.
4	Interval error	This module generates an NRDY interrupt.

Table 61.266 Error Detection when Receiving Data Packets

Priority for Error Detection	Error	Interrupt and Status
1	PID error	This module generates no interrupt (ignores as a damaged packet).
2	CRC error, bit stuffing error	This module generates an NRDY interrupt and sets the CRCE bit.
3	Maximum packet size exceeded error	This module generates a BEMP interrupt and sets the PID bits to STALL.

(2) DATA-PID

This module does not support the High-Bandwidth transfer. The following lists responses to received PIDs when the function controller function is selected.

1. IN direction
   - DATA0: Sent correctly as the PID of data packet.
   - DATA1: Not sent
   - DATA2: Not sent
   - mDATA: Not sent
2. OUT direction (full-speed operation)
   - DATA0: Received correctly as the PID of a data packet.
   - DATA1: Received correctly as the PID of a data packet.
   - DATA2: The packet is ignored.
   - mDATA: The packet is ignored.
3. OUT direction (high-speed operation)
   - DATA0: Received correctly as the PID of a data packet.
   - DATA1: Received correctly as the PID of a data packet.
   - DATA2: Received correctly as the PID of a data packet.
   - mDATA: Received correctly as the PID of a data packet.

(3) Interval Counter

Intervals for isochronous transfers can be set by the IITV bits in PIPEPERI. The functions shown in Table 61.27 are made available with the interval counter.

Table 61.27 Interval Counter Functions

Transfer Direction	Function	Detection Conditions
IN	Transmit buffer flush	No IN token can be successfully received in the interval frame during the isochronous IN transfer.
OUT	Reporting reception of no token	No OUT token can be successfully received in the interval frame during the isochronous OUT transfer.

Since the interval counter is counted upon receiving an SOF or using the interpolated SOF, the isochronism can be maintained even if the SOF is damaged. The specifiable frame interval is 2^{IITV} frames or 2^{IITV} μ frames.

(a) Counter initialization

This module initializes the interval counter as follows:

- Power-on reset
  The IITV bits are initialized.
- Initializing buffer memory by ACLRM
  The IITV bits are not initialized but the interval counter is initialized. Clearing the ACLRM bit to 0 causes the counter to start counting from the set IITV value.
- USB bus reset.

After the interval counter is initialized, the interval counter starts counting in either of the following cases after a packet is correctly transferred.

1. When this module receives an SOF after sending data in response to the IN token with PID = BUF
2. When this module receives an SOF after receiving the OUT token data with PID = BUF

The interval counter is not initialized under the following conditions.

1. When PID = NAK or STALL
   The interval timer does not stop. Try to execute the transaction in the next interval.
2. USB bus reset and USB suspended
   The IITV bits are not initialized. When this module receives an SOF, the interval counter starts counting from the value before receiving the SOF.

(b) Interval count and transfer control

1. When the selected pipe is Isochronous-OUT transfer pipe
   When this module receives no data packet in (μ) frames at the intervals specified by the IITV bits, this controller generates an NRDY interrupt.
   When this module cannot receive data due to a CRC error in the data packet, FIFO buffer full, or other reasons, this module also generates an NRDY interrupt.
   An NRDY interrupt is generated at the SOF packet receive timing. Even if the SOF packet is damaged, this module generates an NRDY interrupt at the SOF packet receive timing using the internal interpolation function.
   When IITV ≠ 0, however, this module generates an NRDY interrupt at the SOF packet receive timing in each interval after the interval count starts.

When PID = NAK is set by the software after the interval timer is activated, this module generates no NRDY interrupt even when this module receives an SOF packet.

The interval count start conditions vary with the set IITV value.

— When IITV = 0: The interval count starts from the next (μ) frame where the PID bits for the selected pipe is changed to BUF.

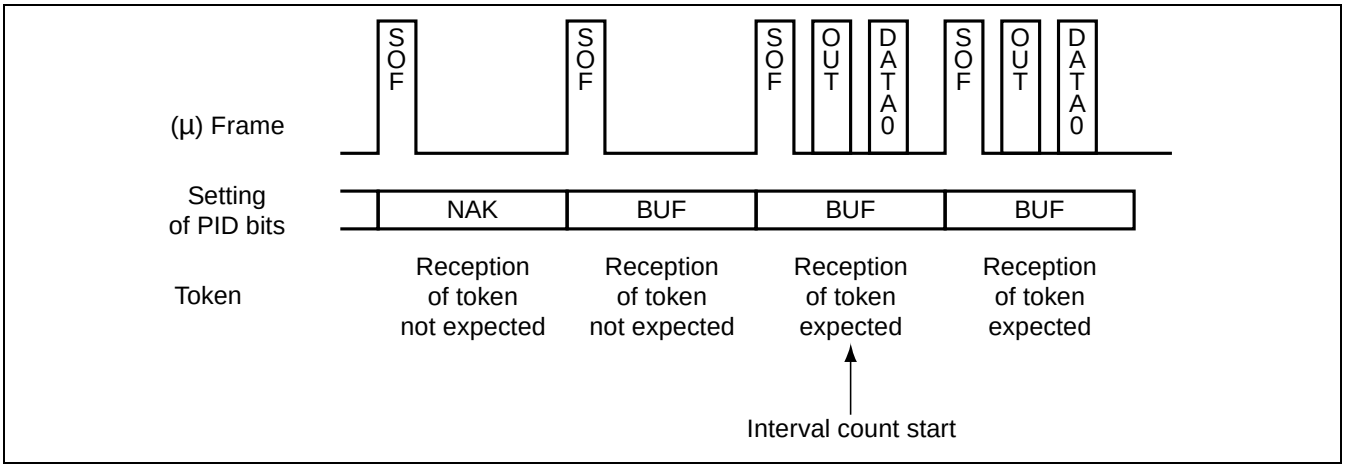

Figure 61.12 (μ) Frames and Expectation of Receiving a Token when IITV = 0

— When IITV ≠ 0: The interval count starts from the time when this module successfully receives the first data packet after the PID bits for the selected pipe is changed to BUF.

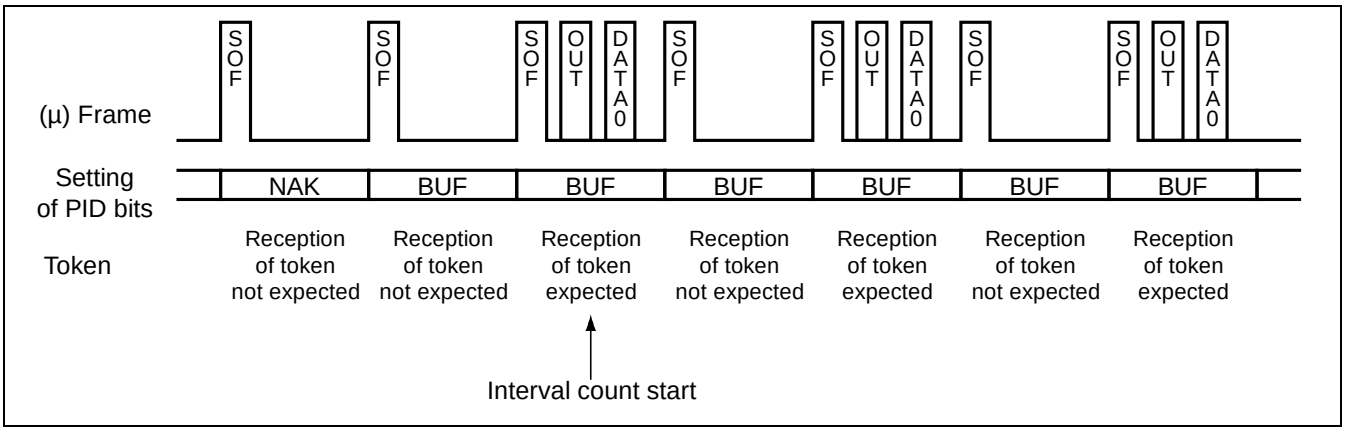

Figure 61.13 (μ) Frames and Expectation of Receiving a Token when IITV ≠ 0

2. When the selected pipe is Isochronous-IN transfer pipe

Use the selected pipe by combining with the setting of IFIS = 1. When IFIS = 0, this module sends data packets in response to received tokens irrespective of the IITV value.

When this module receives no IN-Token in (μ) frames at the intervals specified by the IITV bits with transmittable data stored in the FIFO buffer with IFIS = 1, this module clears the FIFO buffer.

When this module cannot receive data due to a CRC error or another bus error in the IN-Token, this module also clears the FIFO buffer.

The FIFO buffer is cleared at the SOF packet receive timing. Even if the SOF packet is damaged, this module clears the FIFO buffer at the SOF packet receive timing using the internal interpolation function.

The interval count start conditions vary with the set IITV value (same as Isochronous-OUT transfer).

When the function controller function is selected, the interval count start conditions are as follows:

— When this module is reset by the hardware (The set IITV value is also cleared to 0.)

— When ACLRM is set to 1 by the software

— When this module detects a USB reset

(4) Transmit Data Setup in Isochronous Transfer

In isochronous data transmission is selected, this module can send a data packet in the next frame after this module detects an SOF packet after writing data to the buffer. This function is referred to as the isochronous transfer transmit data setup function. With this function, the frame that started data transmission can be identified.

When the buffer memory is used as a double buffer, even if writing data to both buffers is completed, only one side that finished writing earlier becomes transferable. For this reason, even if multiple IN tokens are received in the same frame, only one packet of the buffer memory is sent.

When the buffer memory is ready for transmission in the IN token reception cycle, this module sends data and an ACK response. However, when the buffer memory is not ready for transmission, this module sends a Zero-Length packet and generates an underrun error.

Figure 61.14 shows an example of transmission using the isochronous transfer transmit data setup function of this module when IITV = 0 (each frame). Transmission of a Zero-Length packet is indicated as hatched “Null” in the figure.

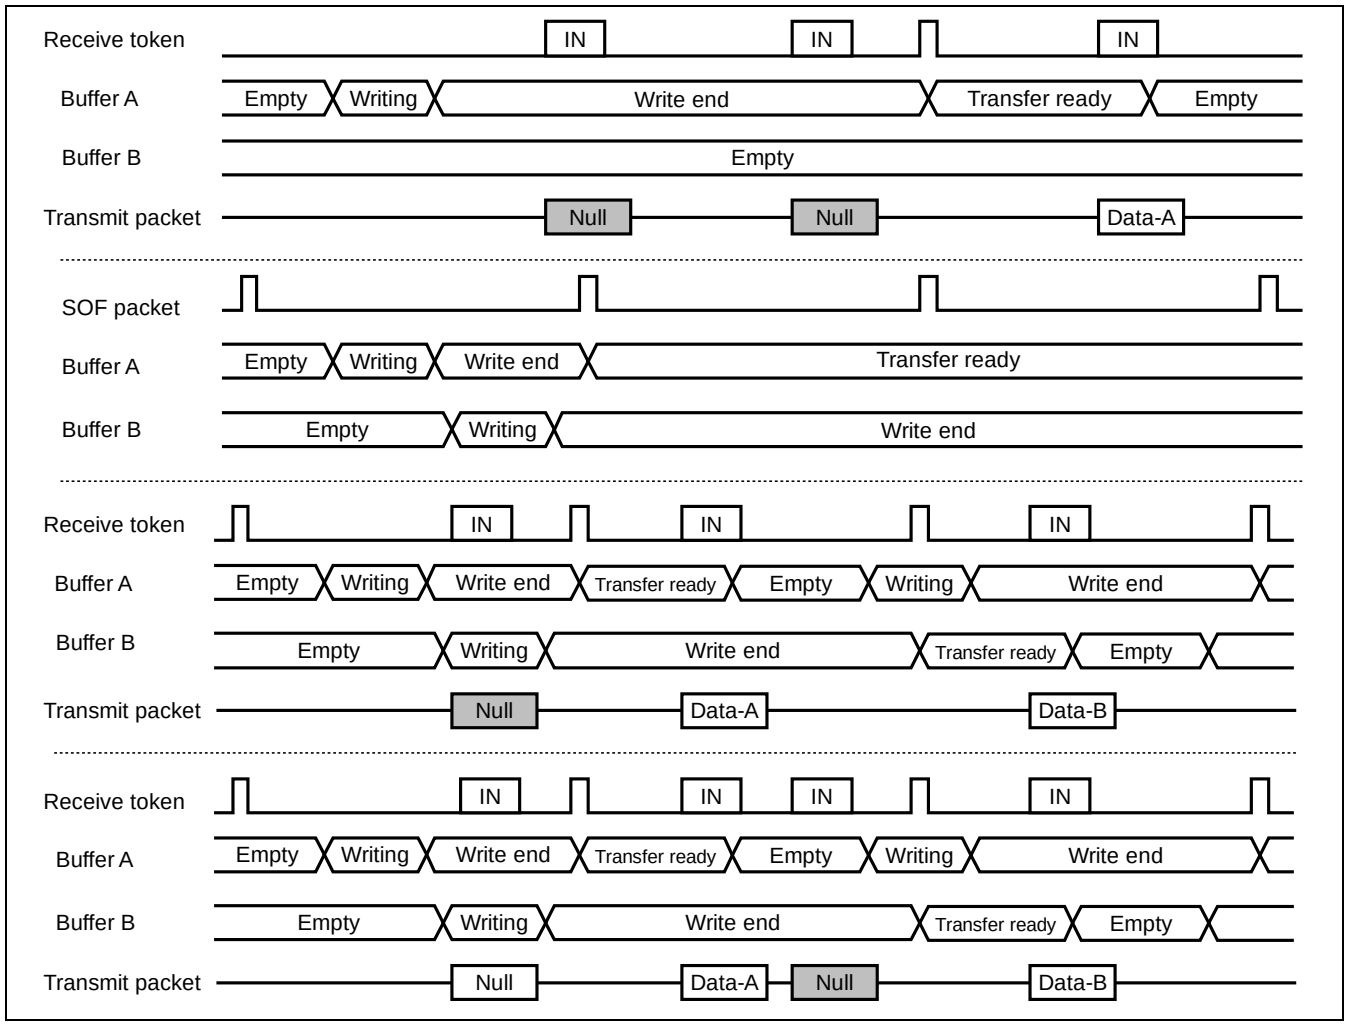

Figure 61.14 Example of Transmit Data Setup Function

(5) Transmit Buffer Flush in Isochronous Transfer

In isochronous data transmission is selected, this module receives no IN token in the interval frame. When this module receives the SOF or μ SOF packet of the next frame, this module regards the IN token as damaged and clears the buffer that is ready for transmission to make it writable.

At this time, when the buffer memory is used as a double buffer and writing data to both buffers is completed, this module regards the discarded buffer memory data as transmitted in the same interval frame, and drives the buffer memory that is not discarded due to the reception of an SOF or μ SOF packet into the transmission ready state.

The buffer flush function activation timing varies depending on the IITV value.

- When IITV = 0
  This module activates the buffer flush function from the next frame after the pipe is enabled.
- When IITV ≠ 0
  This module activates the buffer flush function from the first normal transaction.

Figure 61.15 shows an example of the buffer flush function of this module. For tokens before the interval frame (outside the specified interval), however, this module sends the data stored in the buffer according to the data setup state or sends a Zero-Length packet as an underrun error.

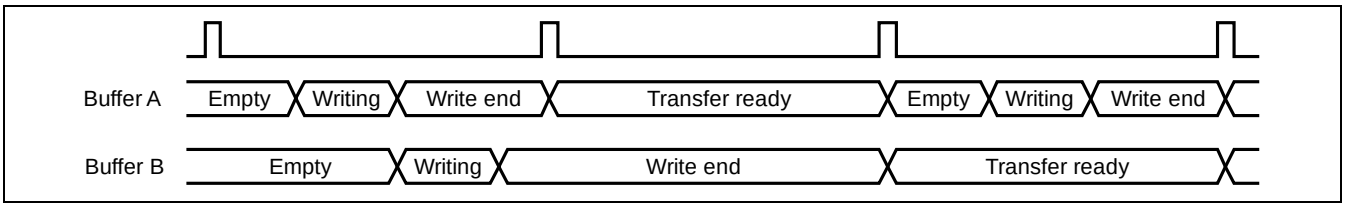

Figure 61.15 Example of Buffer Flush Function

Figure 61.16 shows an example of an interval error of this module. Interval errors are the following five. An interval error occurs at timing [1] in the figure, and the buffer flush function is activated.

When an interval error occurs, the buffer flush function is activated in the IN transfer and an NRDY interrupt occurs in the OUT transfer. Discriminate an NRDY interrupt (including a receive packet error) from an overrun error with the OVRN bit.

This module sends a response to the hatched tokens in the figure according to the buffer memory status.

1. IN direction
   — When the buffer is ready to transmit data, this module sends the data and an ACK response.
   — When the buffer is not ready to transmit data, this module sends a Zero-Length packet and generates an underrun error.
2. OUT direction
   — When the buffer is ready to receive data, this module receives data and sends an ACK response.
   — When the buffer is not ready to receive data, this module discards the data and generates an overrun error.

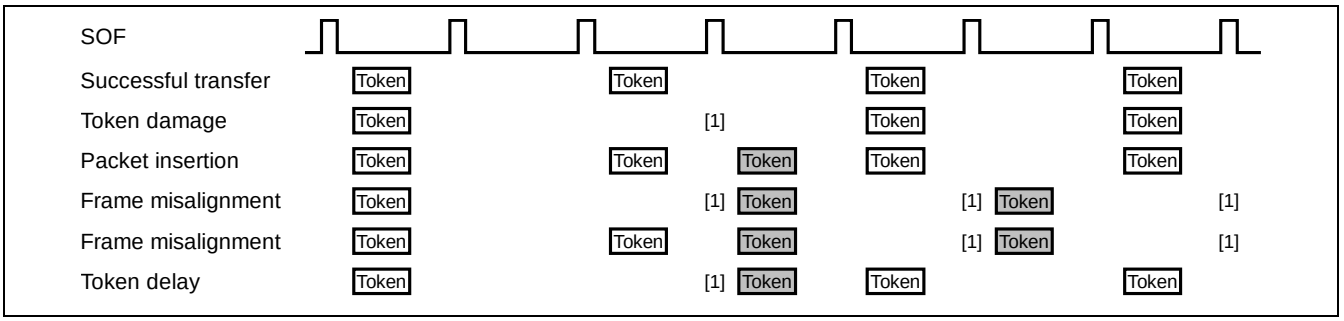

Figure 61.16 Example of Interval Error when IITV = 1

61.3.9 SOF Interpolation Function

In case this module cannot receive SOF packets at intervals of 1 ms (full-speed operation) or 125 μs (high-speed operation) due to damage or missing of SOF packets, this module interpolates the SOF. The SOF interpolation starts functioning when SYSCFG.USBE = 1, LPSTS.SUSPM= 1, and at the SOF packet receive timing. Furthermore, the interpolation function is initialized in the following cases.

- Power-on reset
- USB bus reset
- When the suspended state is detected

The SOF interpolation functions with the following specifications.

- The frame intervals (125 μs or 1 ms) conform to the result of the reset handshake protocol.
- The SOF interpolation does not function until this module receives an SOF packet.
- After receiving the first SOF packet, 125 μs or 1 ms is counted by the internal 48-MHz clock to interpolate the SOF.
- After receiving the second SOF packet or a following packet, the SOF is interpolated using the previous receive intervals.
- The SOF interpolation does not function in the suspended state and during a USB bus reset.
  (When this module enters the suspended state in high-speed operation, the SOF interpolation continues for 3 ms from the final packet.)

This module activates the following functions based on the reception of SOF packets. When one or more SOF packets are lost, normal operation can be continued to perform the SOF interpolation.

- Updating frame numbers and μ frame numbers
- SOFR interrupt timing and μ SOF lock
- SOF pulse output
- Isochronous transfer interval count

When one or more SOF packets are lost in full-speed operation, the FRNM bits in FRMNUM are not updated. When one or more μ SOF packets are lost in high-speed operation, the UFRNM bits in the UFRMNUM are updated. However, when a μ SOF packet with UFRNM = B'000 is lost, the FRNM bits are not updated even if following μ SOF packets with UFRNM ≠ B'000 are successfully received.

61.4 Guidelines for Designing USB2.0 Hi-Speed Boards

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

61.4.1 USB Transmission Line

The USB transmission line indicates the pattern that connects the USB connector and the USB transceiver with built-in this LSI.

The USB2.0 has three communication modes: Hi-Speed, Full-Speed and Low-Speed modes. The transmission speed in the Hi-Speed mode is 480 Mbps. Therefore, the USB transmission line must be designed as a high-frequency circuit. Impedance control is required for the USB transmission line.

- The characteristic impedance required for the USB Hi-Speed transmission line is differential impedance 90 Ω (±15%).
- The pattern width and pattern pitch for impedance control vary depending on the board thickness, material and layer configuration. For details, consult the board manufacturer.
- A maximum delay of 1 ns is allowed from the USB connector to this LSI. Therefore it is recommended that the pattern length from the USB device to the USB connector is less than 50 mm and the difference between the pattern lengths for D+ and D– is less than 2.5 mm for a generic PCB.
- The lower layer of the USB transmission line must be a solid ground plane. The ground must be wider than the USB transmission line by 2 mm or more. The power supply for a solid ground plane is DG33.
- Do not allocate other signal lines near to the USB transmission line. In particular, lines carrying widely fluctuating signals, such as clock and data bus lines, must be assigned far from the USB transmission line. Furthermore, layout of the USB transmission lines must be such that they do not cross with other signal lines.
- Locate the USB transmission line on the same layer without passing it through a through-hole. Do not create stubs.
- Place the USB transmission lines so that they are equally spaced from each other.
- Locate the USB transmission line as far as possible from the oscillator, power supply circuit, and other I/O connectors.
- Try to avoid bending the USB transmission line as far as possible. If it is absolutely necessary to bend it, do not bend it at acute or right angles. Bend it moderately, at not more than 45 degrees, or bend it into an arc.
- It is recommended to guard ring the clock, reset, read, write and chip select signals with grounds.

When a resistance is connected to the USB transmission line, locate it near to the USB transmission line. The connecting wire must be as short as possible.

61.4.2 Power Supply and Ground Pattern

Refer to serial interface PCB design guideline.

61.4.3 Oscillation

- USB clock is supplied by the internal PLL.
- Provide an oscillation circuit near the clock input pin for USB (EXTAL). It is recommended to guard ring EXTAL with a ground.
- When using a crystal resonator, consult its manufacturer to determine the circuit constant.
  Note: RZ/G2E supply 48MHz reference clock from EXTAL/XTAL instead of USB_EXTAL/USB_XTAL.

61.4.4 VBUS

[RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N]

- This HS-USB must not connect directly to the 5V VBUS. The VBUSn pin must be isolated by an 30kΩ±1% external resistor.

[RZ/G2E]

- This HS-USB subsystem cannot connect 5 V signals so that vbus status is informed by OVC signal status.

61.4.5 TXRTUNEn/USB_RREF Pin

- Provide a resistor (hereafter called reference resistor)*[1], between the TXRTUNEn/USB_RREF pin and AVSS, PVSS.

Note: 1. RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N: 200Ω±1%, RZ/G2E : 1.8kΩ ± 1%

- Locate the reference resistor as close as possible to this LSI.
- The RREF pin, the reference resistor, PVSS and AVSS should be wired on wide areas and the shortest length.
- Use a wiring pattern for and only for the reference resistor, PVSS and AVSS. The pattern should be connected to the analog ground. The pattern should be designed avoiding the possibility for common impedance between RREF and other signals.
- To prevent cross talk, very-frequently switched signals such as DP, DM, clocks, and control signals for addresses and data, should not be placed near to the reference resistor, and their patterns should neither get across nor go parallel to the wiring pattern between the reference resistor and the RREF pin.

It is recommended to guard ring the reference resistor and its wiring pattern with ground.

61.5 Battery Charging Control

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

Figure 61.17 shows embedded USB PHY battery charging control. BCCTRL, UGCTRL, and UGSTS provide battery charging control. The embedded USB PHY supports only D+ and D- signals.

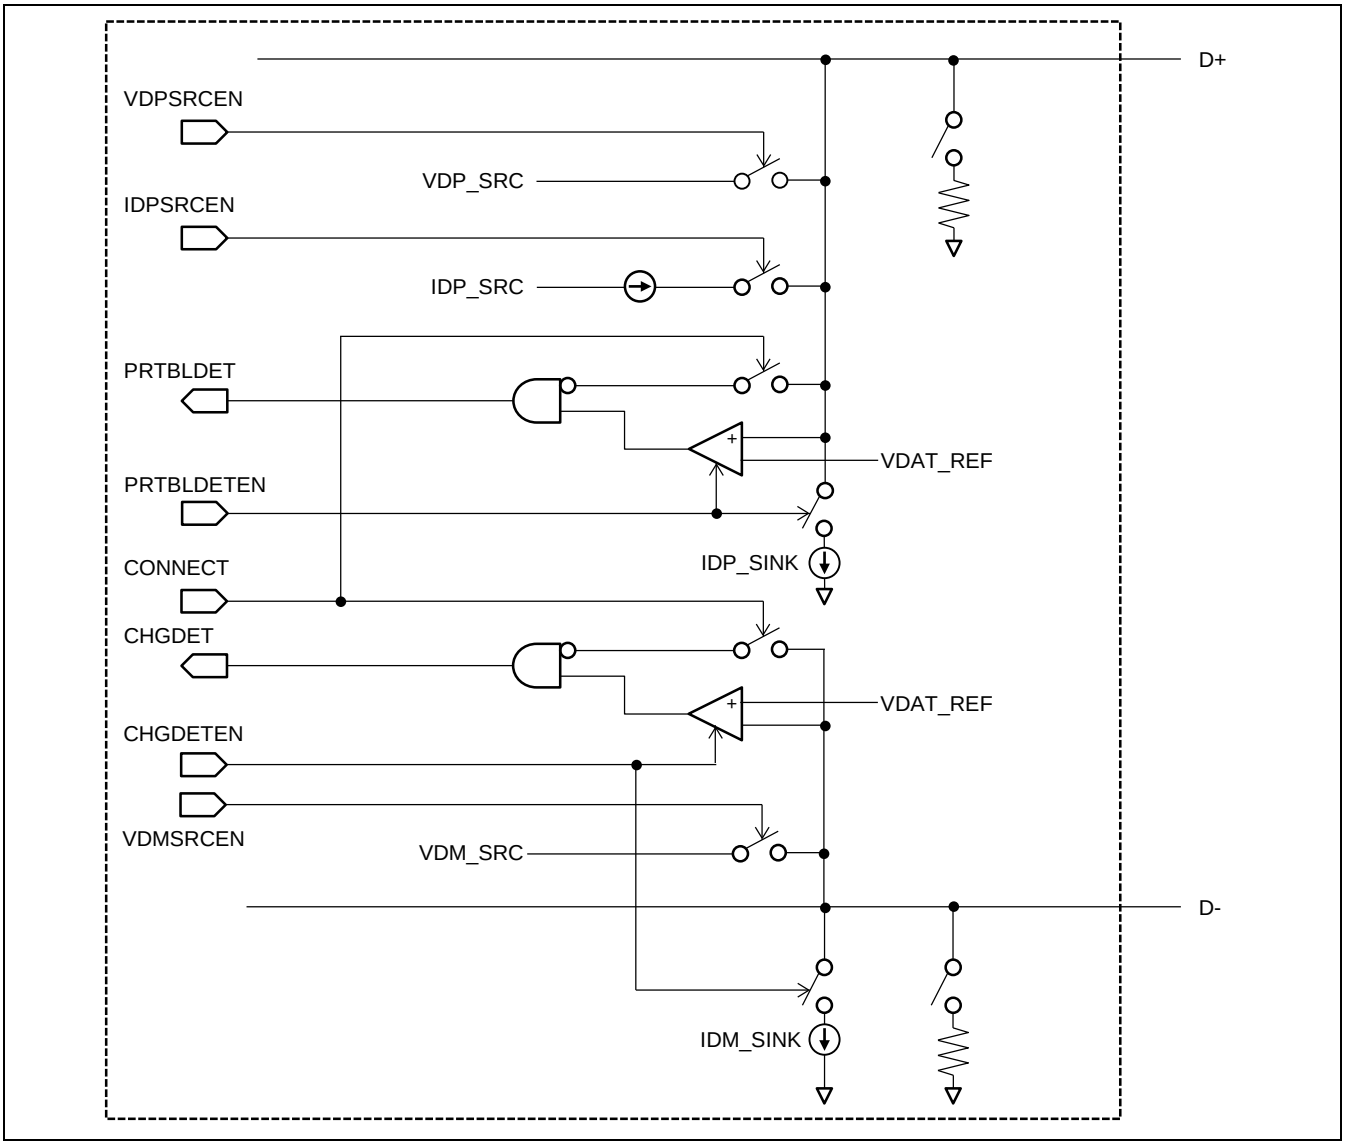

Figure 61.17 Circuit of Battery Charging Control

62. USB High-Speed DMAC (USB-DMAC)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

62.1 Overview

62.1.1 Features

- Three types of clock: S3D1ϕ, S3D2ϕ and HS-USB local bus clock (S3D4ϕ: 66 MHz), which are asynchronously absorbed in the local bus bridge and AXI bus bridge.
- The AXI bus interface functions are implemented.
  The AXI bus interface handles data transfer with the memory and register settings.
- Data communication is performed using the local DMA protocol.
- Supports two channels that can work concurrently.
- Interrupts
  - Setting count end interrupt
  - USB-DMAC is composed of USB-DMAC0 and USB-DMAC1.
  - Transfer end interrupt upon receiving a short packet from the HS-USB
    This function allows generation of an interrupt even in the case where DMA transfer ends after receiving data less than the transfer size set in the DMAC.
  - Timeout interrupt
    A timeout interrupt can be generated after the specified cycles after the last HS-USB transfer request. (This interrupt is used for the timeout when the final packet received is Max packet.)
  - Interrupts can also be generated when a NULL packet is received or an address error is detected.

Table 62.1 Main Functions of This Module

Item	Description
Application	Transfer between HS-USB (FIFO) and AXI bus (4-Gbyte arbitrary space)
Purpose of DMA transfer	High-speed data transfer between HS-USB and AXI bus
DMA transfer end notification to the software	Interrupt signals (transfer count end, HS-USB short packet reception, timeout, etc.)
Transfer space/transfer address direction	4-Gbyte arbitrary space (forward direction) to 4-Gbyte arbitrary space (forward direction)
Maximum transfer count	16,777,216
Transfer unit	8, 16, or 32 bytes
Control signals generated	Address/data read/data write conforming to the HS-USB local bus interface and AXI bus protocols
Number of channels	2 (parallel operation enabled)
Bus specification	AXI bus, local bus (HS-USB local bus)
Clock	AXI bus clock (S3D1ϕ: 266.66 MHz), APB bus clock (S3D2ϕ:133.33 MHz) HS-USB local bus clock (S3D4ϕ: 66 MHz) Note: The restrictions of ratio of the clock S3D1ϕ ≥ S3D2ϕ ≥ S3D4ϕ Do not change the clock frequency during USB-DMAC0 or USB-DMAC1 transferring.
Maximum transfer rate	IN transfer: About 350 Mbps (USB-DMAC0) OUT transfer: About 340 Mbps (USB-DMAC0) IN transfer: About 175 Mbps (USB-DMAC1) OUT transfer: About 170 Mbps (USB-DMAC1)

Table 62.2 Bus Access Type

	Supported Access Type
AXI bus access (USB-DMAC master)	8-byte read/write 16-byte read/write 32-byte read/write
USB-DMAC register setting	4-byte read/write 8-byte read/write

The configuration of this module is shown below.

This module is provided with buffers and bus bridges and controls transfers between the AXI bus and USB High-Speed module (HS-USB).

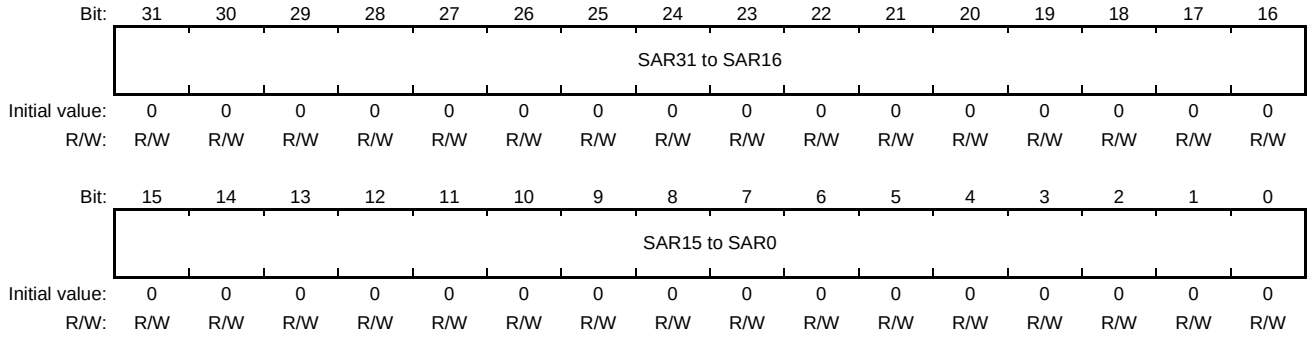
0	TE0	B'0	R	CH0 Transfer End Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (TE in the channel 0 control register is reflected.)

Note: 'n' in Register Name is 0 or 1.

62.2.4 DMAn Source Address Registers 0 and 1 (USBDMAn_SAR_0/1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

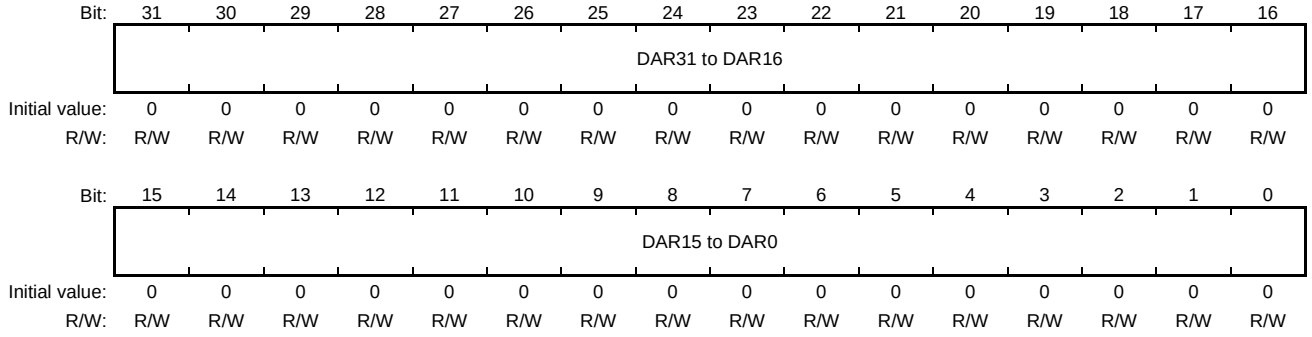


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SAR31 to SAR0	H'0000_0000	R/W	Source Address (H'0000_0000 to H'FFFF_FFFF (4 Gbytes)) Set a value of 8-byte, 16-byte, or 32-byte boundary. Indicate the next transfer source address during a DMA transfer.

Note: 'n' in Register Name is 0 or 1.

62.2.5 DMAn Destination Address Registers 0 and 1 (USBDMAn_DAR_0/1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DAR31 to DAR0	H'0000_0000	R/W	Destination Address (H'0000_0000 to H'FFFF_FFFF (4 Gbytes)) Set a value of 8-byte, 16-byte, or 32-byte boundary. Indicate the next transfer destination address during a DMA transfer.

Note: 'n' in Register Name is 0 or 1.

62.2.6 DMAn Transfer Count Registers 0 and 1 (USBDMAn_TCR_0/1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	TCR23 to TCR16							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCR15 to TCR0															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	TCR23 to TCR0	H'FF_FFFF*	R/W	Transfer Count • When H'00_0001 is set, total transfer volume is as follows: Transfer size = 32 bytes: 32 × 1 bytes Transfer size = 16 bytes: 16 × 1 bytes Transfer size = 8 bytes: 8 × 1 bytes • When H'FF_FFFF is set, 16,777,215 times • When H'00_0000 is set, 16,777,216 times (maximum) • Indicate 0 when a DMA transfer completes successfully.

Note: * To read this register, read the internal transfer counter value (the TCR counter value) directly. This register is read as all 1 after a reset is cleared because the initial value of the TCR counter is all 1 (H'FF_FFFF). When DMA is enabled (DE in USBDMAn_CHCR is asserted), the TCR counter is loaded with the value set in this register and decrements during DMA transfers. This means that the remaining transfer count is read back. Note that the read value may be different from the one set in this register due to this reason.

Note: 'n' in Register Name is 0 or 1.

62.2.7 DMAn Timeout Count Registers 0 and 1 (USBDMAn_TOCNTR_0/1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	TR	BUF	RW	NULL	—	—	—	—	TS1	TS0	IE	TOE	TO	SP	TE	DE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	FTE	B'0	R/W	Forced TE Set Register When a NULL packet is received, the TE bit is forced to 1 to terminate the transfer by setting 1 in this register. (The DREQE bit of the HS-USB should also be controlled accordingly. For details on the control procedure and restrictions, see section 62.3.2 (3), DMA transfer flow.) This bit is always read as 0. 0: No effect (nothing happens). 1: Forces the TE bit to 1.
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	SPIM	B'0	R/W	Short Packet Receive Interrupt Mask Enables or disables the reflection of the short packet (SP) receive flag in the interrupt signal. If this bit is set to 1, no interrupts are generated when an SP is received. However, the SP receive flag (the SP bit) is set regardless of this register setting. 0: The short packet receive interrupt is enabled (default). 1: The short packet receive interrupt is disabled.
19	TRE	B'0	R/W	Transaction End Detect Interrupt Flag Enable Enables or disables the reflection of TR in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the TR bit is always 0.) 0: The TR flag is disabled. 1: The TR flag is enabled.
18	BUFE	B'0	R/W	Buffer End Detect Interrupt Flag Enable Enables or disables the reflection of BUF in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the BUF bit is always 0.) 0: The BUF flag is disabled. 1: The BUF flag is enabled.

Bit	Bit Name	Initial Value	R/W	Description
17	RWE	B'0	R/W	Final Buffer Access Detect Interrupt Flag Enable Enables or disables the reflection of RW in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the RW bit is always 0.) 0: The RW flag is disabled. 1: The RW flag is enabled.
16	NULLE	B'0	R/W	NULL Receive Interrupt Flag Enable Enables or disables the reflection of the NULL receive interrupt flag (NULL) in the interrupt signal. 0: The NULL receive interrupt flag is disabled. 1: The NULL receive interrupt flag is enabled.
15	TR	B'0	R/W*	Transaction End Detect Interrupt Flag When the transaction end is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A transaction end receive interrupt is generated.
14	BUF	B'0	R/W*	Buffer End Detect Interrupt Flag When the end of the buffer is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A buffer end detect interrupt is generated.
13	RW	B'0	R/W*	Final Buffer Access Detect Interrupt Flag When the final access to the buffer is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A final buffer access detect interrupt is generated.
12	NULL	B'0	R/W*	NULL Receive Interrupt Flag When NULL packet is received, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A NULL packet receive interrupt is generated.
11 to 8	—	All 0	R	Reserved The bits should always be written as 0.
7, 6	TS1 to TS0	B'00	R/W	DMA Transfer Size B'00: 8 bytes B'01: 16 bytes B'10: 32 bytes B'11: Setting prohibited Specify the same transfer size and address boundary when setting addresses in USBDMAn_SAR and USBDMAn_DAR as a transfer source and transfer destination. If TS = 11 is set, an address error is generated and DMA transfer is disabled.

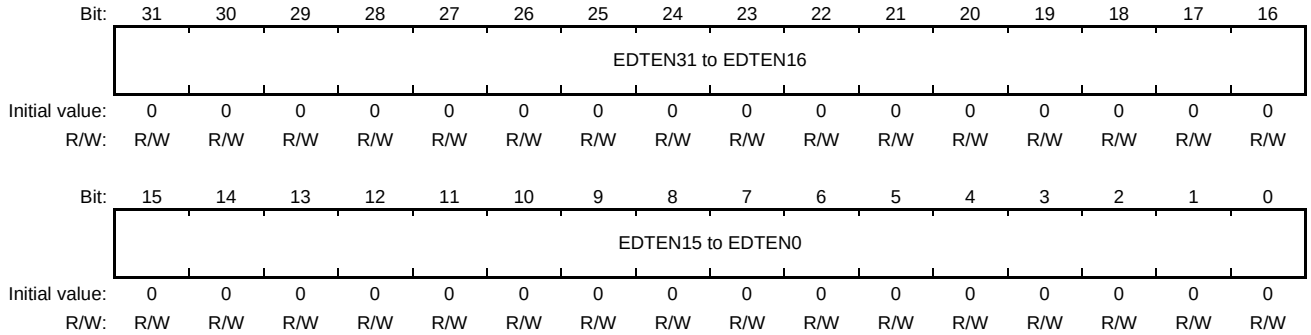
Bit	Bit Name	Initial Value	R/W	Description
5	IE	B'0	R/W	Interrupt Enable Enables or disables an interrupt request to the CPU when DMA transfer ends. When AE, TE, SP, TO, NULL, RW, BUF, or TR bit is set with this bit set to 1, an interrupt request is output to the CPU. However, when the TRE, BUFE, RWE, NULLE, or TOE bit is set to disabled, no interrupt due to TR, BUF, RW, NULL, or TO is generated. 0: An interrupt request is disabled. 1: An interrupt request is enabled.
4	TOE	B'0	R/W	Timeout Enable Enables or disables the reflection of the timeout flag (TO) in the interrupt. 0: Timeout flag is disabled. 1: Timeout flag is enabled.
3	TO	B'0	R/W*	Timeout Flag After a transfer request REQ is negated, a timeout interrupt is generated after the specified cycles. (Used for timeout when the final packet is Max packet.) 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: Timeout is generated.
2	SP	B'0	R/W*	Short Packet Receive Flag A transfer end interrupt is generated upon receiving a short packet from the HS-USB. For example, if DMA transfer size is set to 1 MB but actual data transfer is 900 KB, this interrupt is generated when transfer of 900 KB finishes. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A short packet is received.
1	TE	B'0	R/W*	Transfer End Flag When a DMA transfer ends with USBDMAn_TCR = 0, the TE bit is set to 1. When a DMA address error occurs before USBDMAn_TCR is cleared to 0 and the transfer is suspended by clearing the DE bit and the DME bit in USBDMAn_DMAOR, the TE bit is not set to 1. To clear the TE bit, write 0 after reading 1. When TE = 1, DMA transfer is disabled even if the DE bit is set to 1. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: DMA transfer end (TCR = 0)
0	DE	B'0	R/W	DMA Enable Enables or disables DMA transfer. Setting the DME bit in USBDMAn_DMAOR and the DE bit for the corresponding channel to 1 starts a DMA transfer, provided that all interrupt flags are 0. Clearing the DE bit to 0 suspends the ongoing transfer after the transfer of one transaction is completed. 0: DMA transfer is disabled. 1: DMA transfer is enabled.

Note: * Only writing 0 to clear the flag is enabled.

Notes: 'n' in Register Name is 0 or 1.

62.2.10 DMAn Final Transaction Valid Data Transfer Enable Registers 0 and 1 (USBDMAn_TEND_0/1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	EDTEN31 to EDTEN0	H'0000_0000	R/W	Final Transaction Valid Data Transfer Enable (valid only for IN transfers) Specify valid data size in units of bytes in the final transaction of data transfer (see section 62.3.2, DMA Transfer Function). H'8000_0000: 32 bytes × (n-1) + 1 byte H'C000_0000: 32 bytes × (n-1) + 2 bytes : H'FFFF_FFFF: 32 bytes × (n-1) + 32 bytes Notes: 1. n: Transfer count setting (TCR) 2. For the 8-byte transfer, set EDTEN23 to EDTEN0 to 0. For the 16-byte transfer, set EDTEN15 to EDTEN0 to 0.

Note: 'n' in Register Name is 0 or 1.

62.2.11 DMAn Operation Register (USBDMAn_DMAOR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	—	—	—	—	—	—	—	—	—	TID1 and TID0		RM	PR1 and PR0		AE	DME
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W	R/W	R/W	R/W*	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6, 5	TID1 and TID0	B’00	R/W*	Response Error Channel Identity Information TID1 indicates the channel 1 error information, and TID0 indicates the channel 0 error information. TID1 0: No error 1: Channel 1 response packet error TID0 0: No error 1: Channel 0 response packet error [Setting condition] When a CH0 (1) response error occurs [Clearing condition] Clearing ERR_RCV in USBDMAn_VCR (Channel 0/channel 1 concurrent clear)
4	RM	B’0	R/W	Response Error Mask Mode 0: A response error is output. 1: A response error is masked.
3, 2	PR1 and PR0	B’00	R/W	Priority Mode Specify the priority of channels to execute transactions when transfer requests are made simultaneously in both channel 0 and channel 1 as follows: B’00: Channel 0 > Channel 1 B’01: Channel 1 > Channel 0 B’10: Setting prohibited (If PR = 10 is set, channel 0 > channel 1) B’11: Setting prohibit

Bit	Bit Name	Initial Value	R/W	Description
1	AE	B'0	R/W*	Address Error Flag Indicates that an address error interrupt occurred when setting USBDMAn_SAR or USBDMAn_DAR. This flag is set to 1 when the value of USBDMAn_SAR or USBDMAn_DAR differs from the transfer size (TS) boundary, and when the TS bits are set to 11 (setting prohibited). When the AE bit is set to 1, DMA transfer is not enabled even if the DE bit in DMACHCR and the DME bit in USBDMAn_DMAOR are set to 1. 0: No address error interrupt is generated by the DMAC. [Clearing condition] Setting USBDMAn_SAR and USBDMAn_DAR to values that match the transfer size boundary. 1: An address error interrupt is generated.
0	DME	B'0	R/W	DMA Master Enable Enables or disables DMA transfers for all channels. When the DME bit and the DE bit in USBDMAn_CHCR are set to 1, DMA transfer is enabled, provided that all interrupt flags in USBDMAn_CHCR of the transfer channel are 0. Clearing the DME bit suspends the DMA transfer for all channels. 0: DMA transfer for all channels is disabled. 1: DMA transfer for all channels is enabled.

Note: * Only writing 0 to clear the flag is enabled.

Note: 'n' in Register Name is 0 or 1.

62.3 Operation

RZ/G2N RZ/G2E

62.3.1 Interrupt/Error Detection Function

This section describes the interrupt/error detection function that is implemented in this module.

Table 62.6 lists the mask, source, and flag registers for each interrupt type.

Table 62.6 Registers by Interrupts/Errors

	Interrupt Generation	Interrupt Mask Register	Interrupt Mask Register (Individual Mask)	Source Register	Flag Register
Transfer count end	√	USBDMAn_CHCR_x.IE	—	USBDMAn_DMICR.TEx	USBDMAn_CHCR_x.TE
Short packet receive	√	USBDMAn_CHCR_x.IE	USBDMAn_CHCR_x.SPIM	USBDMAn_DMICR.SPx	USBDMAn_CHCR_x.SP
NULL packet receive	√	USBDMAn_CHCR_x.IE	USBDMAn_CHCR_x.NULLE	USBDMAn_DMICR.NULLx	USBDMAn_CHCR_x.NULL
Timeout	√	USBDMAn_CHCR_x.IE	USBDMAn_CHCR_x.TOE	USBDMAn_DMICR.TOx	USBDMAn_CHCR_x.TO
Transaction end detect	√	USBDMAn_CHCR_x.IE	USBDMAn_CHCR_x.TRE*	USBDMAn_DMICR.TRx	USBDMAn_CHCR_x.TR
Buffer end detect	√	USBDMAn_CHCR_x.IE	USBDMAn_CHCR_x.BUFE*	USBDMAn_DMICR.BUFx	USBDMAn_CHCR_x.BUF
Final buffer access detect	√	USBDMAn_CHCR_x.IE	USBDMAn_CHCR_x.RWE*	USBDMAn_DMICR.RWx	USBDMAn_CHCR_x.RW
Address error	√	USBDMAn_CHCR_x.IE	—	USBDMAn_DMICR.AE	USBDMAn_DMAOR.AE
Response packet error	—	—	—	—	USBDMAn_VCR.ERR_SNT USBDMAn_VCR.ERR_RCV

Note: These registers not only mask interrupt generation but also disable error processing (flag sources and flag clearing).

Note: ‘n’ in Register Name is 0 or 1.

Table 62.7 shows the processing to be executed when different interrupts occur. DMA transfer control is not affected when the NULL packet receive, timeout, or response packet error interrupt occurs. When the transfer count end interrupt occurs, processing is restarted. Processing can be resumed or restarted after interrupts occur from other sources.

Table 62.7 Processing to be Executed When Interrupts Occur (Suspend/Resume/Restart)

	Suspend/Resume	Terminate/Restart	Suspend/Resume/Restart Control Mask Register
Transfer count end	—	√	—
Short packet receive	√	√	—
NULL packet receive	—	√*	—
Timeout	—	√	—
Transaction end detect	√	√	USBDMAn_CHCR_x.TRE
Buffer end detect	√	√	USBDMAn_CHCR_x.BUFE
Final buffer access detect	√	√	USBDMAn_CHCR_x.RWE
Address error	√	√	—
Response packet error	—	—	—

Notes: * When a NULL packet is received, processing is forced to be terminated and restarted by the FTE bit (see section 62.3.2 (3), DMA transfer flow.).
'n' in Register Name is 0 or 1.

The internal circuit is reloaded register values when restarted, but not when resumed.

Table 62.8 lists the interrupt generating conditions.

Table 62.8 Interrupt Generating Conditions

Interrupt Name	Interrupt Conditions
Transfer count end interrupt	When the final data transfer of the specified transfer count (in the USBDMAn_TCR register) completes IN transfer: When the final access to HS-USB completes OUT transfer: When the data transmission to the AXI completes
Short packet receive interrupt	When the data transfer at the time the end of a transaction is detected completes
NULL packet receive interrupt	When a NULL packet is detected or the forced TE register is set
Timeout interrupt	When the specified time elapses after the last transfer request
Transaction end detect interrupt	When the end of a transaction is detected
Buffer end detect interrupt	When the end of the buffer is detected
Final buffer access detect interrupt	When the final access to the buffer is detected
Address error interrupt	When invalid access to the DMAC register is attempted (With invalid USBDMAn_SAR/USBDMAn_DAR values or invalid transfer size (TS) specified)
Response packet error	Error Transmission (ERR_SNT) When accessed by a transaction that is not supported Error Reception (ERR_RCV) When received a response packet error from the system

Note: 'n' in Register Name is 0 or 1.

Figure 62.2 shows a block diagram of the interrupt circuit.

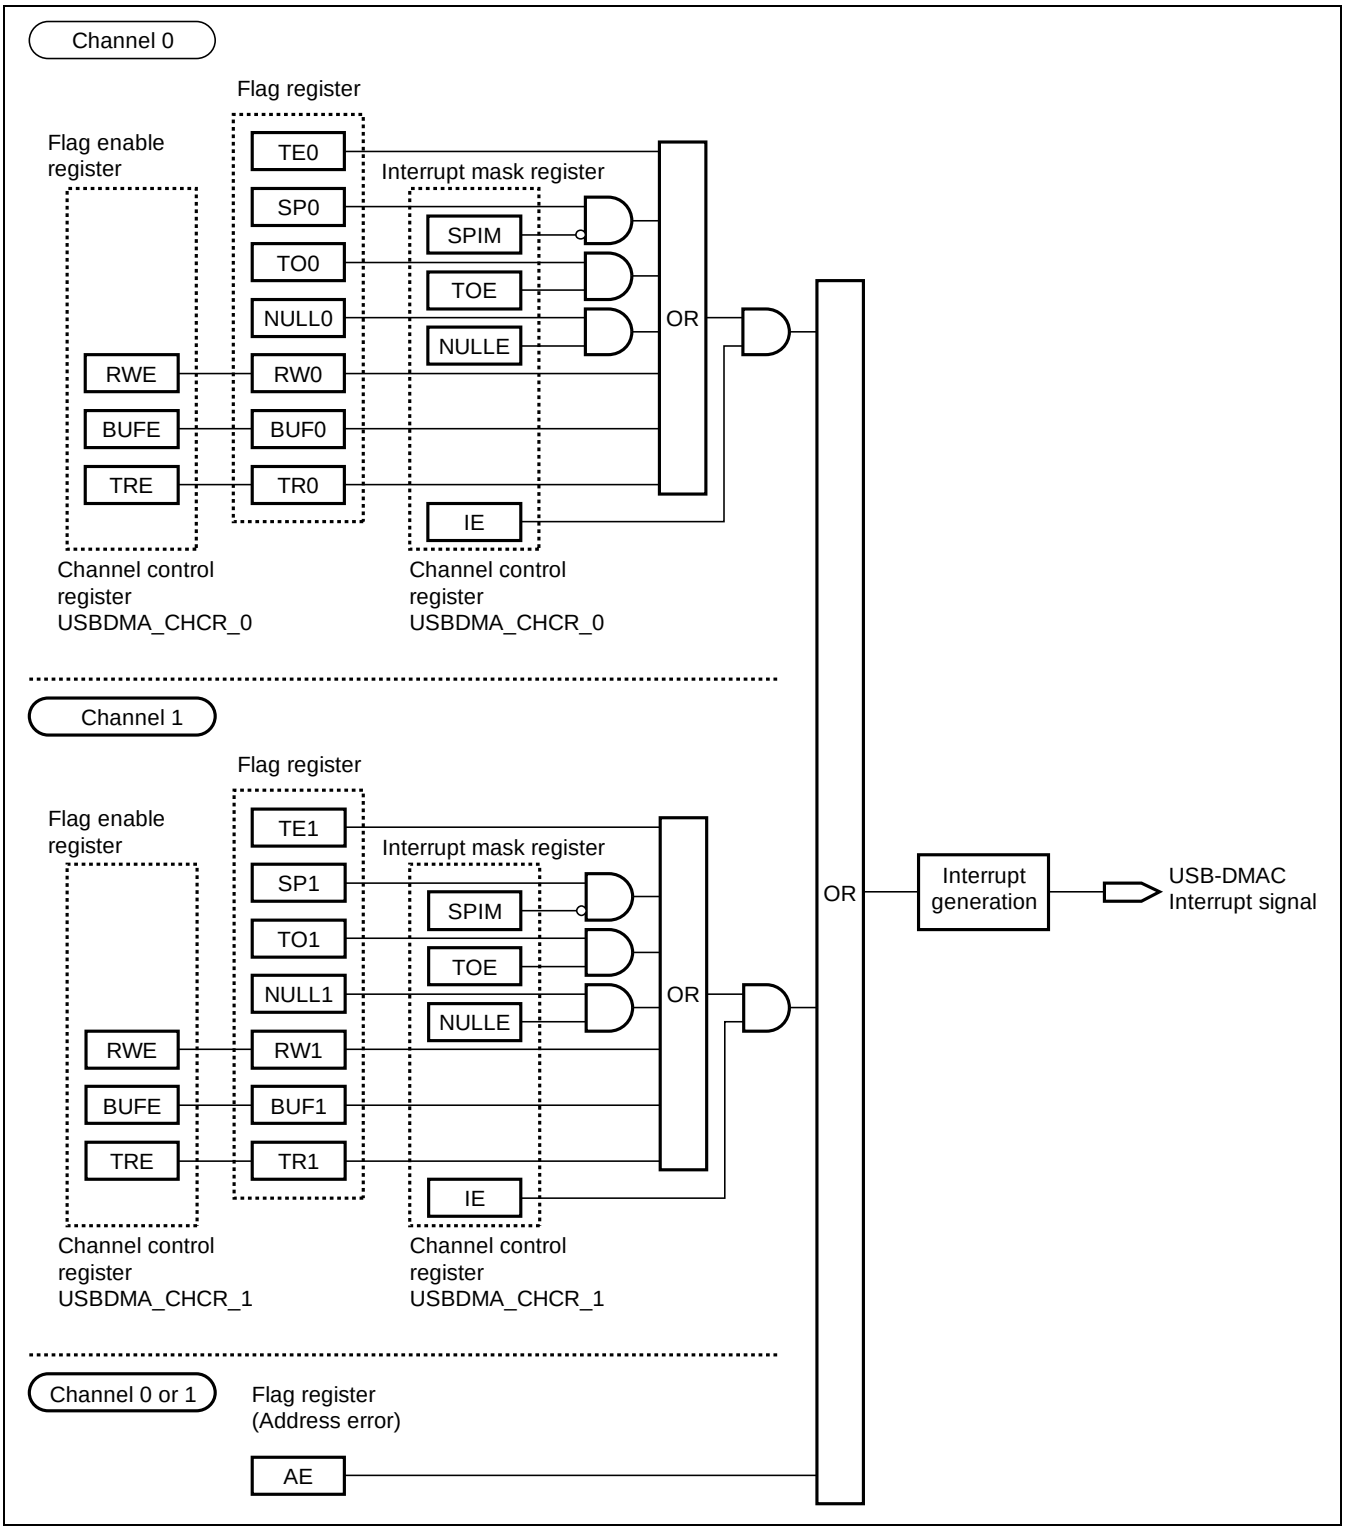

Figure 62.2 Block Diagram of Interrupt Circuit

(1) Transfer count end interrupt (TE flag)

Can be generated when the specified number of transfers complete or the FTE bit in the channel control register (USBDMAn_CHCR_0 to USBDMAn_CHCR_1) is set to 1. When the IE bit in the USBDMAn_CHCR_0 to USBDMAn_CHCR_1 is set to 0, no interrupts are generated. However, the TE bit in USBDMAn_CHCR_0 to USBDMAn_CHCR_1 and the TE0 or TE1 bit in the interrupt source register (USBDMAn_DMICR) are set to 1 regardless of the IE bit setting.

The internal transfer counter is loaded with the value set in the USBDMAn_TCR_x register and decrements based on the AXI clock every time one transaction (8-/16-/32-byte) completes. When the transfer count value reaches 0 (the end of a transfer count), the counter sets the TE (transfer end) flag from 0 to 1 (when the FTE bit is set, it is reflected on the TE flag immediately). The TE bit is cleared by writing 0 to it after reading it as 1 by software.

Note: 'n' in Register Name is 0 , 1.

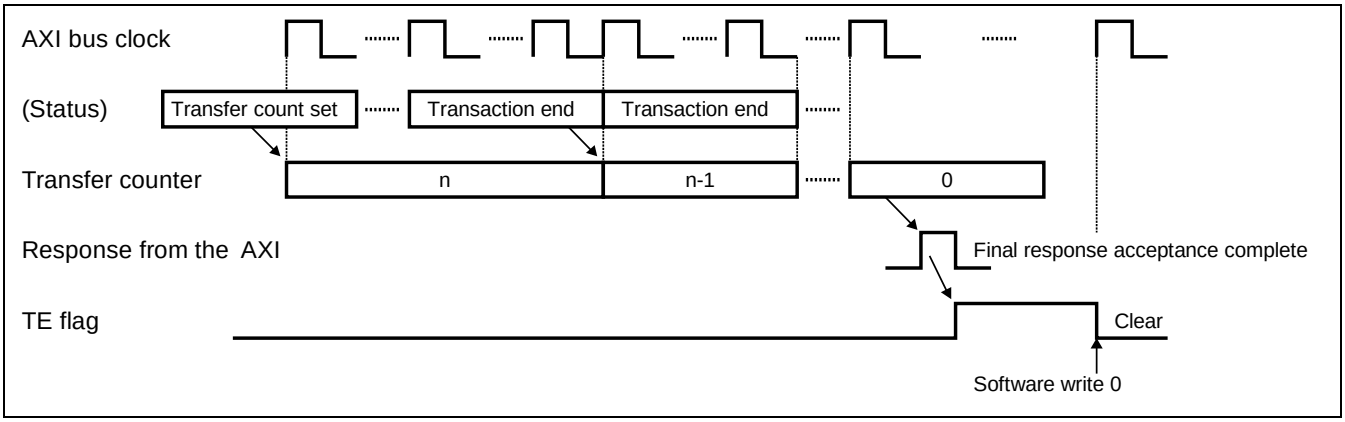

Figure 62.3 Transfer Count End Interrupt (TE) Generation Timing

(2) Short packet receive interrupt (SP flag)

Can be generated when a short packet is detected. When the SPIM bit in the USBDMAn_CHCR_x register is set to 1, no interrupts are generated. However, the SP bit (SP flag) in the USBDMAn_CHCR_x register and the SP0 or SP1 bit in the USBDMAn_DMICR register are set to 1, regardless of the SPIM bit setting. The SP bit is cleared by writing 0 to it after reading it as 1 by software.

Note: 'n' in Register Name is 0 ,1.

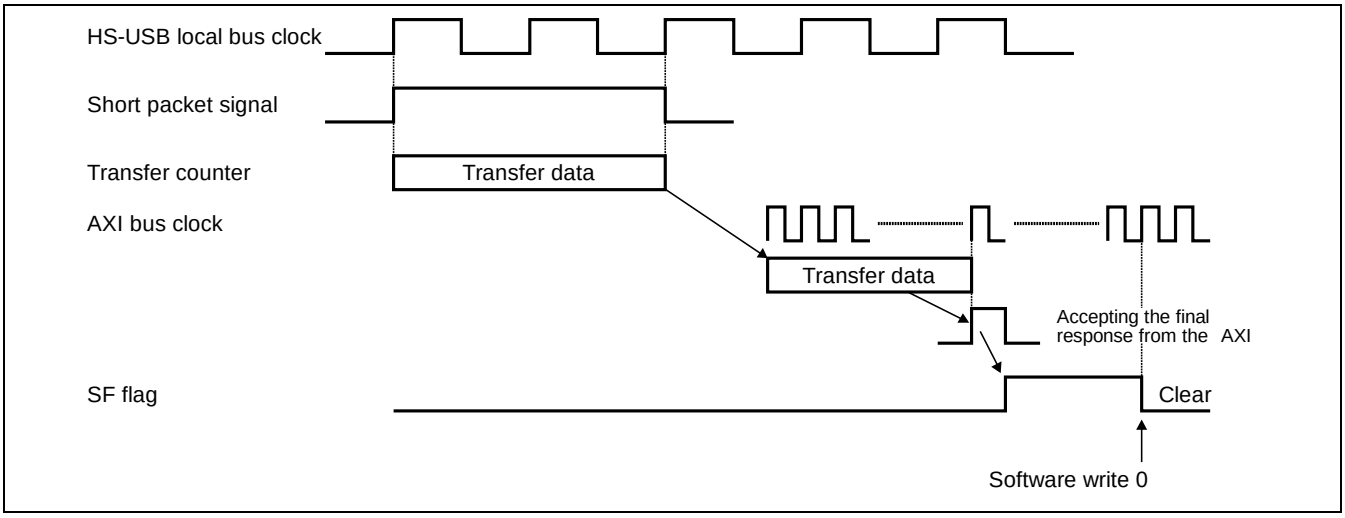

Figure 62.4 Short Packet Receive Interrupt (SP) Generation Timing

(3) NULL packet receive interrupt (NULL flag)

Can be generated when a NULL packet is detected. When the NULLE bit in the USBDMAn_CHCR_x register is set to 0, no interrupts are generated. However, the NULL bit (NULL flag) in the USBDMAn_CHCR_x register and the NULL0 or NULL1 bit in the USBDMAn_DMICR register are set to 1, regardless of the NULLE bit setting. Note also that the DMA transfer control in this module, such as stop, suspend, or resume, is not affected when a NULL packet is received. The software is responsible for implementing special processing if necessary since in this module this interrupt is designed only to signal the software that a NULL packet is received.

Note: 'n' in Register Name is 0 or 1.

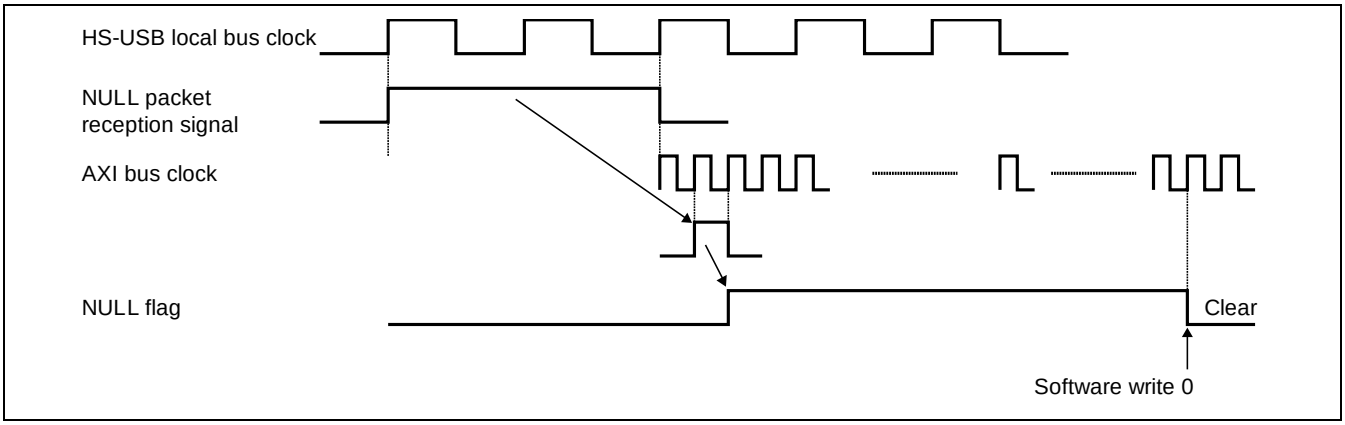

Figure 62.5 NULL Packet Receive Interrupt (NULL) Generation Timing

(4) Timeout interrupt (TO flag)

Can be generated when the time period that is specified in the timeout constant register (USBDMAn_TOCSTR_0 or USBDMAn_TOCSTR_1) elapses after the final transfer request is received from the HS-USB. On detecting the final transfer request, the internal counter is loaded with the value set in the USBDMAn_TOCSTR_x register and starts counting down. When the counter reaches 0, it generates a timeout interrupt. Note that the DMA transfer control in this module, such as stop, suspend, or resume, is not affected when a timeout interrupt occurs. The TO bit is cleared by writing 0 to it after reading it as 1 by software. Figure 62.6 and 62.7 show the timeout interrupt generation timing.

Note: 'n' in Register Name is 0 or 1.

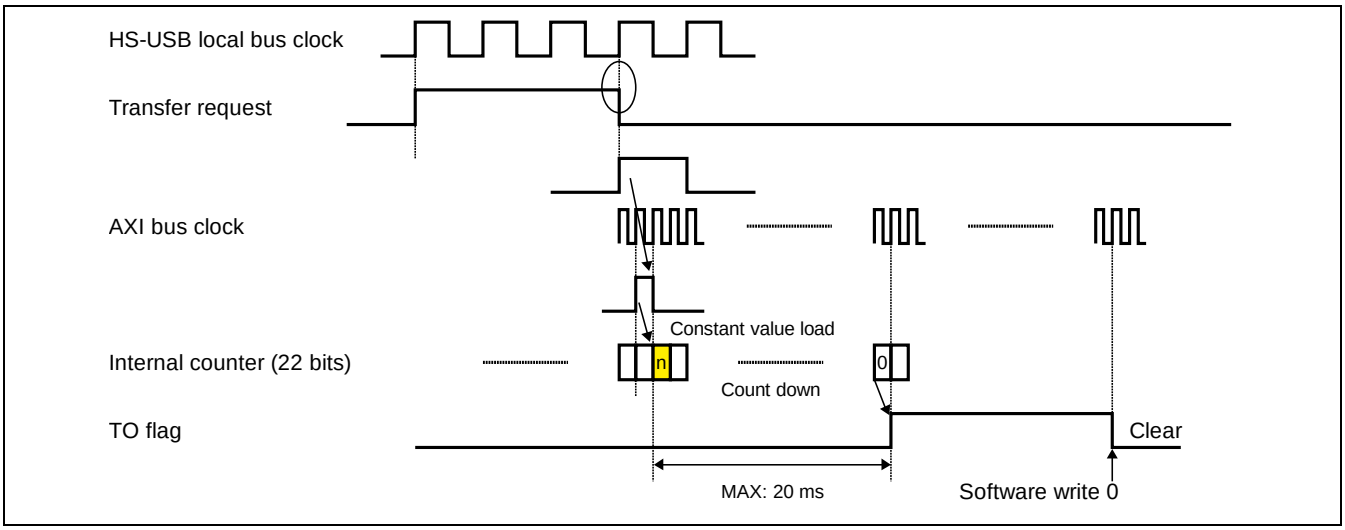

Figure 62.6 Timeout Interrupt (TO) Generation Timing

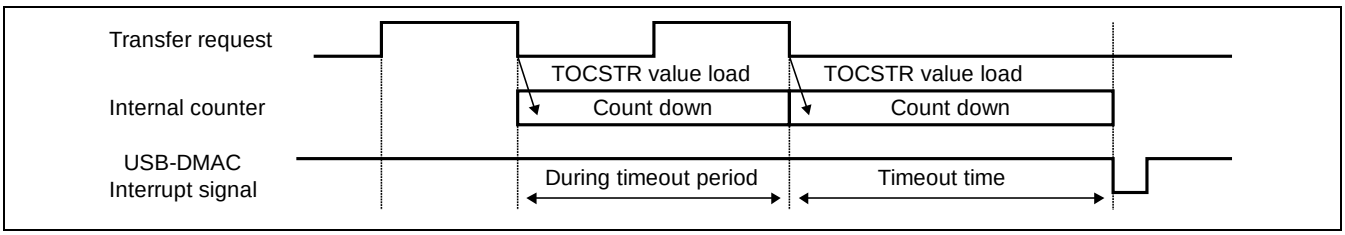

Figure 62.7 Timeout Interrupt Timing

The functions described in section 62.3.1 (5) to 62.3.1 (9) are added to detect and notify the transitions on an individual signal line to the software, but no use is defined. They can be used as required.

(5) Transaction end detect interrupt (TR flag)

Can be generated when the end of a transaction is detected within the HS-USB. Note that the TR bit in the USBDMAn_CHCR_x register and the TR0 or TR1 bit in the USBDMAn_DMICR register are not reflected in the interrupt signal when the TRE bit in the USBDMAn_CHCR_x register is set to 0.

Note: ‘n’ in Register Name is 0 or 1.

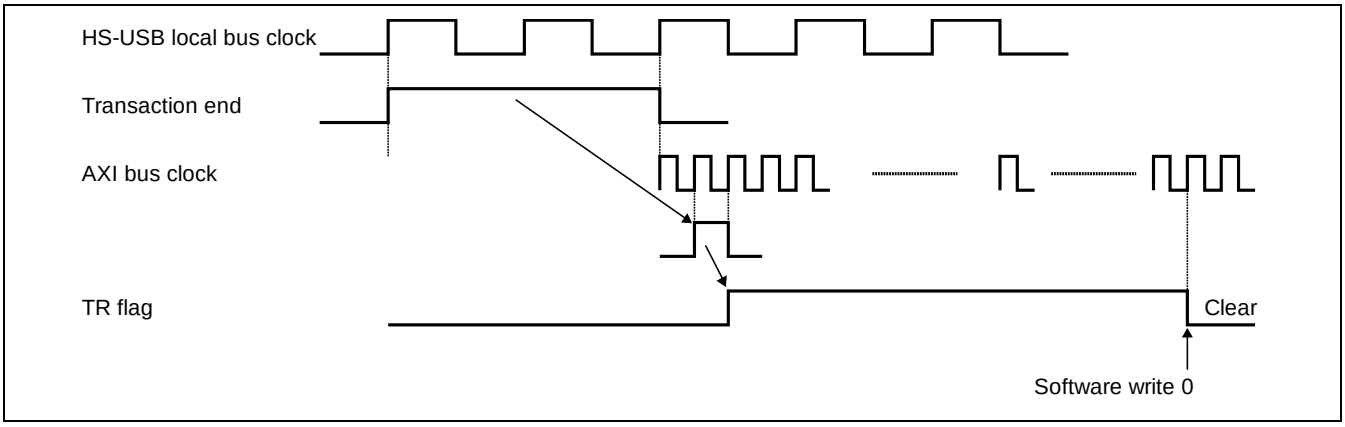

Figure 62.8 Transaction End Detect Interrupt Timing

(6) Buffer end detect interrupt (BUF flag)

Can be generated when the end of the buffer in the HS-USB is detected. Note that the BUF bit in the USBDMAn_CHCR_x register and the BUF0 or BUF1 bit in the USBDMAn_DMICR register are not reflected in the interrupt signal when the BUFE bit in the USBDMAn_CHCR_x register is set to 0.

Note: ‘n’ in Register Name is 0 or 1.

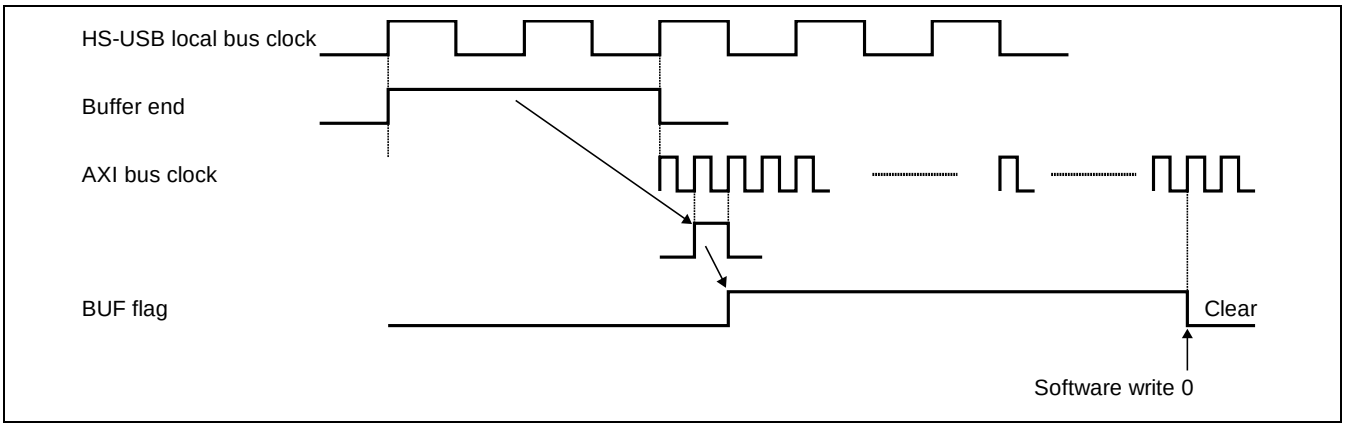

Figure 62.9 Buffer End Detect Interrupt Timing

(7) Final buffer access detect interrupt (RW flag)

Can be generated when the final access to the buffer in the HS-USB is detected. Note that the RW bit in the USBDMAn_CHCR_x register and the RW0 or RW1 bit in the USBDMAn_DMICR register are not reflected in the interrupt signal when the RWE bit in the USBDMAn_CHCR_x register is set to 0.

Note: ‘n’ in Register Name is 0 or 1.

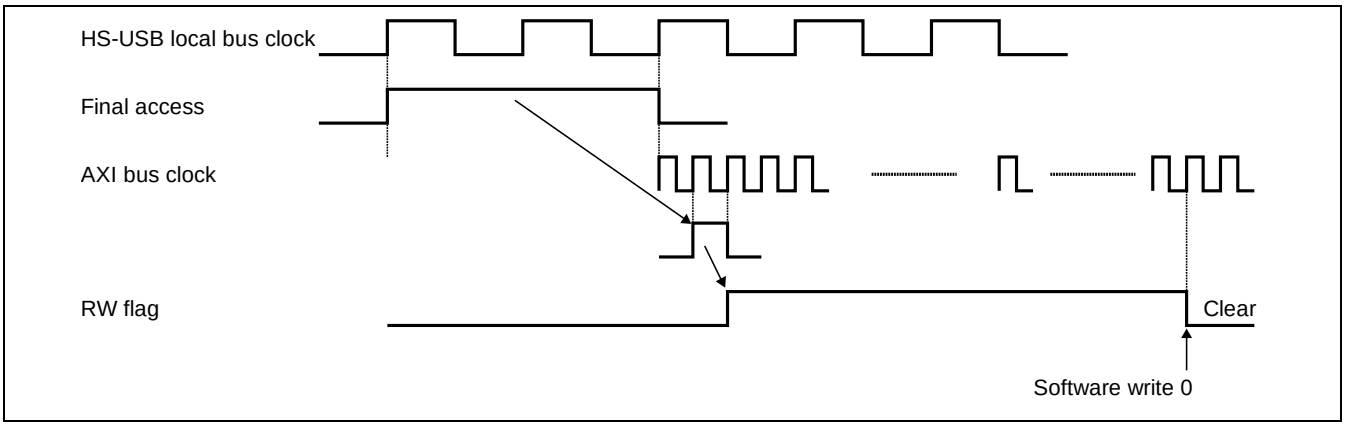

Figure 62.10 Final Buffer Access Detect Interrupt Timing

(8) Address error detection

This is a flag that indicates an address error interrupts has occurred when setting the source address register (USBDMAn_SAR_0 to USBDMAn_SAR_1) and the destination address register (USBDMAn_DAR_0 to USBDMAn_DAR_1). When the value written to the USBDMAn_SAR or USBDMAn_DAR register differs from the transfer size (TS) boundary, and when the TS bits are set to 11 (setting prohibited), the AE bit in the USBDMAn_DMAOR register is set to 1. There is no distinction between CH0 and CH1 for an address error (the AE bit is set to 1 when an address error occurs on CH0 or CH1).

While the AE is set, no DMA transfer is allowed even if the DE bit in the USBDMAn_CHCR_x register and the DME bit in the USBDMAn_DMAOR register are set to 1. The address error interrupt is cleared by setting correct addresses in USBDMAn_SAR_x and USBDMAn_DAR_x.

Note: ‘n’ in Register Name is 0 or 1.

Table 62.9 Address Error Detection Conditions When Setting Transfer Sizes

Transfer Size	Address Error Detection Conditions
TS = B'00 (8-byte transfer)	When data that is not aligned to 8-byte boundaries is written to the USBDMAn_SAR/ USBDMAn_DAR registers (Writes to the USBDMAn_SAR/ USBDMAn_DAR registers are valid.)
TS = B'01 (16-byte transfer)	When data that is not aligned to 16-byte boundaries is written to the USBDMAn_SAR/ USBDMAn_DAR registers (Writes to the USBDMAn_SAR/ USBDMAn_DAR registers are valid.)
TS = B'10 (32-byte transfer)	When data that is not aligned to 32-byte boundaries is written to the USBDMAn_SAR/ USBDMAn_DAR registers (Writes to the USBDMAn_SAR/ USBDMAn_DAR registers are valid.)
—	When B'11 (setting prohibited) is written to the TS bit (Writes to the TS bit are valid.)

Note: ‘n’ in Register Name is 0 or 1.

(9) Response packet error detection

This function reports response packet errors when the interface between the AXI and this module is accessed in ways that are not listed in Table 62.2.

(a) Transmitting response packet errors

When a response packet error occurs during accessing from the AXI to this module, the ERR_SNT bit in the USBDMAn_VCR register is set to 1.* The error signal is also sent to the AXI bus if the RM bit in the USBDMAn_DMAOR register is 0. If the RM bit is set to 1, the error signal is masked (0 is signaled).

Note: * When a response packet error occurs, the ERR_SNT bit is set to 1 regardless of the RM bit setting. The ERR_SNT bit is cleared by writing 0 after reading 1.

Note: 'n' in Register Name is 0 or 1.

Table 62.10 Response Packet Error Generation

USBDMA0_DMAOR (RM bit) Setting	1 (Mask Mode)	0 (Normal Mode)
Response packet error signal notification to AXI	Signals the fixed value (0) to the AXI bus without determining if there is a response packet error.	Reports a response packet error to the AXI bus when it is accessed with a transfer size other than those supported in this module (4-byte read/write and 8-byte read).

(b) Receiving response packet errors

When a response packet error occurs during accessing from this module to the AXI, the ERR_RCV bit in the USBDMAn_VCR register is set to 1. The TID bit in the USBDMAn_DMAOR register indicates on which channel of this module the error has occurred (TID[1] = 1 means it has occurred on CH1 and TID[0] = 1 on CH0).

The ERR_RCV bit is cleared by writing 0 after reading 1.

Note: 'n' in Register Name is 0 or 1.

62.3.2 DMA Transfer Function

(1) Operating mode

The following operating modes (a) to (b) are supported according to the setting of the PR bit in the DMA operation register (USBDMAn_DMAOR).

Note: 'n' in Register Name is 0 or 1.

(a) CH0 first control

Forces CH1 to wait to start a DMA transfer until a DMA transfer completes on CH0.

When there is a timing conflict in starting a DMA transfer between CH0 and CH1, CH0 takes precedence over CH1. If a DMA transfer is in progress on CH1 when CH0 tries to start a DMA transfer, CH0 waits to start it until the ongoing DMA transfer completes on CH1.

(b) CH1 first control

Forces CH0 to wait to start a DMA transfer until a DMA transfer completes on CH1.

When there is a timing conflict in starting a DMA transfer between CH1 and CH0, CH1 takes precedence over CH0. If a DMA transfer is in progress on CH0 when CH1 tries to start a DMA transfer, CH1 waits to start it until the ongoing DMA transfer completes on CH0.

Figure 62.11 shows an overview of the processing of the AXI bridge in each operating mode.

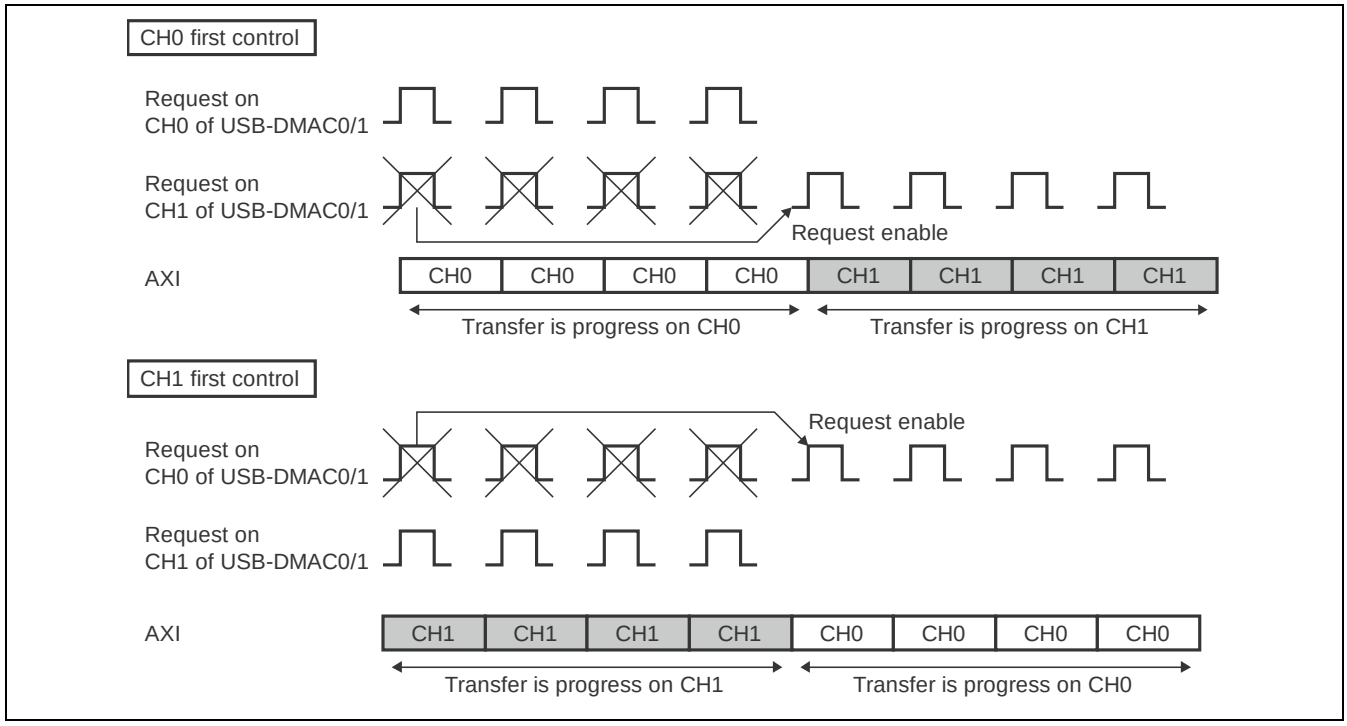

Figure 62.11 Overview of AXI Bridge Processing in Each Mode

(2) Transfer size

The transfer size on the AXI can be selected by setting the channel control register (the TS bit).

8-, 16-, and 32-byte can be set for each channel independently.

The following consideration should be observed during IN transfers.

The minimum transfer size that can be set to the TS bit is 8 bytes while the HS-USB can control transfers in 1-byte units. For example, if valid transfer data that is "8 × (n - 1) + α" (α is less than 7 bytes) in size is to be transferred to the HS-USB with the transfer size set to 8 bytes and the transfer count set to n, α is transferred as a valid transfer unit by controlling byte enables according to the DMA final transaction valid data transfer enable register (the EDTEN bits) setting. Likewise, data is transferred in "transfer size x transfer count" (the final transaction is controlled by EDTEN) for 16- and 32-byte transfer sizes. The EDTEN setting is valid only for IN transfer and is don't care for OUT transfer.

Figure 62.12 shows an example of EDTEN setting. When only EDTEN31 in EDTEN31 to EDTEN0 is 1, one byte is enabled. When only EDTEN31 and EDTEN30 in EDTEN31 to EDTEN0 are 1, two bytes are enabled. Therefore, the total transfer volumes in the example shown above are calculated as "(32 bytes × (n - 1)) bytes + 10 bytes" for 32-byte transfer, "(16 bytes × (n - 1)) bytes + 7 bytes" for 16-byte transfer, and "(8 bytes × (n - 1)) bytes + 2 bytes" for 8-byte transfer. EDTEN15 to EDTEN0 in 16-byte transfer, EDTEN23 to EDTEN0 in 8-byte transfer are invalid (their values are ignored).

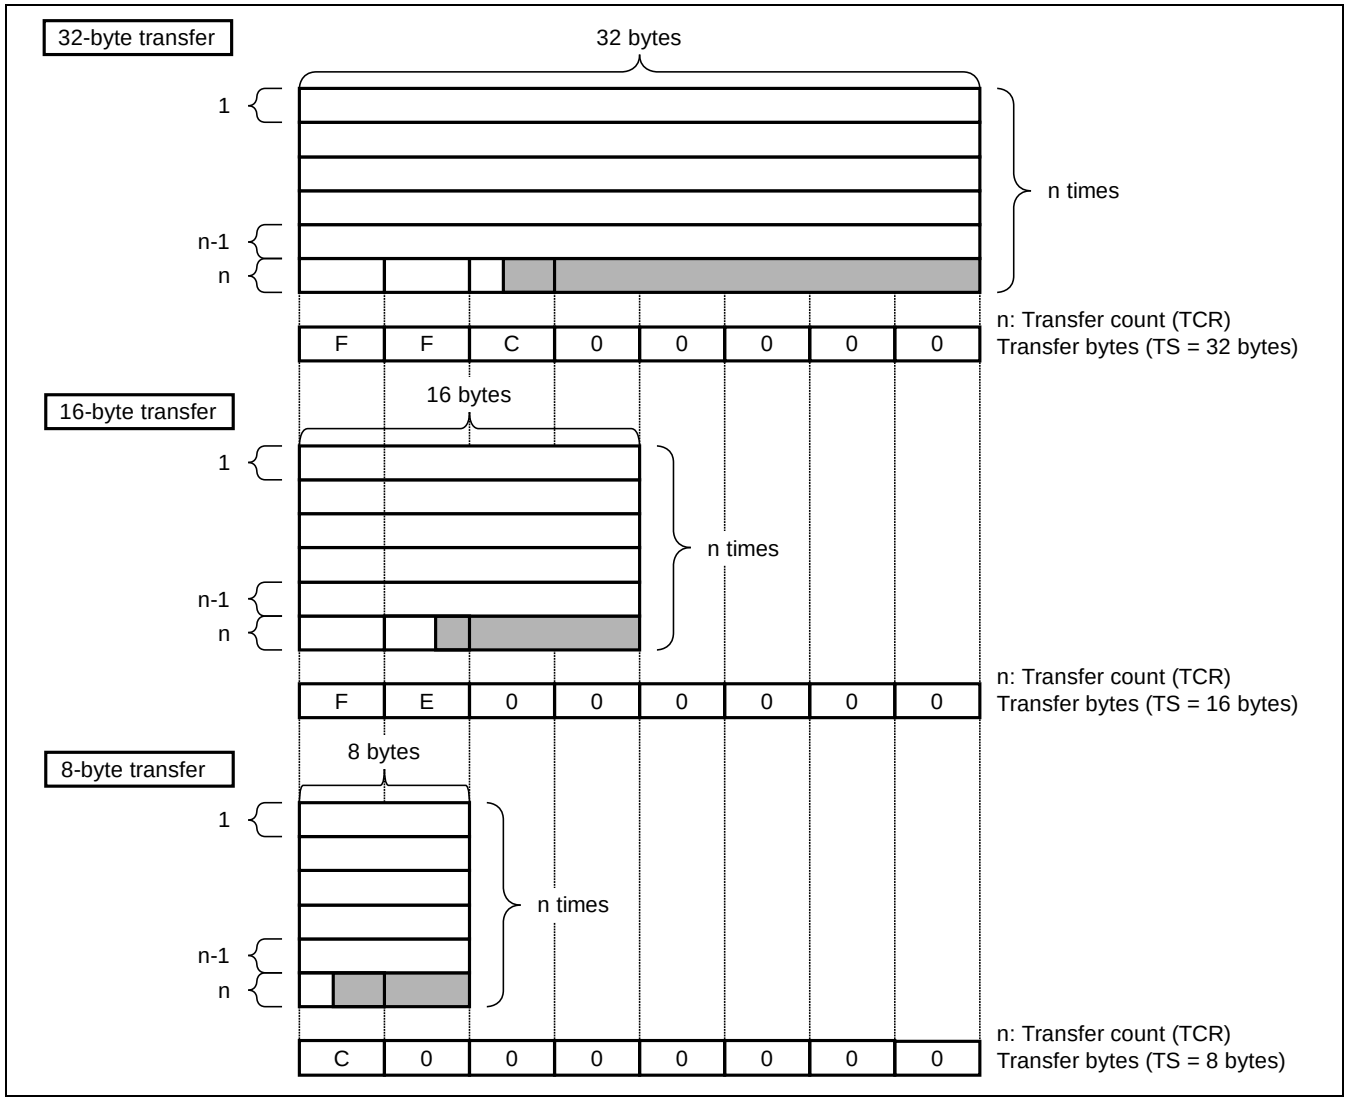

Figure 62.12 Example of Final Transaction Valid Data Transfer Enable (EDTEN) Setting

(3) DMA transfer flow

After the DMA source address register (USBDMAn_SAR), DMA destination address register (USBDMAn_DAR), DMA transfer count register (USBDMAn_TCR), DMA channel control register (USBDMAn_CHCR), final valid data transfer enable register (USBDMAn_TEND), and DMA operation register (USBDMAn_DMAOR) are set appropriately, the DMAC starts data transfer in the following sequence. The DMA timeout constant register (USBDMAn_TOCSTR) may also need to be set.

If the transfer enabling conditions are set as DE = 1, DME = 1, TE = 0, AE = 0, SP = 0, and (TR = 0, BUF = 0, RW = 0), transfers are performed according to the transfer request enables and transfer requests from the HS-USB. The transfer direction (IN/OUT transfer) is determined by the direction signal from the HS-USB. The transfer size is determined by the setting of TS1 to TS0.

Every time one AXI transaction (in the transfer size specified in the TS bit) completes, the internal counter of this module decrements the USBDMAn_TCR value by one. When the specified transfer count ends (the USBDMAn_TCR value reaches 0), it means all transfers complete. At this time, an USB-DMAC interrupt is generated if the IE bit in the USBDMAn_CHCR register is set to 1.

When a NULL packet is received, transfer can be stopped or restarted by setting FTE = 1 after negating the DREQE bit of the HS-USB module. Follow the steps described later in "Control when a NULL packet is received".

Note: ‘n’ in Register Name is 0 or 1.

Table 62.11 shows the conditions for each DMA transfer.

Table 62.11 DMA Transfer Conditions

Transfer enabling condition	TE = 0, SP = 0, (*TR = 0, BUF = 0, RW = 0)
Transfer (starting) condition	When a transfer request is enabled by the HS-USB When a transfer request is issued by the HS-USB
Transfer completing (then restarting) condition	When the transfer count ends (the TE flag is set to 1), (can be restarted by setting DE and DME to 1.) When FTE = 1 (when DREQE = 1 in the HS-USB module is also set), and the steps described later should be followed. When reset (can enter into standby state by releasing the reset.)
Transfer suspending (then resuming) condition	When DE = 0 or DME = 0 (can be resumed by setting DE = 1 or DME = 1.) When SP = 1 (can be resumed by clearing the SP flag.) When RW = 1, BUF = 1, and TR = 1 (can be resumed by clearing the RW, BUF, and TR flag.)* When the module stops (can be resumed by resuming the module.)

Note: * Can be ignored when the RWE, BUFE, and TRE bits are disabled (set to 0).

Figure 62.13 illustrates the high-level DMA transfer flow.

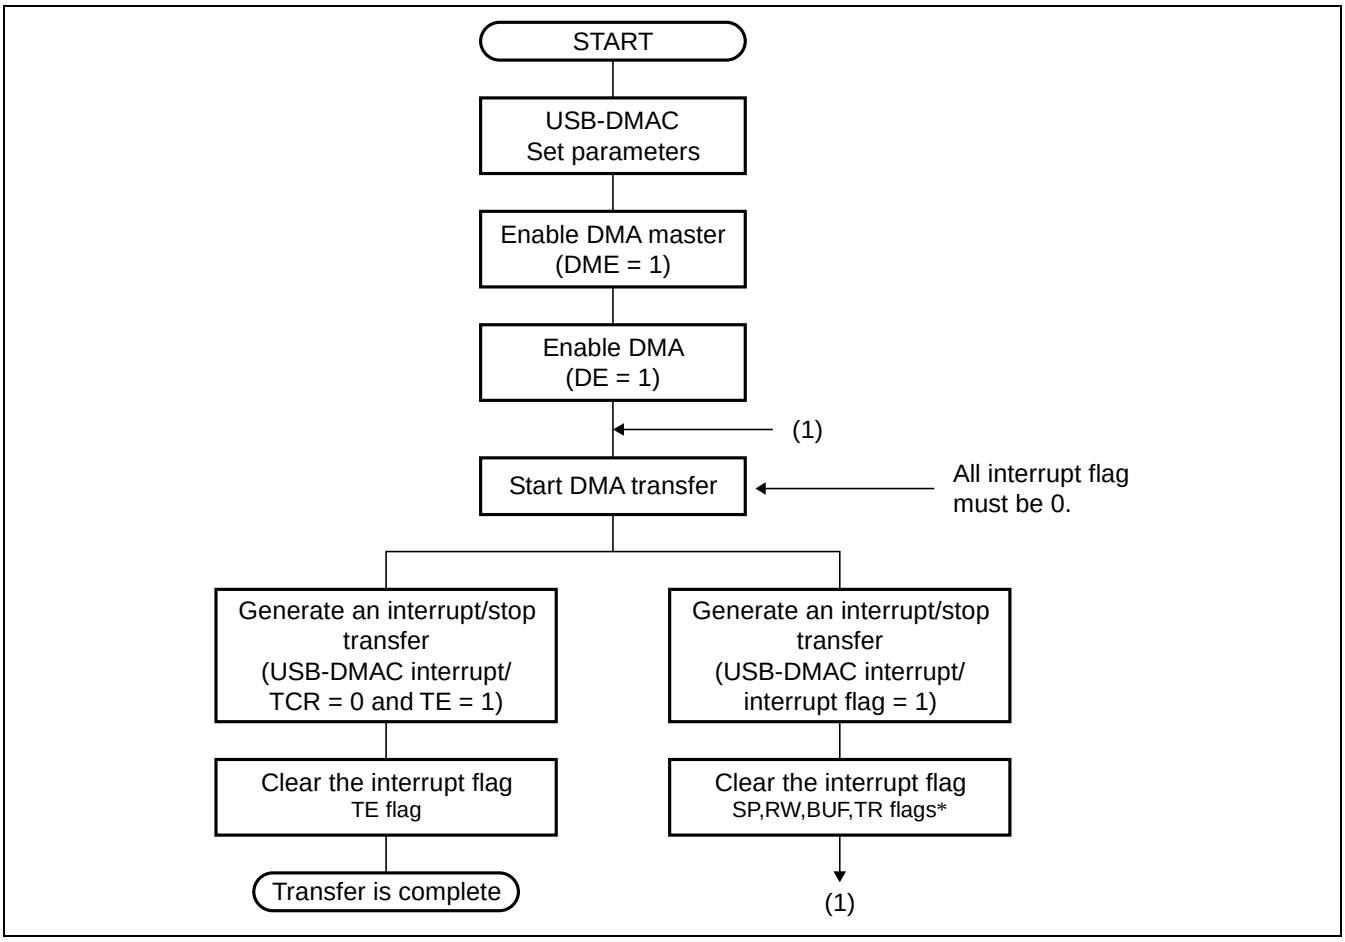

Figure 62.13 DMA Transfer Flow Overview

Note: * RW, BUF, and TR are not set when RWE, BUFE, and TRE are disabled

When to change USB-DMAC parameters

USB-DMAC parameters (such as destination address or transfer count) should be changed while all interrupt flags are cleared and DE = 0 and DME = 0 are set (a transfer is started with the latest parameters when DME = 1 and DE = 1 are set). Furthermore, USB-DMAC parameters should not be changed while the DMA is enabled (DME = 1 and DE = 1).

What to do if freeze

If a transfer should freeze during operation, issue a software reset after setting DE = 0 and DME = 0 and clearing all interrupt flags. All hardware except configuration registers is initialized. Restart by setting DME and DE to 1 after updating USB-DMAC parameters if necessary.

Control when a timeout occurs

Since this module assumes bus access in the transfer units listed in Table 62.2, it cannot be restarted when a timeout occurs in an irregular case where it is being accessed with any size that are not in the table. This irregular case should be handled by software, such as by issuing a software reset (to both CH0 and CH1).

Control when a NULL packet is received

When a NULL packet is received during a DMA transfer, the DMA transfer can be suspended and resumed on each channel independently by controlling the FTE bit of this module and the DREQE bit of the HS-USB module in the following sequence.

[Control sequence]

During a DMA transfer (A)

(1) A NULL packet is received (an interrupt is generated and the NULL flag is detected).
(2) The DREQE bit of the HS-USB module is negated (= 0).
(3) Wait for the internal bus to be stabilized.
(4) Perform three actions at the same time; setting the FTE bit, clearing the NULL bit and negating the DE bit.

An interrupt is generated due to TE.

(5) Clear the interrupt caused by TE.
(6) Set the parameters (such as TCR or DAR) for the next transfer.
(7) Assert the DE bit (= 1). The DMA is restarted.
(8) Assert the DREQE bit (= 1).

Start a DMA transfer (B).

[Restrictions]

1) FTE bit set timing
   If this module is accessing the AXI (SHBSYx bit = 1) when setting the FTE bit, you need to wait to set the FTE bit until this module's internal buffer is empty and the AXI bus access is complete (SHBSYx bit = 0). Note that if you accidentally set the FTE bit while an AXI bus access is in progress, the transfer fails and transfer data may be lost or the transfer may be unable to be restarted.
2) DREQE bit assert (negate clear) timing
   It is necessary to allow at least 20clk@ S3D1ϕ after the DE bit is asserted and before the DREQE is asserted. This is because DREQE needs to be asserted after transfers enabled by the DE bit are ready internally to be started. Asserting DREQE immediately after DE may cause malfunction such as initiating unnecessary bus access.
3) Fractional byte and NULL packet reception
   This module assumes bus access in the transfer units listed in Table 62.2 and goes out of control when it receives a NULL packet in an unsupported transfer unit. Therefore, data transfer in any transfer unit that is not in the table is prohibited.
4) IN/OUT switching after NULL packet reception
   After a NULL is received, transfers cannot be restarted with the transfer direction switched from OUT to IN. This is because this module still considers the terminated transfer as an OUT transfer until the transfer count reaches its end. Note that if you switch the transfer direction to IN transfer accidentally after a NULL packet is received, a conflict occurs between an IN and an OUT transfers, which may cause illegal bus access.
   Use CH0 and CH1 with their transfer direction fixed, or if the transfer direction needs to be switched on the same channel, make sure to do it every time a transfer completes successfully due to the end of transfer count or is terminated by software reset.

Figure 62.14 shows the state transitions for DMA transfers.

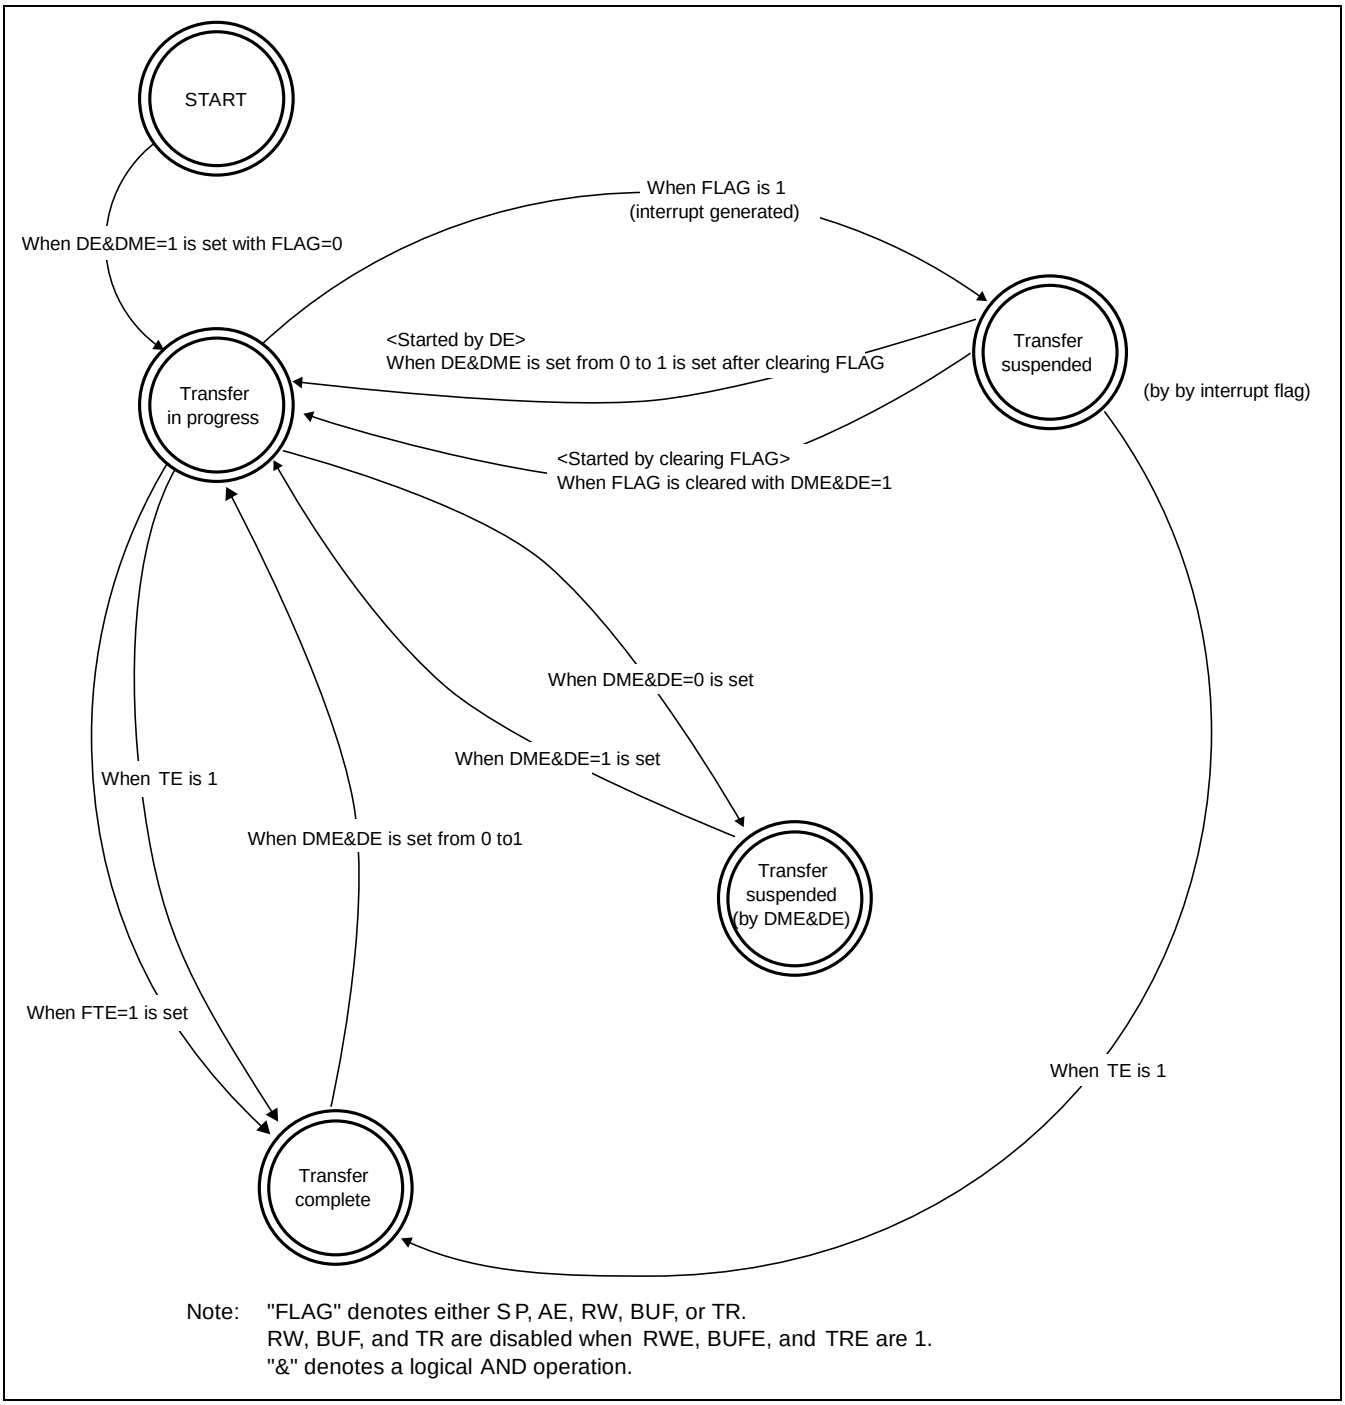

Figure 62.14 State Transitions for DMA Transfer

(4) Control sequence

Figure 62.15 shows an outline of the control sequence of this module.

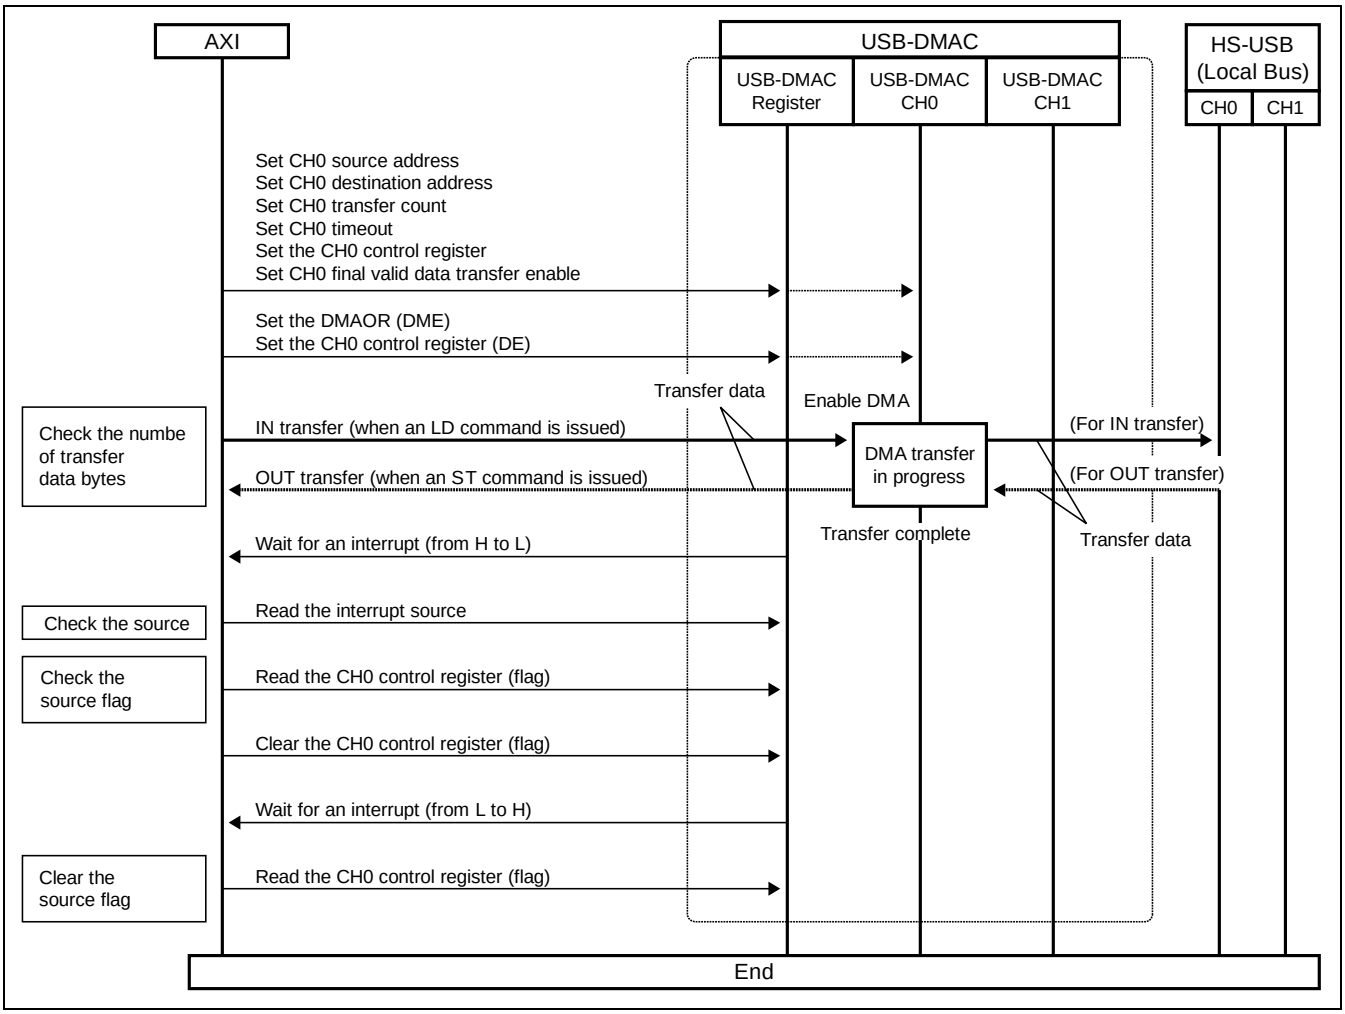

Figure 62.15 Control Sequence Overview

(5) Internal buffer configuration

This module has 64 bytes (64 bits × 8 words) of internal buffer for each of two channels. Thus, the total capacity of this module's internal buffers is 128 bytes (1,024 bits).

The internal buffers are composed of two planes each of which is organized as 64 bits × 4 words and are readable /writable on per-plane basis from the HS-USB local bus or AXI bus (plane 1 is writable when plane 0 is readable or vice versa). For 16-byte transfers, only 2 words in plane 0 and 2 words in plane 1 are used. For 8-byte transfers, only 1 word in plane 0 and 1 word in plane 1 are used.

Note that these internal buffers cannot be accessed directly by software.

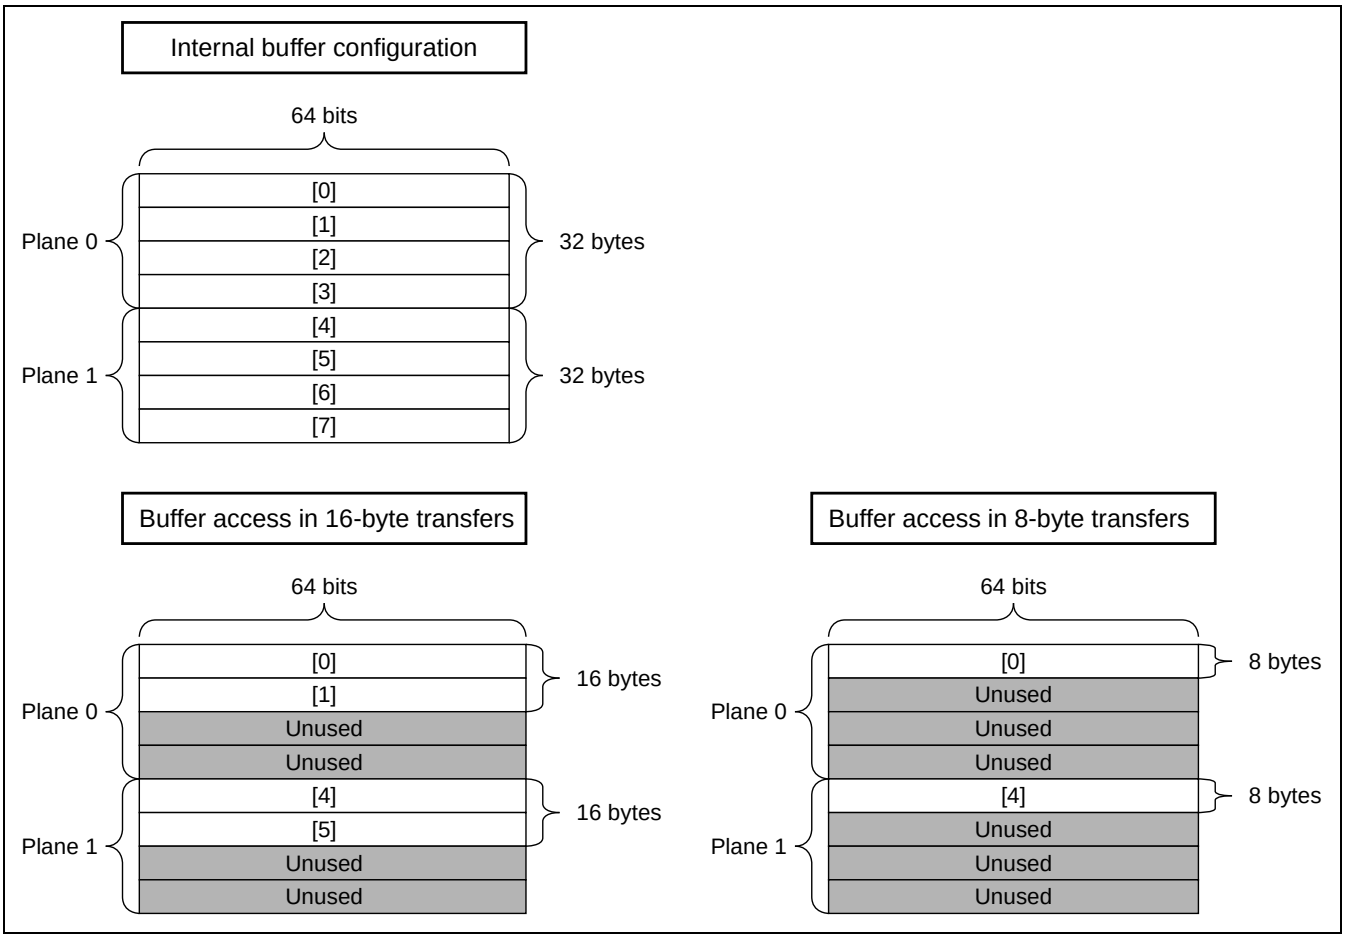

Figure 62.16 Internal Buffer Configuration and Used Area for Each Transfer Size

(6) Internal buffer control (hardware control, for reference)

(a) IN transfer (from AXI to USB)

Retrieves transfer data from a source on the AXI bus and writes it to this module's internal buffer. Reads the written data from the internal buffer and writes it to the HS-USB.

Figure 62.17 shows how the planes of this module's internal buffers are controlled during an IN transfer. In this figure, "read' and 'write" indicate read/write operations to this module's internal buffers.

When a write to plane 0 or plane 1 is complete, the writable plane flag is toggled (every time 2 words* and 1 word* are written for 16-byte and 8-byte transfers, respectively). When a read from plane 0 or plane 1 and a transfer the read data to the HS-USB are complete, the readable plane flag is toggled (every time 2 words* and 1 word* are read for 16-byte and 8-byte transfers, respectively). Access to the AXI is prohibited during the period when both the writable plane flag and readable plane flag are set on the same plane as a read/write access conflict may occur.

Note: * 1 word = 64 bits

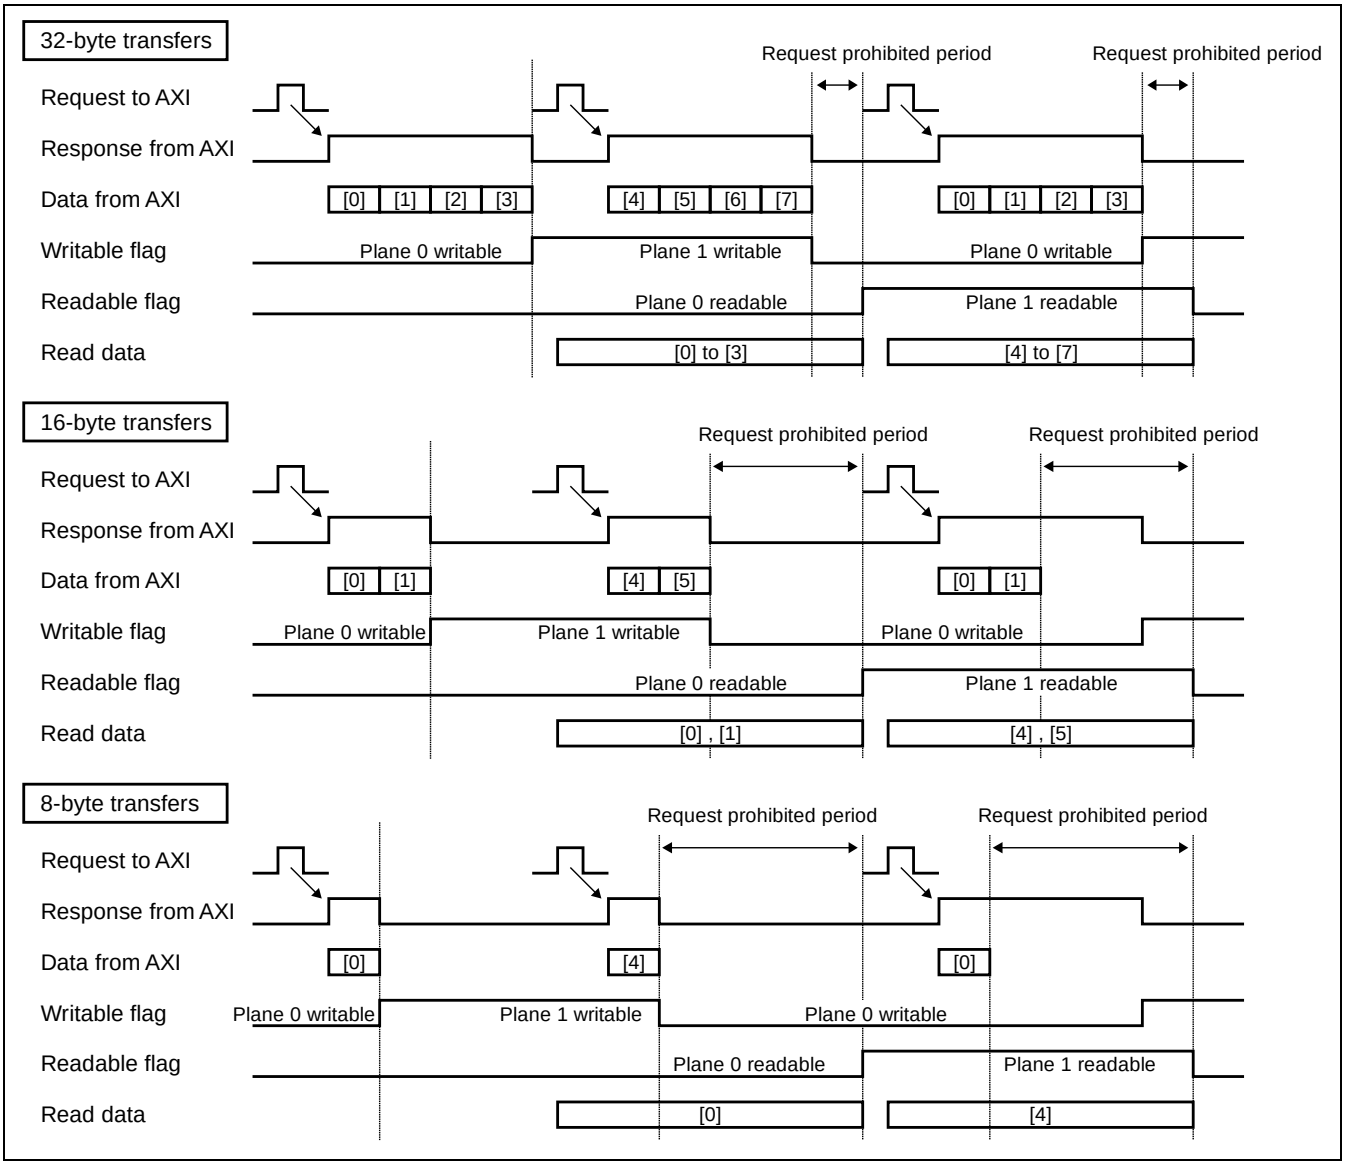

Figure 62.17 Read/Write Control for Internal Buffer: From AXI to USB (IN Transfer)

(b) OUT transfer (from USB to AXI)

Writes data read from the HS-USB to the internal buffers. Reads the written data from this module's internal buffers and writes it to the destination on the AXI bus (OUT transfer).

Figure 62.18 shows how the planes of this module's internal buffers are controlled during an OUT transfer. In this figure, "read' and 'write" indicate read/write operations to this module's internal buffers.

When a write to plane 0 or plane 1 is complete, the writable plane flag is toggled (every time 2 words* and 1 word* are written for 16-byte and 8-byte transfers, respectively). When a read from plane 0 or plane 1 is complete, the readable plane flag is toggled (every time 2 words* and 1 word* are read for 16-byte and 8-byte transfers, respectively). Access to the AXI is prohibited during the period when both the writable plane flag and readable plane flag are set the same plane as a read/write access conflict may occur.

Note: * 1 word = 64 bits

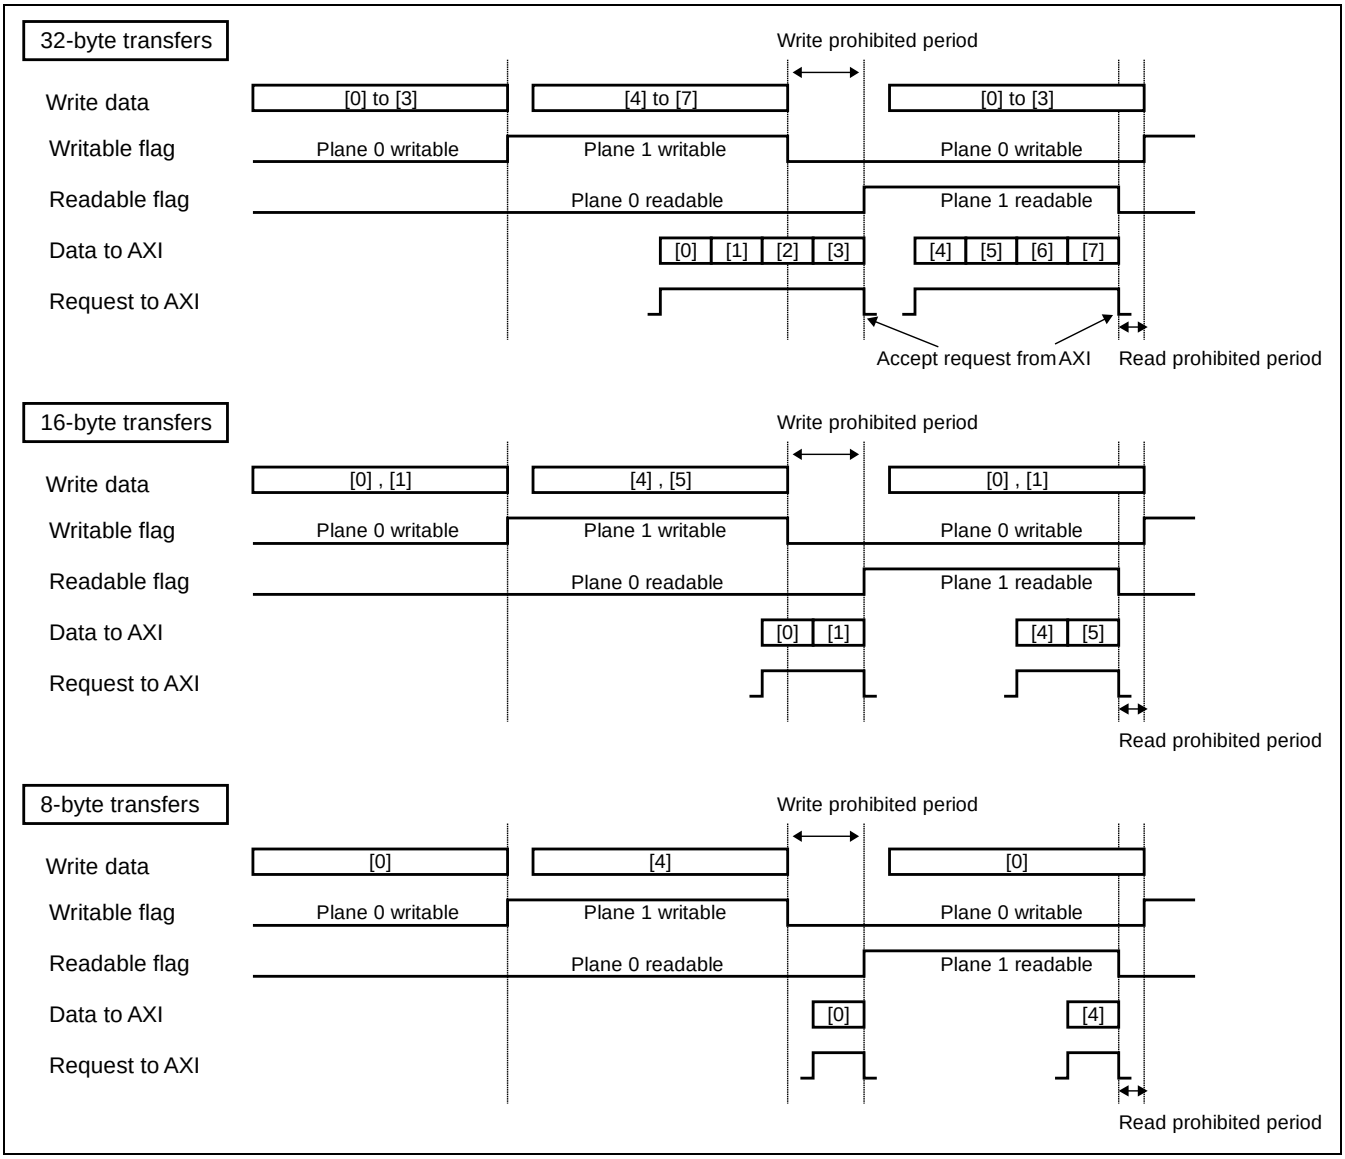

Figure 62.18 Read/Write Control for Internal Buffer: From USB to AXI (OUT Transfer)

62.4 DDM (Descriptor DMAC)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

The DDM is a module that reconfigures the USB-DMAC. The OS on the main CPU is highly sophisticated and the overhead from interrupt notification to reconfiguration increases. To solve this problem, the DDM reconfigures the USB-DMAC in a fast response time on behalf of the CPU.

Figure 62.19 shows the relationship diagram of DDM USB-DMAC connection.

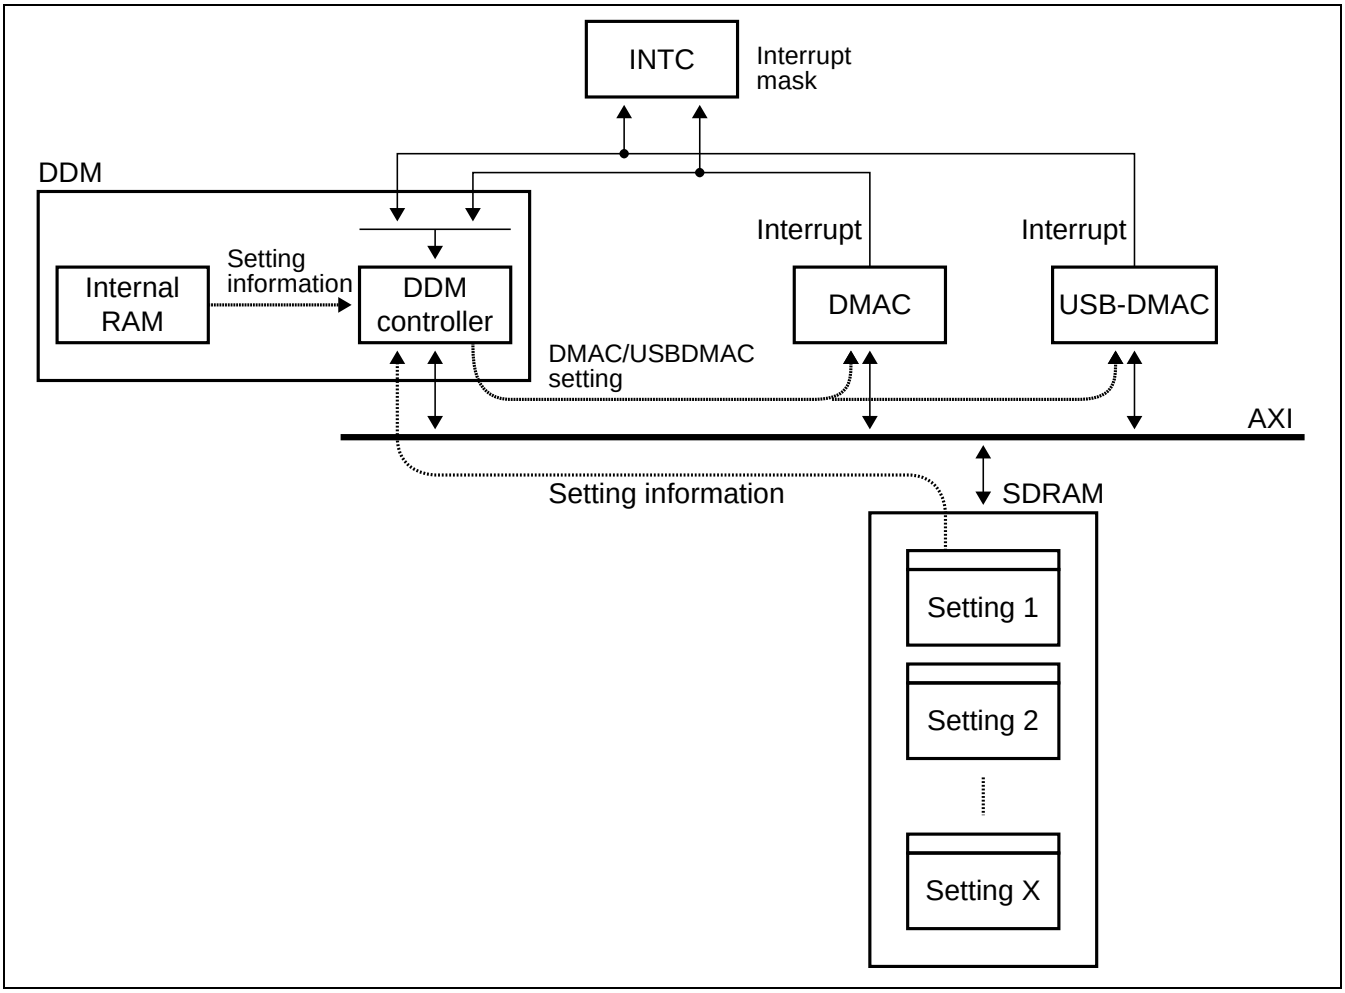

Figure 62.19 Relationship Diagram of DDM Connection

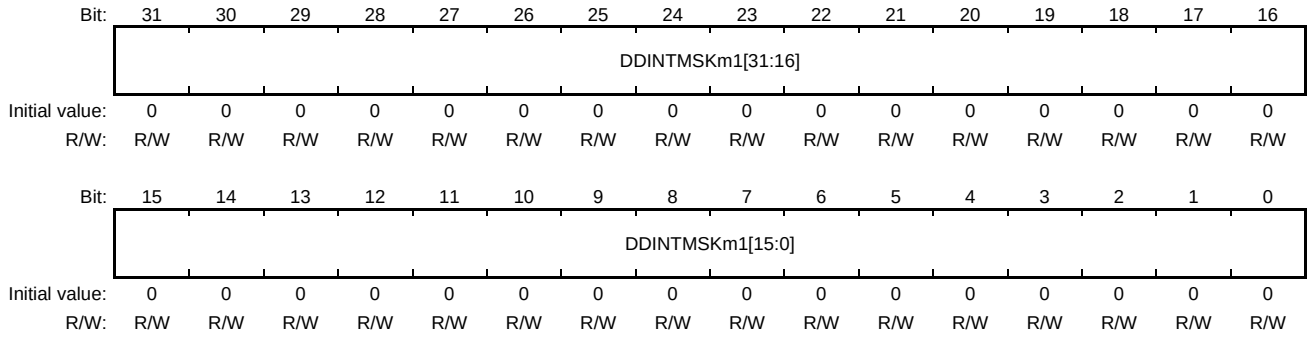
62.4.2.3 DDM CHm Start Source Mask Registers (DDINTMSKm1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

DDM CHm Start Source Mask Registers 1 mask DDM start sources.

Note: “m” of Channels are 1 to 8.



Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	DDINTMSKm1[31:0]	H'0000_0000	R/W	Start Source Mask 0: Does not mask the start source. 1: Masks the start source.

The current source assignment is as follows:

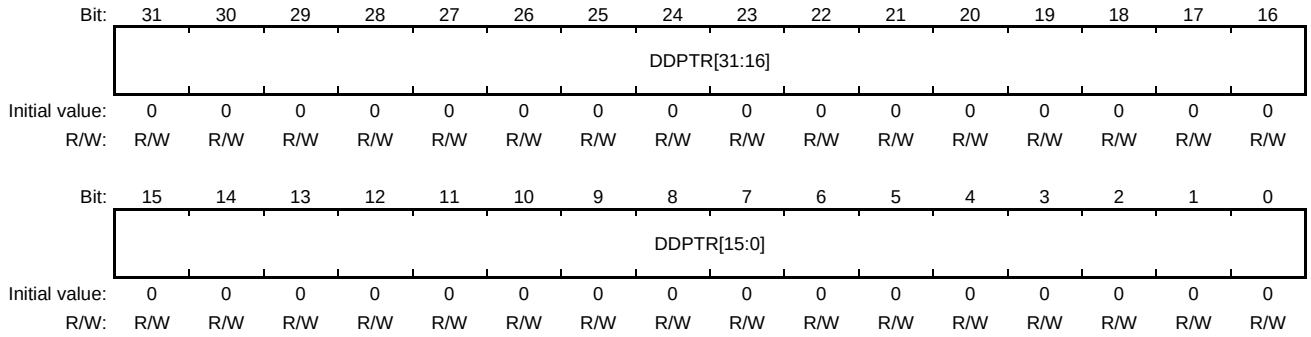
Bit Name	Bit	Assigned Start Source
DDINTMSKm1	31 to 2	Reserved
	1	USB-DMAC1 Interrupt
	0	USB-DMAC0 Interrupt

62.4.2.4 DDM CHm Descriptor Pointer (DDPTRm)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The DDM CHm Descriptor Pointer indicates the start address of setting code allocated onto memory.

Note: “m” of Channels are 1 to 8.



Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	DDPTR[31:0]	H'0000_0000	R/W	Descriptor pointer.

62.4.2.5 DDM CHm Control Register (DDCTRLm)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

The DDM CHm Control Register controls start and stop of DDM.

Note: “m” of Channels are 1 to 8.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 28	PRI3 to PRI0	H'0	R/W	PRI value on the AXI bus.
27, 26	—	B’00	R	Reserved
25	ENDCM	B’0	R/W	Descriptor end Counter Consistent Detection Writing 0 is possible to clear the flag. 0: Counter consistent is not detected. 1: Counter consistent is detected.
24	ENDCMMSK	B’0	R/W	Descriptor end Counter Consistent Detection Mask 0: Masks the ENDCM. (END_CNT is cleared to 0) 1: Does not mask the ENDCM.
23 to 16	END_NUM	All 0	R/W	Number of descriptor ends
15 to 8	END_CNT	All 0	R/W	Descriptor end Counter
7 to 5	—	B’000	R	Reserved
4	STOP	B’0	R/W	Forced Stop Function 0: Does not perform forced stop. 1: Performs forced stop.
3	KICK	B’0	R/W	Forced Start Function without Start Source 0: Does not perform forced start. 1: Performs forced start. This bit is automatically cleared to 0 after 1 is written.
2	DDM_ERR	B’0	R	Error Occurrence. The error is cleared by setting the DDE bit to 0. 0: No error occurred. 1: An error occurred.
1	DDM_END	B’0	R	DDM End. DDM end is cleared by setting the DDE bit to 0. 0: The DDM did not end. 1: The DDM ended.
0	DDE	B’0	R/W	Start Enable 0: Does not enable DDM start. 1: Enables DDM start according to the start source.

62.4.3 Internal RAM

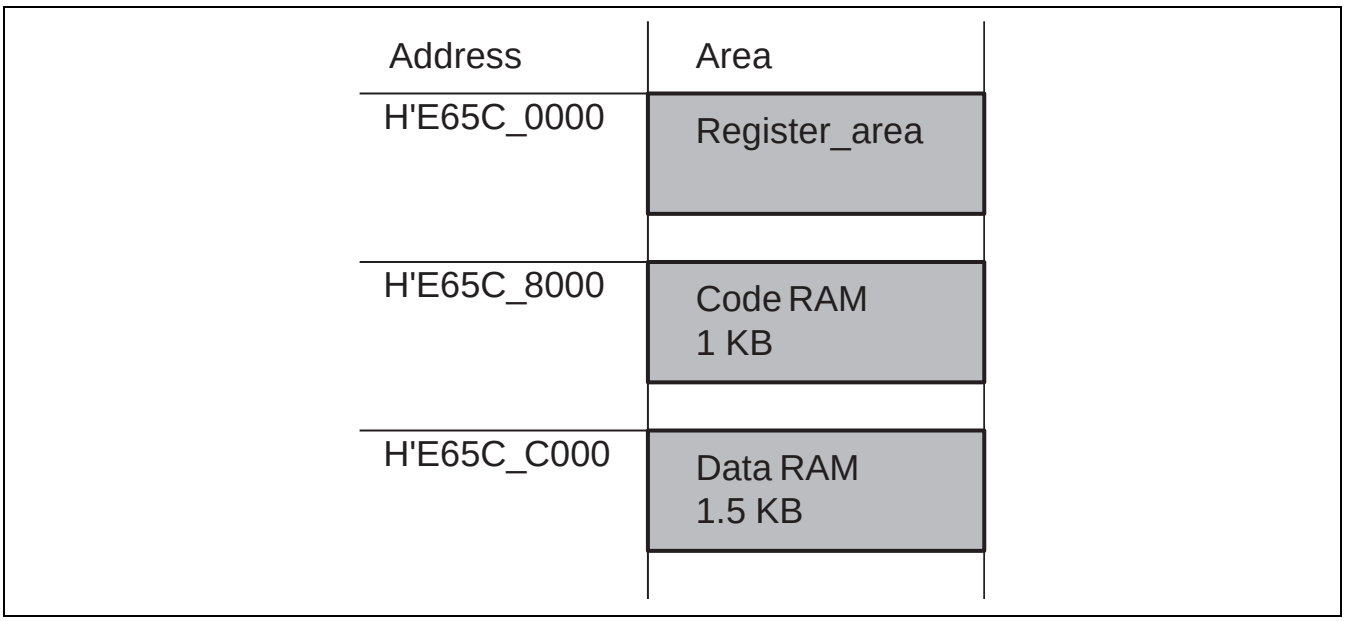

Figure 62.20 Internal RAM

DDM builds in RAM. It is the 2nd page composition of Code RAM and Data RAM. DDM can access without AXI. Access size is arbitrary. In addition, a functional difference is not in both depending on the way of calling depending on which Code RAM and Data RAM were conscious of the use.

62.4.4 Principles of Operation

To reconfigure the DMAC by using the DDM, use the following procedure:

1. Describing setting codes
2. Starting and ending the DDM

(1) Describing setting codes

(a) Data structure

A setting code is fixed-length data consisting of four longwords.

Setting code data consists of the following fields, starting from the beginning:

Field	bit
Operation field	32 bits
Address field	32 bits
Data field	32 bits
Bit mask field	32 bits

Note: Arrange a setting code in 16 bytes boundary.

The following describes the operation field.

(b) Operation field

The structure of the operation field is as follows:

Bit	Bit Name	Descriptions
31 to 16	HEADER	Indicates DDM setting data. H'DDDD: Normal DDM setting code Usually, set this value. H'EEEE: DDM end code Set this value when ending the channel without starting the DDM the next time. If the HEADER bits have other values, a DDM_ERR interrupt occurs. The channel of the DDM stops immediately.
15 to 8	OPERAND	Operand attribute B'00xxyyzz B’00: immediately B’01: register B’10: pointer B’11: pointer (Register value) xx: Bit mask field yy: Data field zz: Address field
7 to 4	SIZE	Specify the data access size to be set. B’0000: Bytes B’0001: Words B’0010: Longwords
3	ENDFLG	End Flag of Setting Processing Based on This Start Source 0: Continuation 1: Setting end. The DDM waits for the next start source.
2 to 0	OPC	Operation Code B’000: read (cmp/eq) (read) B’001: write (write) B’010: rmodw (read modify write) B’011: add (addition) B’100: jmp/eq (branch) B’101: ror (rotate right) Others: DDM_ERR interrupt occurs

The address field, data field, and bit mask field each consist of 32 bits. The data field and bit mask field use the LSB side for word- and byte-size access.

Four of register R0-R3 of longword size can be used for every Ch.

(c) read (cmp/eq)

The read (cmp/eq) code reads the target address and compares the address with the expected values written in the data field and bit mask field.

When the comparison result becomes true, the TFLG internal variable is set to 1. TFLG is cleared to 0 when jmp/eq is executed or operation with ENDFLG is performed.

Description example1:

The read (cmp/eq) code in this example reads the H'FE00_802C address in longwords and checks if bit 1 is set to 1.

H'DDDD_0020
H'FE00_802C
H'0000_0002
H'0000_0002

Description example2:

The read (cmp/eq) code in this example reads the R1 in longwords and checks if bit 1 is set to 1.

H'DDDD_0120
H'0000_0001
H'0000_0002
H'0000_0002

(d) write

The write code writes data to the target address.

Description example1:

The write code in this example accesses the H'FE00_802C address in longwords and writes H'0010_5400.

H'DDDD_0021
H'FE00_802C
H'0010_5400
H'FFFF_FFFF (don't care)

Description example2:

The write code in this example accesses the H'FE00_802C address in longwords and writes the value of H’0000_0001 address to H'FE00_802C address.

H'DDDD_0821
H'FE00_802C
H'0000_0001
H'FFFF_FFFF (don't care)

(2) Description example3:

The write code in this example accesses the H'FE00_802C address in longwords and writes the value of pointer of R1 to the H'FE00_802C address.

H'DDDD_0C21
H'FE00_802C
H'0000_0001
H'FFFF_FFFF (don't care)

(a) rmodw

The rmodw code reads the target address and performs modify-write according to the values of the bit mask field.

Description example:

The rmodw code in this example reads the H'FE00_802C address in longwords and applies H'54 modify-write to bits 11 to 4.

H'DDDD_0022
H'FE00_802C
H'0000_0540
H'0000_0FF0

(b) add

The add code reads the target address and performs add-modify-write according to the values of the bit mask field.

Description example:

The add code in this example reads the H'FE00_802C address in longwords and applies H'200 add-modify-write to bits 11 to 0.

H'DDDD_0023
H'FE00_802C
H'0000_0200
H'0000_0FFF

Use 0 as the addition data corresponding to the area where the bit mask is 0.

(c) jmp/eq

If TFLG is set to 1 by the cmp/eq code, jmp/eq changes the descriptor pointer to the values of the data field. Descriptor pointer change by jmp/eq is not reflected in execution based on the next start source. Changing the descriptor pointer for the next start requires that the CHm descriptor pointer be reconfigured.

Note: “m” of Channels are 1 to 8.

Description example:

The jmp/eq code in this example changes the descriptor pointer when TFLG is 1 to H'E558_000E.

H'DDDD_0024
H'0000_0000 (don't care)
H'E558_000E
H'0000_0000 (don't care)

(d) ror

The ror code reads the target address and performs rotate-right-write according to the values of the bit mask field. The shifted lower bits are rotated to higher bits. The ror command shifts according to the value of the data field.

Description example:

The ror code in this example reads the H'FE00_802C address in longwords and applies 8-bits right-shift.

```
H'DDDD_0025
H'FE00_802C
H'0000_0008
H'00FF_FFFF
```

(e) Settings description order

Describe settings in the following order:

(1) Clearing the start source (source output side, not the DDM start source mask register)
(2) Changing the DDM source mask setting as required
(3) Reconfiguring registers such as DMAC
(4) Reconfiguring the next descriptor pointer

If several start sources are set, the last write may be unable to catch up with the next start. In such a case, end next descriptor pointer setting in (4) in read after write (do not end it in write).

(f) Example of setting DMAC restart

Use DDM CH1. The following shows an example of describing setting codes for reconfiguration when the TE bit of the DMAC1 CH0 channel control register is HI.

```
//TE bit read
    H'DDDD_0020
    H'FE00_802C
    H'0000_0002
    H'0000_0002
//TE bit clear
    H'DDDD_0021
    H'FE00_802C
    H'0010_5400
    H'FFFF_FFFF
//SAR setting
    H'DDDD_0021
    H'FE00_8020
    H'5800_0000
    H'FFFF_FFFF
//DAR setting
    H'DDDD_0021
    H'FE00_8024
    H'0000_0000
    H'FFFF_FFFF
//TCR setting
    H'DDDD_0021
```

H'FE00_8028
H'0000_0010
H'FFFF_FFFF
//DE bit write. DMA start
H'DDDD_0021
H'FE00_802C
H'0010_5401
H'FFFF_FFFF
//Next descriptor pointer write.
H'DDDD_0021
H'E65C_0050
H'5800_02D0
H'FFFF_FFFF
// Setting end by this start. (dummy read)
H'DDDD_0028
H'E65C_0050
H'0000_0000
H'0000_0000

(3) Start and end

(a) Starting the DDM

Make necessary settings in the DDM.

- Enabling interrupt output as required
  - Setting a DDM start source
    - Setting a descriptor pointer

After setting the above, set the DDM Enable bit of the DDM control register to 1 to enable DDM start.

Setting example:

Enable the interrupt by DDM CH1 end.
Address: H'E65C_0008 Write data: H'0000_0001
Enable DDM CH1 start when the DMAC1 TE bit is changed.
Address: H'E65C_0030 Write data: H'0000_1000
Set the DDM CH1 descriptor pointer to H'5800_0210.
Address: H'E65C_0050 Write data: H'5800_0210
Enable DDM CH1 start.
Address: H'E65C_0054 Write data: H'0000_0001

Set the KICK bit to forced start after setting the DDM Enable bit to 1. Do not set these bits at the same time.

(b) Ending the DDM

When the DDM ends, the DDM_END bit is set to 1. DDM end is cleared by setting the DDE bit to 0. To restart the DDM, you must clear the DDM_END bit by setting the DDE bit to 0.

Procedure for stopping the DDM by the STOP bit

Set the STOP bit to 1. Keep the DDE bit at 1.
Check that the DDM_END bit is 1.
Set the DDE bit to 0.

63. USB3.0 Host Controller

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

63.1 Overview

USB3.0 DRD (Dual-role Device) controller is capable of both USB Host and USB Peripheral operation, and is compliant with the Universal Serial Bus (USB) 3.0 Specifications.

The USB3.0 controller supports super speed (5 Gbps), high speed (480 Mbps), full speed (12 Mbps) and low speed (1.5 Mbps). The USB3.0 Peripheral Core supports Super Speed (5 Gbps), High Speed (480 Mbps) and Full Speed (12 Mbps).

Table 63.1 Supported Speed Type

	Speed Type			
	Super Speed	**High Speed**	**Full Speed**	**Low Speed**
Host	√	√	√	√
Peripheral	√	√	√	—

Also, the USB3.0 controller is compliant with battery charging.

It is based on the eXtensible Host Controller Interface for the Universal Serial Bus (xHCI) Specification as a host controller interface.

The USB3.0 controller requires to download FW to operate as a host (see section 63.4.1, FW Download). Contact Renesas to obtain the FW.

The USB3.0 module supports an input reference clock from both external and on-chip clock sources. The external clock source is supplied through USB3S0_CLK_P/USB3S0_CLK_M pins as a dedicated clock to one channel of USB. The on-chip clock source is supplied through USB_XTAL/USB_EXTAL to share the reference clocks with other USB2.0 channels. See “Design Guidelines for Serial Interface Printed Circuit Boards with Second Generation RZ/G Series Products” for more details.

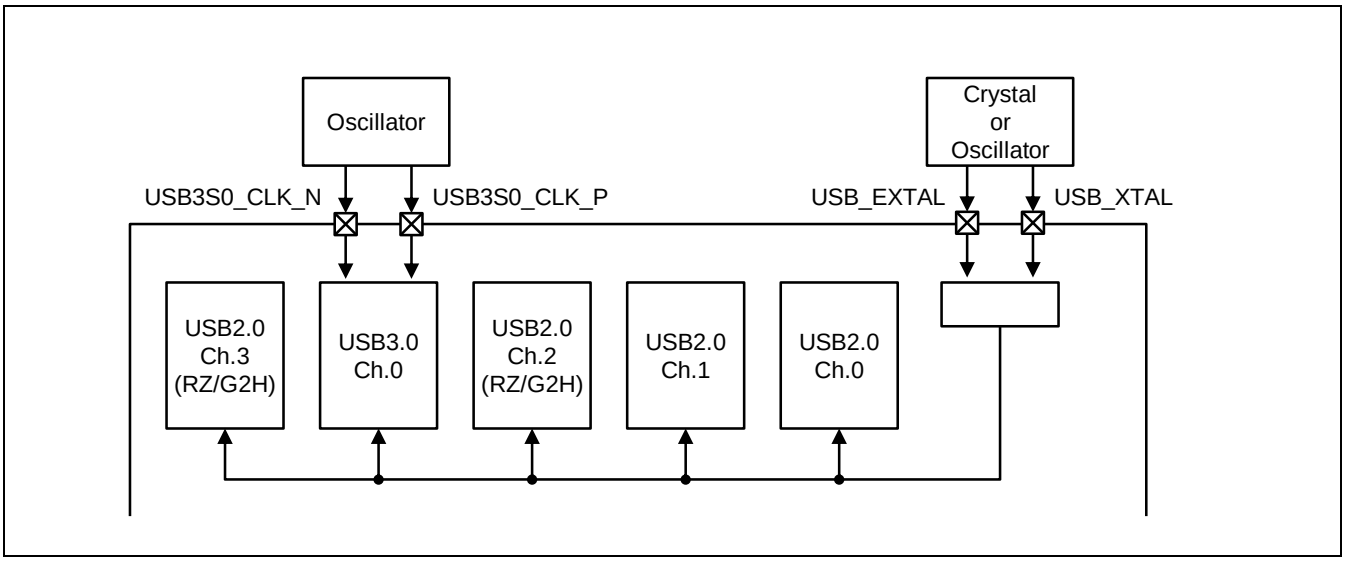

Figure 63.1 Clock Distribution [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N]

63.1.1 Features

The functions of the USB3.0 DRD controller are listed below.

(1) USB3.0 Host Controller Function

Compliant with Universal Serial Bus 3.0 Specification Revision 1.0

- Supports one downstream port
- Supports control, bulk, interrupt, and isochronous transfers.
- Supports all USB bus speeds, USB 3.0 super speed (5 Gbps), high speed (480 Mbps), full speed (12 Mbps) and low speed (1.5 Mbps).
- Supports power control and overcurrent detection
- Supports BIOS USB.
  - Pre-OS and OS hand-off
  - xHCI legacy support control
- Implements the USB2.0ECN USB 2.0 Link Power Management Addendum and LPM function that is compliant with the xHCI specification.
- Supports polarity inversion of USB3.0 SS differential data pin pair.

Has the following capabilities that are compliant with the eXtensible host controller interface for Universal Serial Bus Specification Revision 1.0.

- 64-bit addressing capability
- BW negotiation capability
- Port power control
- Latency tolerance message capability
- xHCI host capability
  - Number of device slots (MaxSlots): 32
  - Number of total endpoints: 128
  - Number of stream IDs (MaxPSASize): 64 per endpoint (1 EP for reserved bit)
  - Number of event ring segment tables: 2 (max. 512 events/ring) (ERST Max = 1)
  - Supported page size: 8 Kbytes
  - Context size: 64 bytes
- Debug Port

  Supports debug port compliant with xHCI debug capability

(2) USB3.0 Peripheral Controller Function

- Compliant with Universal Serial Bus 3.0 Specification Revision 1.0
- Supports USB2.0 Speed types, High and Full Speed.
  - — **Restriction**
    Peripheral function doesn't support Low Speed.
- The maximum PIPE is 5 except PIPE0 and EP0.
- Able to be set to the following Configurations for each PIPE with USB3.0 Super Speed.
  - ・ Endpoint Number: 0 to 15
  - ・ Transfer Type: Control (PIPE0 only)/Bulk/Interrupt
  - ・ Max Burst Size: 1 (value fixed. PIPE0 (Control)), 1 to 16(Bulk), 1 to 3(Interrupt)
  - ・ Max Sequence Number: 31 (fixed)
  - — **Restriction**
    Peripheral function doesn't support Isochronous transfer.
- Able to be set to the following Configurations for each PIPE with USB2.0 Speeds.
  - ・ Endpoint Number: 0 to 15
  - ・ Transfer Type: Control (PIPE0 only)/Bulk/Interrupt
- Supports Stream ID Control (Compliant with UASP specification)
  - ・It can be assigned both StreamIDs, one is in transfer process and
  the other will be used after that process.
- Suspend and Resume
  - ・Supports Power Management by Link Command transaction
  - ・Supports sending of Remote Wakeup Command.
- Supports sending of Arbitrary LMP, TP, and DP.
- Supports Link Power Management(LPM)

[Battery Charging]

Supports the following modes that are compliant with Battery Charging Specification Revision 1.2

Charging port device

- Standard downstream port mode (SDP)
- Charging downstream port mode (CDP)
- DCP is not supported

63.1.2 External Pins

USB D+/ D- signal	USB3HS0_DP USB3HS0_DM	I/O	D+/D- Input/output of the HS/FS/LS transceiver.	√	√	√	√
USB VBUS	USB3HS0_VBUS	I/O	Connect to USB VBUS with external 30kΩ±1% series resistor.	√	√	√	—
USB Identification	USB3HS0_ID	I	Connect to the pin on the Micro connectors that is used to differentiate a Micro-A plug from a Micro-B plug.	√	√	√	√
Power IC Interface	USB30 PWEN	O	Power Enable	√	√	√	√
	USB30 OVC	I	Over Current Flag	√	√	√	√

63.1.3 Register Configuration

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

63.1.3.1 Register Attributes

Table 63.3 Register Bit-field types

Register Attribute	Description
R/W	Register bits can be read and written.
RW1C	Register bits can be read. A clear bit may be set by writing “1”; writing 0 to RW1C bits has no effect.
RWT	Register bits can be read. An inversion bit may be set by writing “1”; writing 0 to RWT bits has no effect.
RW1S	Register bits can be read and written. A bit may be set to 1 by writing “1”; writing 0 to RW1S bits has no effect.
R	Register bits can only be read.
W	Register bits can only be written.
Reserved	Reserved bits are Read Only field.

63.1.3.2 Register Overview

Register groups in host cores are consisted of following registers.

- PHY Register
- AXI Register
- xHCI Register

CLK60 (from USB PHY) shall be supplied to host core when user reads or writes valid value at host register.

The Peripheral’s register groups are assigned as follows.

- PHY Register
- AXI Register
- EPC & USB Common Register
- USB3.0 Super Speed Interface Register

63.1.3.3 USB3.0 Host Register Configuration

Base address is H'EE00_0000 for ch.0. Following sections describe only offset address from the base address.

63.1.4 Connected Module

Table 63.4 The connected modules to USB3.0 Controller

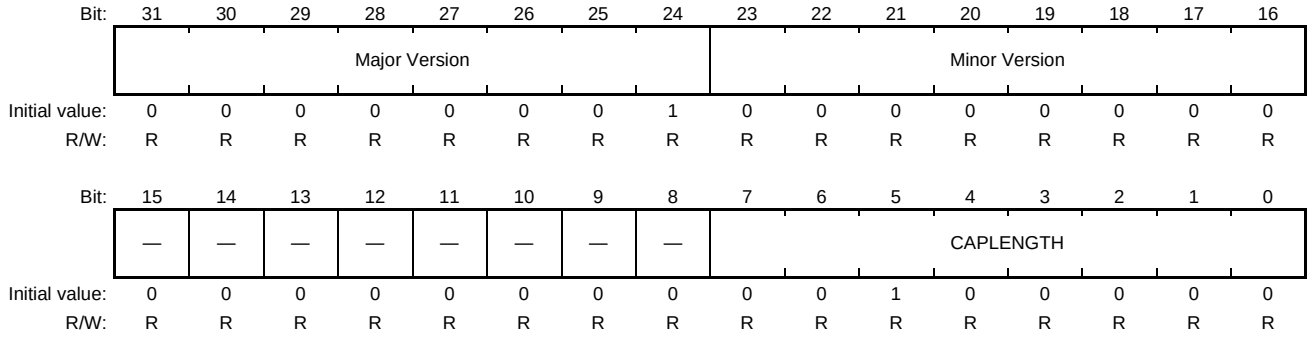
Module name	Connected module name	Function of connected module
USB3.0 Controller	AP-System Core	Access the Register
	CPG	Output Clocks
	PFC	Select External pins
	Module Standby	Control to stop clocks
	Software Reset	Execute software reset
	INTC	Control to interrupt

63.2 Register Description

63.2.1 USB3.0 Host Register

63.2.1.1 Host Controller Capability Register (HCSPARAMS0)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Major Version	H'01	R	Displays Major version of xHCI Specification
23 to 16	Minor Version	H'00	R	Displays Minor version of xHCI Specification
15 to 8	—	All 0	R	Reserved
7 to 0	CAPLENGTH	H'20	R	Displays Capability Register Size

63.2.1.2 Host Controller Capability Register (HCSPARAMS1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

For MaxPorts, the total number of ports for USB3 port and USB2 port is set. The host core has 1 port for each of USB3 and USB2, so the maxports value is 2. For MaxInters, the total number of Interrupters supported by the host controller is set. The host core has 1 interrupter, so bit is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

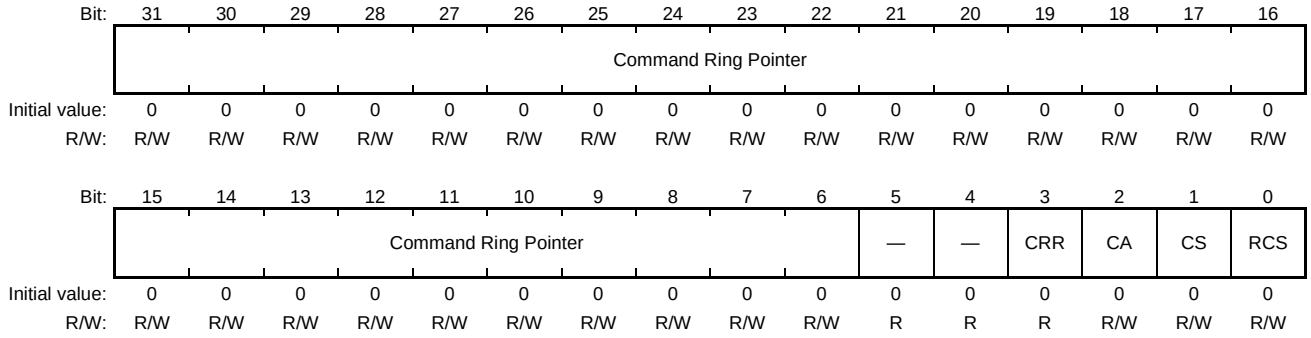
63.2.1.12 Host Controller Operational Register (CRCRL)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 6	Command Ring Pointer	H'000_0000	R/W	Defines a 64-bit Command Ring Dequeue Pointer default value (lower 32-bit). When Command Ring Running (CRR) is 1, any writing to this bit is ignored. The read value from AXI is 0.
5, 4	—	All 0	R	Reserved
3	CRR	B'0	R	Command Ring Running This bit is set when the Run/Stop bit is 1 and the DB reason field in the host controller doorbell register is set to 1 by the host controller command. This bit is cleared to 0 when the command ring stops after command stop or command abort is set to 1, or when Run/Stop bit is cleared to 0.
2	CA	B'0	R/W	Command Abort When this bit is set to 1, stops all commands and stops command ring, changes completion code to "Command Ring Stop", and sends command completion with the completion code set to current command ring dequeue pointer value. When Command Ring Running (CRR) is 0, xHC ignores any writing to this field. The read value is 0.
1	CS	B'0	R/W	Command Stop Writing 1 causes command ring operation to be stopped after the command's completion, then the completion code is changed to command ring stop. Command completion with the command TRB pointer set to the current command ring dequeue pointer value is sent. When Command Ring Running (CRR) is 0, xHC ignores any writing to this field. The read value is 0.
0	RCS	B'0	R/W	Ring Cycle State Defines the xHC Consumer Cycle State (CCS) referred to by the command ring pointer. When Command Ring Running (CRR) is 1, any writing to this field is ignored. The read value is 0.

63.2.1.13 Host Controller Operational Register (CRCRH)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	RW1C	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved
4	SMI_STA	B’0	R	SMI Interrupt Status bit. When an SMI interrupt occurs, this bit is set to 1.
3	LTM_STA	B’0	RW1C	LTM Interrupt status bit. It is asserted when Latency Tolerance Message Device Notification is sent from deice and set BELT value at LTR Register. When an LTM interrupt occurs, this bit is set to 1 by FW. AXI sets 1 to clear the bit.
2	HSE_STA	B’0	R	HSE Interrupt Status bit. When USBSTS.HSE = 1 & USBCMD.HSEE = 1, this bit is set to 1. AXI sets 1 to clear the bit.
1	PME_STA	B’0	R	PME Interrupt Status bit. When PME_STA = 1 & PME_ENA = 1, this bit is set to 1.
0	XHC_STA	B’0	R	xHCI Interrupt Status bit. When EventRing is updated and then the INT signal, which indicates asserting of the interrupt in the core, is detected, this bit is set to 1. When the INT signal, which indicates deasserting of the interrupt in the core, is detected, this bit is set to 0 and cleared.

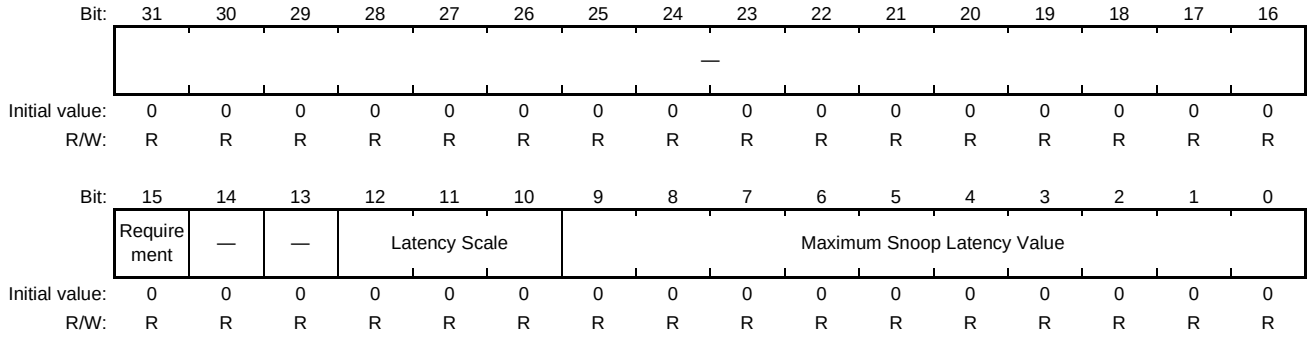
63.2.1.23 Latency Tolerance Reporting Register (LTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Optional normative feature information as USB3.0 Specification.

The register reports the worst value of Best Effort Latency Tolerance (BELT) of Latency Tolerance Message (LTM) Device Notification from device. The “worst” means the maximum BELT value.

Those displayed BELT values are already converted into the format specified by PCI Express Specification.



Bit	Bit Name	Initial Value	R/W	Description
31	WPR	B'0	RW1S	Warm Port Reset Write 1: Starts warm reset sequence, and sets PR bit to 1. Conformity with the warm reset sequence, is reflected in the PR bit setting of PR, PRC, and WRC.
30	DR	B'0	R	Device Removable 0: Device connected to this Port is removable 1: Device connected to this Port is non-removable
29, 28	—	All 0	R	Reserved
27	WOE	B'0	R/W	Wake on Over-current Enable Write 1: Enables over-current condition as system wake-up event. If Port Power is 0, this bit is set to 0.
26	WDE	B'0	R/W	Wake on Disconnect Enable Write 1: Enables device disconnect as system wake-up event. If Port Power is 0, this bit is set to 0.
25	WCE	B'0	R/W	Wake on Connect Enable Write 1: Enables device connect as system wake-up event If Port Power is 0, this bit is set to 0.
24	CAS	B'0	R	Cold Attach Status 1: Far-end receiver Termination is detected but port status cannot transition to enabled state. If PP is 0 or at USB2.0 Port, this bit is set to 0.
23	CEC	B'0	RW1C	Port Config Error Change This bit is set when configuration with link partner fails.
22	PLC	B'0	RW1C	Port Link State Change This bit is set when link transitions from U3 to U0 state. 0: No Change 1: Link state Changed Software writes 1 and then the bit is cleared.
21	PRC	B'0	RW1C	Port Reset Change This bit is set when port reset process completes. (Port Reset Change from 1 to 0) 0: No change 1: Reset complete Software writes 1 and then the bit is cleared.

Bit	Bit Name	Initial Value	R/W	Description
20	OCC	B'0	RW1C	Over-current Change When over-current active changes, this bit is set to 1. Software writes 1 and then the bit is cleared.
19	WRC	B'0	RW1C	Warm Port Reset Change This bit is set to 1 when a warm reset is completed.
18	PEC	B'0	RW1C	Port Enable/Disable Change 0: No change 1: Port enabled/disabled status has changed This bit is set when USB2 protocol port is disabled due to exiting from appropriate conditions at EO2 point. Software writes 1 and then this bit is cleared. If Port Reset is 0, this bit is set to 0.
17	CSC	B'0	RW1C	Connect Status Change 0: No change 1: Change in current connect status xHC sets this bit to 1 at change of port device connect status. Software writes 1 and then this bit is cleared. If Port Reset is 0, this bit is set to 0.
16	LWS	B'0	R/W	Port Link State Write Strobe Write 0: Writing to PLS field is ignored. 1: Writing to PLS field is enabled. The read value is 0
15, 14	PIC	B'00	R/W	Port Indicator Control If Port Indicator (PIND) bit in HCCPRAMS register is 0, writing to this field has no effect. If Port Indicator (PIND) bit is 1; B'00: Port indicators are off B'01: Amber B'10: Green B'11: Undefined If Port Reset is 0, this field is set to 0.
13 to 10	Port Speed	H'0	R	Speed type of USB device connected to the port. This is enabled only when a device is connected to the port. (Current Connect Status is 1) After a port reset, this field indicates the speed of the device connected to the port. If the reset or speed detection fails, this field indicates Unknown Speed. When the Current Connect Status changes from 0 to 1, this field indicates Undefined Speed. H'0: Undefined Speed (Before Speed detection) H'1: Full-speed device attached H'2: Low-speed device attached H'3: High-speed device attached H'4: SuperSpeed device attached H'5 to H'E: Reserved H'F: Unknown Speed (Error detected during speed detection or Port Reset.)

Bit	Bit Name	Initial Value	R/W	Description
9	PP	B'1	R/W	Port Power This field reflects a port's logical power state. 0: This port is in the Powered-off state. 1: This port is not in the Powered-off state. When the Port Power Control (PPC) bit in the HCSPATAMS1 register is 1, xHC has a port power control switch and this bit shows the current state of the switch. (0: off, 1: on) When the Port Power Control (PPC) bit in the HCSPATAMS1 register is 0, xHC has no port power control switch and each port is hard wired to power and not affected by this bit. If an over-current condition is detected at a powered port, the PP bit of each port is changed from 1 to 0.
8 to 5	PLS	H'5	R/W	Port Link State This field is used for port power management and shows the Current Link state. When PED is 1, System software sets this bit then sets Link U state. Port Link State is not set to Disabled, RxDetect, or Inactive State. H'0: The link shall transition to the U0 state from any of the U states. H'1: The link should transition to the U1 State. H'2: The link should transition to the U2 State. H'3: The link shall transition to the U3 state from any of the U states. H'4 to H'F: Ignored. To write to this field, the Port Link State Write strobe should be 1. For USB2 Protocol port, writing 2 requests LPM. Software reads this field to determine success/failure of transition to U2 state. Write 0: Deasserts L1 signal Write 1: No influence Read Value Meaning H'0: Link is in the U0 State H'1: Link is in the U1 State H'2: Link is in the U2 State H'3: Link is in the U3 State (Device Suspended) H'4: Link is in the Disabled State H'5: Link is in the RxDetect State H'6: Link is in the Inactive State H'7: Link is in the Polling State H'8: Link is in the Recovery State H'9: Link is in the Hot Reset State H'A: Link is in the Compliance Mode State H'B: Link is in the Loopback State H'C to H'F: Setting prohibited If Port Reset is 0, this field is ambiguous.

Bit	Bit Name	Initial Value	R/W	Description
4	PR	B'0	R/W	Port Reset 0: port is not in reset 1: port reset assert When software sets this bit from 0 to 1, the bus reset sequence is started. Port Enable/Disable bit is 0. Port Enable bit is 0. This bit remains set to 1 until reset by root hub is completed. When error is detected during resetting, Port Speed bits indicate Unknown Speed. If Port Power is 0, this field is set to 0.
3	OCA	B'0	R	Over-current Active 0: Over-current condition 1: Not over-current condition When an over-current condition is removed, this bit changes from 1 to 0 automatically.
2	—	B'0	R	Reserved
1	PED	B'0	RW1C	Port Enable/Disable 0: Disable 1: Enable After detecting a connection at a port, if SS port initialization or reset by the system software is successful, this bit is automatically enabled by xHC. Port is disabled by fault condition (disconnect event or other fault condition), or USB System Software. Bit status doesn't change until port status changes. If Port Power is 0, this field is set to 0.
0	CCS	B'0	R	Current Connect Status 0: No device is present 1: Device is present on port Reflects current port status. If Port Power is 0, this field is set to 0.

21	PRC	B’0	RW1C	Port Reset Change This bit is set when Port reset process completes. (Port Reset changes from 1 to 0) 0: No change 1: Reset complete Software writes 1 and then the bit is cleared.

Bit	Bit Name	Initial Value	R/W	Description
20	OCC	B’0	RW1C	Over-current Change When Over-current Active changes, this bit is set to 1. Software writes 1 and then the bit is cleared.
19	—	B’0	R	Reserved
18	PEC	B’0	RW1C	Port Enable/Disable Change 0: No change 1: Port enabled/disabled status has changed This bit is set when USB2 protocol port is disabled due to exiting from appropriate conditions at EO2 point. Software writes 1 and then this bit is cleared. If Port Power is 0, this bit is set to 0.
17	CSC	B’0	RW1C	Connect Status Change 0: No change 1: Change in Current Connect Status xHC sets this bit to 1 at change of port device connect status. Software writes 1 and then this bit is cleared. If Port Power is 0, this bit is set to 0.
16	LWS	B’0	R/W	Port Link State Write Strobe Write 0: Writing to PLS field is ignored. 1: Writing to PLS field is enabled. The read value is 0
15 to 14	PIC	B’00	R/W	Port Indicator Control If Port Indicator (PIND) bit in HCCPRAMS Register is 0, writing to this field has no effect. If Port Indicator (PIND) bit is 1; B’00: Port indicators are off B’01: Amber B’10: Green B’11: Undefined If Port Power is 0, this field is set to 0.
13 to 10	Port Speed	H'0	R	Speed type of USB device connected to the port. This is enabled only when a device is connected to the port. (Current Connect Status is 1) After a port reset, this field indicates the speed of the device connected to the port. If the reset or speed detection fails, this field indicates Unknown Speed. When the Current Connect Status changes from 0 to 1, this field indicates Undefined Speed. H'0: Undefined Speed (Before Speed detection) H'1: Full-speed device attached H'2: Low-speed device attached H'3: High-speed device attached H'4: SuperSpeed device attached H'5 to H'E: Reserved H'F: Unknown Speed (Error detected during speed detection or Port Reset.)

Bit	Bit Name	Initial Value	R/W	Description
9	PP	B’1	R/W	Port Power This field reflects a port’s logical power state. 0: This port is in the Powered-off state. 1: This port is not in the Powered-off state. When the Port Power Control (PPC) bit in the HCSPATAMS1 register is 1, xHC has a port power control switch and this bit shows the current state of the switch. (0: off, 1: on) When the Port Power Control (PPC) bit in the HCSPATAMS1 register is 0, xHC has no port power control switch and each port is hard wired to power and not affected by this bit. If an over-current condition is detected at a powered port, the PP bit of each port is changed from 1 to 0.
8 to 5	PLS	H'5	R/W	Port Link State This field is used for port power management and shows the Current Link state. When PED is 1, System software sets this bit then sets Link U state. Port Link State is not set to Disabled, RxDetect, or Inactive State Write Value: Description H'0: The link shall transition to the U0 state from any of the U states. H'1: The link should transition to the U1 State. H'2: The link should transition to the U2 State. H'3: The link shall transition to the U3 state from any of the U states. H'4 to H'F: Ignored. To write to this field, the Port Link State Write strobe should be 1. For USB2 Protocol port, writing 2 requests LPM. Software reads this field to determine success/failure of transition to U2 state. Write 0: Deasserts L1 signal Write 1: No influence Read Value Meaning H'0: Link is in the U0 State H'1: Link is in the U1 State H'2: Link is in the U2 State H'3: Link is in the U3 State (Device Suspended) H'4: Link is in the Disabled State H'5: Link is in the RxDetect State H'6: Link is in the Inactive State H'7: Link is in the Polling State H'8: Link is in the Recovery State H'9: Link is in the Hot Reset State H'A: Link is in the Compliance Mode State H'B: Link is in the Loopback State H'C to H'F: Setting prohibited If Port Power is 0, this field is ambiguous.

Bit	Bit Name	Initial Value	R/W	Description
4	PR	B'0	R/W	Port Reset 0: Port is not in reset 1: Port reset assert When software sets this bit from 0 to 1, the bus reset sequence is started. Port Enable/Disable bit is 0. Port Enable bit is 0. This bit remains set to 1 until reset by root hub is completed. When error is detected during resetting, Port Speed field indicates Unknown Speed. If Port Power is 0, this field is set to 0.
3	OCA	B'0	R	Over-current Active 0: Over-current condition 1: Not over-current condition When an over-current condition is removed, this bit changes from 1 to 0 automatically.
2	—	B'0	R	Reserved
1	PED	B'0	RW1C	Port Enable/Disable 0: Disable 1: Enable After detecting a connection at a port, if SS port initialization or reset by the system software is successful, this bit is automatically enabled by xHC. Port is disabled by fault condition (disconnect event or other fault condition), or USB System Software. Bit status doesn't change until port status changes. If Port Power is 0, this field is set to 0.
0	CCS	B'0	R	Current Connect Status 0: No device is present 1: Device is present on port Reflects current port status. If Port Power is 0, this field is set to 0.

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	Port Test Control	H'0	R/W	0: port is not operating in test mode Non-zero: port is operating in test mode A non-zero Port Test Control value is valid when the port is in the Disabled, Disconnected, or Suspend State. <USB2 protocol port> Value Test Mode H'0: Test mode not enabled H'1: Test J_STATE H'2: Test K_STATE H'3: Test SE0_NAK H'4: Test Packet H'5: Test FORCE_ENABLE H'6 to H'E: Setting prohibited H'F: Port Test Control Error
27 to 17	—	All 0	R	Reserved
16	HLE	B'0	R/W	Hardware LPM Enable Writing 1 enables hardware controlled LPM. If Hardware LMP is not supported, this bit is reserved.
15 to 8	L1 Device Slot	H'00	R/W	Device Slot ID of Device directly connected to Root Hub Port. 0: No device
7 to 4	HIRD	H'0	R/W	Host Initiated Resume Duration Duration of Resume that xHC drives to start resume from L1 state.
3	RWE	B'0	R/W	Remote Wake Enable This bit is set to enable or disable device for Remote Wakeup from L1.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	L1S	B’000	R	L1 Status Software uses this field to determine whether L1-based suspend request is successful. Value Meaning B’000: Invalid B’001: Success - Port succeed in transition to L1 during resume request (ACK) B’010: Not Yet - Device fails to transition to L1 (NYET) B’011 Not Supported - Device doesn’t support L1 transitions (STALL) B’100: Timeout/Error - Device fails LPM Transaction or error occurs B’101 to B’111: Reserved This field is valid when port is in either L0 or L1 state (PLS = 0 or 2).

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	AXI_RESET	B’0	W	Force reset for AXI-IF. Force reset to AXI Master Block when 1 is written in this bit. Read value of this bit is always 0. Reset is done to area except Slave Control Circuit of AXI Bridge and Registers. PRD_EN* shall be “0” in all register field before setting this bit when reset is pursued forcedly
30	—	B’0	R/W	The initial value of this bit is 0. This bit can be read and written but it is not allowed to change the value of this bit. Only 0 is allowed as the value to be written.
29	—	B’1	R/W	The initial value of this bit is 1. This bit can be read and written but it is not allowed to change the value of this bit. Only 1 is allowed as the value to be written.
28	—	B’0	W	This bit is writable and write-only bit but is not allowed to write 1 to this bit. Only 0 is allowed as the value to be written.
27 to 25	—	All 0	R	Reserved
24	—	B’0	W	This bit is writable and write-only bit but is not allowed to write 1 to this bit. Only 0 is allowed as the value to be written.
23 to 20	MST_PCACHE	H'0	R/W	Specifies CACHE signal (MARCACHE/MAWCACHE) for access to Read and Write Back PRD Table in AXI Master IF. This is not applied to CACHE signal for DATA transfer with DMA. Setting of Descriptor in PRD Table is applied during DATA Transfer. This setting should not be changed during DMA Transfer.
19 to 18	—	All 0	R	Reserved
17 to 16	MST_BSIZE	B’11	R/W	Specifies burst size (AxSIZE) in AXI Master IF. Specifies burst size of transfer that is initiated by Master IF. This setting should not be changed during DMA Transfer. Check transfer is stopped with DMA_TRANS0 after setting MST_WAIT0 in order to change the setting during transfer. B’00: 1 Byte (AxSIZE = B’000) B’01: 2 Byte (AxSIZE = B’001) B’10: 4 Byte (AxSIZE = B’010) B’11: 8 Byte (AxSIZE = B’011)
15	—	B'0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
14 to 12	Renesas Private bit	B'010	R	Renesas Private field. This is write inhibit field.
11	—	B'0	R	Reserved
10 to 8	Renesas Private bit	B'010	R	Renesas Private field. This is write inhibit field.
7 to 1	—	All 0	R	Reserved
0	MST_WAIT0	B'0	R/W	Request DMA Transfer of all PRD table in AXI Master IF to be suspended. In case suspension of transfer is requested with this bit during processing transferring, it indicates 1 (during DMA transfer) by AXI_STA/DMA_TRANS bit.

63.2.2.2 AXI Status Register (AXI_STA)

Bit	Bit Name	Initial Value	R/W	Description
31	AXI_RESET_STA	B'0	R	Indicate Reset Status of AXI-IF. 1: Reset State 0: Reset is cancelled
30 to 24	—	All 0	R	Reserved
23	EXTPRD_EN4_R	B'0	R	Indicates status of EXTPRD_EN4. This bit is dedicated for Read of bit 1 (EXTPRD_EN4) of DMA_Ch0_CON4 Register
22	EXTPRD_EN3_R	B'0	R	Indicates status of EXTPRD_EN3. This bit is dedicated for Read of bit 1 (EXTPRD_EN3) of DMA_Ch0_CON3 Register
21	EXTPRD_EN2_R	B'0	R	Indicates status of EXTPRD_EN2. This bit is dedicated for Read of bit 1 (EXTPRD_EN2) of DMA_Ch0_CON2 Register
20	EXTPRD_EN1_R	B'0	R	Indicates status of EXTPRD_EN1. This bit is dedicated for Read of bit 1 (EXTPRD_EN1) of DMA_Ch0_CON1 Register
19	PRD_EN4_R	B'0	R	Indicate status of PRD_EN4. This bit is dedicated for Read of bit 0 (PRD_EN4) of DMA_Ch0_CON4 Register.
18	PRD_EN3_R	B'0	R	Indicate status of PRD_EN3. This bit is dedicated for Read of bit 0 (PRD_EN3) of DMA_Ch0_CON3 Register.
17	PRD_EN2_R	B'0	R	Indicate status of PRD_EN2. This bit is dedicated for Read of bit 0 (PRD_EN2) of DMA_Ch0_CON2 Register.
16	PRD_EN1_R	B'0	R	Indicate status of PRD_EN1. This bit is dedicated for Read of bit 0 (PRD_EN1) of DMA_Ch0_CON1 Register.
15	PRD_DIR0	B'0	R	Indicate the direction of transfer for the PIPE where is current processing at AXI Master I/F. This bit indicates the direction of transfer for the PIPE where is currently processing when the transfer is processing (DMA_TRANS = 1). This bit indicates the direction of transfer for the PIPE where was transferred at the last.
14 to 10	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
9 to 8	DMA_PRDN0	B'00	R	Indicate PRD table number that is in process in AXI Master IF. This bit indicates PRD Table number during DMA transfer that is in progress (DMA_TRANS = 1) and PRD Table number that was transferred last time when in stand-by state (DMA_TRANS = 0).
7	PRD_ WRITE0	B'0	R	Indicate that PRD Table is Write in AXI Master IF. This bit indicates that Write of PRD Table of PIPE number indicated by DMA_PIPE is in progress. 1: Read of PRD Table of PIPE number indicated by DMA_PIPE is progress. 0: Others
6	PRD_READ0	B'0	R	Indicate that PRD Table is Read in AXI Master IF. This bit indicates that Read of PRD Table of PIPE number indicated by DMA_PIPE is in progress. 1: Read of PRD Table of PIPE number indicated by DMA_PIPE is progress. 0: Others
5 to 1	DMA_PIPE0	All 0	R	Indicate PIPE number that is currently being processed in AXI Master IF. This bit indicates PIPE number that is currently being transferred in case DMA Transfer in progress (DMA_TRANS = 1) or PIPE number that was transferred at the end in case it is in Stand-by state (DMA_TRANS = 0).
0	DMA_ TRANS0	B'0	R	Indicate DMA Transfer is in progress in AXI Master IF. DMS transfer control is performed by packet unit in USB. This bit indicates EPC buffer and data transfer is in progress with packet unit. 1: DMA Transfer in Progress 0: Stand-by

63.2.2.3 AXI Interrupt Status Register (AXI_INT_STA)

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	RW1C	RW1C	RW1C	RW1C

Bit	Bit Name	Initial Value	R/W	Description
31	DMAINT_STA	B'0	R	Indicate an Interrupt occurred due to status change during DMA Transfer. Interrupt with AXI_INT_DMA occurs when this bit is set. Refer to DMA_INT_STA Register to check at which PIPE Transfer was completed in case this bit is set. This bit is cleared when all factors of DMA_INT_STA are cleared. 1: DMA Transfer Completion Interrupt occurred 0: Interrupt has not occurred
30	EPCINT_STA	B'0	R	Indicates an Interrupt occurred due to EPC_INTR_USB from EPC. Need to check That factor for Interrupt due to EPC register and to clear the status of Interrupt when this bit is set. This bit is cleared when all status of EPC is cleared. 1: DMA Transfer Completion Interrupt occurred 0: Interrupt has not occurred
29 to 20	—	All 0	R	Reserved
19	PRDEN4_CLR_STA	B'0	RW 1C	Indicate that PRD_EN that is set in CH0-4 is cleared by HW. Interrupt with AXI_INT_SYS occurs when this bit is set. This bit may be set for the interruption when PRD_EN is ready for clearing by HW due to the completion of targeted transfer process even though PRD_EN is cleared by FW after the transfer process is started.
18	PRDEN3_CLR_STA	B'0	RW 1C	Indicate that PRD_EN that is set in CH0-3 is cleared by HW. Interrupt with AXI_INT_SYS occurs when this bit is set. This bit may be set for the interruption when PRD_EN is ready for clearing by HW due to the completion of targeted transfer process even though PRD_EN is cleared by FW after the transfer process is started.
17	PRDEN2_CLR_STA	B'0	RW 1C	Indicate that PRD_EN that is set in CH0-2 is cleared by HW. Interrupt with AXI_INT_SYS occurs when this bit is set. This bit may be set for the interruption when PRD_EN is ready for clearing by HW due to the completion of targeted transfer process even though PRD_EN is cleared by FW after the transfer process is started.

Bit	Bit Name	Initial Value	R/W	Description
16	PRDEN1_CLR_STA	B'0	RW 1C	Indicate that PRD_EN that is set in CH0-1 is cleared by HW. Interrupt with AXI_INT_SYS occurs when this bit is set. This bit may be set for the interruption when PRD_EN is ready for clearing by HW due to the completion of targeted transfer process even though PRD_EN is cleared by FW after the transfer process is started.
15 to 4	—	All 0	R	Reserved
3	PRDERR0-4_STA	B'0	RW 1C	Indicate that information of PRD Table set in CH0-4 is invalid. This bit is set to 1 when it is determined that PRD Table set in DMA_Ch0_CON4/DMA_Ch0_PRD_ADR4 Register is not valid and applicable PRD Table is Disabled. This is cleared to 0 by writing 1 from FW. This bit is set in any of the case provided below. Refer to "Procedure of Error Occur" in [63.7.5 AXI DMA Transfer Control]. - Target PIPE is duplicated with other setting. - Falsely specified by PIPE_DIR/PIPE_NO. - Format of PRD Table is invalid. - Transfer has occurred. Interrupt with AXI_INT_ERR occurs when this bit is set.
2	PRDERR0-3_STA	B'0	RW 1C	Indicates information of PRD Table set in CH0-3 is invalid. This bit is set to 1 when it is determined that PRD Table set in DMA_Ch0_CON3/DMA_Ch0_PRD_ADR3 Register is not valid and applicable PRD Table is Disabled. This is cleared to 0 by writing 1 from FW. Interrupt with AXI_INT_ERR occurs when this bit is set.
1	PRDERR0-2_STA	B'0	RW 1C	Indicates information of PRD Table set in CH0-2 is invalid. This bit is set to 1 when it is determined that PRD Table set in DMA_Ch0_CON2/DMA_Ch0_PRD_ADR2 Register is not valid and applicable PRD Table is Disabled. This is cleared to 0 by writing 1 from FW. Interrupt with AXI_INT_ERR occurs when this bit is set.
0	PRDERR0-1_STA	B'0	RW 1C	Indicates information of PRD Table set in CH0-1 is invalid. This bit is set to 1 when it is determined that PRD Table set in DMA_Ch0_CON1/DMA_Ch0_PRD_ADR1 Register is not valid and applicable PRD Table is Disabled. This is cleared to 0 by writing 1 from FW. Interrupt with AXI_INT_ERR occurs when this bit is set.

R/W:	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved
15	PIPE_DIR4	B’0	R/W	Specify Transfer Direction in AXI Master IF. 1: In Transfer (Memory → EPC) 0: Out Transfer (EPC → Memory)
14 to 13	—	All 0	R	Reserved
12 to 8	PIPE_NO4	All 0	R/W	Specify PIPE number that this PRD Table is applied. Setting value between 1 and 5 is valid. (Note)
7 to 6	—	All 0	R	Reserved
5 to 4	EXTPRD_NO4	B’00	R/W	Specify PRD Table number that is linked to this PRD Table. This is valid only when PRD_EN4 is set to 1. B’00: PRD_EN1 B’01: PRD_EN2 B’10: PRD_EN3 B’11: Setting prohibited
3 to 2	—	All 0	R	Reserved
1	EXTPRD_EN4	B’0	R/W	Enable Link of PRD Table by EXTPRD_NO4. In case both PRD_EN4 and this bit are set to 1, setting of this PRD Table is enabled upon completion of transfer of PRD Table that was specified by PRD_NO4. This bit is cleared automatically when PRD Table is enabled. However, this is not cleared when transfer of linked PRD Table has been completed. Confirm that PRD_EN that was linked is still 1 after setting this bit. 1: PRD Table is linked 0: PRD Table is not linked

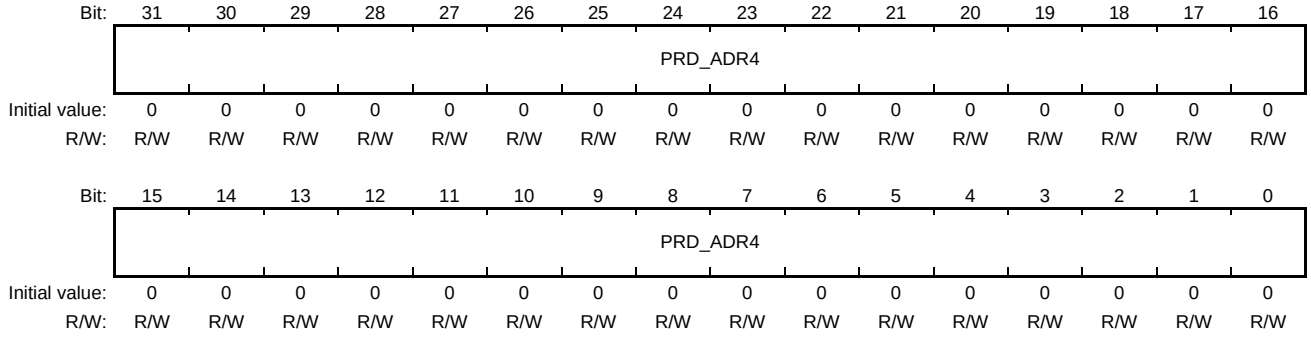
Bit	Bit Name	Initial Value	R/W	Description
0	PRD_EN4	B'0	R/W	Allow DMA Transfer of PIPEn in AXI Master. Make sure to set this bit after preparing PRD Table and setting address where PRD Table for applicable PIPE is stored from DMA_Ch0_PRD_ADR4 Register. DMA Transfer is enabled as PRD Table in the address set in DMA_Ch0_PRD_ADR4 is valid when PRD_EN4 is 1 and EXTPRD_EN4 is 0. (Note) This is cleared to 0 automatically in case the process specified by PRD Table is completed or the process is aborted due to an Error. 1: Allow DMA Transfer 0: Stop DMA Transfer

Note:

- Those registers shall not be set in each PRD_Table to be valid multiple PRD Tables for same PIPE number.
- PRD_EN is not set to 1 when PRDERR status is set due to recognizing a mistake of setting for PIPE number during requesting for writing of PRD_EN = 1

63.2.2.17 DMA Ch0 PRD Address Register4 (DMA_Ch0_PRD_ADR4)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PRD_ADR4	H'0000_0000	R/W	Specify address of Physical Region Descriptor (PRD) Table that is located in memory space. Indicates PRD Table Address where is using in case this Register is read during transfer at the applicable PRD Table. Indicates the PRD Table Address where is used when next transfer is started in case reading this bit with stopping the transfer Note that lower 3 bits are all fixed to "0" (Reserved). It is unknown value when PRD Table is completed.

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved
24	CONF	B'0	R/W	Bit to select whether Endpoints other than EP0 shall be enabled. 1: Enable Endpoints other than EP0 0: Disable Endpoints other than EP0
23	Pn_WDATAIF_NL	B'0	R/W	This bit is used to enable the write of ZLP to be transmitted in IN transfer through Data interface or on AXI DMA transfer. 1: The write of ZLP to be transmitted through Data Interface or on AXI DMA transfer is enabled 0: The write of ZLP to be transmitted through Data Interface or on AXI DMA transfer is disabled When ZLP is transferred through Data Interface or on AXI DMA transfer, set this bit to 1. Otherwise, set this bit to 0.
22	Pn_RDATAIF_NL	B'0	R/W	This bit is used to enable the read of received ZLP in OUT transfer through Data Interface or on AXI DMA transfer. 1: The read of received ZLP through Data Interface or on AXI DMA transfer is enabled 0: The read of received ZLP through Data Interface or on AXI DMA transfer is disabled. When ZLP is transferred through Data Interface or on AXI DMA transfer, set this bit to 1. Otherwise, set this bit to 0.
21	Pn_LSTTR_PP	B'0	R/W	This bit is used to disable the function to interpret the received packet with PP=0 as the last one of the transfer. 1: The received packet with PP=0 is not interpreted as the last one. 0: The received packet with PP=0 is interpreted as the last one. When ZLP is transferred through Data Interface or on AXI DMA transfer, set this bit to 1. Otherwise, set this bit to 0.
20 to 18	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
17	SPD_MODE	B'0	R/W	This is a register to set operational mode of EPC. Output clock to SRAM is switched by setting in this register. Setting values are output to Pin, spd_mode as is. 1: USB2.0 (HS/FS) 0: USB3.0 (SS)
16	EP0_EN	B'0	R	This is a bit to select whether PIPE0 (EP0) shall be enabled. 1: PIPE0 is enabled 0: PIPE0 is disabled
15	—	B'0	R	Reserved
14 to 8	Device Address	All 0	R	Value written in this bit is reflected as Device Address upon completion of STATUS Stage of SetAddress Request. Device Address value specified by the HOST shall be set before completion of STATUS Stage of Set Address Request. This is cleared automatically by WarmReset/HotReset/BusReset detection or PIPE_CLR or P0_CLR.
7 to 2	—	All 0	R	Reserved
1	RX_ DETECTION	B'0	W	Write this to 1 before starting RX Detection of USB3.0 from the state USB3.0 is stopped and USB2.0 is in use. This bit is valid at only USB30_CON.B3_CONNECT=1 This is valid when PORTSC.PLS is Disable state
0	PIPE_CLR	B'0	W	Write 1 in this bit when initialize (clear Sequence Number, DataPID and Buffer for transmit and receive) all PIPE (PIPE0 and PIPEn) all at once. It will set them in the same condition as all of P0_CLR and Pn_CLR provided for each PIPE are set. Initializing operation of PIPE varies depending on number of PIPE to be installed. This bit keeps indicating 1 until unitization is completed. Do not access other registers until this bit is cleared to 0 after 1 is written in this bit.

63.2.2.19 USB20 Control Register (USB20_CON)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R	R	W

Bit	Bit Name	Initial Value	R/W	Description
31	B2_PUE	B’0	R/W	This bit sets whether D+ Signal shall be pulled-up. The value written in this bit is output to B2_PUE Pin without any change. Note that B2_CONNECT needs to be set to 1 as well as this bit in order to connect. 1: Pull-up D+ Signal 0: Not to pull-up D+ Signal
30 to 26	—	All 0	R	Reserved
25	B2_RSUM_IN	B’0	R/W	This is a bit to set whether USB20 resume signal shall be transmitted or not. The value written in this bit is output to B2_RSUM_IN Pin and cleared automatically when Resume is started internally. This bit is used when Remote Wakeup function is supported. 1: resume signal is transmitted. 0: resume signal is not transmitted.
24	B2_SUSPEND	B’0	R/W	This is a bit to set whether PLL of USB20 PHY shall be stopped. By setting this bit to 1 when B2_SPND_OUT that indicates USB20 PHY is Suspended is set to 1, PLL of USB20PH is stopped and power consumption is reduced. PLL can be resumed by setting this to 0 when PLL is stopped. This is cleared to 0 in case B2_RSUM_OUT or B2_PLL_WAKEIN is asserted. Make sure to activate PLL before operating a register that is related to USB2.0 operation other than this bit. 1: Stop PLL of PHY 0: Not to stop PLL of PHY.
23	B2_FORCE_HS	B’0	R/W	Force HS mode operation when this bit is set. This allows the simulation time to reduce by removing Bus Reset). This bit should be set to 0 in normal operation 1: Force HS mode operation 0: Normal operation This bit is applicable for only simulation.

Bit	Bit Name	Initial Value	R/W	Description
22	B2_FORCE_FS	B'0	R/W	Force FS mode operation when this bit is set. This allows the simulation time to reduce by removing Device Chirp). This bit should be set to 0 in normal operation 1: Force FS mode operation 0: Normal operation This bit is applicable for only simulation.
21	B2_SUS_CLKMD	B'0	R/W	Control gating clock operation of CLK60_G/PG during Sleep/Suspend state in USB2.0. The setting value is present on the signal of B2_SUS_CLKMD. 1: No clock gating (CLK60_G/PG) 0: Clock gating (CLK60_G/PG) during Sleep/Suspend state
20	LPM_DISABLE	B'0	R/W	Select Enabling/Disabling LPM 1: Disable 0: Enable No response is made to receiving Extended Token (LPM) from Host when this bit is set to 1
19 to 18	LPM_ENABLE	B'00	R/W	Selects response to LPM reception. B'00: Accepted Automatically transmit ACK/NYET According to status of Buffer of EPC. * NYET Transmission in case any of The conditions provided below is met. There is a Packet Data that is being written in transmission PIPE While CTRL transfer is processing. B'01: Force Accepted Perform ACK Transmission unconditionally Regardless of EPC Buffer status. B'10: Force Rejected Perform NYET Transmission unconditionally Regardless of EPC Buffer status. B'11: Force Unsupported Perform STALL Transmission unconditionally Regardless of EPC Buffer status. * Make sure to use this with Default (=B'00) setting in normal use.
17	B2_CONNECT	B'0	R/W	Set this to 1 in case of USB2.0 connection. The value written in this bit is reflected to Output Pin B2_CONNECT without any changes. Set this bit to 1 after approx. 100 ms after detection of VBus in order to avoid chattering of VBus (it is same when it is cleared as 0). Note that bit31 B2_PUE must be set to 1 at the same time as this bit is set to1 to connect.
16	B2_PHYRST	B'0	R/W	This is a bit to reset USB20 PHY. The value of this bit is output to B2_PHY_RESET Pin. When use this bit, connect the pin so thatUSB20 PHY is reset with this bit set to 1. 1: Reset State 0: Normal state
15 to 11	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
10 to 8	B2_TSTMOD	All 0	R/W	This bit specifies Test type for USB2 Compliance TEST. Set value in this bit after Status Stage for SET_FEATURE TEST_MODE Request is successfully completed. The Core goes into a test mode when bit0: B2_TSTMOD_EN is set after (or at the same time as) setting this bit. B'000: Normal / B'001: Test_J / B'010: Test_K B'011: Test_SE0_NAK / B'100: Test_Packet B'101 - B'111: Reserved
7 to 1	—	All 0	R	Reserved
0	B2_ TSTMOD_EN	B’0	W	When this bit is set to 1, the values set in bit10...8: B2_TSTMOD is validated at the point.

Bit	Bit Name	Initial Value	R/W	Description
31	Renesas Private bit	B’0	R/W	Renesas Private bit This bit can be written only “0”. DO NOT write “1”.
30 to 29	—	All 0	R	Reserved
28 to 27	U3_POW_ SEL	B’10	R/W	PHY POWERDOWN mode immediately after transition to U3 State by reception of LGO_U3. Select (PHY_POWERDOWN [1:0]). B'00: P0 B'01: Setting prohibited B'10: P2 B'11: Setting prohibited Use POW_SEL [2:0] in case changing POWERDOWN mode after transition to U3 State.
26 to 24	POW_SEL	B’000	R/W	This is set to request change PHY POWERDOWN mode (PHY_POWERDOWN [1:0]). B'000: Transit from P0 to P2 in disconnected state (SS.Disabled) B'001: Transit from P0 to P3 in disconnected state (SS.Disabled) B'010: Transit from P2 to P0 in disconnected state (SS.Disabled) B'011: Setting prohibited B'100: Transit from P0 to P2 in U3 State B'101: Transit from P0 to P3 in U3 State B'110: Transit from P2 to P0 in U3 State B'111: Setting prohibited Transition of POWERDOWN mode other than the above is automatically done by H/W. The value in this bit is transmitted as a request when this bit is set bit2: POW_SEL_WEN. Success/Fail of the requested transition is informed by PS_SUCS/PS_FAIL interrupt. Make sure PLL is operating properly to operate with it when registers regarding to USB3.0.

Bit	Bit Name	Initial Value	R/W	Description
23	B3_ PLLWAKE	B’0	R/W	Transition from P3 to P0 will Wakeup PLL in case PHY POWERDOWN mode is in P3 (PLL Stop). Clear this bit from FW after PLL Wakeup is confirmed. 1: PLL Wakeup is requested 0: Normal state Make sure PLL is operating properly to operate with it when registers regarding to USB3.0.
22 to 20	—	All 0	R	Reserved
19 to 18	LPS_ ENABLE	B’00	R/W	Selects allow/deny transition to U1/U2 State. B'00: Accepted Automatically transmit LGO/LAU/LXU depending on status of EPC Buffer. * Transition is denied in case any of the following conditions is met. - ACK_TP is not received for DP transmitted from Transmission PIPE. - There is a Packet Data being written in Transmission PIPE. - PP of DP that was received at the end for Reception PIPE is 1. - While CTRL transfer is processing B'01: Force Accepted Transmit LGO_U1/LGO_U2 unconditionally when U1/U2 Timeout that was set in PORTPMSC Register is reached. Reply LAU for reception of LGO forcibly except in case of LXU response in LINK layer. B'10: Force Rejected LGO_U1/LGO_U2 is not transmitted even when U1/U2 Timeout that was set in PORTPMSC Register is reached. Forcibly respond with LXU for LGO reception. B'11: Setting prohibited * Use this with Default (=B'00) setting.
17	B3_ CONNECT	B’0	R/W	Set this to 1 in case of USB3.0 connection. The value written in this bit is reflected to Output Pin, B3_CONNECT without any changes. Set this bit to 1 after approx. 100 ms after detection of VBus in order to avoid chattering of VBus. Set this bit to 1. (it is same when it is cleared as 0)
16	B3_PHYRST	B’0	R/W	This is a bit to reset logic area of USB30 PHY. The value of this bit is output to Pin, B3_PHY_RESET. When this bit is used, make sure to connect pin so that USB30 PHY is reset with this bit is set to 1. 1: Reset State 0: Normal state
15 to 3	—	All 0	R	Reserved
2	POW_SEL_ WEN	B’0	W	When this bit is set to 1, it is requested to request any transfer by value of POW_SEL [2:0].

Bit	Bit Name	Initial Value	R/W	Description
1	B3_HOTRST_CMP	B'0	W	This is a bit to inform completion of Hot Reset process to Link Controller. Make sure to write 1 to this bit after necessary process of reset is completed according to the process of HotReset where is described in 7.3.3 Hot Reset Process. This bit shall be set within 12ms from the start of HotReset by B3_HOTRST_STA. The completion of HotReset is told by TS1/TS2 exchanges in Link Controller because of set of this bit.
0	B3_TP_SEND	B'0	W	Write 1 in this bit to allow transmission to TP Data that was set in USBB3_TPDAT_0/1/2 Reg. It is not sent if WarmReset or HotReset is detected before sending TP_Data

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved
28	Renesas Private bit	B’0	R	Renesas Private bit This bit can be written only “0”. DO NOT write “1”.
27 to 25	—	All 0	R	Reserved
24	PERI_CON	B’0	R/W	Peripheral/Host Switching bit Switching Core’s role. 1: Select Peripheral function 0: Select Host function
23 to 21	—	All 0	R	Reserved
20	TISRDPRE	B’0	R/W	[Host Mode] Not used [Peripheral Mode] Control signal of the executing Receiver Detection in USB30PHY.
19	Renesas Private bit	B’0	R/W	Renesas Private bit This bit can be written only “0”. DO NOT write “1”.
18	B3_FORCE_INACT	B’0	R/W	Signal for enforced transition of SS.Inactive state. 1: Enable 0: Disable
17	Renesas Private bit	B’0	R/W	Renesas Private bit This bit can be written only “0”. DO NOT write “1”.
16	B3_RSP_WPR	B’0	R/W	When this bit is set to 1, a Warm Reset is issued for RSP. The bit is set to 1 and thus determined to be for Role Swap, after which Upstream/Downstream switching starts. HW clears this bit to 0 upon the detection of a Warm Reset. 1: Start Role Swap after Warm Reset
15 to 14	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
13	DCDEN	B'0	R/W	DCD Enable bit. [Host Mode] Not used [Peripheral Mode] Select bit whether use DCD or not 1: Operate DCD 0: NOT operate DCD
12	IDPSRCEN	B'0	R/W	[Host Mode] Not used [Peripheral Mode] Signal of D+ Source Voltage Enable. Controlled by SW.
11	IDMSINKEN	B'0	R/W	[Host Mode] Not used [Peripheral Mode] Signal of D- Sink Current Enable. Controlled by SW.
10	IDPSINKEN	B'0	R/W	[Host Mode] Not used [Peripheral Mode] Signal of D+ Sink Current Enable. Controlled by SW.
9	VDMSRCEN	B'0	R/W	[Host Mode] Not used [Peripheral Mode] Signal of D- Source Voltage Enable. Controlled by SW.
8	VDPSRCEN	B'0	R/W	[Host Mode] Not used [Peripheral Mode] Signal of D+ Source Voltage Enable. Controlled by SW.
7	SHDN_ MODE	B'1	R/W	Shutdown mode bit. Software controls SHDN bit for Power IC such as Power IC type-2). 1: Normal Mode 0: Shutdown Mode
6	Renesas Private bit	B'0	R/W	Renesas Private bit This bit can be written only "0". DO NOT write "1".
5	OTG_RPUEN	B'0	R/W	OTG DP_RPU Enable bit. Controlled by Software. Set 1, DP_RPU bit is enabled 1: DP_RPU Enable Mode 0: Normal Mode
4	RPDEN	B'0	R/W	DP/DM RPD Enable bit. Set 1, bit1：DP_RPD and bit2：DM_RPD are enabled. 1: DP/DMRPD Enable Mode 0: Normal Mode
3	DP_RPU	B'0	R/W	DP Pull-up with OTG 1: Pull up enable (TermSelect = 1, XcrSelect = 1, OpMode = 0) 0: Pull up disable (TermSelect = 0, XcrSelect = 1, OpMode = 1)

Bit	Bit Name	Initial Value	R/W	Description
2	DM_RPD	B'0	R/W	[Host Mode] Not used [Peripheral Mode] UTMI+ Dm Pull down Enable bit. Controlled by SW. 1: Pull down enable 0: Pull down disable SW controls this bit only when RPDEN = 1
1	DP_RPD	B'0	R/W	[Host Mode] Not used [Peripheral Mode] UTMI+ Dp Pull down Enable bit. Controlled by SW. 1: Pull down enable 0: Pull down disable SW controls this bit only when RPDEN = 1
0	VBOUT	Note	R/W	VBUS Output Enable bit. [A-device Mode] When This bit is 1, DO_VBOUT is set to 1. [B-device Mode] Not used Note: Default value depends on signal "DI_PERICON_INIT". If DI_PERICON_INIT = 1, - VBOUT = 0 If DI_PERICON_INIT = 0, - VBOUT = 1

R/W:	R	R	RW1C	RW1C	RW1C	RW1C	RW1C	RW1C	R	R	R	R	R	R	RW1C	RW1C

Bit	Bit Name	Initial Value	R/W	Description
31	B3_PLLWKUP_STA	B'0	RW1C	Set 1 in this bit when clk125 is activated due to any one of PLL Wakeup (assertion of register set of B3_PLL_WAKEUP or assertion of B3_PLL_WAKEIN) or U3 Wakeup LFPS reception.
30	B3_LUPSUCS_STA	B'0	RW1C	Set 1 in this bit when Link Up of USB3.0 is successfully completed. (Transition of LTSSM from Polling to U0).
29	B3_POLLING_STA	B'0	RW1C	Set 1 in this bit when LTSSM transits to Polling State.
28	B3_INACTV_STA	B'0	RW1C	Set this bit to 1 when LTSSM transits to Inactive State.
27	B3_DISABLE_STA	B'0	RW1C	Set this bit to 1 when LTSSM transits to Disabled State. (only the case of transit when LTSSM transit to Disable State after setting B3_CONNECT = 1)
26	B3_VNDTST_STA	B'0	RW1C	Set this bit to 1 when Vendor Device Test LMP is received.
25	B3_U2INACT_STA	B'0	RW1C	Set this bit to 1 when U2 Inactivity Timeout LMP is received.
24	B3_SETLNK_STA	B'0	RW1C	Set this bit to 1 when Set Link Function LMP is received.
23	—	B'0	R	Reserved
22	B3_LNKCNG_STA	B'0	RW1C	Set this bit to 1 when LTSSM transits as below. U0 -> U1 U0 -> U2 U0 -> U3 U3 -> Recovery -> U0 U2 -> Recovery -> U0 U1 -> Recovery -> U0 Refer to PLS[3:0] in PORTSC Register to check current state.
21	B3_WRMRST_STA	B'0	RW1C	Set this bit to 1 when Warm Reset is received.
20	B3_HOTRST_STA	B'0	RW1C	Set this bit to 1 when Hot Reset is received.
19	B3_PSFAIL_STA	B'0	RW1C	Set this bit to 1 when Request to transit POWERDOWN mode by POW_SEL[2:0] in USB3.0_PWR_MNGCON Register is failed.

Bit	Bit Name	Initial Value	R/W	Description
18	B3_PSSUCS_STA	B'0	RW1C	Set this bit to 1 when Request to transit POWERDOWN mode by POW_SEL[2:0] in USB3.0_PWR_MNGCON Register is succeeded.
17	B3_U12REQ_STA	B'0	RW1C	Set this bit to 1 when U1/U2 TIMER is expired in SSIF in case a request to transit to U1/U2 state is accepted. According to the value in LPS_ENABLE[1:0] in USB3.0_PWR_MNGCON Register, either reply with LAU/LXU when the request of U1/U2 transition is received or send LGO_U1/LGO_U2 when U1/U2_TIMER is expired (No FW treatment is needed when the transition request is received)
16	B3_TP_SUCS_STA	B'0	RW1C	This bit is set to 1 in case transmission of TP (Device Notification) is successfully completed by USB30_CON Register B3_TP_SEND. It is not set when the transmit is not occurred due to WarmReset or HotReset during requesting the transmit by B3_TP_SEND
15 to 14	—	All 0	R	Reserved
13	B2_LPMRCV_STA	B'0	RW1C	This bit is set to 1 when ACK is replied after receiving normal LPM from USB20 Host. * At the point this status occurs, transition to L1 state is not completed. * Make sure to check for occurrence of B2_L1SPND_STA to process after transition to L1. Reply it automatically according to LPM_ENABLE[1:0] (No FW treatment is needed when the transition request is received).
12	B2_USBRST_STA	B'0	RW1C	This bit is set to 1 when Bus Reset is received from USB20 Host. This bit is set when a change of Input Pin B2_USB_RST from Low to High is detected.
11	B2_L1SPND_STA	B'0	RW1C	This bit is set to 1 when L1 Suspend Request is received from USB20 Host (when B2_L1_SPND_OUT is changed from 0 to 1).
10	B2_L1RSUM_STA	B'0	RW1C	This bit is set to 1 when clk60 is activated at the same time when requesting PLL Wakeup (either B2_SUSPEND = 0 or B2_PLL_WAKEIN assert) or L1 Resume Request is received from USB20 Host (when B2_L1_RSUM_OUT is changed from 0 to 1) during L1 (B2_L1SPND_OUT = 1).
9	B2_SPND_STA	B'0	RW1C	This bit is set to 1 when Suspend Request is received from USB20 Host (when B2_SPND_OUT is changed from 0 to 1).
8	B2_RSUM_STA	B'0	RW1C	This bit is set to 1 when clk60 is activated at the same time when PLL Wakeup is requested (B2_SUSPEND = 0 or B2_PLL_WAKEIN is asserted), Resume Request is received from USB20 Host (when B2_RSUM_OUT is changed from 0 to 1) during L2 (B2_SPND_OUT = 1) or L3 (B2_CONNECT = 0).
7 to 2	—	All 0	R	Reserved
1	SPEED_STA	B'0	RW1C	This bit is set to 1 when there is any change in Speed Mode of USB. Refer to USB_STA Register bit2. 1: SPEED to check which speed mode it is running currently. SPEED bit may be taken same value between before and after the speed mode is changed.
0	VBUS_CNG_STA	B'0	RW1C	This bit is set to 1 when Level of Input Signal VBUS is changed. Read Level of VBUS from USB_STA Register.

	—	—	—	—	—	P0_BYTE_EN		P0_SEND	P0_RES_WEN	—	—	—	—	—	P0_BCLR	P0_CLR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	W	W	W	W	R	R	R	R	R	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved
27 to 26	P0_ST_RES	B’00	R/W	This bit controls response for PIPE0 STATUS reception. B’00: Force NRDY/NAK Response B’01: Normal Response [In case of SS] ACK Response for STATUS_TP reception. [In case of HS/FS] When Control Write/NoData, Transmit Null Data for IN Token of Status Stage. When Control Read Respond ACK for OUT Token of Status Stage. B’10: Force STALL Response B’11: Setting prohibited This bit is updated to B’00 automatically upon reception of SETUP.
25 to 24	P0_OT_RES	B’00	R/W	This bit controls response for PIPE0 OUT Data reception. B’00: Force NRDY/NAK Response B’01: Normal Response (Data can be accepted depending on Buffer status) B’10: Force STALL Response B’11: Setting prohibited This bit is updated to B’00 automatically when SETUP Data reception. In case buffer status is “acceptable” in SS, ERDY is transmitted when this bit is changed from B’00 to B’01. Set this bit to B’10 during Data Stage of Control Read Request just in case Transfer Request of different direction generated from the Host.
23 to 18	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
17 to 16	P0_IN_RES	B'00	R/W	This bit controls response for PIPE0 IN Data Transmission Request. B'00: Force NRDY/NAK Response B'01: Normal Response (Data can be transmitted depending on Buffer status) B'10: Force STALL Response B'11: Setting prohibited This bit is updated to B'00 automatically when SETUP Data reception. In case buffer status is "transmittable" in SS, ERDY is transmitted when this bit is changed from B'00 to B'01. Set this bit to B'10 during Data Stage of Control Write Request just in case Transfer Request of different direction generated from the Host.
15 to 11	—	All 0	R	Reserved
10 to 9	P0_BYTE_EN	B'00	W	Specifies number of valid byte of the data written in P0_WRITE Reg. This bit is set at the same time as writing to P0_SEND. B'00: 4 Bytes is valid. B'01: Only 1 Byte is valid. (Only DATA[7:0] is valid.) B'10: Only 2 Byte is valid. (Only DATA[15:0] is valid.) B'11: Only 3 Byte is valid. (Only DATA[23:0] is valid.)
8	P0_SEND	B'0	W	Write 1 in this bit to allow to transmit the data written in P0_WRITE Reg.
7	P0_RES_WEN	B'0	W	Set this bit to 1 when writing to change the value in P0_OT_RES/P0_IN_RES/P0_ST_RES.
6 to 2	—	All 0	R	Reserved
1	P0_BCLR	B'0	W	Write 1 in this bit to clear Buffer Data of PIPE0. Set P0_IN_RES/P0_OT_RES to B'00 (Force NRDY/NAK Reply Mode) prior to clear the Buffer and confirm that P0_ACKSTS = 0 (no data is begin transferred) and stopping write operation to data buffer and then, set this bit. The interrupt status and operation mode are not cleared by setting this bit. This bit keeps indicating 1 until initialization is completed. Make sure not to access other registers until this bit is cleared to 0 after writing 1.
0	P0_CLR	B'0	W	Write 1 in this bit to initialize PIPE0 (clear Sequence Number/DataPID and transmit/receive Buffer). P0_IN_RES/P0_OT_RES is set to B'00 (forced NRDY/NAK response mode) and confirm that P0_ACKSTS = 0 (there is no data during transfer) and stopping writing to the DATA buffer, and then this bit is set before the initialization of PIPE0 is processing. Interrupt Status and Operational mode setting are not cleared by setting a value in this bit. This bit keeps indicating 1 until initialization is completed. Make sure not to access other registers until this bit is cleared to 0 after writing 1.

63.2.2.45 PIPE0 Status Register (P0_STA)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	P0_FLOWSTS	P0_ACKSTS	P0_SNDSTS	P0_BUFSTS

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved
3	P0_FLOWSTS	B’0	R	Indicates FLOW CONTROL State in PIPE0. 1: FLOW CONTROL State 0: Normal state
2	P0_ACKSTS	B’0	R	Indicates existence of Data that is currently being transferred. -In case transfer direction is OUT (P0_DIR = 0): 1 is displayed if there is any reception data that has not received ACK for. -In case transfer direction is IN (P0_DIR = 1): 1 is displayed if there is any transmission data that has not received ACK for.
1	P0_SNDSTS	B’0	R	1 is displayed if there is any Data that has not transmitted in Transmission Buffer (FIFO). This bit is cleared when written data is transmitted and ACK is received for the Data. This is invalid in case transfer direction is OUT (P0_DIR = 0).
0	P0_BUFSTS	B’0	R	Indicates status of P0_READ/P0_WRITE Reg. 1: Read/Write of Data is enabled. 0: Read/Write of Data is disabled. -In case transfer direction is OUT (P0_DIR = 0): 1 is displayed when there is reception Data that can be read from P0_READ Reg. -In case transfer direction is IN (P0_DIR = 1): 1 is displayed when there is transmission Data that can be written to P0_READ Reg.

Note: Shall not access to those bits during Read/Write process until completion of transferring one packet size through Pn_READ/Pn_WRITE. Contact to Renesas for more detail.

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	All 0	R	Reserved
18	P0_STSED_STA	B'0	RW1C	This bit is set to 1 when STATUS Stage is completed successfully.
17	P0_STSST_STA	B'0	RW1C	This bit is set to 1 upon start of STATUS Stage.
16	P0_SETUP_STA	B'0	RW1C	This bit is set to 1 when valid SETUP Data is received. Make sure to start processing a request after clearing this bit.
15 to 9	—	All 0	R	Reserved
8	P0_RCVNL_STA	B'0	RW1C	This bit is set to 1 when Null Data that was received in PIPE0 is readable. Null Data is automatically discarded when P0 Length Register is read.
7	P0_ERDY_STA	B'0	RW1C	This bit is set to 1 when transmission condition of ERDY for PIPE0 is met. This is invalid in case of HS/FS. In case P0_IN_RES/P0_OT_RES/P0_ST_RES is set to any except Forced NRDY/NAK Response (B'00), ERDY is transmitted to Host.
6	P0_FLOW_STA	B'0	RW1C	This bit is set to 1 when PIPE0 is transited to Flow Control State. This is invalid in case of HS/FS. -In case transfer direction is IN (P0_DIR = 1): This bit is set to 1 upon transmission of NRDY_TP. -In case transfer direction is OUT (P0_DIR = 0): This bit is set to 1 upon transmission of NRDY_TP or transmission of ACK_TP with NumP = 0.
5 to 3	—	All 0	R	Reserved
2	P0_STALL_STA	B'0	RW1C	This bit is set to 1 when STALL is transmitted in response to requests of IN/OUT/STATUS to PIPE0.
1	P0_NRDY_STA	B'0	RW1C	This bit is set to 1 when NRDY/NAK is transmitted in response to requests of IN/OUT/STATUS to PIPE0.

Bit	Bit Name	Initial Value	R/W	Description
0	P0_BFRDY_STA	B'0	RW1C	In case transfer direction is IN (P0_DIR = 1): This bit is set to 1 when the next data can be written in P0_WRITE Reg. This bit is not set for interruption before writing at the first packet when the buffer is empty, where is like Reset. -In case transfer direction is OUT (P0_DIR = 0): This bit is set to 1 when the next data can be read from 0_READ Reg.

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved
9 to 0	P0_LENGTH	B'00_0000_0000	R	This field shows the number of bytes in received packet which is currently read from P0_READ register. The value is decremented every time P0_READ register is read. Since P0_READ register allows only 32-bit access, the value is decremented by 4. Since P0_READ register is controlled in a unit of a packet, the length of received packet is shown in this register when the first 4 bytes of it are shown in P0_READ register and have not been read yet. This register is valid only for OUT direction.

Note: Once the access to one of P0_READ, Pn_READ, P0_WRITE and Pn_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in the unit of packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet. See section 63.9.2 for details.

63.2.2.51 PIPE0 Read Register (P0_READ)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

If there is no data in buffer, H'0000_0000 is returned. Only 32-bit access is allowed to this register.

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	P0_RDATA	H'0000_0000	R	Read data from PIPE0. This register is controlled in a unit of a packet and can't be read across the packet. That is, this register is updated in a unit of a packet. The current packet is never concatenated with the next packet even when the length of the current packet is not multiples of 4 and the last word of it is less than 4 bytes. In that case, the first 4 bytes of the next packet are shown in this register after the last word of the previous packet has been read. If the length of the current packet is not multiples of 4 and the last word of it is less than 4 bytes, the last word has one or more invalid bytes. In order to know how many valid bytes the last word has, see P0_LENGTH[7:0] before the read of the packet and calculate from it. The valid bytes are aligned from P0_RDATA[7:0]. This register is valid only for OUT direction.

Note: Once the access to one of P0_READ, Pn_READ, P0_WRITE and Pn_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in the unit of packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet. See section 63.9.2 for details.

63.2.2.52 PIPE0 Write Register (P0_WRITE)

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved
25 to 24	Pn_ERDY_CON	B’00	R/W	This field specifies the condition to resume the transfer for PIPE. In case the device works in SS, the controller requests the exit from U1 or U2 if it is in the low power state or transmits ERDY if it is in the flow-control state, when the condition below is satisfied. In case the device works in HS or FS and the direction of transfer is IN (Pn_MOD.Pn_DIR==1), the controller requests the exit from L1 if it is in the low power state when the condition below is satisfied. The condition is as follows. In case the direction of transfer is OUT (Pn_MOD.Pn_DIR==0): the device is in the flow-control state and the buffer of PIPEn has available space equivalent to the value in this field or more. In case the direction of transfer is IN (Pn_MOD.Pn_DIR==1): the device is in the flow-control state or L1 and the buffer of PIPEn has packets equivalent to the value in this field or more. the device is in the flow-control state or L1 and the buffer of PIPEn has the last packet of the transfer. Note that the controller requires clock from USB3.0-PHY when it requests the exit from U1 or U2 and clock from USB2.0-PHY when it requests the exit from L1. If not, the controller doesn’t request the exit from the states. [Setting Value] B’00: 1 Block (Packet) B’01: 2 Blocks (Packets) B’10: 4 Blocks (Packets) B’11: 8 Blocks (Packets)
23 to 18	—	All 0	R	Reserved
17	Pn_BOT	B’0	R/W	This bit specifies whether Bulk Only Transfer (BOT) mode is used or not. 1: BOT mode 0: Normal mode In case this bit is set to 1, Pn_INT_STA.Pn_CBW_STA is enabled.

Bit	Bit Name	Initial Value	R/W	Description
16	Pn_STREAM	B’0	R/W	This bit is specified whether Stream bulk protocol is used or not. 1: Stream bulk mode 0: Normal mode This bit can be used only for bulk PIPE. (Pn_TYPE[1:0]== B’10)
15 to 7	—	All 0	R	Reserved
6	Pn_DIR	B’0	R/W	This bit specifies the direction of transfer. 0: OUT 1: IN
5 to 4	Pn_TYPE	B’00	R/W	This field specifies the type of transfer of PIPEn. B’00: Reserved (This setting is prohibited) B’01: Isochronous (This setting is prohibited) B’10: Bulk B’11: Interrupt
3 to 0	Pn_EPNUM	H’0	R/W	This field specifies the index of endpoint of PIPEn.

63.2.2.56 PIPEn RAM Mapping Register (Pn_RAMMAP)

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	Pn_RAMAREA	B’000	R/W	This field specifies the area in SRAM for PIPEn. The area of SRAM attached to the interface specified in Pn_RAMIF[1:0] is given to PIPEn. The area is calculated as 1 Kbytes × 2^ (Pn_RAMAREA[2:0]). 1 Block requires 1 Kbytes regardless of the max packet size in Pn_MPKT[10:0]. Pn_RAMAREA[2:0] the area given to PIPEn B’000 1 Kbytes (1 Block) B’001 2 Kbytes (2 Blocks) B’010 4 Kbytes (4 Blocks) B’011 8 Kbytes (8 Blocks) B’100 16 Kbytes (16 Blocks) B’101- B’111 Setting prohibited
28 to 27	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
26 to 16	Pn_MPKT	B'000_0000_0000	R/W	This field specifies the max packet size of PIPEn. Select the value set to this field from among 8, 16, 32, 64, 512 and 1024. PIPE0 or bulk PIPE are defined to have the max packet size from among them in all speed mode. But interrupt PIPE may have the max packet size which doesn't equal to any of them. In that case, select the value which is more than the max packet size and proximate one, and set it to this field. The controller controls buffer in the unit of the values above.
15 to 14	Pn_RAMIF	B'00	R/W	This field specifies the index of SRAM interface connected to SRAM allocated to PIPEn.
13 to 0	Pn_BASEAD	B'00_0000_0000_0000	R/W	This field specifies the base address in SRAM allocated to PIPEn. Sets Base Address of 64 bit buffer RAM for EPC to be allocated to PIPEn. The address for 64 bit word is used. (ex: If 4K bytes from the start of RAM is assigned to PIPE1 and the area from the boundary is assigned to PIPE2, set H'200 to this field for PIPE2.) This field can be modified when Pn_CON.Pn_EN==0. Since the area is assigned in the unit of 1K bytes, the lower 7 bits of this field is read only and fixed to 0.

63.2.2.57 PIPEn Control Register (Pn_CON)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

R/W:	R	R	R	R	W	W	W	W	W	R	R	R	R	R	W	W

Bit	Bit Name	Initial Value	R/W	Description
31	Pn_EN	B’0	R/W	This bit enables or disables PIPEn. The setting in this bit is valid when USB_COM_CON.CONF==1. In case this bit is disabled, make sure that no data transfer is executed to PIPEn. In case this bit is enabled, make sure that the initialization of PIPEn has been done. 1: PIPEn Enabled 0: PIPEn disabled (PIPEn gives no response for any access.)
30	Pn_DATAIF_EN	B’0	R/W	This bit enables or disables Data Interface of the controller for PIPEn. As the controller also uses Data Interface of the controller, Data Interface should be enabled in the configuration with AXI-IF. 1: Data Interface is enabled 0: Data Interface is disabled Note that this bit is reset to 0 every time CBW is received with Bulk Only Transfer (BOT) mode. (Pn_MOD.Pn_BOT==1). If data transfer is requested in CBW, it is required to set this bit to 1 again before the data transfer.
29 to 25	—	All 0	R	Reserved
24	Pn_SEND	B’0	W	When 1 is written to this bit, the controller requests the exit from U1, U2 or L1 if it is in the states, or it transmits ERDY with no condition if it is not in the states. Since the controller automatically sends ERDY when it wants to resume the transfer, it is not required to use this bit basically. If there is any case ERDY is required to be sent intentionally, this bit is available for that case. This bit is write only and the value read from this bit is always 0.
23 to 18	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
17 to 16	Pn_RES	B'00	R/W	In case of the direction of transfer is OUT (Pn_MOD.Pn_DIR==0), this field specifies the response of PIPEn for the reception of OUT data. B'00: Forced NRDY/NAK Response B'01: Normal Response (Data can be accepted depending on the buffer status) B'10: Forced STALL Response B'11: Setting prohibited ERDY is transmitted when the value of this bit is changed from B'00 to B'01 if the device works in SS and the buffer has available space for PIPEn. In case of Stream bulk OUT (Pn_MOD.Pn_STREAM==1), this bit is automatically changed to B'00 (Forced NRDY/NAK response) when DP(PRIME) or DP(NoStream) is received. In case of the direction of transfer is IN (Pn_MOD.Pn_DIR==1), this field specifies the response of PIPEn for the transmission of IN data. B'00: Forced NRDY/NAK Response B'01: Normal Response (Data can be transmitted depending on the buffer status) B'10: Forced STALL Response B'11: Setting prohibited ERDY is transmitted when the value of this bit is changed from B'00 to B'01 if the device works in SS and the buffer has data to be transmitted from PIPEn. In case of Stream bulk OUT (Pn_MOD.Pn_STREAM==1), this bit is automatically changed to B'00 (Forced NRDY/NAK response) when ACK (PRIME) is received. Note that Pn_RES_WEN is set to 1 at the same timing this field is modified.
15 to 12	—	All 0	R	Reserved
11	Pn_LAST	B'0	W	This bit indicates whether the packet written through Pn_WRITE register is the last one of the transfer (of the Stream ID). This bit is set at the same timing Pn_SEND is set in order to transmit the packet written through Pn_WRITE register. In case that the packet is the last one, set this bit and Pn_SEND in one word access. 1: The last packet 0: Not the last packet Pn_INT_STA.Pn_LSTTR_STA is asserted when the packet with this bit set has been sent and has been acknowledged by host. This bit is write only and the value read from this bit is always 0.
10 to 9	Pn_BYTE_EN	B'00	W	This bit specifies the number of valid bit in the last word that was written through Pn_WRITE register. This bit is set the same time as writing a value in Pn_SEND. 00: 4 bytes are valid. 01: Only 1 byte is valid. (Only DATA[7:0] is valid.) 10: Only 2 bytes are valid. (Only DATA[15:0] is valid.) 11: Only 3 bytes are valid. (Only DATA[23:0] is valid.) This field is write only and the value read from this field is always 0.

Bit	Bit Name	Initial Value	R/W	Description
8	Pn_SEND	B'0	W	Write 1 to this bit in order to transmit the packet written to Pn_WRITE register. This bit is write only and the value read from this bit is always 0.
7	Pn_RES_WEN	B'0	W	Write 1 to this bit when changing Pn_RES[1:0]. This bit is write only and the value read from this bit is always 0.
6 to 2	—	All 0	R	Reserved
1	Pn_BCLR	B'0	W	Write 1 to this bit in order to clear buffer of PIPEn. Set Pn_RES[1:0] to B'00 (forced NRDY/NAK response mode) and make sure Pn_ACKSTS==0 (no data is being transferred) and stop the access to buffer before initializing the buffer with this bit. In case of Stream bulk protocol (Pn_MOD.Pn_STREAM==1), Pn STREAM register is also initialized when this bit is used. This bit shows 1 until the initialization is completed. It is not allowed to access other registers until this bit is cleared to 0 after writing 1 to this bit.
0	Pn_CLR	B'0	W	Write 1 to this bit in order to initialize PIPEn (clearing sequence number, data PID and buffer). Set Pn_RES[1:0] to B'00 (forced NRDY/NAK response mode) and make sure Pn_ACKSTS==0 (no date is being transferred) and stop the access to the buffer of PIPEn before PIPEn is initialized. This bit shows 1 until the initialization is completed. It is not allowed access other registers until this bit is cleared to 0 after writing 1 to this bit.

63.2.2.58 PIPEn Status Register (Pn_STA)

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved
3	Pn_FLOWSTS	B'0	R	This bit shows the flow control state of PIPEn. 1: flow control state 0: normal state
2	Pn_ACKSTS	B'0	R	This bit shows whether PIPEn has data that is currently being transferred or not. In case that the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit shows 1 if PIPEn has data which has been received but ACK for it has not been transmitted yet. In case that the direction of transfer is IN (Pn_MOD.Pn_DIR==1), this bit shows 1 if PIPEn has data which has already been transmitted but has not received ACK for it yet.
1	Pn_SNDSTS	B'0	R	This bit shows 1 if PIPEn has data which has not been transmitted yet. This bit is reset to 0 when all of written data have been transmitted and ACKs for them have been received. This bit is invalid for the case that the direction of transfer is OUT (Pn_MOD.Pn_DIR==0).
0	Pn_BUFSTS	B'0	R	This bit shows the buffer status of PIPEn. 0: The buffer can't accept data for write, or it has no packet for read. 1: the buffer can accept data for write, or it has one or more packets for read. In case that the direction of transfer is OUT (Pn_MOD.Pn_DIR==0), this bit shows 1 if it has one or more received packets in the buffer. In case that the direction of transfer is IN (Pn_MOD.Pn_DIR==1), this bit shows 1 if data to be transmitted can be written to the buffer.

Note: Once the access to one of P0_READ, Pn_READ, P0_WRITE and Pn_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in the unit of packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet. See section 63.9.2 for details.

63.2.2.59 PIPEn Interrupt Status Register (Pn_INT_STA)

R/W:	R	R	R	R	R	R	R	RW1C	RW1C	RW1C	R	RW1C	R	RW1C	RW1C	RW1C

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved
24	Pn_CBW_STA	B'0	RW1C	This bit is valid only when Bulk Only Transfer is supported (Pn_MOD.Pn_BOT = 1) and the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0). This bit is set to1 when CBW is received to PIPEn and the data can be read from Pn_READ register. CBW is defined by following conditions. — The length of the packet is 31 bytes. — The first 4 bytes of the packet (dCBWSignature) equals to 43425355h.
23 to 21	—	All 0	R	Reserved
20	Pn_STERR_STA	B'0	RW1C	This bit is set to 1 when Stream bulk protocol error occurs in PIPEn. See USB3.0 specification for detail of error in Stream bulk protocol. This bit is invalid in case of HS and FS.
19	Pn_STRMX_STA	B'0	RW1C	This bit is set to 1 when Stream ID of the packet received at PIPEn from host doesn't equal to the value in Pn_STREAM.Pn_STREAM_C (except for PRIME and NoStream). See Pn_NRDYSTRM register to know the Stream ID of received packet which has been rejected. This bit is invalid in case of HS and FS.
18	Pn_CSTRM_STA	B'0	RW1C	This bit might be changed and an interrupt due to it might be generated if not masked. Make sure not to set bit18 in Pn_INT_ENA register in order to disable the interrupt due to this bit.

Bit	Bit Name	Initial Value	R/W	Description
17	Pn_NSTRM_STA	B'0	RW1C	This bit indicates that NoStream is designated as Stream ID for PIPEn and is valid only in case Stream bulk protocol is used. (Pn_MOD.Pn_STREAM = 1). In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this bit is set when ACK(NoStream) is received. Pn_CON.Pn_RES[1:0] is automatically set to NRDY response (=B'00) in that case. In case of the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit is set when DP(NoStream) is received. Pn_CON.Pn_ERS[1:0] is automatically set to NRDY response (=B'00) in that case. This bit is invalid in case of HS/FS.
16	Pn_PRIME_STA	B'0	RW1C	This bit indicates that PRIME is designated as Stream ID for PIPEn and is valid only in case Stream bulk protocol is used. (Pn_MOD.Pn_STREAM = 1). In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this bit is set when ACK(PRIME) is received. Pn_CON.Pn_RES[1:0] is automatically set to NRDY response (=B'00) in that case. In case of the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit is set when DP(PRIME) is received. Pn_CON.Pn_ERS[1:0] is automatically set to NRDY response (=B'00) in that case. This bit is invalid in case of HS/FS.
15 to 9	—	All 0	R	Reserved
8	Pn_RCVNL_STA	B'0	RW1C	This bit indicates that zero length packet has been received at PIPEn and becomes ready to be read. The zero length packet received is automatically discarded when Pn_LNG register is read for it. Therefore, this bit is asserted when Pn_LNG register shows 0 for the zero length packet received. When this bit is asserted, it is required to read Pn_LNG register as the read action for the zero length packet. If Pn_LNG register shows 0, it means the zero length packet has been read.
7	Pn_ERDY_STA	B'0	RW1C	This bit indicates that the condition to transmit ERDY from PIPEn is satisfied. If Pn_CON.Pn_RES[1:0] has the value other than NRDY response and this bit is asserted, ERDY is transmitted to host. For Stream bulk protocol, Pn_CON.Pn_RES[1:0] should be set to normal response (=B'01) so that ERDY is transmitted to specify Stream ID. This bit is invalid in case of HS and FS.
6	Pn_FLOW_STA	B'0	RW1C	This bit indicates that PIPEn enters the flow control state. In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this bit is set to 1 when PIPEn sends NRDY or DP with EOB = 1. In case the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit is set to 1 when PIPEn sends NRDY or ACK with NumP = 0. This bit is also set to 1 when PIPEn receives the deferred packet. This bit is invalid in case HS and FS.
5	—	B'0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
4	Pn_LSTTR_STA	B'0	RW1C	This bit indicates that PIPEn has transmitted or received the last packet of the transfer. In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this bit is set to 1 when PIPEn has transmitted the packet for which Pn_CON.Pn_LAST is set. In case the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit is set to 1 when PIPEn has received the short packet or the packet with PP = 0.
3	—	B'0	R	Reserved
2	Pn_STALL_STA	B'0	RW1C	This bit is set to 1 when STALL has been transmitted from PIPEn.
1	Pn_NRDY_STA	B'0	RW1C	This bit is set to 1 when NRDY or NAK has been transmitted from PIPEn.
0	Pn_BFRDY_STA	B'0	RW1C	This bit indicates the buffer status of PIPEn. In case the direction of transfer is IN (Pn_MOD.Pn_DIR = 1), this bit is set to 1 when the buffer of PIPEn is ready to accept the next IN data. This bit is not asserted for the wirte of first packet after the controller is initialized by reset (hardware reset, USB_COM_CON.PIPE_CLR, Pn_CON.Pn_BCLR and Pn_CON.Pn_CLR). After reset, the first packet can be written immediately although this bit is not asserted. In case the direction of transfer is OUT (Pn_MOD.Pn_DIR = 0), this bit is set to 1 when the next packet in the buffer of PIPEn is ready to be read.

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved
15 to 0	Pn_LENGTH	H'0000	R	This field shows the number of bytes in received packet which is currently read from Pn_READ register. The value is decremented every time Pn_READ register is read. Since Pn_READ register allows only 32-bit access, the value is decremented by 4. Since Pn_READ register is controlled in a unit of a packet, the length of received packet is shown in this register when the first 4 bytes of it are shown in Pn_READ register and have not been read yet. This field is valid only for OUT PIPE.

Note: Once the access to one of P0_READ, Pn_READ, P0_WRITE and Pn_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in the unit of packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet. See section 63.9.2 for details.

63.2.2.63 PIPEn Read Register (Pn_READ)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

If there is no data in buffer, H'0000_0000 is returned. Only 32-bit access is allowed to this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Pn_RDATA															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

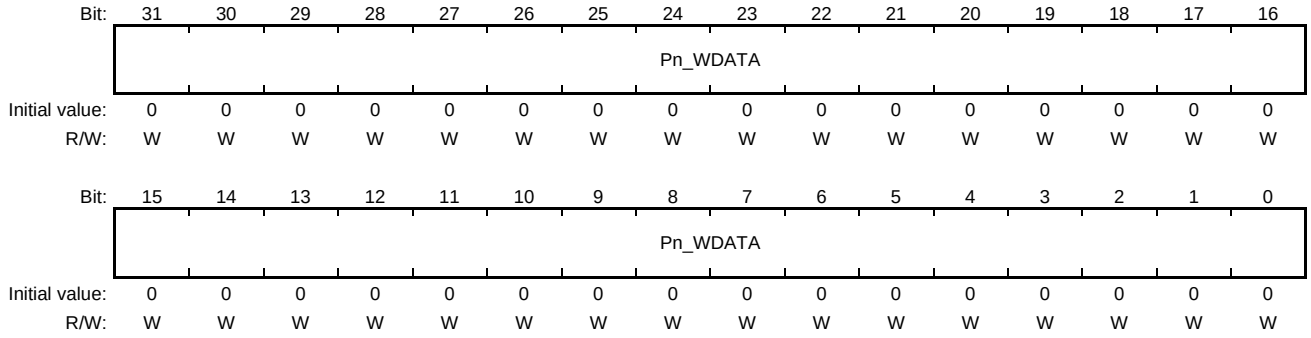
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Pn_RDATA															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Pn_RDATA	H'0000_0000	R	Read data from PIPEn. This register is controlled in a unit of a packet and can't be read across the packet. That is, this register is updated in a unit of a packet. The current packet is never concatenated with the next packet even when the length of the current packet is not multiples of 4 and the last word of it is less than 4 bytes. In that case, the first 4 bytes of the next packet are shown in this register after the last word of the previous packet has been read. If the length of the current packet is not multiples of 4 and the last word of it is less than 4 bytes, the last word has one or more invalid bytes. In order to know how many valid bytes the last word has, see Pn_LENGTH[7:0] before the read of the packet and calculate from it. The valid bytes are aligned from Pn_RDATA[7:0]. This register is valid only for OUT PIPE.

Note: Once the access to one of P0_READ, Pn_READ, P0_WRITE and Pn_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in the unit of packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet. See section 63.9.2 for details.

63.2.2.64 PIPEn Write Register (Pn_WRITE)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

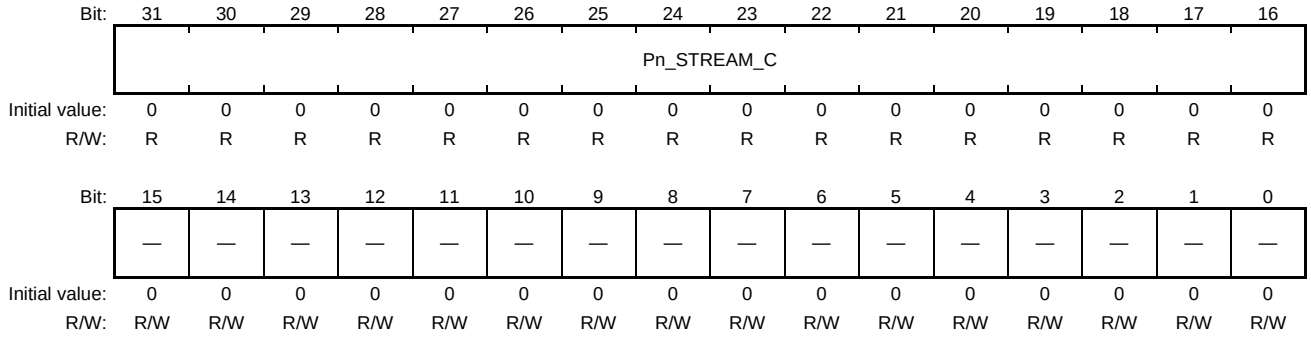


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Pn_WDATA	H'0000_0000	W	Write data to PIPEn. This register is controlled in a unit of a packet and can't be written across the packet. That is, it is not allowed to concatenate the current packet with the next packet to write them to this register even when the length of the current packet is not multiples of 4 and the last word of it is less than 4 bytes. In that case, the next packet can be written to this register after the write of the previous packet has been completed and it has been transmitted. This register is valid only for IN PIPE.

Note: Once the access to one of P0_READ, Pn_READ, P0_WRITE and Pn_WRITE registers is started in order to read or write a packet, it is prohibited to access to other Px_yyy register before whole of a packet has been read or written with the register which is currently used. The access to these registers is controlled in the unit of packet, so the targeted register can be changed at the point that the read or write of the current packet has been completed and the access for the next packet is not started yet. See section 63.9.2 for details.

63.2.2.65 PIPEn Stream ID Register (Pn_STREAM)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Pn_STREAM_C	H'0000	R	This field indicates the Stream ID that is currently valid. This field is invalid in case of HS/FS. This field is valid only in case that the type of transfer is bulk (Pn_TYPE = B'10) and Stream ID is supported (Pn_MOD.Pn_STREAM = 1) for PIPEn. When this field shows H'0000, it means that Stream ID is not set yet. This field is reset when Pn_CON.Pn_BCLR is set.
15 to 0	—	All 0	R/W	The initial value of this field is 0. This field can be read and written but it is not allowed to change the value of this field. Only 0 is allowed as the value to be written.

63.2.2.66 PIPEn NRDY Stream ID Register (Pn_NRDYSTRM)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved
16	LWS	B’0	R	Write 1 to this bit in order to enable the write access to PLS[3:0]. When this bit is 0, write to PLS[3:0] is ignored. This bit is write only and the value read from this bit is always 0.
15 to 9	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
8 to 5	PLS	H’4	R/W	[for write access] This field is used to request the direct transition of LTSSM state. For the timeout control of the transition to U1 or U2, see section 63.2.2.70. Set LWS bit to 1 when this field is written. As only 32-bit access is allowed to this register, make sure to set LWS to 1 in one word write for this register in order to change PLS[3:0]. When the same state as the current state is written to this field, the write access is ignored. If the transition using this function has not been completed but the next write access to this filed comes, the next write data is also ignored. If the request of transition to U2 state is written during the transition to U1 state is being executed due to U1 timeout, the request is ignored. If the request of transition to U0 state is written when LTSSM state is in U1, U2 or U3 state, the exit operation or the resume operation is started. If the remote wakeup is requested when LTSSM state is U1 or U2 state, hardware executes the resume operation to U0 state automatically and PLS[3:0] shows U0 after the operation has been completed. H'0: Transition request to U0 state H'1: Transition request to U1 state H'2: Transition request to U2 state H'3-H'F: Setting prohibited It is prohibited to request the transition to U1 or U2 state during control transfer. [for read access] This field shows the current state of LTSSM. H'0: U0 state H'1: U1 state H'2: U2 state H'3: U3 state H'4: Disabled state H'5: RxDetect state H'6: Inactivity state H'7: Polling state H'8: Recovery state H'9: Hot Reset state H'A: Compliance state H'B: Loopback state H'C- H'F: Setting prohibited
4 to 0	—	All 0	R	Reserved

63.2.2.68 Port PM Status and Control Register (PORTPMSC)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	U2_TIMEOUT								U1_TIMEOUT							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved
16	FLA	B’0	R	This bit is set to 1 when Force LinkPM Accept bit in the received Set LInk Function LMP equals to 1. In case this bit shows 1, the port accepts LGO_U1 and LGO_U2 with no condition. This bit is cleared to 0 when Set Link Function LMP with Force LinkPM Accept bit = 0 is received. Software can write 0 to clear this bit, but basically this bit is set or reset on the reception of Set Link Function LMP.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	U2_TIMEOUT	H'00	R/W	This field indicates the timeout value in U2 inactivity timer. H'00: No timeout but LGO_Ux is always denied with LXU: default H'01: 256 us H'02: 512 us ... ... H'FE: 65.204 ms H'FF: No timeout and LGO_Ux is basically accepted. (But it might be rejected due to other reasons.) This field is automatically updated when U2 Inactivity LMP is received. When this field has the value from H'01 to H'FE, it means the idle timeout value for LTSSM to request the transition from U0 state to U1state as well as the idle timeout value for to make the transition from U1 state to U2 state. If U1_TIMEOUT[7:0] has H'00 or H'FF but U2_TIMEOUT[7:0] has a value from H'01 to H'FE, U2 timeout occurs although U1 timeout never. In that case Peripheral portion never sends LGO_U1 but sends LGO_U2 to request the transition from U0 state to U2 state. If downstream port accepts the request, the downstream port and Peripheral portion enter U2 state. Otherwise, U1 timeout occurs first and Peripheral portion sends LGO_U1 to request the transition from U0 state to U1 state. If downstream port accepts the request, the downstream port and Peripheral portion enter U1 state. If they stay in U1 state and U2 timeout occurs, they make the transition from U1 state to U2 state silently, without going back to U0 state. The transition is executed automatically by hardware when the timeout occurs. Note: This field is initialized to H'00 during reset and just after reset, but changed to H'FF when Peripheral portion detects disconnect as USB3.0 device. If reset (in this case, it will be power on reset) is asserted but the device is in the disconnected state, H'FF might be loaded to this field. Since this field is changed to H'FF when disconnect is detected, set the adequate value to this field after the connection if required.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	U1_ TIMEOUT	H’00	R/W	This field indicates the timeout value in U1 inactivity timer. H'00: No timeout but LGO_Ux is always denied with LXU: default H'01: 1 us H'02: 2 us ... ... H'7F: 127 us H'80- H'FE: Setting prohibited H'FF: No timeout and LGO_Ux is basically accepted. (But it might be rejected due to other reasons.) This field is not automatically updated unlike U2_TIMEOUT[7:0]. Software is required to set this field. When this field has the value from H'01 to H'7F, it means the idle timeout value for LTSSM to request the transition from U0 state to U1 state. The hardware automatically sends LGO_U1 when the timeout occurs. If it is accepted, the transition is also executed by hardware automatically. Note: This field is initialized to H'00 during reset and just after reset, but changed to H'FF when Peripheral portion detects disconnect as USB3.0 device. If reset (in this case, it will be power on reset) is asserted but the device is in the disconnected state, H'FF might be loaded to this field. Since this field is changed to H'FF when disconnect is detected, set the adequate value to this field after the connection if required.

	—	—	—	—	—	—	SSIF_URES		SSIF_UDIR		SSIF_UREQ		—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved
9 to 8	SSIF_URES	B’00	R/W	This field specifies the response of EPC when it receives LGO_U1 or LGO_U2. [bit1] this bit specifies the response when LGO_U2 is received. 0: Normal response. (default) Peripheral portion basically accepts LGO_U2. (But it might be rejected due to other reasons.) 1: Forced LXU response. Peripheral portion never accepts LGO_U2 and always returns LXU to it. [bit0] this bit specifies the response when LGO_U1 is received. 0: Normal response. (default) Peripheral portion basically accepts LGO_U1. (But it might be rejected due to other reasons.) 1: Forced LXU response. Peripheral portion never accepts LGO_U1 and always returns LXU to it

Bit	Bit Name	Initial Value	R/W	Description
7 to 6	SSIF_UDIR	B’11	R/W	This field enables to transmit LGO_U1 or LGO_U2 when the transition to U1 or U2 state is requested directly through PORTSC.PLS[3:0]. The transition to U1 or U2 state can be requested by writing the state to PORTSC.PLS[3:0]. If SSIF_UDIR[1:0] enables to send LGO_U1 or LGO_U2, Peripheral portion sends LGO_U1 or LGO_U2. If it is accepted, LTSSM transits to U1 or U2 state. If SSIF_UDIR[1:0] disables, EPC doesn’t send LGO_U1 and LGO_U2 and writing to PORTSC_PLS[3:0] has no meaning. [bit1] this bit specifies the behavior when the transition to U2 state is requested. 0: LGO_U2 is transmitted. 1: LGO_U2 is not transmitted. (default) [bit0] this bit specifies the behavior when the transition to U1 state is requested. 0: LGO_U1 is transmitted. 1: LGO_U1 is not transmitted. (default)
5 to 4	SSIF_UREQ	B’00	R/W	This field enables the transmission of LGO_U1 or LGO_U2 when the timeout on U1/U2 inactivity timer occurs. [bit1] this bit specifies the behavior when the timeout on U2 inactivity timer occurs. 0: LGO_U2 is transmitted. (default) 1: LGO_U2 is not transmitted. [bit0] this bit specifies the behavior when the timeout on U1 inactivity timer occurs. 0: LGO_U1 is transmitted. (default) 1: LGO_U1 is not transmitted. Note: This field is initialized to B’00 during reset and just after reset, but changed to B’11 when Peripheral portion detects disconnect as USB3.0 device. If reset (in this case, it will be power on reset) is asserted but the device is in the disconnected state, B’11 might be loaded to this field. Since this field is changed to B’11 when disconnect is detected, set this field to enable the transmission of LGO_Ux after the connection if required.

63.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

63.3.1 Reset

The USB3.0 controller reset diagram is provided below.

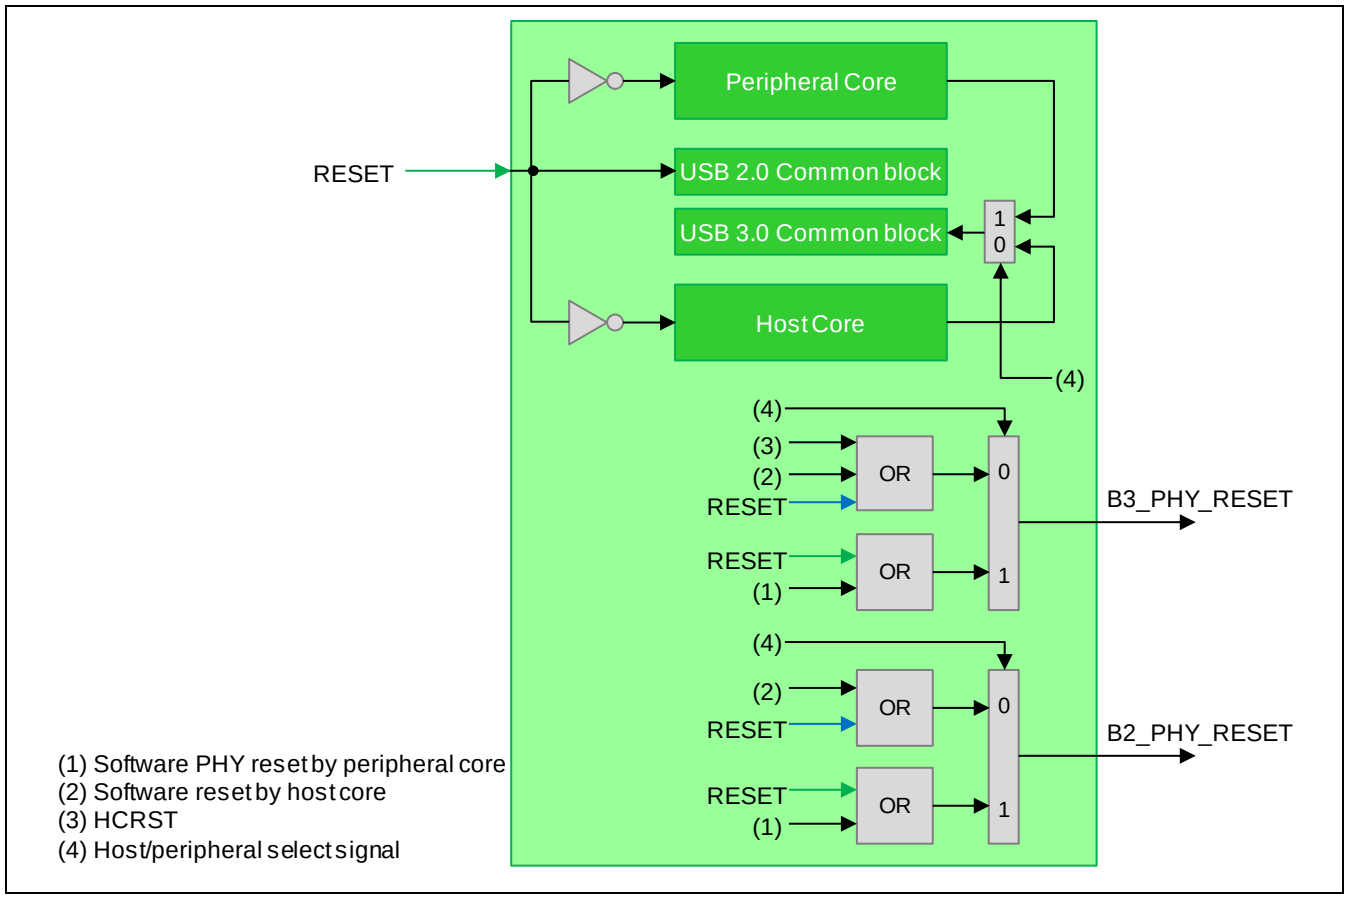

Figure 63.2 Reset Diagram

Note: (2) Software Reset by Host core is output by setting AXH_CON.B3_PHYRST bit.
(3) HCRST, Refer to [HCRST].
RESET in Figure 63.2 is the reset signal from CPG.

63.3.1.1 Host Controller core

(1) Reset Operation

- When the power is ON or USB3.0 module is reset, RESET is asserted.
- The reset is deasserted when USB2.0PLL becomes stable because reset synchronization is cleared.

(2) Reset in Cold Boot

- During cold boot and when the power is ON, RESET is asserted.
- The reset is deasserted when USB2.0 PLL becomes stable because reset synchronization is cleared.

(3) HCRST

- The host controller reset (HCRST) is asserted when the USBCMD.HCRST bit is set to 1 by software, after which the USBSTS.HCH bit (HCHalted bit) will be 0.
- When HCRST is set, Host core is reset by FW, and initialized.

63.3.1.2 Peripheral Controller core

- The Peripheral controller's main Reset is generated by a module reset.
- The Reset is deasserted when AXI clock becomes stable because Reset synchronization is cleared.

63.3.1.3 PHY Reset

B3_PHY_RESET and B2_PHY_RESET are used for a reset of USB3.0 PHY and USB2.0 PHY respectively.
Each PHY reset signal is generated by reset signals from the host core. (Refer to Table 63.5)

Table 63.5 B3_PHY_RESET and B2_PHY_RESET

USB3.0 Controller	Register Setting	Reset Target PHY
Host core	AXH_CON.B3_PHYRST = 1	USB3 PHY is reset
	AXH_CON.B2_PHYRST = 1	USB3 PHY is reset
Peripheral core	USB30_CON.B3_PHYRST = 1	USB3 PHY is reset
	USB20_CON.B2_PHYRST = 1	USB3 PHY is reset

Table 63.6 Resources of B3_PHY_RESET and B2_PHY_RESET

	DRD_CON .PERI_CON	HCRST	RESET (Software Reset)
B3_PHY_RESET	0 (Host)	√	√
	1 (Peripheral)		√
B2_PHY_RESET	0 (Host)		√
	1 (Peripheral)		√

Note: RESET (Software Reset) shows “RESET” described in Figure 63.2.

The reset signal is selected at the selector by the “Host/Peripheral Select Signal”.

It is controlled by DRD_CON.PERI_CON.

- DRD_CON.PERI_CON = 0, the reset signal from the Host Core is selected.
- DRD_CON.PERI_CON = 1, the reset signal from the Peripheral Core is selected.

63.4 Description of Host Functions

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

63.4.1 FW Download

The USB3.0 controller requires to download FW via AXI to operate as a host.

FW Download is realized by writing FW image data to a specific area in the AXI Register space. Upon the completion of FW Download, there is no need to write or reload FW.

63.4.1.1 Download Data Format

The following format is used for FW Download.

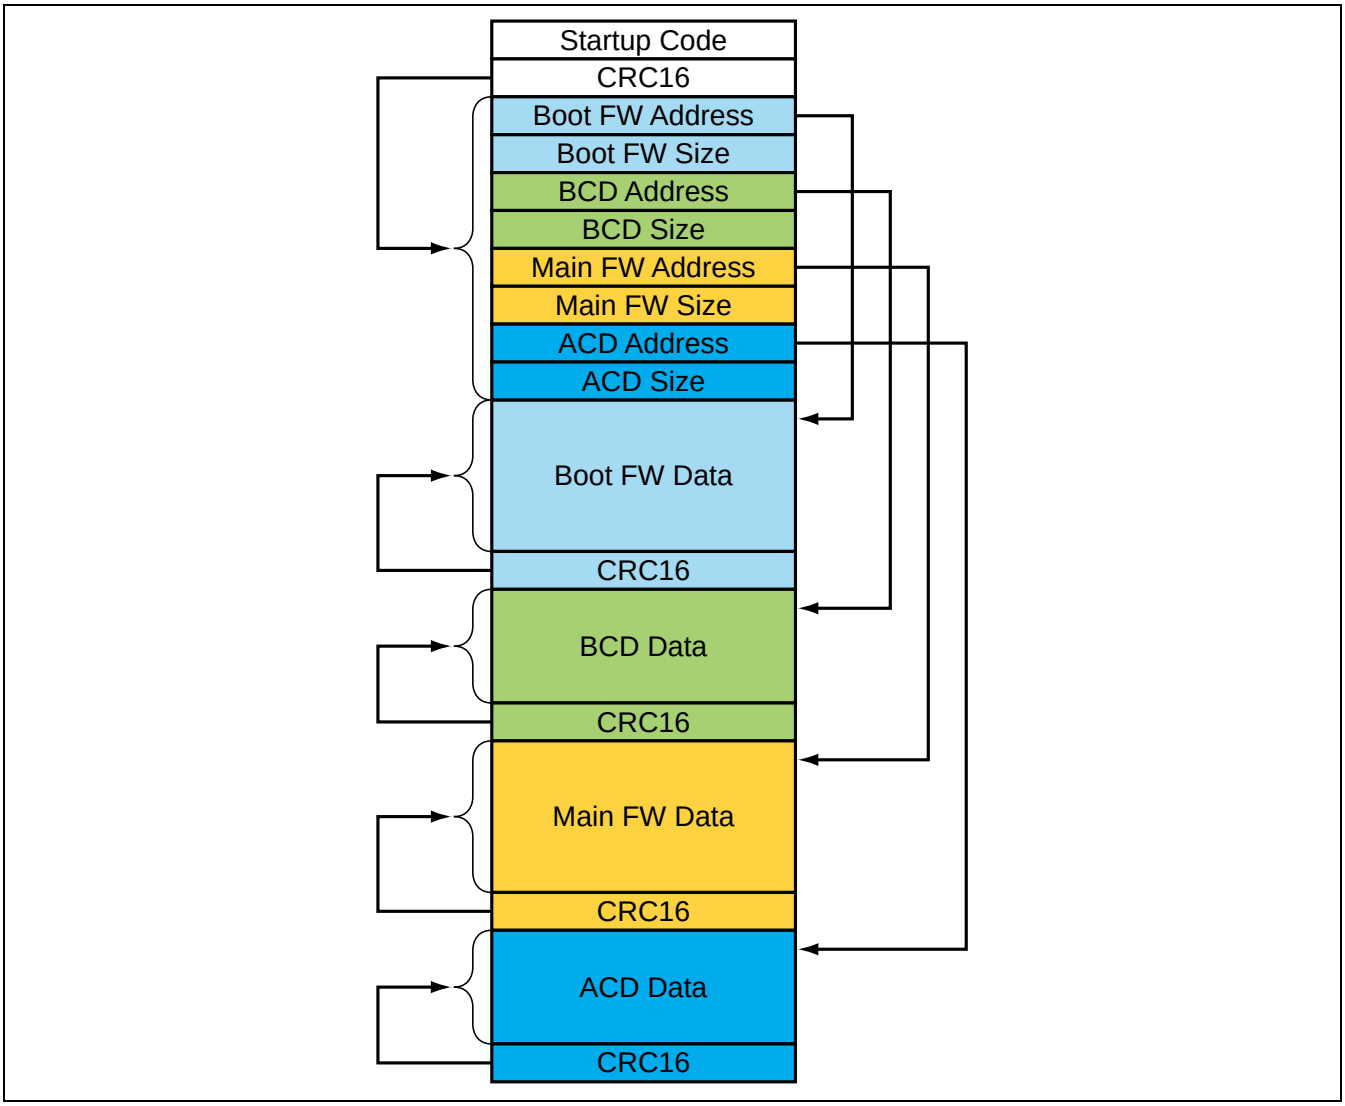

Figure 63.3 The Format of FW Download

Offset (Byte)	Size (Byte)	Field	Field Explanation
H'0000	2	Startup Code	Flag bit to show the storing of ROM Data. H'55AA is set.
H'0002	2	Header CRC16	CRC16 value from BCD Address to ACD size.
H'0004	2	Boot FW Address	Offset from the beginning of ROM Data in Boot FW Data field.
H'0006	2	Boot FW Size	Size of Boot FW field. (L)
H'0008	2	BCD Address	Offset from the beginning of Start Code in BCD Data field.
H'000A	2	BCD Size	Size of BCD Data field. (M)
H'000C	2	Main FW Address	Offset from the beginning of Startup Code in Main FW Data field. (N)
H'000E	2	Main FW Size	Size of Main FW field.
H'0010	2	ACD Address	Offset from the beginning of Startup Code in ACD Data field. (P)
H'0012	2	ACD Size	Size of ACD Data field.
H'0014	L	Boot FW Data	Bootstrap Code
(H'0014+L)	l	Boot FW CRC16	CRC16 of Boot FW Data field. If Boot FW Size field value is 0, it doesn't exist.
(H'0014+L+l)	pl	Padding	Padding to assign the beginning of BCD Data to 2-byte boundary.
(H'0014+L+l+pl)	M	BCD Data	BCD Data (Boot conf)
(H'0014+L+M+l+pl)	m	BCD CRC16	CRC16 of BCD Data field. If BCD Size field value is 0, it doesn't exist.
(H'0014+L+M+l+m+pl)	pm	Padding	Padding to assign the beginning of Main FW Data to 2-byte boundary.
(H'0014+L+M+l+m+pl+pm)	N	Main FW Data	Main FW
(H'0014+L+M+N+l+m+pl+pm)	n	Main FW CRC16	CRC16 of Main FW Data field. If Main FW Size field value is 0, it doesn't exist.
(H'0014+L+M+N+l+m+n+pl+pm)	pn	Padding	Padding to assign the beginning of ACD to 2-byte boundary.
(H'0014+L+M+N+l+m+n+pl+pm+pn)	P	ACD Data	ACD Data (Application conf)
(H'0014+L+M+N+P+l+m+n+pl+pm+pn)	p	ACD CRC16	CRC16 of ACD Data field. If ACD Size field value is 0, it doesn't exist.

Note: If "l", "m", "n", and "p" exist in each CRC16 field then the value is 2.
If they do not exist, then the value is 0.

63.4.1.2 System Interface

The USB3.0 controller delivers data through the AXI Register.

A register for delivering FW data has no specified data length, so data is always delivered at a 4-byte rate.

If delivered data cannot be allocated to a 4-byte boundary, Host calculates a length of necessary data and discards extra data.

When starting FW Download, the System first sets DL_CTRL.FW Download Enable to 1, and then starts delivering data to the Host.

After writing a value to FW_DATA0 or FW_DATA1, and setting value 1 to the corresponding bit of DL_CTRL.SetData0/1, the System shall put the data delivery on hold until the bit changes to 0.

FW Data0/1 can be used in either of the following ways.

- Use FW Data0 and FW Data1 alternately.
- Use only FW Data0

After writing the last data to FW Data, the System sets DL_CTRL.FW Download Enable to 0 and notifies the Host that Data transfer completes.

After the System makes a notification and confirms that DL_CTRL.Result Code is 1 (Success), the flow completes.

Then if Result Code is 2 (Error), it indicates that Host cannot be used due to some error in FW Download.

(Almost caution is illegally data load.)

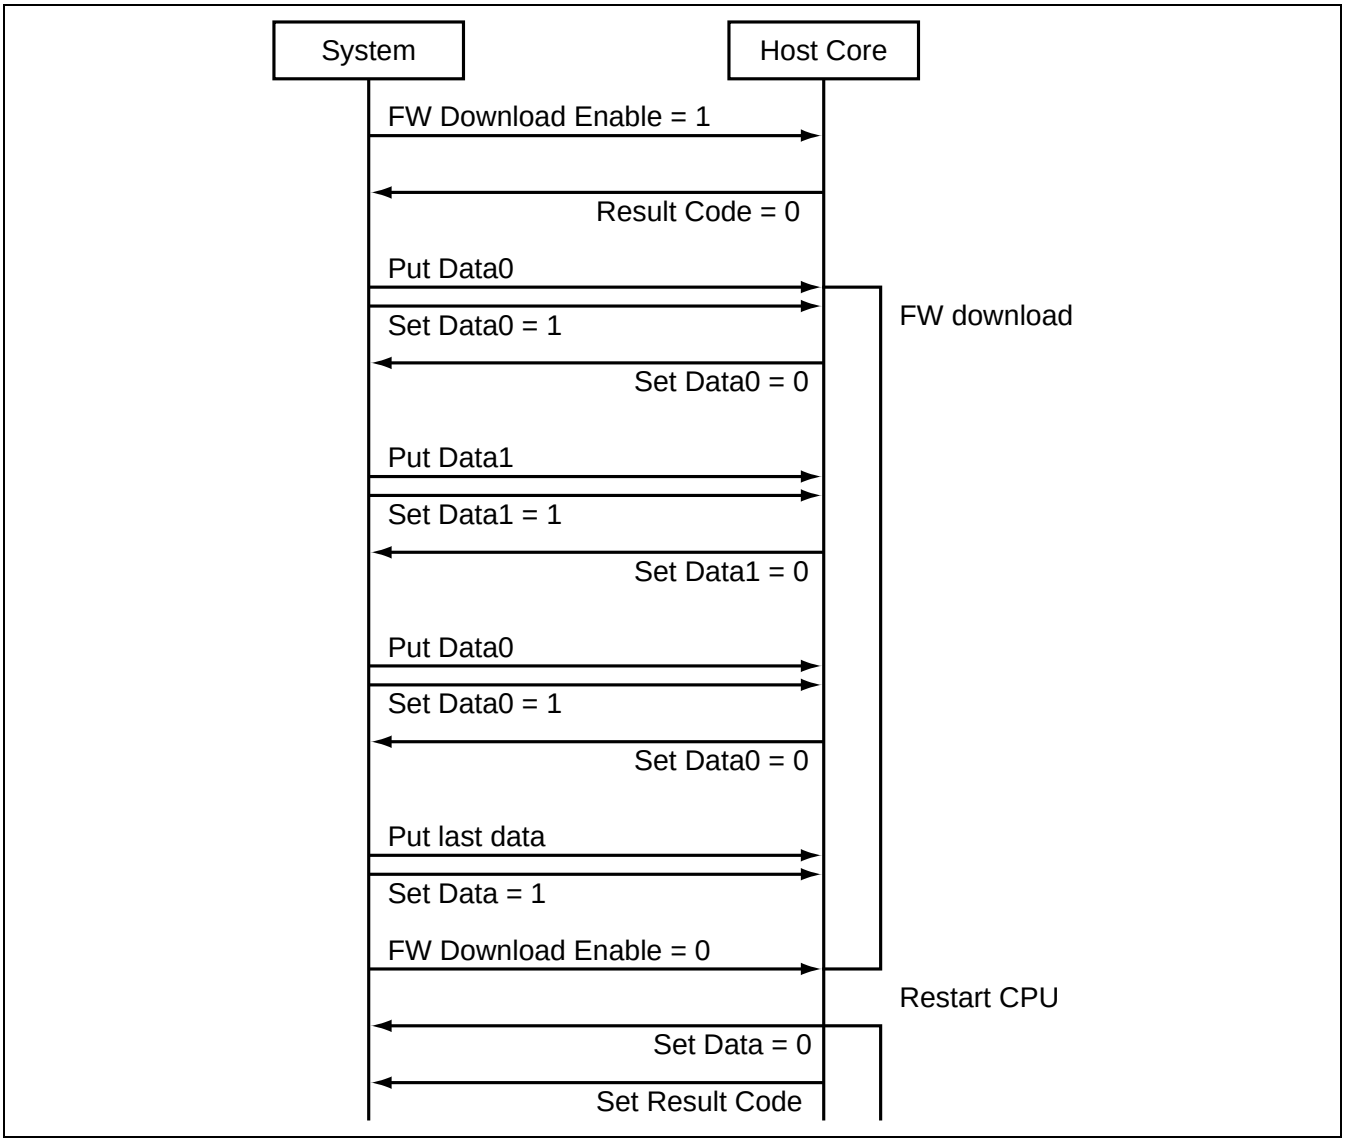

Figure 63.4 The Flow of FW Download

63.4.2 Battery Charging

The USB3.0 controller supports the Battery Charging function of A-Device, which is on the supply side.

In the A-Device, the function is controlled by HW/FW of Host Core.

And it is required that CLK60 (from USB PHY) is working before starting Battery Charging flow.

Note: For details, refer to Battery Charging Specification Revision1.2.
This function is supported in Host.

63.4.2.1 A-Device side (Charging Port Device)

The Battery Charging function is used to pull more current from VBUS than specified in USB specification.

Following Port Modes are supported in A-Device;

- Standard Downstream Port (SDP)
- Charging Downstream Port (CDP)
- Dedicated Charging Port (DCP)

(1) Setting BC_MODE

At first for HW preparing, it shall be set Battery Charging Mode at BC_MODE[3:0] at Battery Charging Register in AXI Register.

(Refer to section 63.2.1.24)

Battery Charging

H'233	—	—	—	—	—	—	—	PTPWR_CTRL
H'232	—	—	—	—	—	—	Renesas Private field	
H'231	—	—	—	—	—	LCLK_NOSTOP_FREQ		
H'230	—	—	—	—	BC_MODE			

Table 63.7 Setting Value for Battery Charging

Setting Value	BC_MODE	Description
0	Always SDP Mode	Default value after resetting HW. A-Device operates in the “SDP” mode both normal function state and D3 state.
1	Always CDP Mode	A-Device operates in the “CDP” mode both normal function state and D3 state.
2	SDP-DCP Auto-change Mode	A-Device operates in the “SDP” mode in a normal function state and operates in the “DCP” mode in the D3 state.
3	CDP-DCP Auto-change Mode	A-Device operates in the “CDP” mode in a normal function state and operates in the “DCP” mode in the D3 state.

Table 63.8 BC Mode and Port Type in D0 and D3 State

BC_MODE	Normal Operation (D0) Port Type	Suspended (D3) Port Type
Always SDP Mode	SDP	SDP
Always CDP Mode	CDP	CDP
SDP-DCP Auto-change Mode	SDP	DCP*1
CDP-DCP Auto-change Mode	CDP	DCP*1

Notes: 1. If WakeOnConnect/WakeOnDisconnect is valid, it shall be kept Port type in Normal Operation.

(2) Each case of changing BC_MODE

Case-1) After Host HW Reset, BC_MODE is set “Always SDP Mode”.

SDP is a default Mode.

Red-colored flow in Figure 63.5 is for default setting.

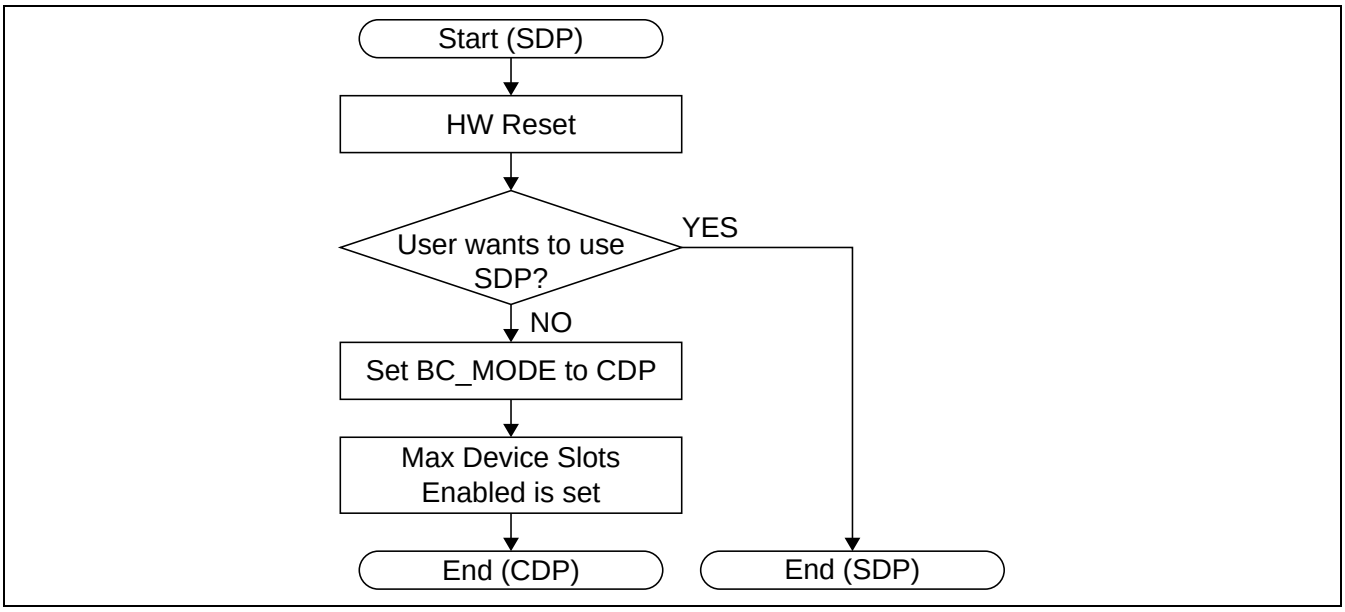

Figure 63.5 Default Setting

Case-2) If user wants to change Mode from SDP/CDP to DCP Mode during A-device working, BC_MODE shall be changed when transition from D0 to D3.

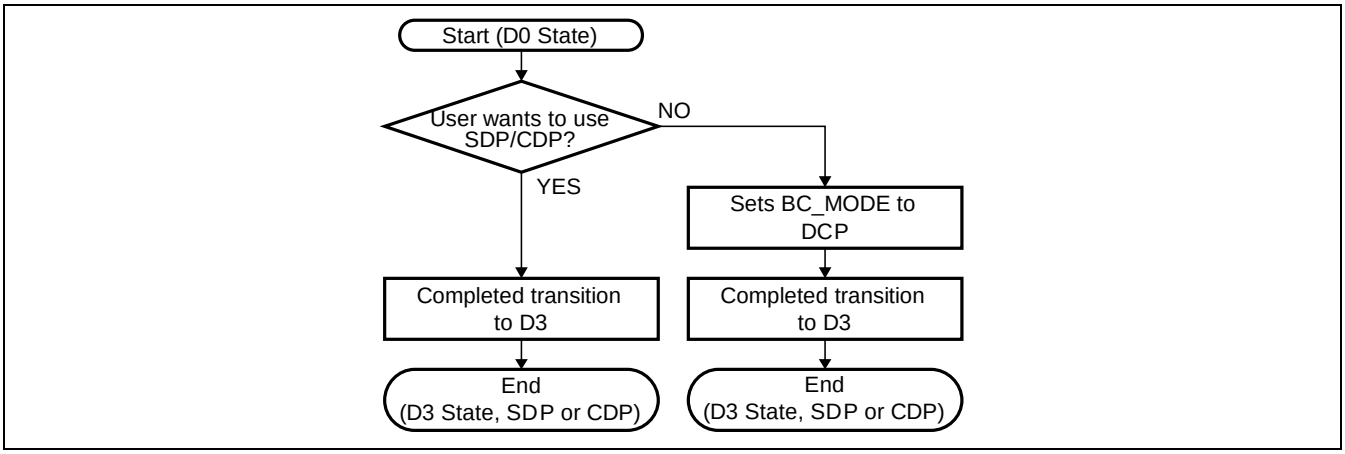

Figure 63.6 Changing BC_MODE during Transition between D0 and D3 States

Case-3) When user wants to use A-Device with except default (SDP) Mode after Host HW Reset, BC_MODE shall be changed before setting value of "Max Device Slots Enabled" in xHCI CONFIG register [H'058].

For the selectable modes, refer to Table 63.8.

Red-colored flow in Figure 63.7 is for BC_MODE setting.

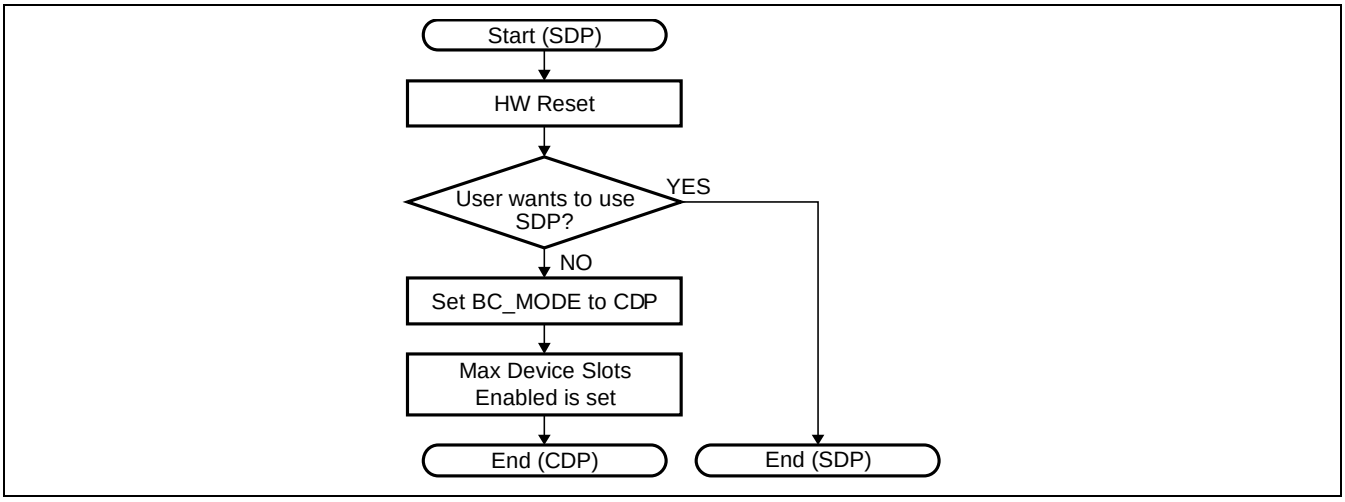

Figure 63.7 Changing BC_MODE

[Caution]

- On the port in which WakeOnConnect/WakeOnDisconnect is enabled, a transition to DCP is not allowed because the port shall detect connect/disconnect of Device.
- When going D3 state with connecting USB device, current Mode shall be kept up setting because that any USB communication doesn't continue with setting DCP.

When changing Battery Charging type, it is required by Battery Charging Specification that VBUS shall be off more than 100-ms and prompting reconnection of device. Host FW operates this process.

63.4.3 Power Management

63.4.3.1 Power Management Capability

USB3.0 controller Host Core sets pseudo D3 state.

It is controlled by xHCI Extended Power Management Capability Register (HCEXTDPWMNGCAP2).

- xHCI Extended Power Management Capability (HCEXTDPWMNGCAP2).
  This register controls pseudo PCIe Power State.
  Bit 15: PME Status: Showing which there was a Wakeup event during pseudo D3 state
  Bit 8: PME Enable: It asserts an interrupt from pseudo D3 state at Wakeup.
  When this bit is set to 1, if PME Status is changed 1 then the interrupt occurs.
  Bit [1:0]: Power State: Setting pseudo Power state.
  The valid value is as follows.
  0: D0 (Do not save power)
  3: D3 (Do power save)

Note: In the after section, D3 means pseudo D3 state which is described here.

63.4.3.2 Low Power Management of Receiver Detection

It is intended to saving power of Receiver Detection circuit at PHY Hard Macro (PHYHM).

There are two ways, setting initial value in define file and changing value at field of Register.

For changing value, the field shall be set before starting FW download when occurs after reset.

(1) D3

USB3.0 Common Block operates periodically Receiver Detection with LCLK during RxDetect state of LTSSM and P3 of PHY state.

However if a system is in Suspend and WakeOnConnect is disabled, there is no need to do Receiver Detection.

To reduce power consumption of PHY by above discarded Receiver Detection, FW can halt the process.

(2) D0

Receiver Detection at opened Port in D0 shall be operated.

HW operates reducing power at interval of Receiver Detection.

TimeMax is that decides operational interval of Detection in P3.

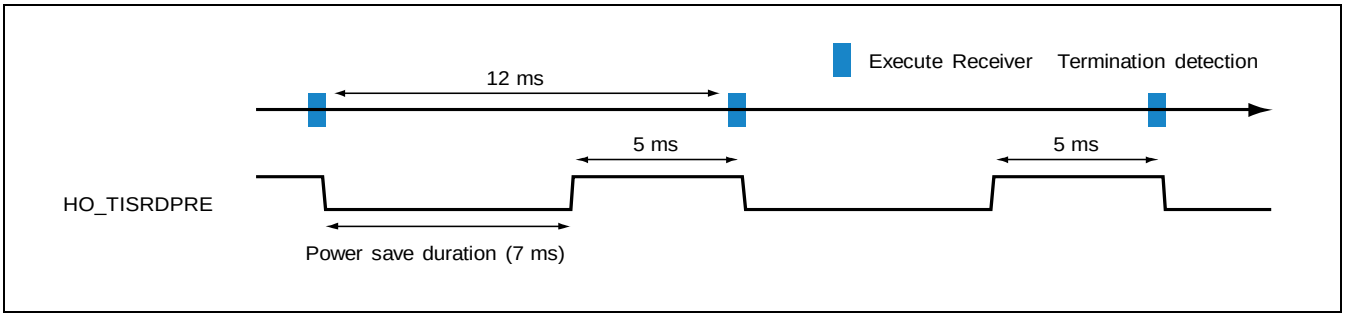

Figure 63.8 Low-Power of Receiver Detection

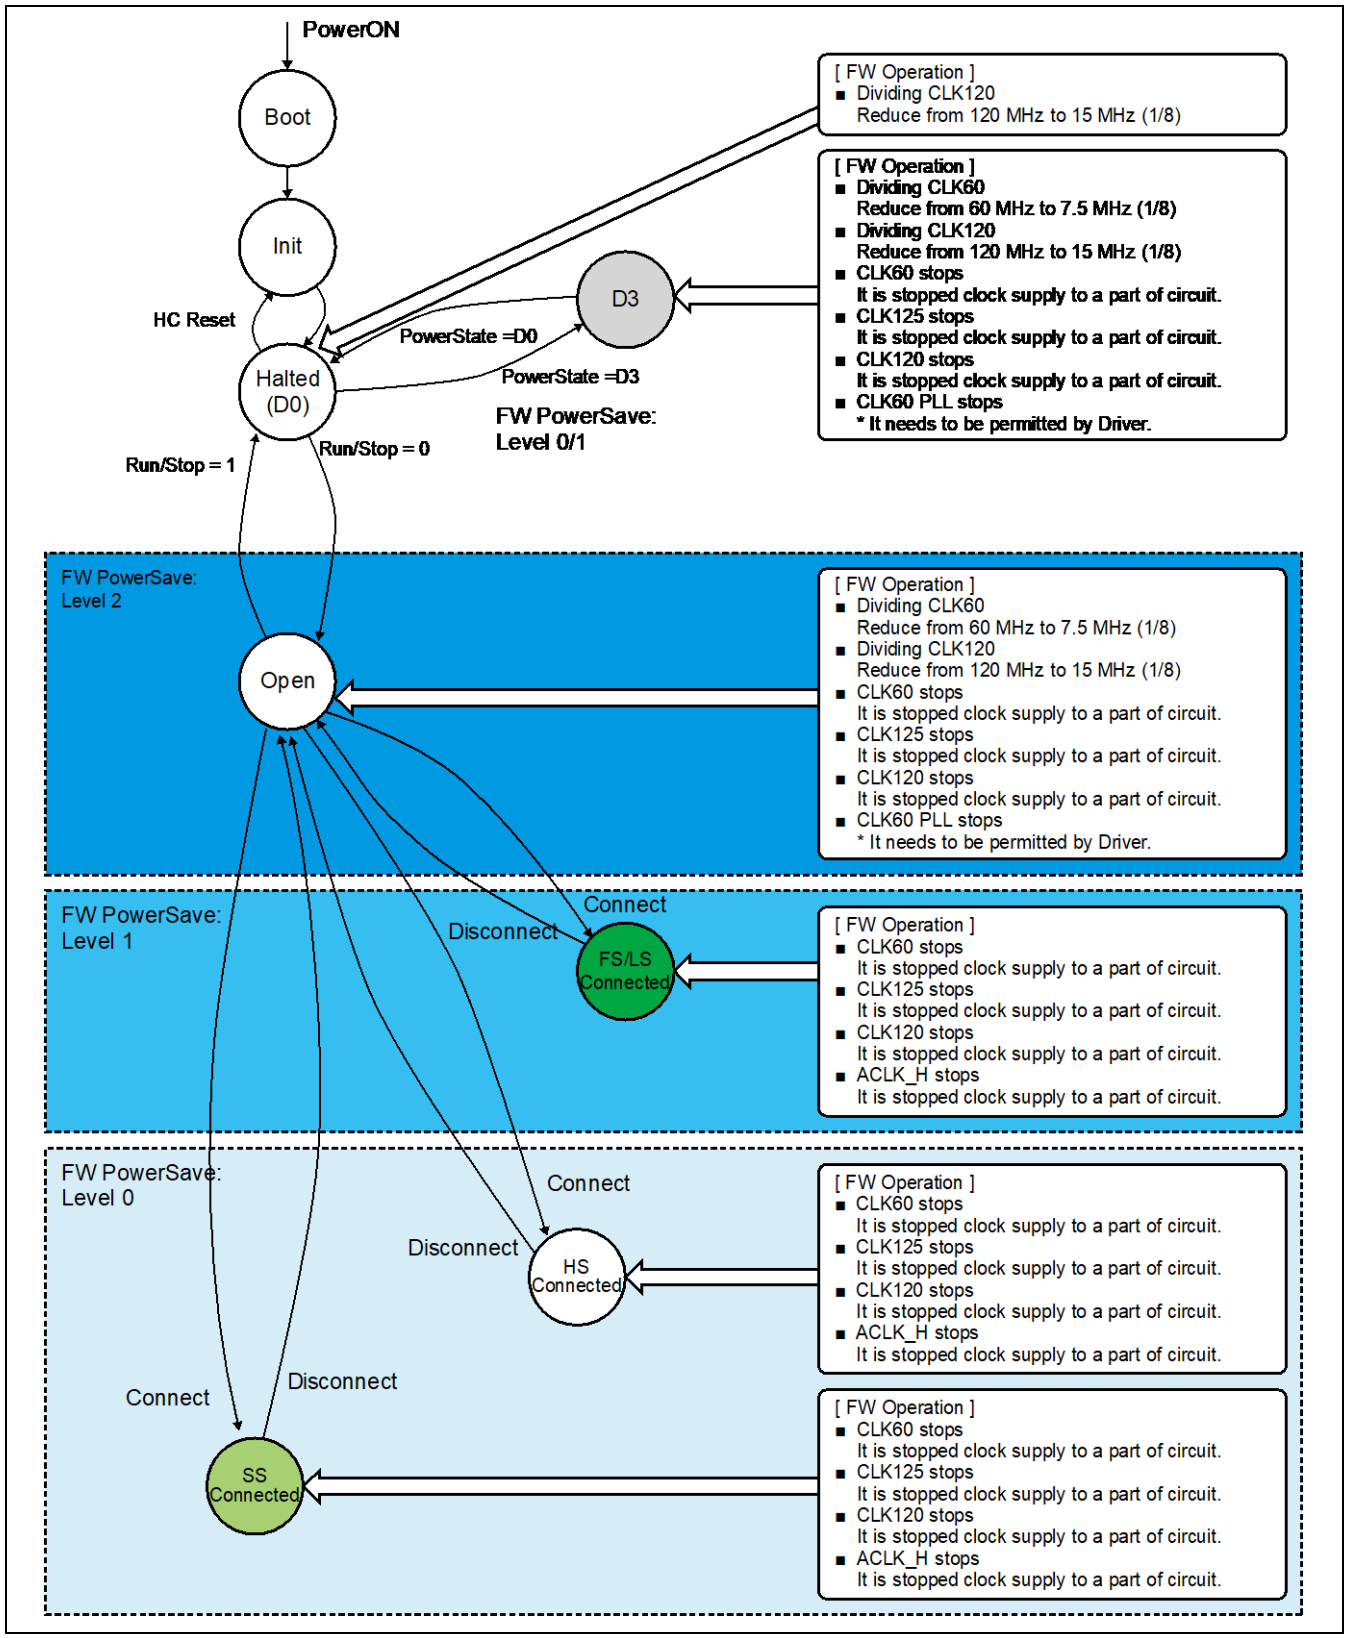
63.4.3.3 Power Control for Each State

The overview of power control state flow is shown as below.



Note: CLK60/CLK120/CLK125 (from USB PHY)

Figure 63.9 Overview of Power Control State Flow

63.4.3.4 Clock Termination by USB3PHY and LTSSM State

USB3PHY may stop PLL which generates CLK125 by USB3PHY's power state.

Table 63.9 LTSSM State and USB3PHY Condition

LTSSM State	USB3PHY POWERDOWN	PLL Operation	Supplement
SS.Disabled	P2	Run	
Rx.Detect	P2	Run	Default
	P0	Run	
	P3	Run	
U0	P0	Run	
U1	P1	Run	
U2	P2	Run	
U3	P0	Run	
	P3	Run	
U3 → U3_Wakeup, Reset	P0	Run	Transition by receiving LFPS
U3 → RemoteWakeup	P0	Run	Transition is required by PLS (Need Register operation)
Other	P0	Run	

63.4.3.5 Flow of System Suspend and Resume

When following all permission for suspend are met, system goes to suspend.

- Host system sets AXH_CON.SYS_SUSPEND to 1 and completes host core's preparations for suspend.

When host core resumes from System Suspend, user shall confirm the bit of B2_PLL_ACTIVE at AXH_STA register [H'104 to H'107] in AXI register is set to 1 before accessing register.

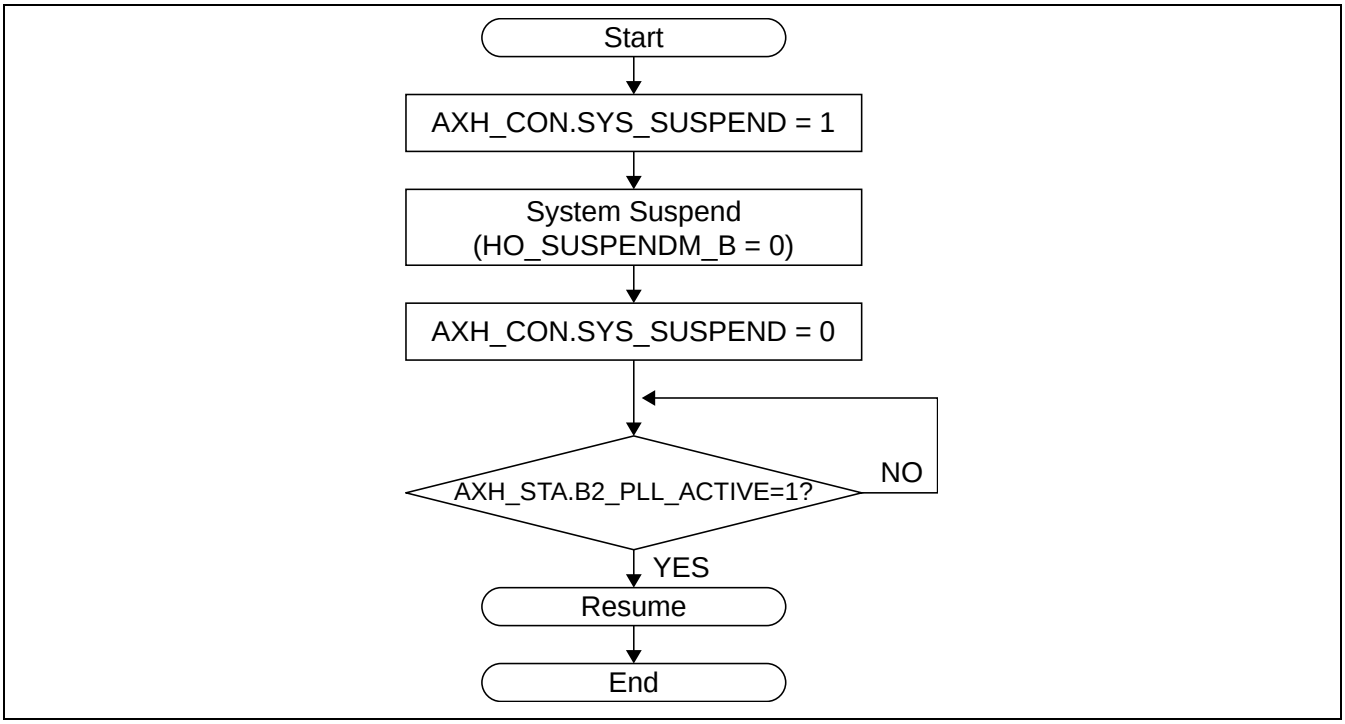


Figure 63.10 System Suspend and Resume Flow

63.4.4 Power Control

The process of VBUS ON/OFF and Over Current detection are described below.

63.4.4.1 VBUS On

When VBUS will be on, at first host driver shall execute processes as below.

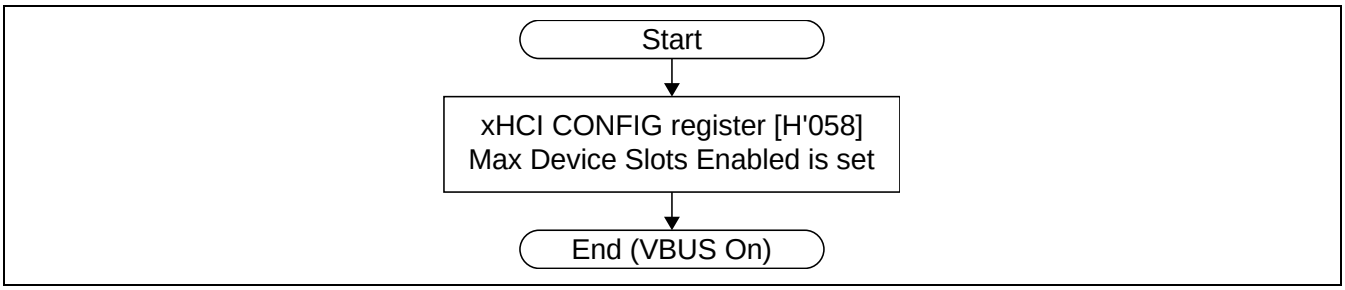

Figure 63.11 Flow of VBUS On

63.4.4.2 VBUS Off

When port power will be off, at first host driver shall execute processes as below.

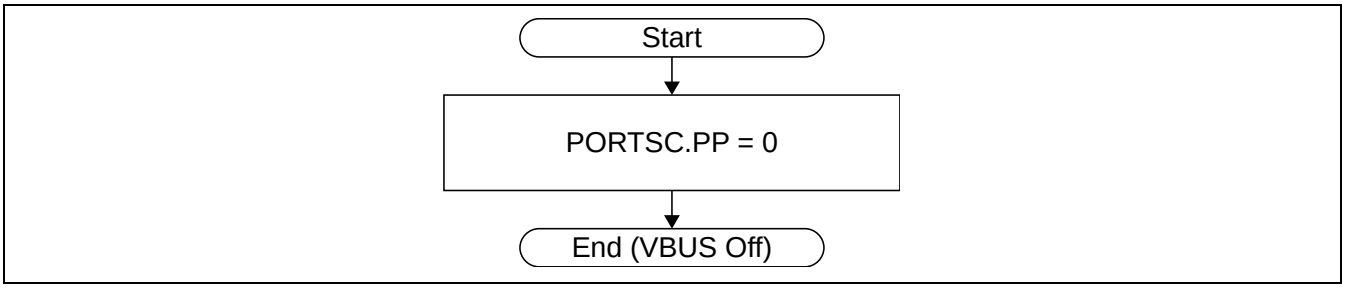

Figure 63.12 Flow of VBUS Off

63.4.4.3 Over Current Detection

When port will detect over current during the core working, following flow is executed on host.

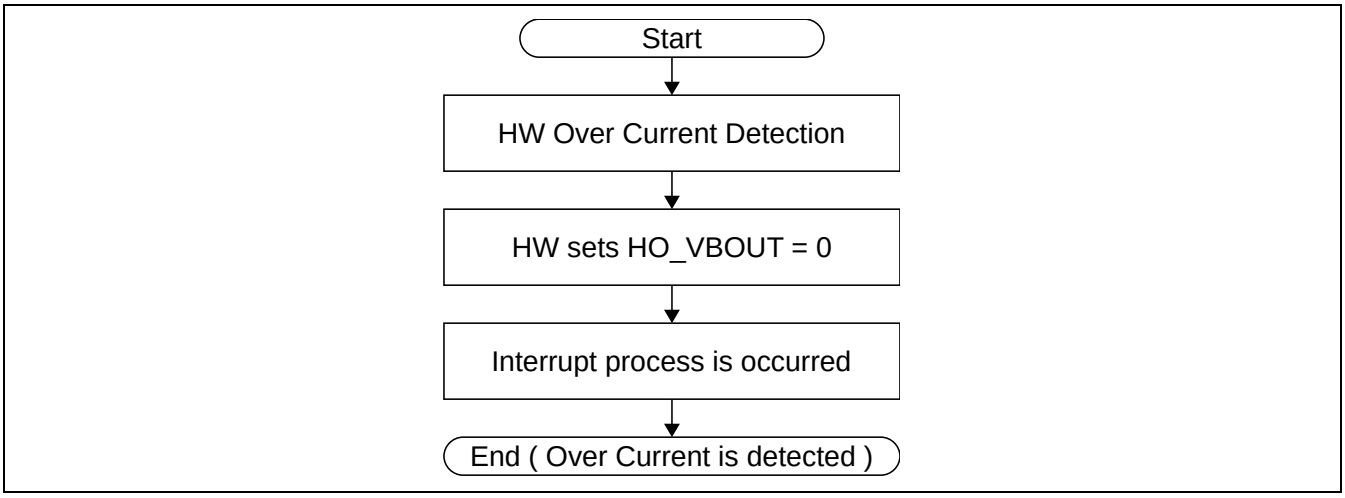

Figure 63.13 Flow of Over Current Detection

63.4.5 Structure of Notification for Elements of Interrupt

In USB3.0 controller, the elements of interrupt are noticed by following layered structure.

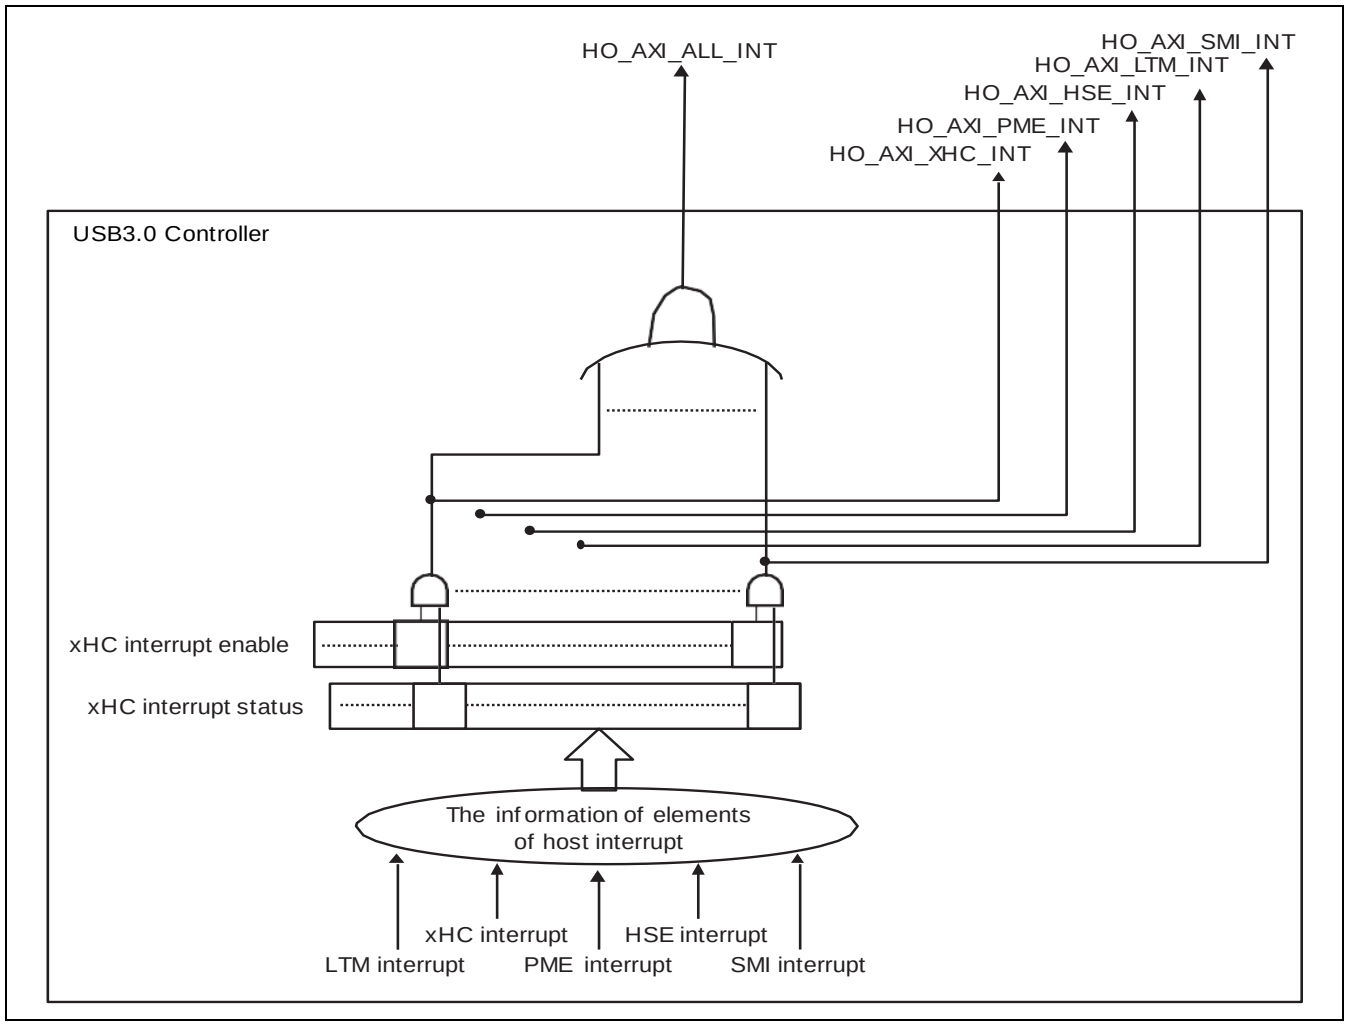

Figure 63.14 Interrupt Layered Structure

- This Host core doesn't use WAKEB but PME. Interrupt pin by PME is HO_AXI_INT_PME.

Note: About occurrence factor of PME interrupt, refer to xHCI Specification.

- Interrupt occurrence factor of xHCI shall be switched its meaning as PCIINT.
- The abstract of Interrupt signals from Figure 63.14 are below.

Table 63.10 Function of Interrupt Signals

Signal Name	Function
HO_AXI_INT_XHC	xHCI Interrupt
HO_AXI_INT_PME	PME Interrupt
HO_AXI_INT_HSE	HSE Interrupt
HO_AXI_INT_LTM	LTM Interrupt
HO_AXI_INT_SMI	SMI Interrupt
HO_AXI_INT_ALL	All Interrupt Signals from Host Core.

63.4.6 Implementation Constraint of Host Core

The USB3.0 controller core has implementation constraint.

- 1 Packet shall be composed of 8 TRB or less.

63.5 Example of Transaction

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

This section describes transaction when using Host core. As examples, Bulk OUT and Bulk IN transactions are described. The USB3.0 controller core complies with xHCI Specification.

Refer to xHCI Specification for details.

63.5.1 Bulk OUT Transaction

Bulk OUT transaction flow is shown as below.

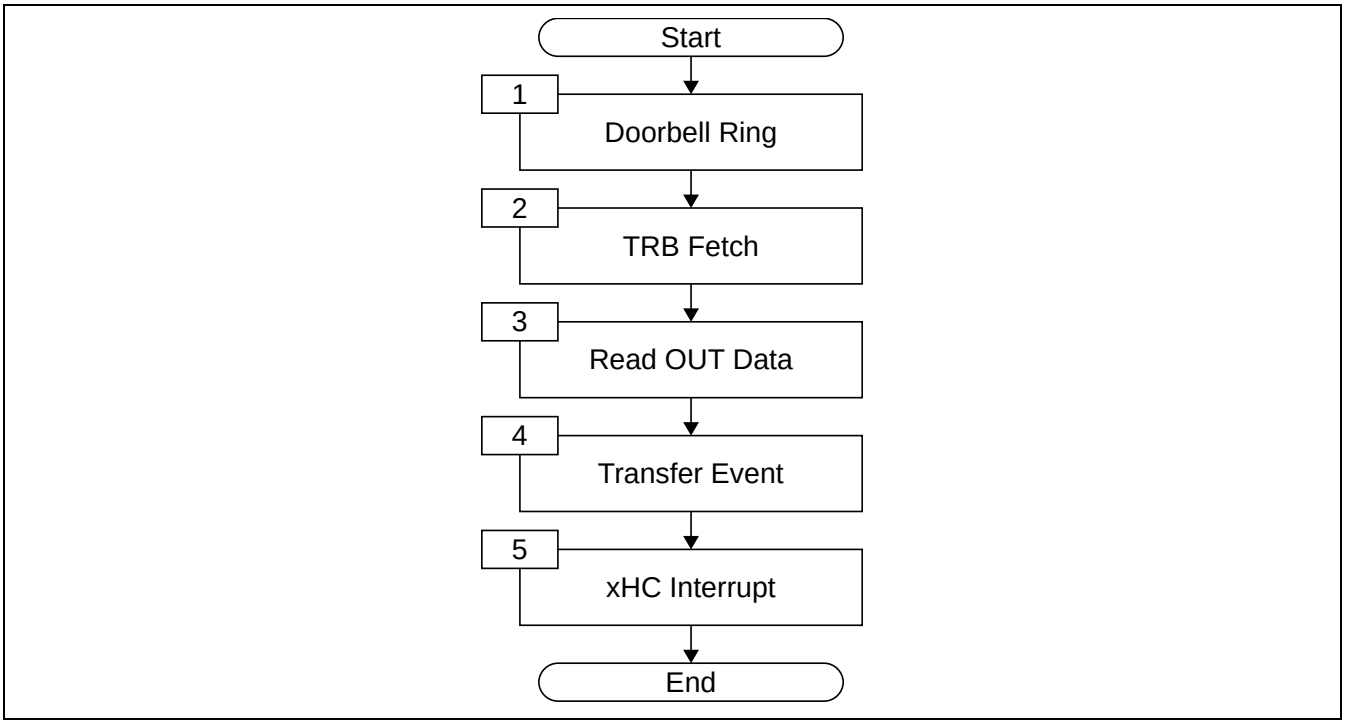

Figure 63.15 Example of Bulk OUT Transaction Flow

1) Doorbell Ring
   System rings Doorbell to prepare Transfer Data.
2) TRB Fetch
   Host core fetches TRB from OUT Transfer Ring,
3) Read OUT Data
   Host reads OUT Data from Data Buffer Pointer.
4) Transfer Event
   Host writes Transfer Event TRB to Event Ring.
5) xHC Interrupt
   Host sends Interrupt to System.

63.5.2 Bulk IN Transaction

Bulk IN transaction flow is shown as below.

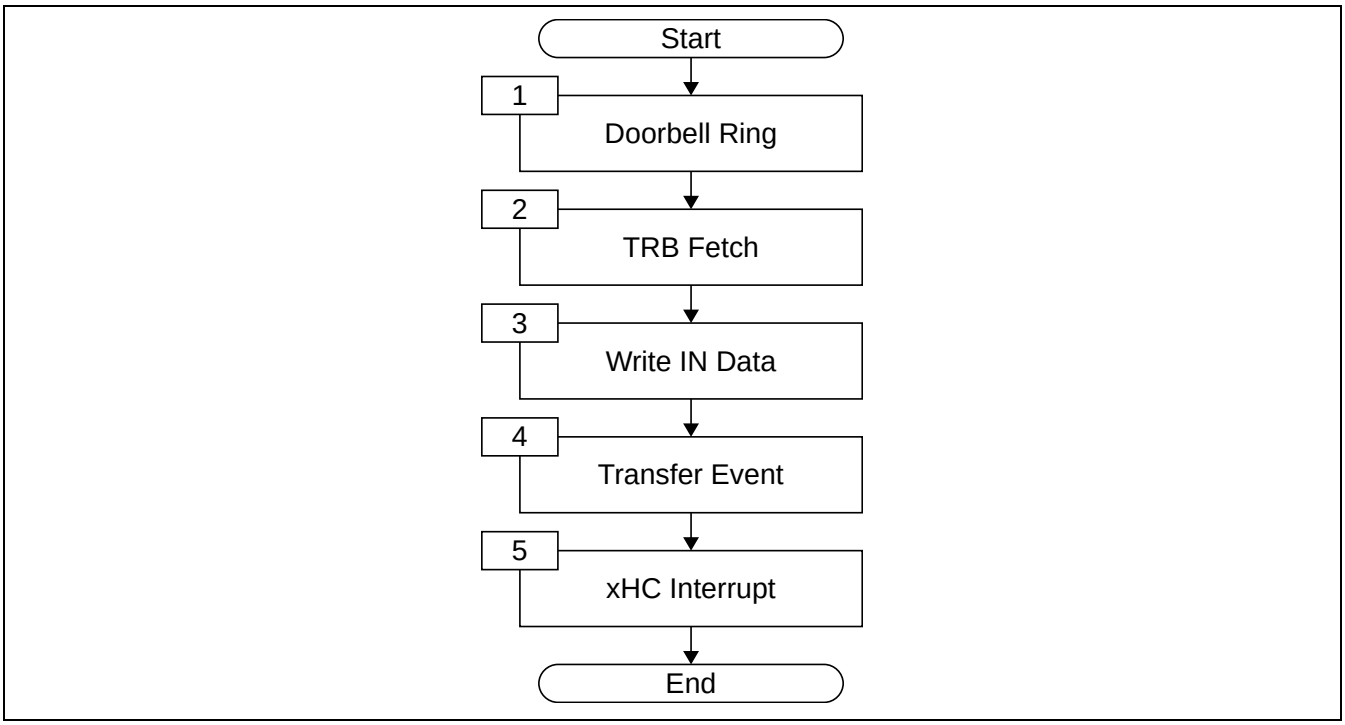

Figure 63.16 Example of Bulk IN Transaction Flow

1) Doorbell Ring
   System rings Doorbell to prepare Transfer Data.
2) TRB Fetch
   Host core fetches TRB from OUT Transfer Ring,
3) Write IN Data
   Host writes IN Data to Data Buffer Pointer.
4) Transfer Event
   Host writes Transfer Event TRB to Event Ring.
5) xHC Interrupt
   Host sends Interrupt to System.

63.6 Power IC Interface Connection

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

The USB3.0 controller core has power signal detection.

- Power IC has Outputting Over Current Flag signal and the USB3.0 controller can detect the signal.
- Battery Charging function is able to use at the USB3.0 controller.

63.6.1 Usable Power IC type

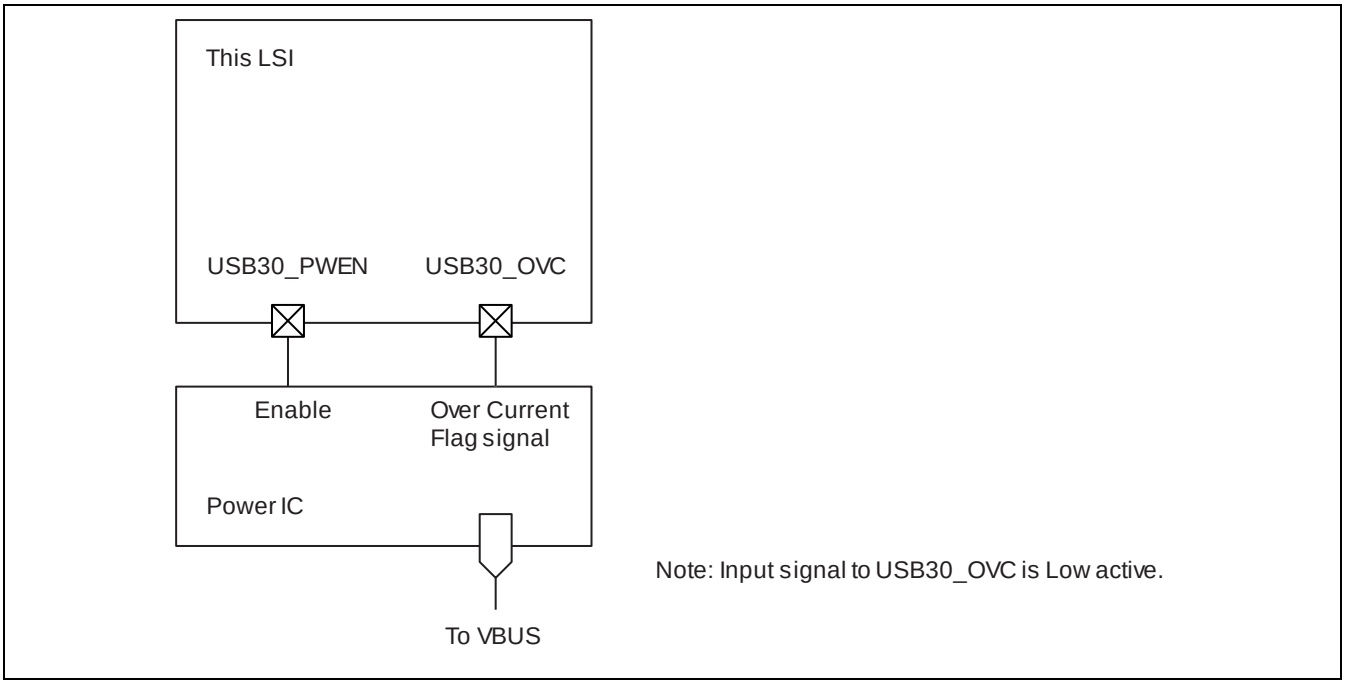

Figure 63.17 Usable Power IC Type

Table 63.11 Setting Registers and Signals for Power IC

Signal	Description
USB30_OVC	Connecting to Over Current Flag signal
USB30_PWEN	Connecting to Enable

- **Restriction**

  Do not use another type of Power IC.

63.7 Descriptions of functions

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

63.7.1 VBUS Connection

The overview of connection of VBUS signal is shown in Figure 63.18.

VBUS is the power supply signal from USB host or hub, device can know that it is connected to host or hub when VBUS is asserted. But since VBUS input might be unstable just after device is connected, device should wait for a certain time till it becomes stable especially if it is bus-powered device. In order to control the interval from the assertion of VBUS to the time VBUS becomes stable, VBUS signal is not directly connected to link layer but USB30_CON.B3_CONNECT is connected to it instead. The value of the bit is output to link layer which sees the value to know whether it is being connected or not. This mechanism enables that firmware inserts the wait time between when it detects the assertion of VBUS by USB_INT_STA_1.VBUS_CNG_STA and when it sets USB30_CON.B3_CONNECT.

In the same way, VBUS signal is not directly connected to UTMI2SIE and USB2.0-PHY but USB20_CON.B2_CONNECT is used to notify them that device is connected.

Note: VBUS or USB30_CON.B3_CONNECT is not provided directly to USB3.0-PHY. USB3.0-PHY provided from Renesas is designed not to see the state of VBUS but to follow the instruction of power down from upper layer on POWERDOWN[1:0] for its power management. But some USB2.0-PHYs provided from Renesas are designed to see the state of VBUS and require that VBUS or similar signal is connected. See the specification of USB-PHY for details.

When device is in suspended state or unconnected, PLLs in USB3.0-PHY and USB2.0-PHY can be stopped in order to reduce their power consumptions. But if the device is disconnected when it is in suspended state, it means that the request to wake up from host never comes any more. In such case, it might be required to resume PLLs if they have been stopped so that device initializes by itself and prepares for the next connection. On the other side, device might be required to resume PLLs if they have been stopped in unconnected state but device detects the connection. The state of connection or disconnection can be known on VBUS state. The change of VBUS state is notified on USB_INT_STA_1.VBUS_CHG_STA. As shown in the cases above, the software is required to control PLLs in USB3.0-PHY and USB2.0-PHY depending on VBUS state.

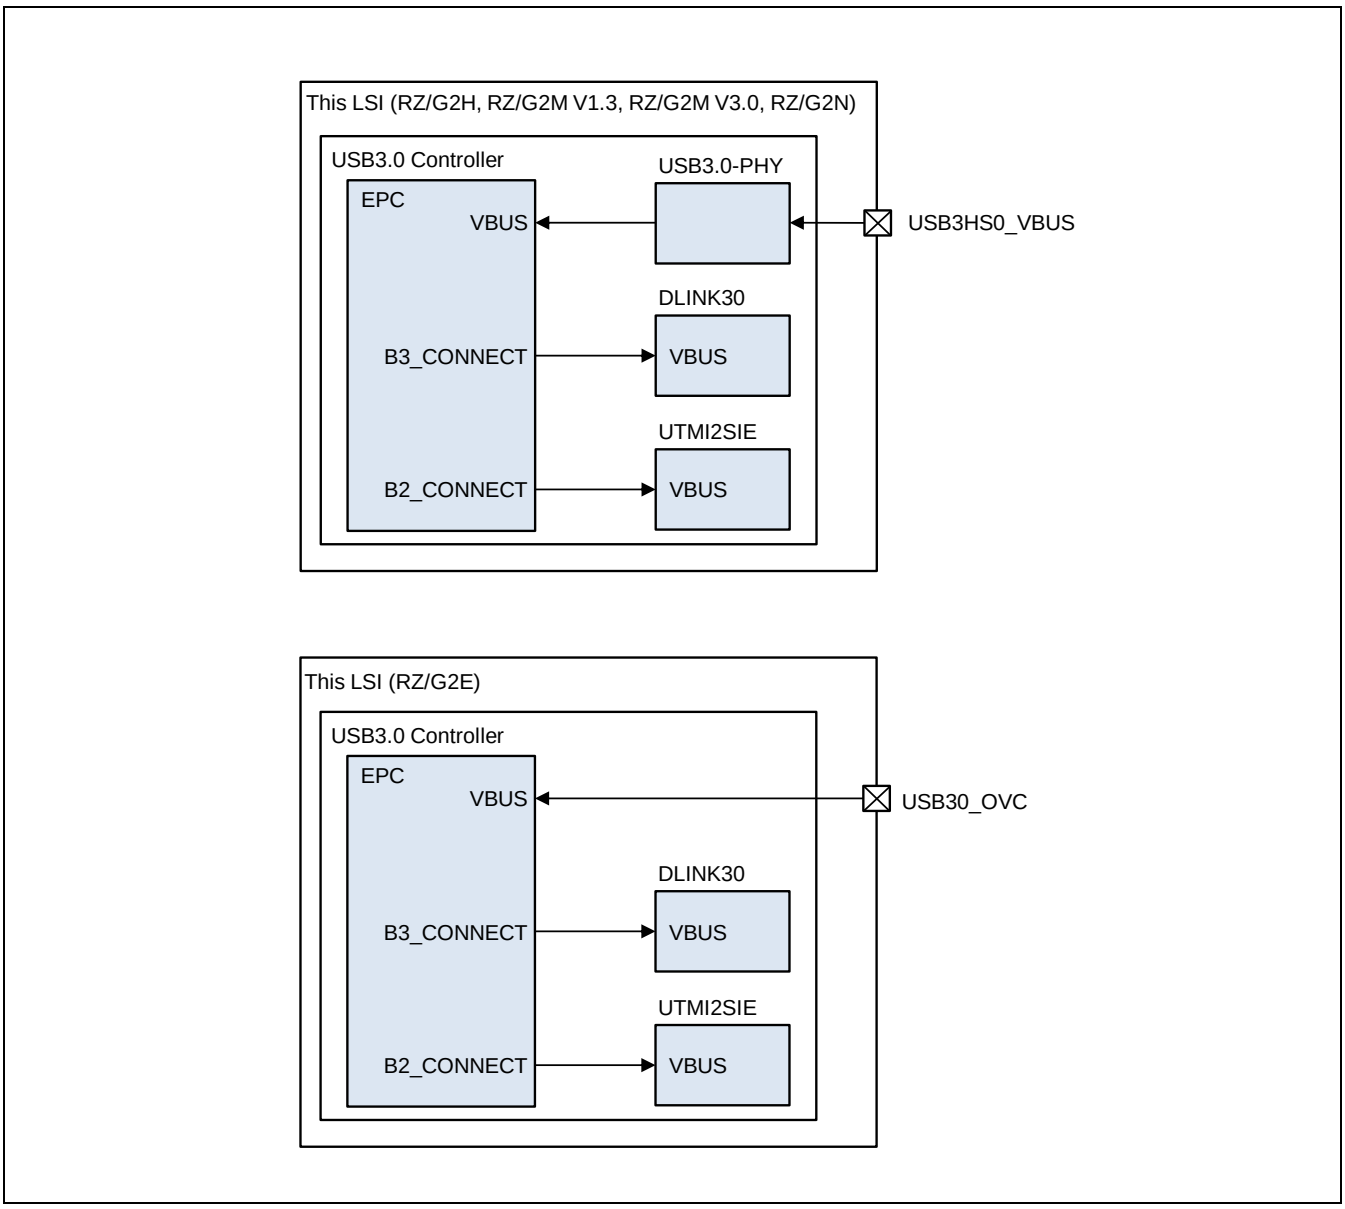

Figure 63.18 VBUS connection

63.7.2 Functions of EPC

63.7.2.1 Buffering for transmission and reception on USB

- Buffer for the received data at OUT endpoint
  (1) PERIPHERAL PORTION receives OUT packet from host.
  (2) PERIPHERAL PORTION stores the received packet in RAM if it has an available space.
  (3) PERIPHERAL PORTION checks whether the received packet has an error (CRC error, PID error, sequence number error etc.) or not.
  If PERIPHERAL PORTION completes the reception of OUT packets and finds no error in them, PERIPHERAL PORTION informs Interrupt Controller with an interrupt signal.
  PERIPHERAL PORTION sends the received packets to UDL side if required.
  (4) AXI-bus reads the received packets

- Buffer for data to be transmitted at IN endpoint
  (1) PERIPHERAL PORTION receives IN token (USB2.0) or ACK TP (USB3.0) from host.
  (2) PERIPHERAL PORTION sends data packet if it has data in RAM.
  (3) PERIPHERAL PORTION checks whether it receives handshake (ACK, for example) for transmitted packet or not.
  If PERIPHERAL PORTION completes the transmission of IN packets and receives ACKs from host for them, PERIPHERAL PORTION informs Interrupt Controller with an interrupt signal.
  If PERIPHERAL PORTION can't send IN packet correctly or can't receive ACK from host, PERIPHERAL PORTION transmits the same data again when next IN token (USB2.0) or ACK TP (USB3.0) comes.
  (4) AXI-bus can write data for the next transmission if it wants.

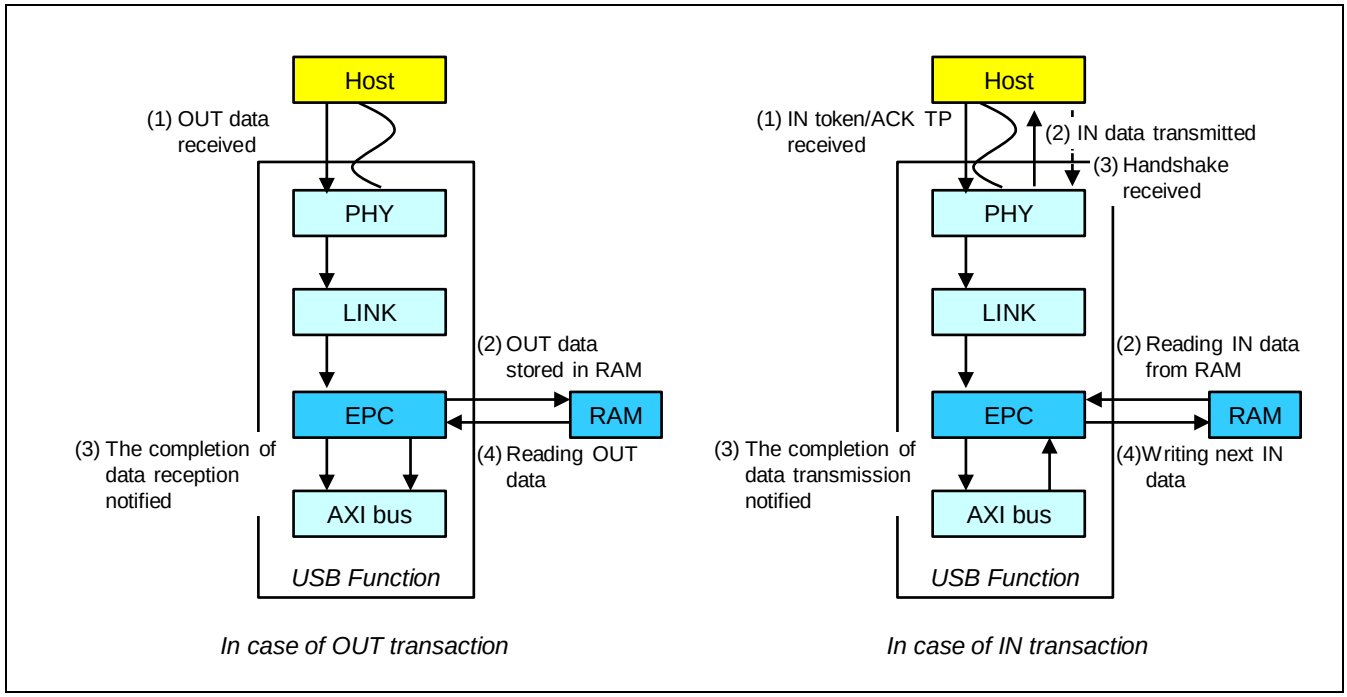

Figure 63.19 buffer for transmission and reception on USB

63.7.2.2 Handshake

Peripheral portion automatically selects the response depending on the setting, its internal status and the receiving status of the packet.

(1) Handshake response for OUT transaction

Peripheral portion sends the handshake response for OUT transaction as shown in Table 63.12 and Table 63.13.

Table 63.12 Handshake for OUT transactions (HS/FS)

Reception Data Corrupted (Error)	Endpoint Halt	Data Toggle Check	Data Reception Allowed/Not Allowed	Handshake
Yes	N/A	N/A	N/A	No Response
No	Set	N/A	N/A	STALL
No	Not Set	NG	N/A	ACK
No	Not Set	OK	Allowed	ACK
No	Not Set	OK	Not Allowed	NAK

Table 63.13 Handshake for OUT transaction (SS)

Invalid DPH Reception	Deferred Reception	Endpoint Halt	Reception Data Corrupted (Error)	Data Reception Allowed or Not allowed	Handshake
Yes	N/A	N/A	N/A	N/A	No Response
No	Yes	Yes	N/A	N/A	ERDY
No	Yes	No	N/A	Not allowed	ERDY when PIPE becomes available
No	Yes	No	N/A	Allowed	ERDY
No	No	Yes	N/A	N/A	STALL
No	No	No	N/A	Not allowed	NRDY
No	No	No	Yes	Allowed	ACK (Retry required)
No	No	No	No	Allowed	ACK

(2) Handshake response for IN transaction

Peripheral portion sends the handshake response for IN transaction as shown in Table63.14 and Table 63.15.

Table 63.14 Handshake for IN transaction (HS/FS)

Token Corrupted (Error)	Endpoint Halt	Transmission Data is in buffer or not	Handshake
Yes	N/A	N/A	No Response
No	Set	N/A	STALL
No	Not Set	No	NAK
No	Not Set	Yes	Data Transmission

Table 63.15 Handshake for IN transaction (SS)

Invalid TP Reception	Deferred Reception	Endpoint Halt	Transmission Data is in buffer or not	Handshake
Yes	N/A	N/A	N/A	No Response
No	Yes	Yes	N/A	ERDY
No	Yes	No	No	ERDY when PIPE becomes available
No	Yes	No	Yes	ERDY
No	No	Yes	N/A	STALL
No	No	No	No	NRDY
No	No	No	Yes	Data Transmission

63.7.3 USB3.0/USB2.0 connection

In this section the outline of USB3.0 and USB2.0 connection in USB3.0 specification is explained.

See section 63.8.3.6 for details of the software flow.

The behavior of peripheral device upstream port state machine is described in section 10.16.2 of USB3.0 specification Revision 1.0 June 6, 2011. This behavior was proposed as ECN#011 at first.

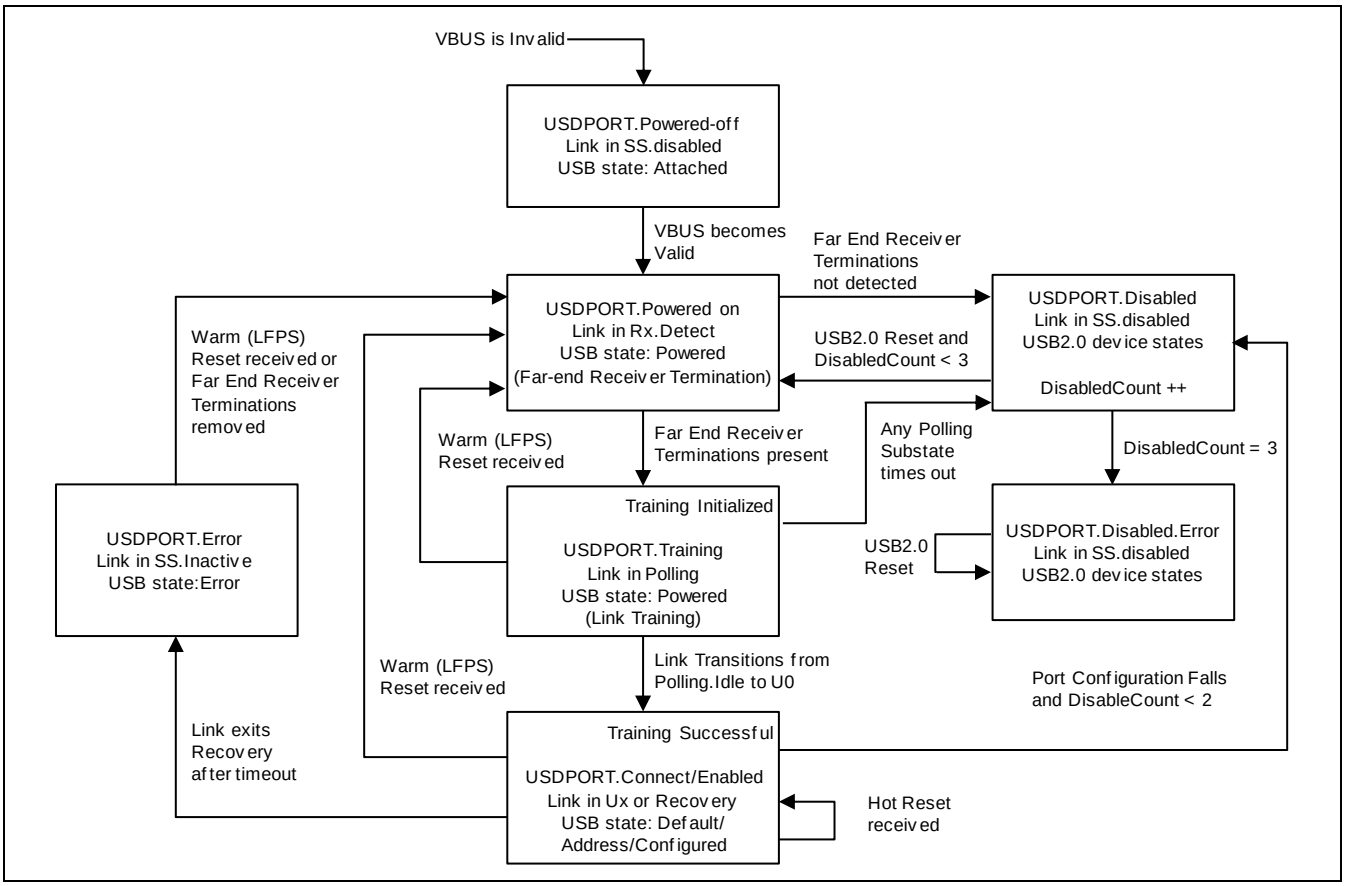

Figure 63.20 Peripheral Upstream Device Port State Machine
(from Figure10-25 in USB3.0 specification)

As initial state, in which VBUS is off, the upstream port of the device is in USDPORT.Powered-off. The port should have the variable “DisableCount” to control the transition to or from USDPORT.Disabled. The DisabledCount should be initialized to 0 when power is off or when the port’s link completes the port configuration.

When VBUS becomes valid (on), the port transits to USDPORT.Powered on. In this state, the port’s link is in Rx.Detect. On this first entry to USDPORT.Powered on, the port’s link makes the trial of Rx detection up to 8. If it detects Far End Receiver Termination of the link partner, the upstream port enters USDPORT.Training, and after the training has successfully completed it enters USDPORT.Connected/Enabled.
But if the port fails in the port configuration, it enters USDPORT.Disabled.

But if the port’s link can’t detect Far End Receiver Termination even when it tries 8 times, the port enters USDPORT.Disabled. With this transition DiableCount is incremented if it is less than 3. In this state, the function of

USB3.0 is disabled once and the function of USB2.0 starts working.
If downstream port detects D+ line is pulled up, it recognizes the device wants to be connected as USB2.0 device. The downstream port asserts USB2.0 bus reset to start the process of USB2.0 connection.

Receiving USB2.0 bus reset, the upstream port returns to USDPORT.Powered on. On this entry to USDPORT.Powered on, the function of USB3.0 is enabled again and the port's link makes the trial of Rx detection only one time. Note that the pull-up of D+ line is still enabled and the process of USB2.0 connection is still valid.

If the port's link detects Far End Receiver Termination of the link partner, the upstream port enters USDPORT.Training and the connection as USB2.0 device is disabled within tUSB2SwitchDisconnect (=1ms). If the port succeeds in the training, it enters USDPORT.Connected/Enabled.
But if the port's link can't detect Far End Receiver Termination, the function of USB3.0 is disabled again. When the port succeeds in USB2.0 connection, the device works in HS or FS of USB2.0. With this failure of Rx detection, the port enters USDPORT.Disabled as USB3.0 port and DisabledCount is incremented if it is less than 3.

If DisabledCount equals to 3 when the port enters USDPORT.Disabled, it makes the transition to USDPORT.Disabled_Error.

Whenever the port is in USDPORT.Disabled and USB2.0 bus reset comes, the port transits to USDPORT.Powered on and Rx detection for USB3.0 connection is started one time. Pull up of D+ can be seen from downstream port and USB2.0 connection is still active.
But if the port is in USDPORT.Disabled_Error when USB2.0 bus reset comes, it tries Rx detection no more and can only executes USB2.0 connection. Since DisabledCount is initialized to 0 when power is off or when the port configuration is completed, the port can exit from the state only when the power is removed.

63.7.4 Power Management Control

63.7.4.1 USB3.0 Power Control

Table 63.16 USB3.0 power management

LTSSM State	USB3.0 PHY POWERDOWN	PLL Operation	Note
SS.Disabled	P2	Running	Default
	P0/P2	Running	The setting on USB30_CON.POW_SEL[2:0] is required.
	P3	Running	The setting on USB30_CON.POW_SEL[2:0] is required.
Rx.Detect	P2	Running	
U0	P0	Running	
U1	P1	Running	
U2	P2	Running	
U3	P0/P2	Running	Default Select P0 or P2 as the initial state on USB30_CON.U3_POW_SEL[1:0].
	P0/P2	Running	The setting on USB30_CON.POW_SEL[2:0] is required.
	P3	Running	The setting on USB30_CON.POW_SEL[2:0] is required.
U3 -> U3_Wakeup,Reset	P0	Running	Transition due to the reception of LFPS from host
U3 (P0/2) -> RemoteWakeup	P0	Running	The setting on PORTSC.PLS[3:0] is required after waking up PLL in USB3.0-PHY.
U3(P3) -> RemoteWakeup	P0	Running	The setting on USB30_CON.POW_SEL[2:0] is required.
Others	P0	Running	

Table 63.17 USB3.0 power management and configured state

Configured/Unconfigured (CONF)	USB3.0 PHY POWERDOWN	CLK Gating			Note
		EPC	DLINK30		
		CLK125_P	CLK125	CLKLFPS	
Unconfigured	P0/P1/P2	Stopped	Running	Running	Only PIPE0 is accessible in EPC.
(CONF = 0)	P3	Stopped	Running	Running	PLL Running
Configured	P0/P1/P2	Running	Running	Running	All PIPEs are accessible in EPC
(CONF = 1)	P3	Running	Running	Running	PLL Running

[The behavior of PHY_POWERDOWN[1:0] in Disconnected state (SS.Disabled)]

- P2 is designated on PHY_POWERDOWN[1:0] with default setting.
- P0 or P3 is selectable as the request on PHY_POWERDOWN[1:0] with the setting of USB30_CON.POW_SEL[2:0].

[The behavior of PHY_POWERDOWN[1:0] in U3 state]

- P0 or P2 is designated on PHY_POWERDOWN[1:0] depending on the setting of USB30_CON.POW_SEL[2:0].
- In order to place PHY in U3 state, the additional operation is required. See 63.8.8.1 for details.

[In case of recovery from P3]

- Transition from P3 to P0 can be requested on USB30_CON.B3_PLLWAKE or B3_PLL_WAKEIN signal
  See 63.8.8.6 for details.

63.7.4.2 USB3.0 Power State Control

(1) In case downstream port requests the transition from U0 to U1

When LGO_U1 as the request of transition to U1 state from the downstream port comes, Peripheral portion decides whether it accepts or not depending on the setting in registers and the internal status.

There are two fields in registers related to accepting LGO_U1, SSIFCMD.SSIF_URES[0] and USB30_CON.LPS_ENABLE[1:0].
SSIFCMD.SSIF_URES[0] is referred first in the decision whether LGO_U1 is accepted or not. If SSIFCMD.SSIF.URES[0]== 1 (forced LXU response), LGO_U1 is rejected and Peripheral portion returns LXU. If SSIFCMD.SSIF.URES[0]== 0 (normal response), USB30_CON.LPS_ENABLE[1:0] is referred next.
If USB30_CON.LPS_ENABLE[1:0]==B'10 (forced rejected), LGO_U1 is rejected and Peripheral portion returns LXU.
If USB30_CON.LPS_ENABLE[1:0]==B'01 (forced accepted), LGO_U1 is accepted and Peripheral portion returns LAU.
If USB30_CON.LPS_ENABLE[1:0]==B'00 (basically accepted), it depends on the internal status of Peripheral portion whether it accepts LGO_U1 or not.

With USB30_CON.LPS_ENABLE[1:0]==B'00, LGO_U1 is rejected and Peripheral portion returns LXU if one of the conditions below is satisfied. Otherwise, it is accepted and Peripheral portion returns LAU.

- Peripheral portion is still in U0 state
- 500ms has not passed yet or the response from host has not come from the time Peripheral portion sends ERDY.
- ACK has not been received for the transmitted DP.
- IN PIPE has one or more packets to be transmitted in buffer.
- PP is 1 in the last packet received at OUT PIPE the control transfer is in progress
- USB_COM_CON.CONF== 0

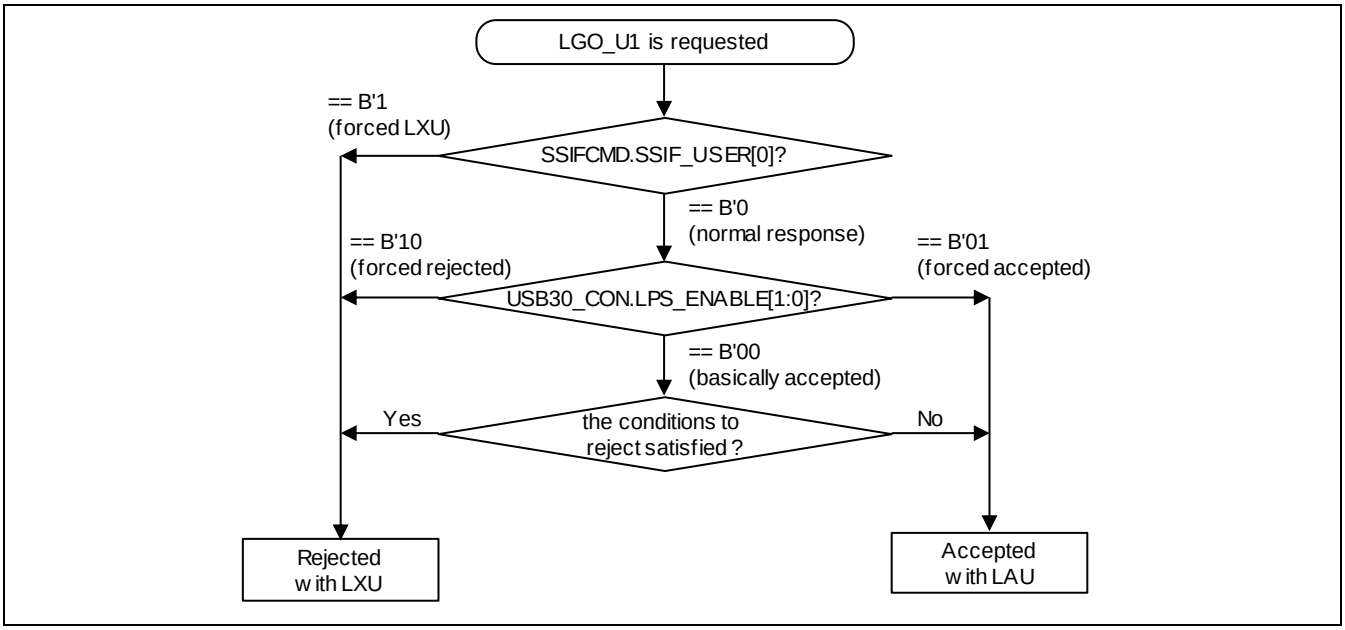

Figure 63.21 the decision flow whether the transition request to U1 is accepted or not

(2) In case device requests the transition from U0 to U1

On the timeout of PORTPMSC.U1_TIMEOUT[15:0], PERIPHERAL PORTION requests the transition from U0 state to U1 state. But it depends on the setting in registers and the internal status of PERIPHERAL PORTION whether it really requests the transition from U0 state to U1 state.

There are two fields in registers related to sending LGO_U1, SSIFCMD.SSIF_UREQ[0] and USB30_CON.LPS_ENABLE[1:0].
SSIFCMD.SSIF.UREQ[0] is referred first in the decision whether LGO_U1 is sent or not. If SSIFCMD.SSIF.UREQ[0]== 1, LGO_U1 isn't sent and PERIPHERAL PORTION never requests the transition from U0 state to U1 state. If SSIFCMD.SSIF.UREQ[1]== 0, USB30_CON.LPS_ENABLE[1:0] is referred next.
If USB30_CON.LPS_ENABLE[1:0]==B'10 (forced rejected), LGO_U1 isn't sent and PERIPHERAL PORTION never requests the transition from U0 state to U1 state. If USB30_CON.LPS_ENABLE[1:0]==B'01 (forced accepted), LGO_U1 is sent and PERIPHERAL PORTION requests the transition from U0 state to U1 state on the timeout of PORTPMSC.U1_TIMEOUT[15:0]. If USB30_CON.LPS_ENABLE[1:0]==B'00 (basically accepted), it depends on the internal status of PERIPHERAL PORTION whether it sends LGO_U1 or not.

With USB30_CON.LPS_ENABLE[1:0]==B'00, LGO_U1 isn't sent even when the timeout of PORTPMSC.U1_TIMEOUT[15:0] occurs If one of the conditions below is satisfied. Otherwise, LGO_U1 is sent and PERIPHERAL PORTION requests the transition from U0 to U1 on the timeout of PORTPMSC.U1_TIMEOUT[15:0].

- PERIPHERAL PORTION is still in U0 state
- 500ms has not passed yet or the response from host has not come from the time PERIPHERAL PORTION sends ERDY.
- ACK has not been received for the transmitted DP.
- IN PIPE has one or more packets to be transmitted in buffer.
- PP is 1 in the last packet received at OUT PIPE

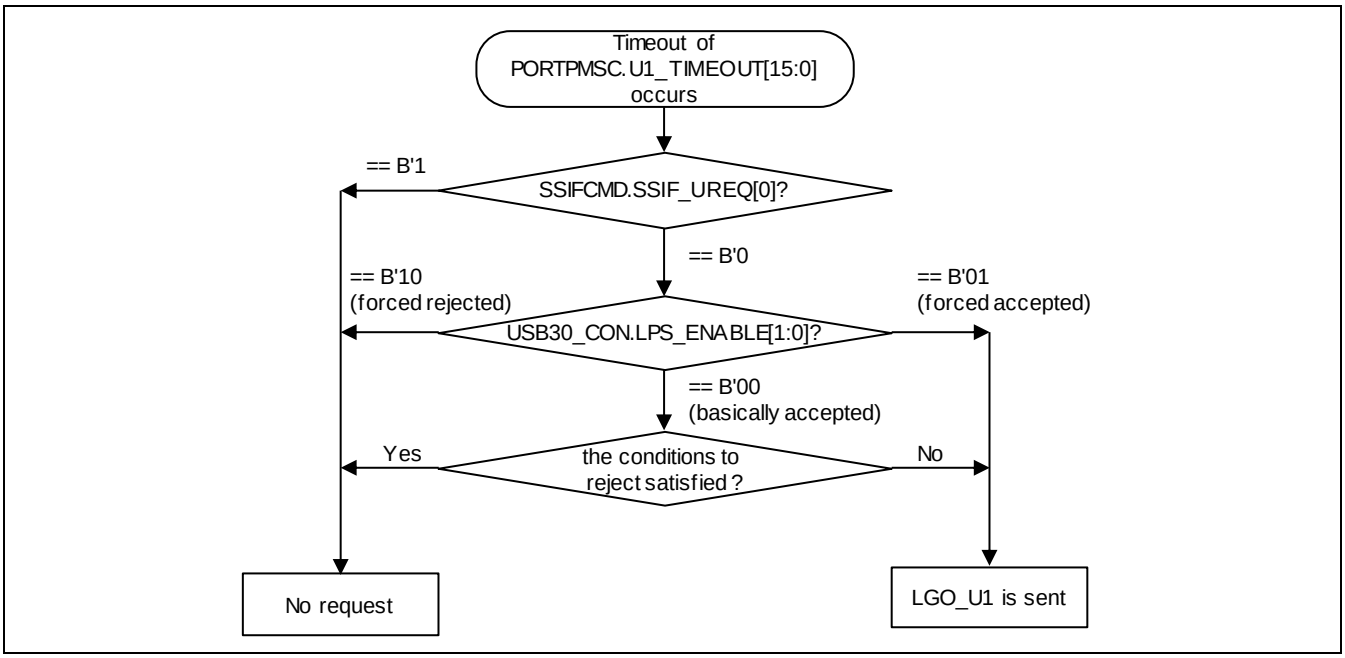

Figure 63.22 the decision flow whether the request of the transition from U0 to U1 is sent or not

It is also available to use PORTPSC.PLS[3:0] in order to send LGO_U1 at any point the software wants. See section 63.8.8.11 for details.

When the downstream port wants to exit from U1 state and U1 Exit LFPS comes, PERIPHERAL PORTION automatically responds to it and returns to U0 state.
At that time, USB_INT_STA_1.B3_LNKCNG_STA is asserted and an interrupt due to it is asserted if enabled.
PORTSC.PLS[3:0] shows U0 state (=H'0) after USB_INT_STA_1.B3_LNKCNG_STA is asserted.

(3) In case device requests the transition from U1 to U0

PERIPHERAL PORTION automatically requests the exit from U1 state to the downstream port by sending U1 Exit LFPS when one of the conditions below is satisfied.

- when PERIPHERAL PORTION wants to send ERDY for the next transfer
- when PERIPHERAL PORTION wants to send the transaction packet written in USB3_TPDAT_x (x=0,1,2) registers

In the first case, PERIPHERAL PORTION sends ERDY when the packet to be transmitted is prepared in buffer for IN PIPE and when the PIPE becomes ready to receive the next packet (Pn_CON.Pn_RES[1:0] is changed from B'00 to B'01, for example) for OUT PIPE.
In the second case, PERIPHERAL PORTION sends the transaction packet in USB3_TPDAT_x (x=0,1,2) registers when USB30_CON.B3_TP_SEND is set to 1.

For both cases, the operations to send packet or start transfer are required, but there is no additional operation to exit from U1 state. Therefore, it is not required for user to mind whether the link is in U1 state or not before sending packet or starting transfer.

(4) In case downstream port requests the transition from U0 to U2.

When LGO_U2 as the request of transition to U2 state from the downstream port comes, PERIPHERAL PORTION decides whether it accepts or not depending on the setting in registers and the internal status.

There are two fields in registers related to accepting LGO_U2, SSIFCMD.SSIF_URES[1] and USB30_CON.LPS_ENABLE[1:0].
SSIFCMD.SSIF.URES[1] is referred first in the decision whether LGO_U2 is accepted or not. If SSIFCMD.SSIF.URES[1]== 1 (forced LXU response), LGO_U2 is rejected and PERIPHERAL PORTION returns LXU. If SSIFCMD.SSIF.URES[1]== 0 (normal response), USB30_CON.LPS_ENABLE[1:0] is referred next.
If USB30_CON.LPS_ENABLE[1:0]==B'10 (forced rejected), LGO_U2 is rejected and PERIPHERAL PORTION returns LXU. If USB30_CON.LPS_ENABLE[1:0]==B'01 (forced accepted), LGO_U2 is accepted and PERIPHERAL PORTION returns LAU. If USB30_CON.LPS_ENABLE[1:0]==B'00 (basically accepted), it depends on the internal status of PERIPHERAL PORTION whether it accepts LGO_U2 or not.

With USB30_CON.LPS_ENABLE[1:0]==B'00, LGO_U2 is rejected and PERIPHERAL PORTION returns LXU If one of the conditions below is satisfied. Otherwise, it is accepted and PERIPHERAL PORTION returns LAU.

- PERIPHERAL PORTION is still in U0 state
- 500ms has not passed yet or the response from host has not come from the time PERIPHERAL PORTION sends ERDY.
- ACK has not been received for the transmitted DP.
- IN PIPE has one or more packets to be transmitted in buffer.
- PP is 1 in the last packet received at OUT PIPE

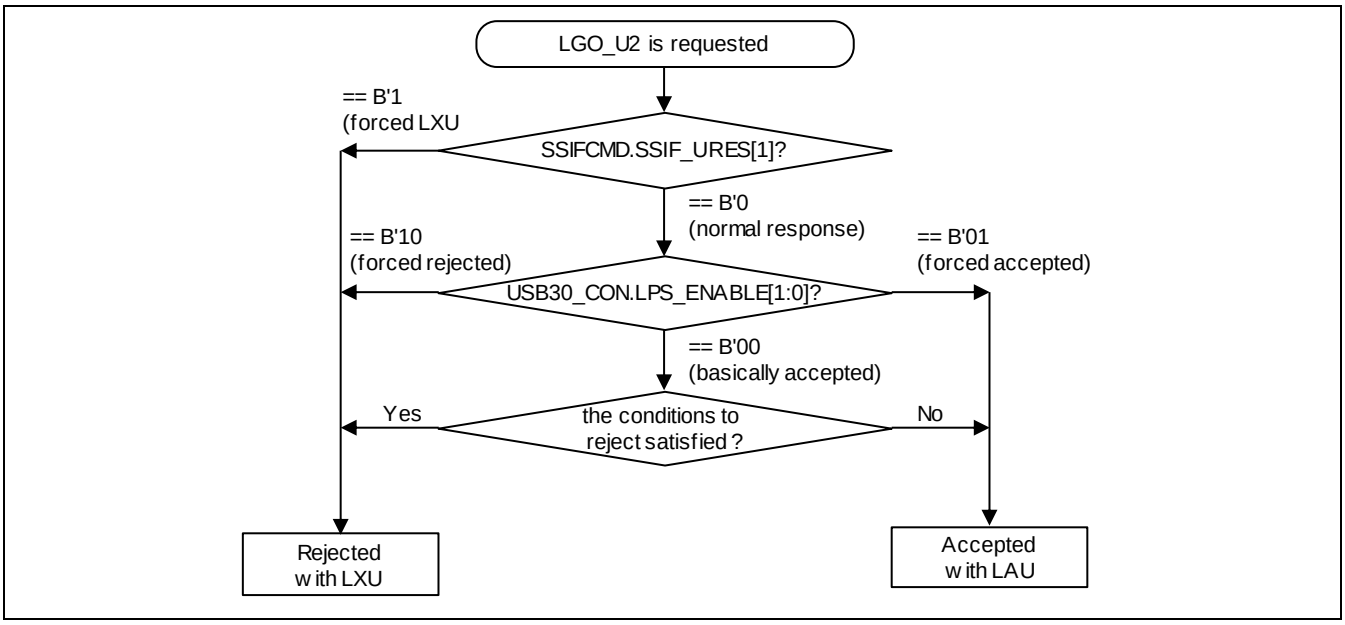

Figure 63.23 the decision flow whether the transition request to U2 is accepted or not

(5) In case device requests the transition from U0 to U2

On the timeout of PORTPMSC.U2_TIMEOUT[15:0], PERIPHERAL PORTION requests the transition from U0 state to U2 state. But it depends on the setting in registers and the internal status of PERIPHERAL PORTION whether it really requests the transition from U0 state to U2 state.

But the timeout value in U1_TIMEOUT[15:0] is smaller than that in U2_TIMEOUT[15:0] in general. In that case, U1 timeout occurs first, then U2 timeout occurs next if the device is still in U1 state. See section 63.7.4.2 (6) for the case.

There are two fields in registers related to sending LGO_U2, SSIFCMD.SSIF_UREQ[1] and USB30_CON.LPS_ENABLE[1:0].
SSIFCMD.SSIF.UREQ[1] is referred first in the decision whether LGO_U2 is sent or not. If SSIFCMD.SSIF.UREQ[1]== 1, LGO_U2 isn't sent and PERIPHERAL PORTION never requests the transition from U0 state to U2 state. If SSIFCMD.SSIF.UREQ[1]== 0, USB30_CON.LPS_ENABLE[1:0] is referred next.
If USB30_CON.LPS_ENABLE[1:0]==B'10 (forced rejected), LGO_U2 isn't sent and PERIPHERAL PORTION never requests the transition from U0 state to U2 state. If USB30_CON.LPS_ENABLE[1:0]==B'01 (forced accepted), LGO_U2 is sent and PERIPHERAL PORTION requests the transition from U0 state to U2 state on the timeout of PORTPMSC.U2_TIMEOUT[15:0]. If USB30_CON.LPS_ENABLE[1:0]==B'00 (basically accepted), it depends on the internal status of PERIPHERAL PORTION whether it sends LGO_U2 or not.

With USB30_CON.LPS_ENABLE[1:0]==B'00, LGO_U2 isn't sent even when the timeout of PORTPMSC.U2_TIMEOUT[15:0] occurs If one of the conditions below is satisfied. Otherwise, LGO_U2 is sent and PERIPHERAL PORTION requests the transition from U0 to U2 on the timeout of PORTPMSC.U2_TIMEOUT[15:0].

- PERIPHERAL PORTION is still in U0 state.
- 500ms has not passed yet or the response from host has not come from the time PERIPHERAL PORTION sends ERDY.
- ACK has not been received for the transmitted DP.
- IN PIPE has one or more packets to be transmitted in buffer.
- PP is 1 in the last packet received at OUT PIPE
- the control transfer is in progress
- USB_COM_CON.CONF== 0

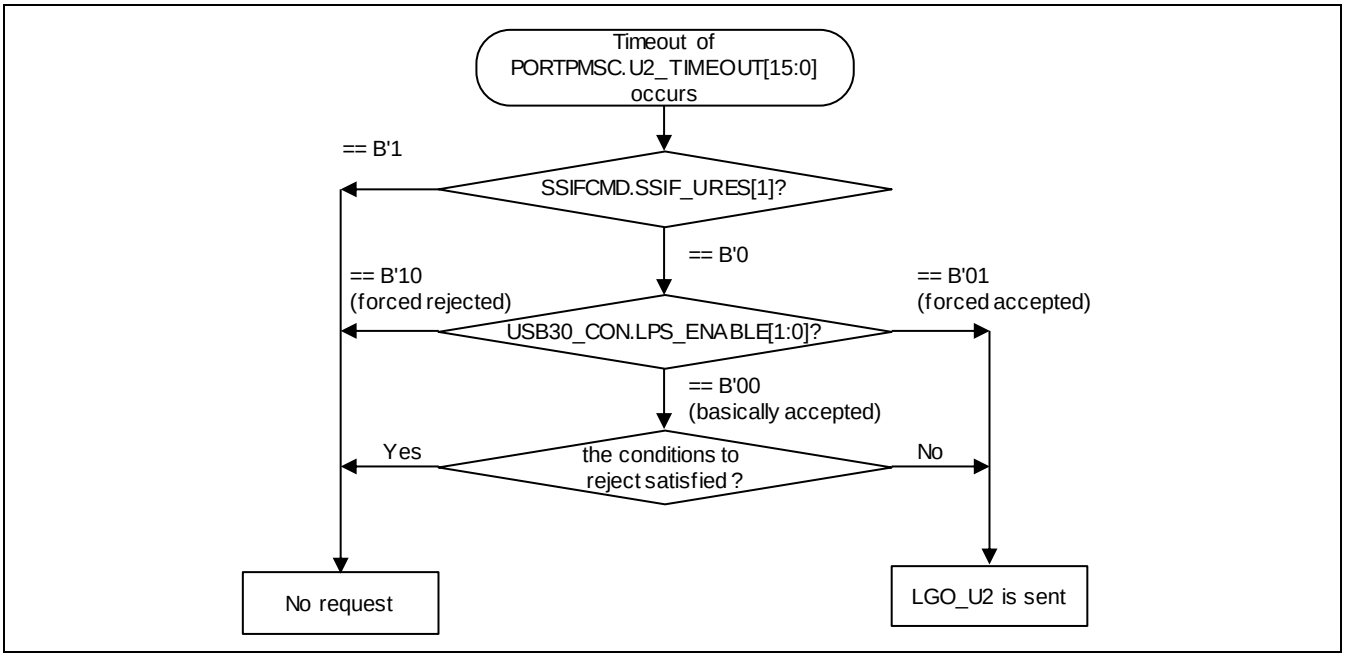

Figure 63.24 the decision flow whether the request of the transition from U0 to U2 is sent or not

(6) In case device requests the transition from U1 to U2

As explained in section 63.7.4.2 (5), When PERIPHERAL PORTION is in U1 state and the timeout of PORTPMSC.U2_TIMEOUT[15:0] occurs, PERIPHERAL PORTION transits from U1 state to U2 state without returning to U0 state. In that case, it is required that SSIFCMD.SSIF_UREQ[1] is set to 0.

At that time, USB_INT_STA_1.B3_LNKCNG_STA is asserted and an interrupt due to it is asserted if enabled. PORTSC.PLS shows U2 state (=H'2) after USB_INT_STA_1.B3_LNKCNG_STA is asserted.

(7) In case downstream port requests the transition from U2 to U0

When the downstream port wants to exit from U2 state and U2 Exit LFPS comes, PERIPHERAL PORTION automatically responds to it and returns to U0 state.
At that time, USB_INT_STA_1.B3_LNKCNG_STA is asserted and an interrupt due to it is asserted if enabled. PORTSC.PLS[3:0] shows U0 state (=H'0) after USB_INT_STA_1.B3_LNKCNG_STA is asserted.

(8) In case device requests the transition from U2 to U0

PERIPHERAL PORTION automatically requests the exit from U2 state to the downstream port by sending U2 Exit LFPS when one of the conditions below is satisfied.

- when PERIPHERAL PORTION wants to send ERDY for the next transfer
- when PERIPHERAL PORTION wants to send the transaction packet written in USB3_TPDAT_x (x=0,1,2) registers

In the first case, PERIPHERAL PORTION sends ERDY when the packet to be transmitted is prepared in buffer for IN PIPE and when the PIPE becomes ready to receive the next packet (Pn_CON.Pn_RES[1:0] is changed from B'00 to B'01, for example) for OUT PIPE.
In the second case, PERIPHERAL PORTION sends the transaction packet in USB3_TPDAT_x (x=0,1,2) registers when USB30_CON.B3_TP_SEND is set to 1.

For both cases, the operation to send packet or start transfer is required, but there is no additional operation to exit from U2 state. Therefore, it is not required for user to mind whether the link is in U1 state or not before sending packet or starting transfer.

(9) In case downstream port requests the transition from U0 to U3

Only downstream port can initiate U3 entry. An upstream port shall not reject U3 entry.
PERIPHERAL PORTION automatically responds to LGO_U3, accepts it and transits to U3 state.
USB_INT_STA_1.B3_LNKCNG_STA is asserted and an interrupt due to it is asserted if enabled. PORTSC.PLS[3:0] shows U3 state (=H'3) after USB_INT_STA_1.B3_LNKCNG_STA is asserted.

But only with the transition to U3 above, USB3.0 PHY is placed in P0 state or P2 state. If it is required to place PHY in P3 state, See the flow shown in section 63.8.8.1.

(10) In case downstream port requests the transition from U3 to U0

When the downstream port wants to exit from U3 state and U3 Wakeup LFPS comes, PERIPHERAL PORTION automatically responds to it and returns to U0 state.
At that time, USB_INT_STA_1.B3_LNKCNG_STA is asserted and an interrupt due to it is asserted if enabled. PORTSC.PLS[3:0] shows U0 (=H'0) after USB_INT_STA_1.B3_LNKCNG_STA is asserted.

(11) In case device requests the transition from U3 to U0

PERIPHERAL PORTION automatically requests the transition from U3 state to U0 by sending U3 Wakeup LFPS when the transition is requested on PORTSC.PLS[3:0]. In U3, PORTSC.PLS[3:0] shows U3 state (=H'3). If PORTSC.PLS[3:0] is changed to U0 state (=H'0), PERIPHERAL PORTION sends U3 Wakeup LFPS to the link partner in order to request the transition from U3 state to U0 state.

When the LFPS handshake is completed and the link goes back to U0 state, USB_INT_STA_1.B3_LNKCNG_STA is asserted and an interrupt due to it is asserted if enabled. PORTSC.PLS[3:0] shows U0 state (=H'0) after USB_INT_STA_1.B3_LNKCNG_STA is asserted.

63.7.4.3 USB2.0 Power State Control

In the specification of USB2.0 link power management, L0 state is defined as “On” state.
L3 state is defined as “Off” state and corresponds to the powered-off, disconnected and disabled state.
L2 state is defined as “Suspend” state and corresponds to so-called “USB2.0 suspend” in the past.
L1 state is defined as “Sleep” state. LPM transaction is defined for the state.

Table 63.18 USB2.0 power management

State	Configured (CONF)	PLL Operation	CLK Gating				Supplement
			CLK60	CLK60_G	CLK60_P	CLK60_PG	
L3	—	Running	Running	Stopped	Stopped	Stopped	(default)
		Stopped	Stopped	Stopped	Stopped	Stopped	PLL stop is requested on USB20_CON.B2_SUSPEND
L0	Unconfigured (CONF = 0)	Running	Running	Running	Stopped	Stopped	Only PIPE0 is running
	Configured (CONF = 1)	Running	Running	Running	Running	Running	All PIPEs are running
L1/L2		Running	Running	Stopped	Running	Stopped	(default)
		Stopped	Stopped	Stopped	Stopped	Stopped	PLL stop is requested on USB20_CON.B2_SUSPEND
L1/L2 → L0		Running	Running	Running	Running	Running	Wakeup received from Host
		Running	Running	Running	Running	Running	Remote wakeup initiated by device

[L3 (Off) State]

- Disconnected state for USB2.0
- PLL is running in default setting but it can be stopped on USB20_CON.B2_SUSPEND.
- 60MHz clock other than CLK60 is suspended.

[L0 (On) State]

- Active state in USB2.0 connection
- PLL is running
- In unconfigured state, CLK60_P and CLK60_PG are suspended. It means that clock to PIPEs other than PIPE0 is suspended.
  In configured state, all clocks of 60MHz is running.

[L1 (Sleep) State]

- Low power state selected on LPM in USB2.0 connection
- PLL is running.
- CLK60_G and CLK60_PG are suspended.

[L2 (Suspend) State]

- Suspended state in USB2.0 connection
- PLL is running but it can be stopped on USB20_CON.B2_SUSPEND.
  PLL is resumed automatically when the wakeup request from downstream port is received.
- CLK60_G and CLK60_PG are suspended.

(1) Transition from L0 to L1

L1 state in USB2.0 is similar to U1 state and U2 state in USB3.0 in the point that the hardware should control the transition to or the exit from the state mainly. But unlike the transition to U1 state or U2 state, the transition to L1 state is initiated only by downstream port.
LPM token is defined as one of extended token packet for the transition. The device returns ACK if it accepts the transition or NYET if it rejects the transition when LPM token comes. It is also allowed to return STALL if it doesn't support LPM function.

PERIPHERAL PORTION can respond with "no response" or return STALL to LPM token with the setting to do so, but it should return only ACK or NYET basically.

When LPM token from downstream port comes, PERIPHERAL PORTION decides whether it accepts or not depending on the setting in the registers and the internal status.

LPM function can be enabled or disabled on USB20_CON.LPM_DISABLE. When USB20_CON.LPM_DISABLE== 1, PERIPHERAL PORTION disables LPM function and return no response to LPM token and take no action for it. But the device should support LPM function, so it should enable LPM function.
USB20_CON.LPM_ENABLE[1:0] also defines the response of PERIPHERAL PORTION to LPM token. If USB20_CON.LPM_ENABLE[1:0]==B'10 (forced rejected), the request is rejected and PERIPHERAL PORTION returns NYET to LPM token. If USB20_CON.LPM_ENABLE[1:0]==B'01 (forced accepted), the request is accepted and PERIPHERAL PORTION returns ACK to LPM token. If USB20_CON.LPM_ENABLE[1:0]==B'00 (basically accepted), it depends on the internal status of PERIPHERAL PORTION whether it accepts the request or not. If USB20_CON.LPM_ENABLE[1:0]==B'11 (unsupported), PERIPHERAL PORTION returns STALL to LPM token. But the device should not return STALL if it supports LPM function.

If one of the conditions below is satisfied, the request is rejected and PERIPHERAL PORTION returns NYET. Otherwise, it is accepted and PERIPHERAL PORTION returns ACK.

— IN PIPE has one or more packets to be transmitted in buffer.

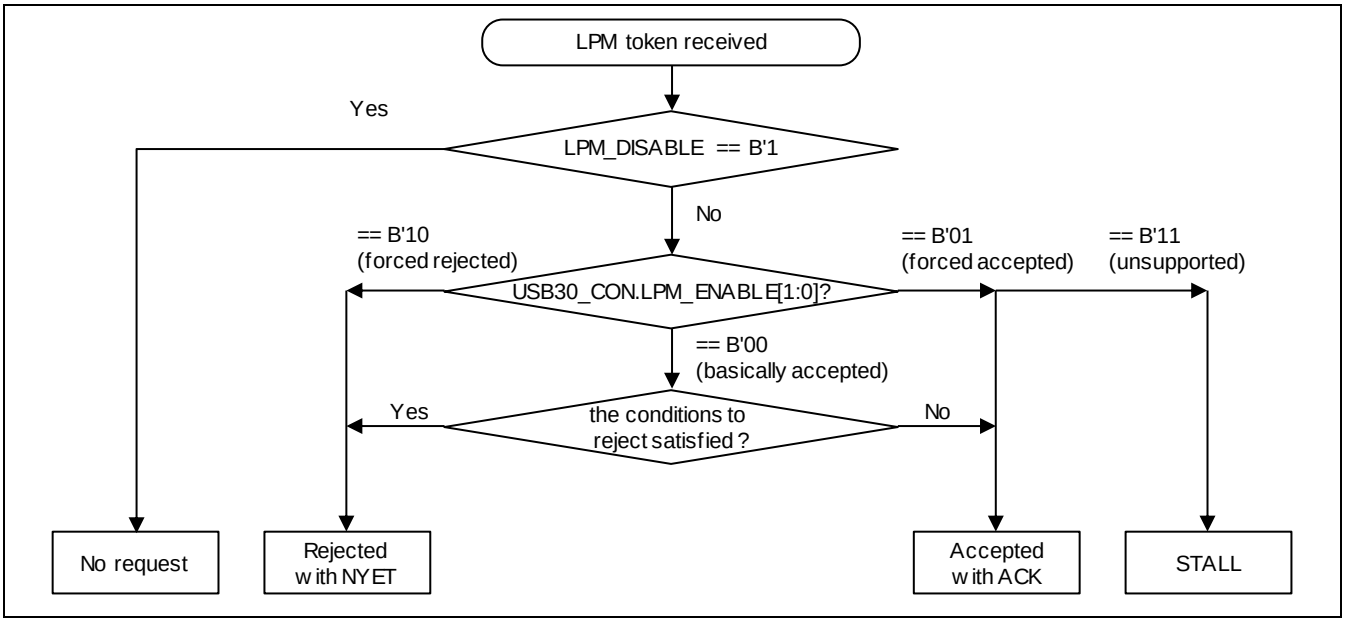

Figure 63.25 the decision flow whether the transition request to L1 is accepted or not

The software can knows that the transition to L1 state is requested on USB_INT_STA_1.B2_L1SPND_STA. An interrupt due to it is asserted if enabled.

(2) In case downstream port requests the transition from L1 to L0

When the downstream port wants to exit from L1 state and the resume signal comes, PERIPHERAL PORTION automatically responds to it and returns to L0 state.
At that time, USB_INT_STA_1.B2_L1RSUM_STA is asserted and an interrupt due to it is asserted if enabled.

(3) In case device requests the transition from L1 to L0

PERIPHERAL PORTION automatically requests the exit from L1 state to the downstream port by sending the resume signal when it has one or more packets to be transmitted in buffer for IN PIPE. In this case, there is no additional operation to exit from L1 state.

The transition from L1 state to L0 state is also required by setting USB20_CON.B2_RSUM_IN. When this bit is set, the resume signal to request the exit from L1 state is sent to the downstream port.

(4) Transition from L0 to L2 (Suspend)

L2 state is defined as USB2.0 Suspend in the original USB2.0 specification. The transition to L2 state is requested only from downstream port and is controlled automatically by the hardware of PERIPHERAL PORTION.

The downstream port can request the transition to L2 state by stopping any bus activity and put USB bus in a constant idle state for more than 3.0ms and device can not deny the transition.

When PERIPHERAL PORTION detects that the transition to L2 state is being requested from downstream port (that is, USB bus stays in idle state for more than 3.0ms), it automatically follows it and asserts USB_INT_STA_1.B2_SPND_STA.

PERIPHERAL PORTION follows to the request of the transition to L2 state, but PLL in USB2.0-PHY is still running in L2 state. If it is required to stop PLL, set USB20_CON.B2_SUSPEND. See section 63.8.8.7 for details.

(5) In case downstream port requests the transition from L2 to L0

When the downstream port wants to exit from L2 state and the resume signal comes, PERIPHERAL PORTION automatically responds to it and returns to L0 state.
At that time, USB_INT_STA_1.B2_RSUM_STA is asserted and an interrupt due to it is asserted if enabled.

(6) In case device requests the transition from L2 to L0

The sofware can requests the wakeup of PERIPHERAL PORTION from L2 state. If PLL in USB2.0-PHY is suspended, it should be awaken first. See section 63.8.8.10 for how to awake PLL in USB2.0-PHY.

After PLL is resumed, the software can send the resume signal from PERIPHERAL PORTION by setting USB20_CON.RSUM_IN. See section 63.8.8.9 for details

63.7.5 AXI DMA Transfer Control

PERIPHERAL PORTION executes DMA transfer to or from data buffers connected to SRAM interface using the bus master function of Peripheral portion. The DMA master function of Peripheral portion uses Physical Region Descriptor (PRD) Table on system memory, which has source address, destination address, the size of transfer and other informations related to the DMA transfer. It is assumed that the software (driver, for example) prepares PRD table on system memory. PRD tables are prepared separately for each PIPE.

The operation flow of DMA transfer using master function of Peripheral portion is described below.

63.7.5.1 OUT Transfer

(1) Interrupt is asserted if PRD table is not prepared

Peripheral portion asserts AXI_INT_SYS if a certain PIPE receives OUT packet and the OUT packet becomes ready to be read but PRD table is not prepared for it yet.

If PRD table is already prepared for the PIPE and DMA transfer is enabled, Peripheral portion doesn't assert AXI_INT_SYS here. In that case, (2) and (3) can be skipped.

(2) Making PRD table

The software makes PRD table according to the defined format.

(3) Setting for bus master

The software specifies PRD table made at (2) to registers of Peripheral portion, and enables DMA transfer.

(4) Start of DMA transfer

Peripheral portion reads PRD table when it detects EPC_D_Pn_DATAEN[n] (n is the index of the PIPE for which PRD table is prepared for) is asserted and knows Peripheral portion requests DMA transfer. Then, Peripheral portion writes received data in a unit of packet to the address which is assigned by PRD table.

(5) Writing back the result of transfer to PRD table

When DMA transfer is completed, Peripheral portion writes back the result of transfer to PRD table.

(6) Interrupt is asserted to notify completion of DMA transfer

Peripheral portion asserts AXI_INT_DMA when it completes DMA transfer.

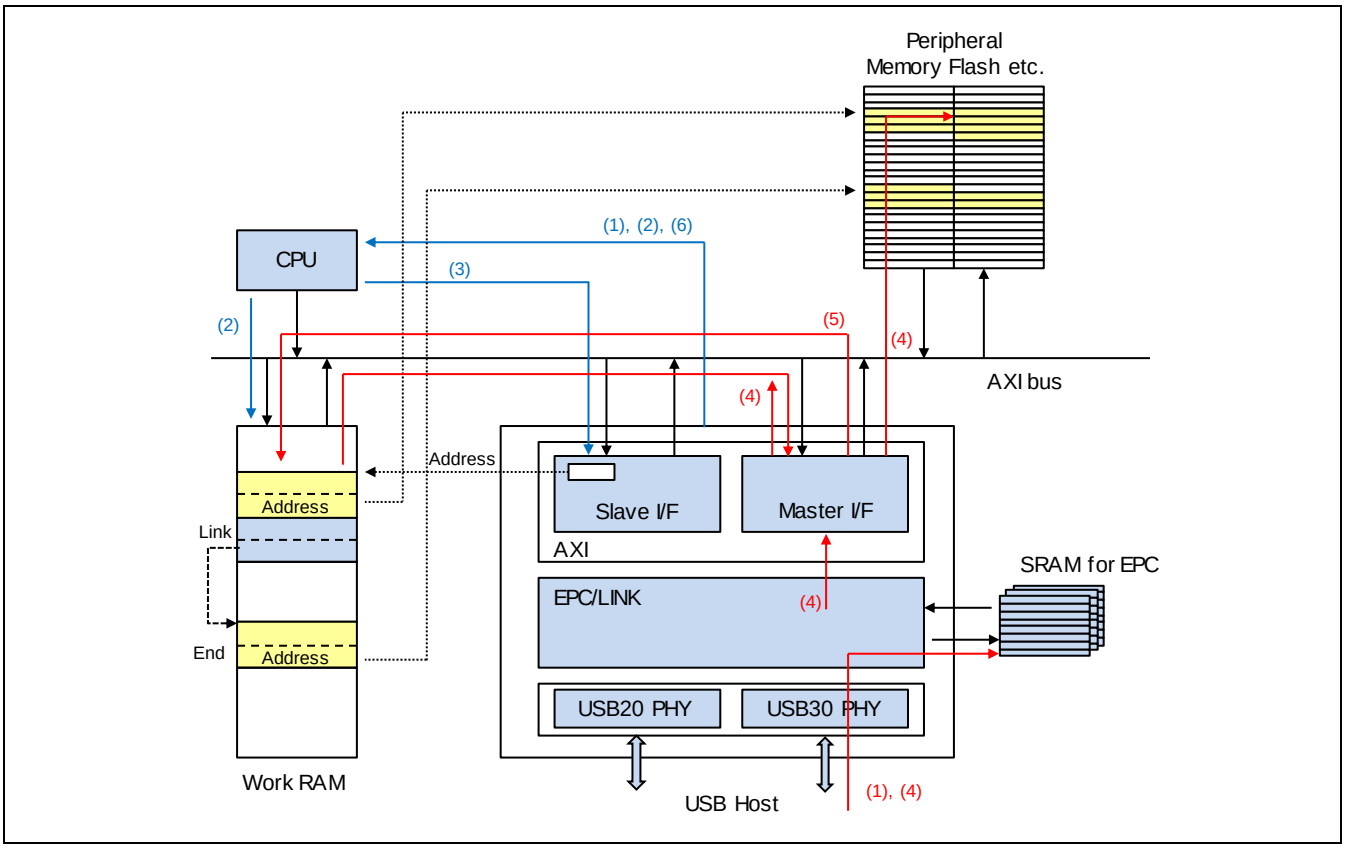

Figure 63.26 example of operation for OUT transfer

63.7.5.2 IN Transfer

(1) Interrupt is asserted if PRD table is not prepared

Peripheral portion asserts AXI_INT_SYS if a certain PIPE becomes ready to be written for IN packet but PRD table is not prepared for it yet.

If PRD table is already prepared for the PIPE and DMA transfer is enabled, Peripheral portion doesn't assert an interrupt. In that case, (2) and (3) can be skipped.

(2) Making PRD table

The software makes PRD table according to the defined format.

(3) Setting for bus master

The software specifies PRD table made at (2) to registers of Peripheral portion, and enables DMA transfer.

(4) Start of DMA transfer

Peripheral portion reads PRD table when it detects EPC_D_Pn_DATAEN[n] (n is the index of the PIPE for which PRD table is prepared for) is asserted and knows Peripheral portion requests DMA transfer. Then, Peripheral portion read data to be transmitted in unit of a packet from the address which is assigned by PRD table.

(5) Write back of result of transfer to PRD table

When DMA transfer is completed, Peripheral portion writes back the result of transfer to PRD table.

(6) Interrupt asserted to notify completion of DMA transfer

Peripheral portion asserts AXI_INT_DMA when it completes DMA transfer.

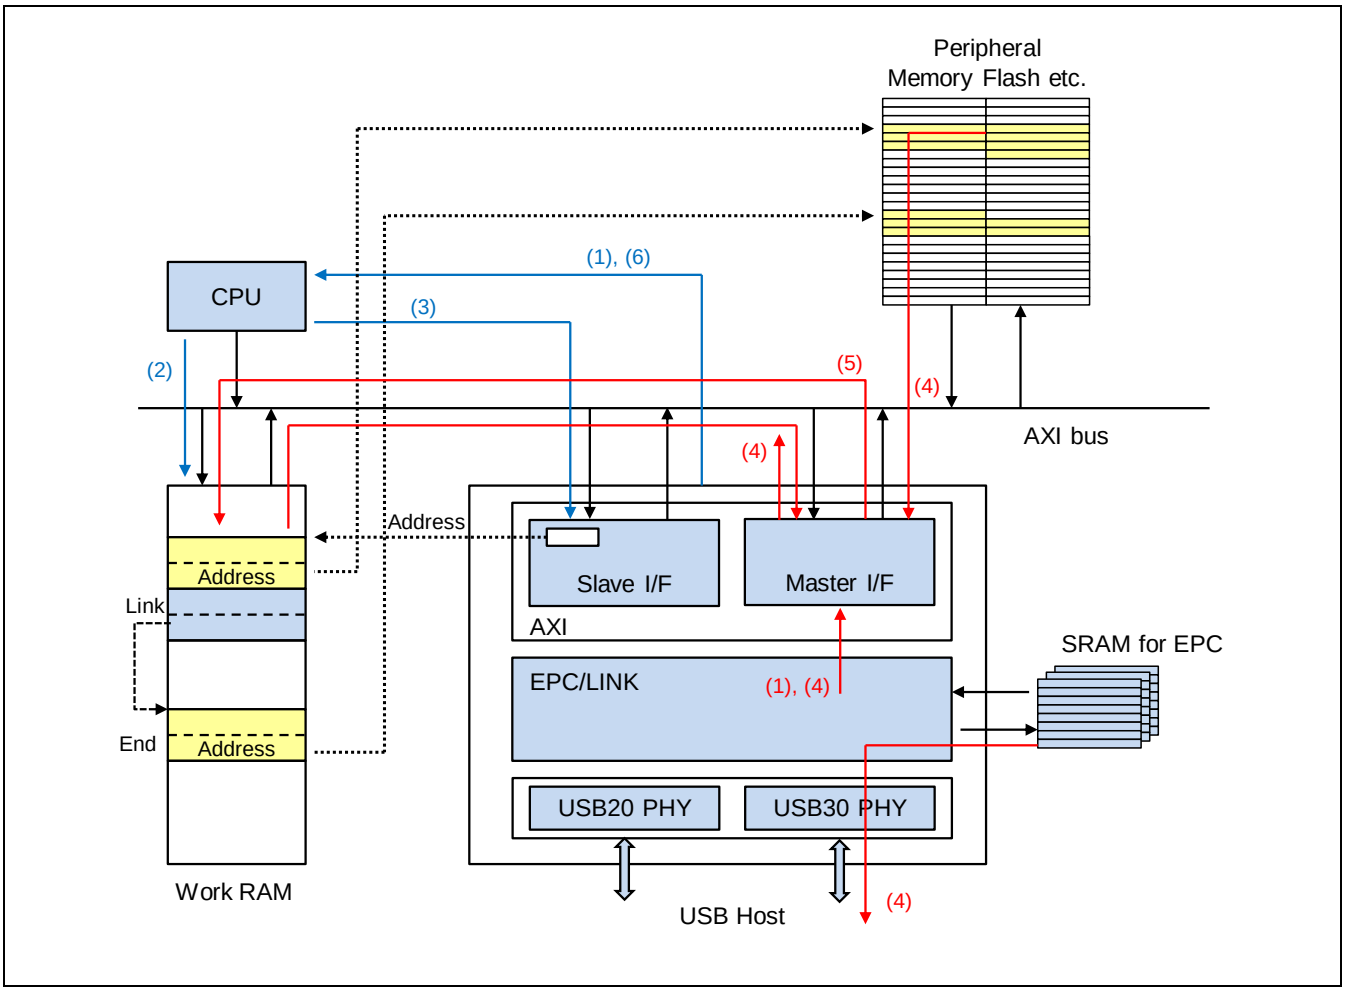

Figure 63.27 example of operation for IN transfer

63.7.5.3 Two PRD tables for one group of transfer

The basic concept of two PRD tables used for one group of transfer is described below. Especially the Stream bulk protocol is assumed here.

For Stream bulk transfer, Stream ID is assigned to PERIPHERAL PORTION and it executes transfer related to the Stream ID. The Stream ID is set before PRD table is allocated to PERIPHERAL PORTION.
From the viewpoint of the performance of system, it is desirable to prepare for the next transfer just before the current OUT transfer is completed. PERIPHERAL PORTION can execute transfer seamlessly in that case.

In order to do so, there is a way to use PRD tables for one group of transfer.

Two PRD tables are prepared so that the group of transfer is divided to them beforehand. One PRD table has the part from the first packet to the (n)-th packet, and the other table has that from the (n+1) th packet to the last packet. The (n) is assumed as the second or the third packet from the last. The Int bits are set for both tables. With this usage, the software can know the current transfer is almost completed by the interrupt of the first PRD table. When the interrupt of the first PRD table comes, software can start the preparation for the next transfer. It can also confirm the completion of the current transfer by the interrupt of the second PRD table.

This method is applicable for non Stream bulk transfer.

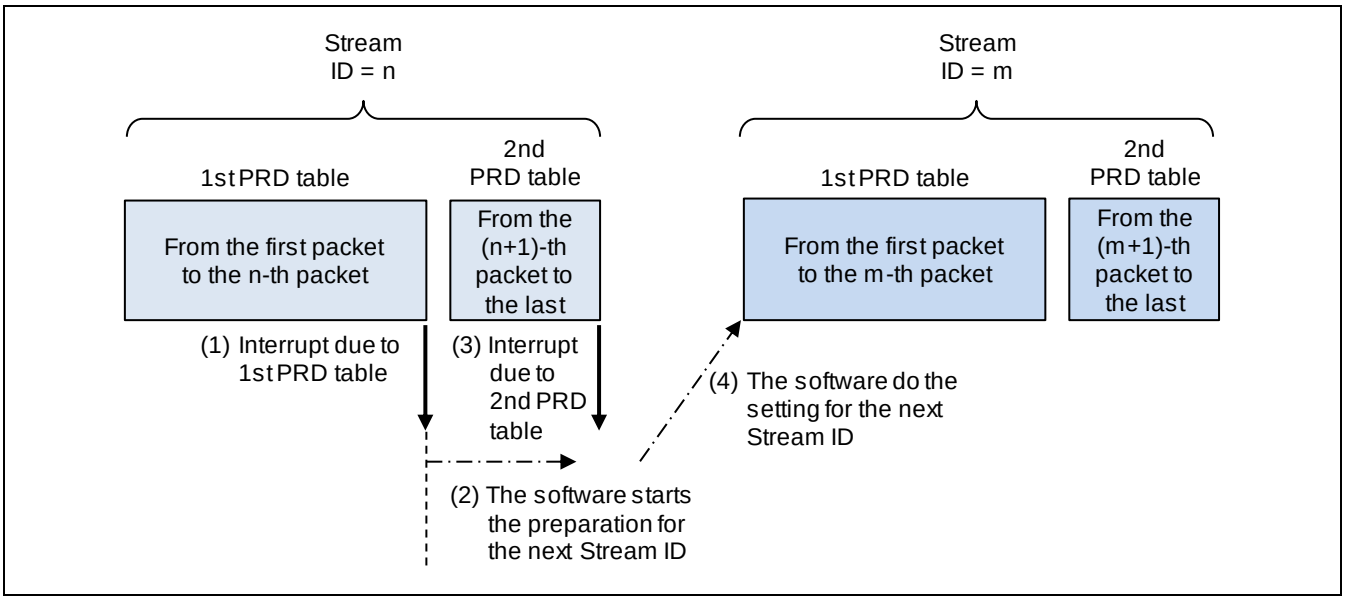

Figure 63.28 Two PRD tables used for one group transfer

63.7.5.4 DMA Transfer using EXTPRD_EN

Peripheral portion has four register groups used for DMA transfers, -- DMA_Ch0_CONx and DMA_Ch0_PRD_ADRx (x = 1 to 4). USB3.0 Controller can coordinate multiple PRD tables and their transfers by making links between those PRD tables on DMA_Ch0_CONx.EXPRD_ENx and DMA_Ch0_CONx.EXTPRD_NOx[1:0].

An example in case that multiple PRD tables and their transfers are coordinated on DMA_Ch0_CONx.EXPRD_ENx is described below. In this example, PRD tables from (1) to (4) are set to registers at first, and then PRD table of (5) is set after DMA transfer of (1) is completed. Since DMA_Ch0_CONx.EXPRD_ENx is set to 1 for (2), (3) and (5), each DMA_Ch0_CONx.PRD_ENx is masked and each DMA transfer is kept waiting until the transfer related on DMA_Ch0_CONx.EXTPRD_NOx[1:0] is completed.

As for (2), DMA_Ch0_CON2.EXTPRD_NO2[1:0]=0 is specified. In this case, the transfer related to (2) is suspended until the transfer at PIPE1 with DMA_Ch0_CON1 is completed. When the transfer at PIPE1 with DMA_CH0_CON1 is completed and DMA_Ch0_CON1.PRD_EN1 is cleared by hardware, DMA_Ch0_CON2.EXTPRD_EN2 is cleared automatically by hardware at the same time. The clearing of DMA_Ch0_CON2.EXTPRD_EN2 means that DMA_Ch0_CON2.PRD_EN2 gets unmasked, and the transfer of (2) is allowed at this point.

[Example of PRD Table Setting]

No.		PRD_EN	PIPE_NO	EXTPRD_EN	EXTPRD_NO
(1)	DMA_Ch0_CON1	1	PIPE1	0 (Normal)	—
(2)	DMA_Ch0_CON2	1	PIPE1	1 (Expanded)	0 (CON1)
(3)	DMA_Ch0_CON3	1	PIPE2	1 (Expanded)	1 (CON2)
(4)	DMA_Ch0_CON4	1	PIPE3	0 (Normal)	—
(5)	DMA_Ch0_CON1	1	PIPE1	1 (Expanded)	2 (CON3)

[Example of Operation]

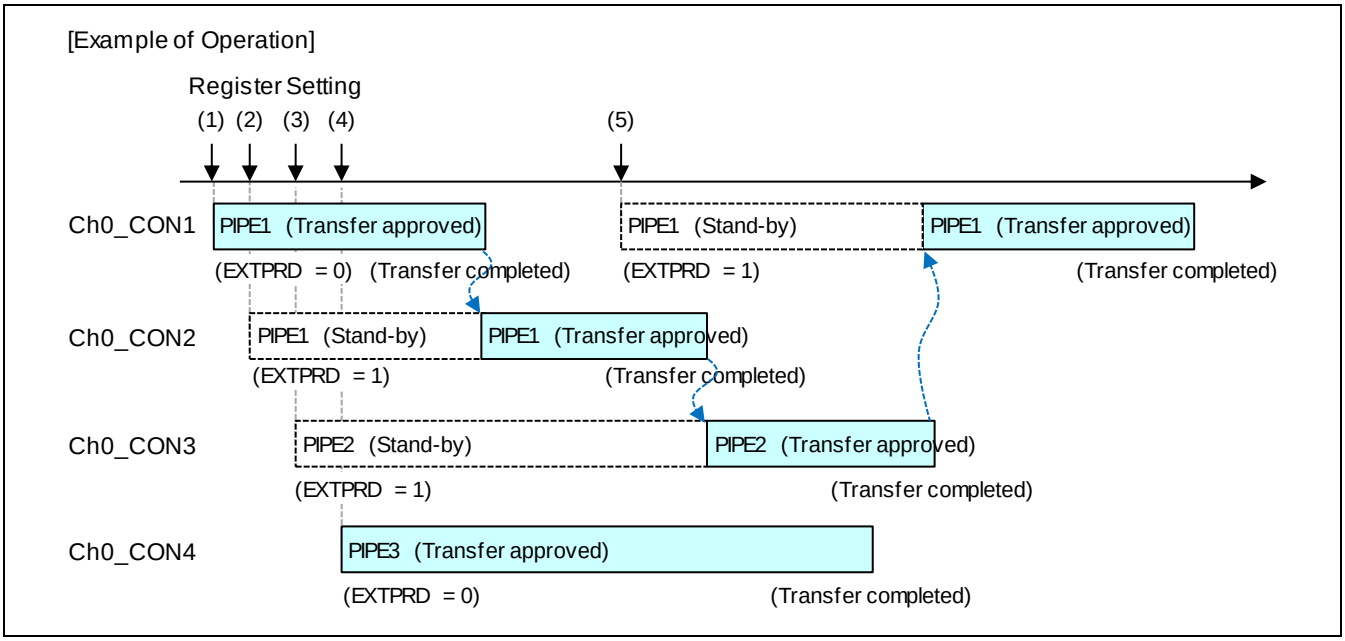

Figure 63.29 Transfer using EXTPRD_EN

This function is also used for the case a certain PIPE is expected to start the transfer just after that at other PIPE is completed.

DMA_Ch0_CONx.EXTPRD_NOx[1:0] and DMA_Ch0_CONx.EXTPRD_ENx should be set before the transfer for PRD table related on DMA_Ch0_CONx.EXTPRD_NOx[1:0] is completed (when it is completed, DMA_Ch0_CONx.PRD_ENx is cleared). Make sure that DMA_Ch0_CONx.PRD_ENx is still 1 just when DMA_Ch0_CONx.EXTPRD_NOx[1:0] and DMA_Ch0_CONx.EXTPRD_ENx are set and related to it. If DMA_Ch0_CONx.PRD_ENx has already been cleared, don’t use DMA_Ch0_CONx.EXTPRD_NOx[1:0] and DMA_Ch0_CONx.EXTPRD_ENx for it.

63.7.5.5 Example of transfer using bus master function

An Example in which short packet is received as the last one at OUT (AXI write) PIPE is described below.

Peripheral portion provides 4 register groups to have the information of PRD Tables. The software prepares PRD Table on system memory and requests the transfer by setting the start address of PRD table, the information of PIPE (index of PIPE and direction of transfer) and DMA_Ch0_CONx.PRD_ENx to one of register groups. Especially setting of DMA_Ch0_CONx.PRD_ENx to 1 means the transfer on the PIPE is enabled.

Peripheral portion indicates whether transfer is enabled or not for each PIPE on EPC_D_Pn_DATAEN[n] (n=1-30), which is one of the signals at Data Interface of Peripheral portion.

Peripheral portion is kept waiting until Peripheral portion notifies it that the transfer of PIPE related on the PRD table is enabled. Peripheral portion starts the transfer when it detects that one of transfers related on PRD tables is enabled.

Upon the start of transfer, Peripheral portion reads the first PRD table. When the type of PRD table is a link pointer, Peripheral portion executes writing-back in order to set used bit of the PRD table first and then reads the next PRD table from the address which is held in BAP. When the type of PRD table is a buffer pointer, Peripheral portion starts data transfer according to the PRD table.

Peripheral portion executes data transfer at Data Interface in a unit of a packet of USB (the size of packet is up to the max packet size of USB).

When the transfer of the packet is completed, Peripheral portion updates the PRD table that was read just prior to the transfer and writes back it so that SIZE field and BAP field in the table are updated. If the remain size of the PRD table is not zero and Peripheral portion notifies Peripheral portion that it can still continue transfer of the PIPE when Peripheral portion completes writing-back of PRD table, Peripheral portion uses PRD table currently held and start transfer of the next packet for the PIPE. On the contrary, in case that all transfers specified by the PRD table held currently in Peripheral portion have been done, case that the transfer for the PRD table is terminated by receiving short packet or case that EPC notifies that no transfer on the PIPE is pending, Peripheral portion returns back to the status to wait for transfer.

When the transfer is completed, the size information in SIZE field of table is updated to the value that the size of transferred packet is subtracted from the remaining size before the transfer, then Peripheral portion writes back the PRD table.

If it is required to know the actual size transferred, store the remaining size before the transfer, and subtract the size in the updated PRD table after the transfer from it.

In case that short packet is received in the middle of PRD Table or case that all transfers specified by PRD table have been completed, Peripheral portion completes the process of the current PRD table. At this time Peripheral portion clears DMA_Ch0_CONx.PRD_ENx, sets the status bit in DMA_INT_STA register and asserts AXI_INT_DMA if enabled.

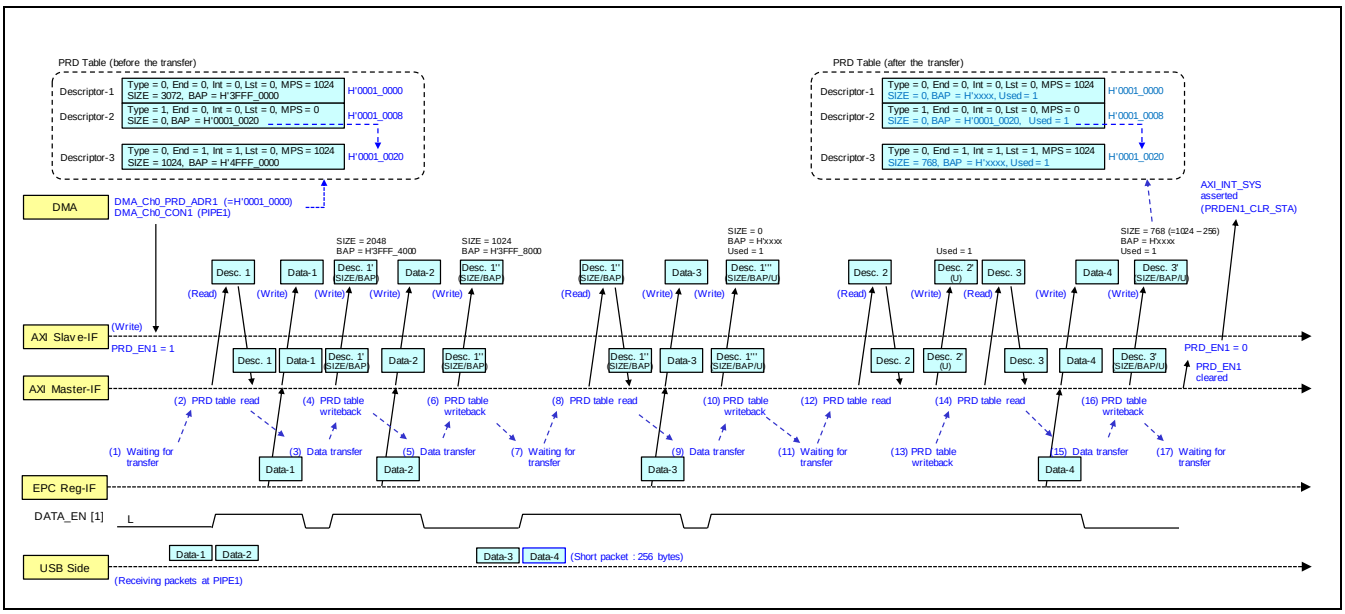

Figure 63.30 example of OUT transfer terminated with short packet

63.7.5.6 Finishing the process for PRD table and its conditions

Peripheral portion has DMA_Ch0_CONx and DMA_Ch0_PRD_ADRx (x = 1 to 4) to have the information of PRD tables, and starts transfer when it detects EPC_D_Pn_DATAEN[n] (n = 1 to 30) at Data Interface is asserted from Peripheral portion. Asserting EPC_D_Pn_DATAEN[n] indicates that transfer on PIPE specified in one of register groups is enabled. Transfer is executed in a unit of a packet of USB (that is, the size is up to the max packet size of USB), following the order specified by PRD tables. When one of the conditions to finish the transfer is satisfied, Peripheral portion recognizes that the process of the current PRD table has been completed, clears DMA_Ch0_CONx.PRD_ENx and sets the interrupt status in DMA_INT_STA register. Peripheral portion finishes the transfer of PRD table when one of conditions below is satisfied.

(1) All transfers related from the first PRD table to the last one (End bit is set) have been completed, or
(2) Transfer is terminated by receiving short packet in OUT transfer (AXI write transfer), or
(3) EPC_D_DBRTRANSEND which indicates the end of transfer is asserted in OUT transfer (AXI Write transfer), or
(4) PRD_Table is incorrect, or
(5) Peripheral portion requests ABORT during transfer on Data-IF.
(Peripheral portion never requests ABORT as far as the operation of the software is compliant to the flow in this manual.)

The following cases are the conditions of abnormal termination of transfer due to error. But they are avoidable by the configuration of system and assumed that they never occur in the normal usage. Make sure to configure the system so that those errors never occur.

(6) An error occurs in read process of PRD table, or
(7) An error response is received during data transfer on AXI, or
(8) An error occurs in writing-back of PRD Table.

In cases of (2) and (3) transfer is terminated in the middle of PRD tables. In these cases, used bit in the PRD table of the completed transfer is set. Besides, if the amount of transferred data is less than the size specified in PRD table, the size field of the PRD table is changed to the remaining amount of data after the transfer has been terminated. The actual

amount of transferred data can be calculated by subtracting the remaining amount of data from the size specified in PRD table initially.

The case of (5) occurs when clearing buffers of Peripheral portion is requested on Pn_CON.Pn_BCLR or P0_CON.P0_BCLR during transfer is being executed at Data interface. But since it is not recommended in this manual, the case of (5) is assumed to never occur as long as the software is compliant to the flow. When the case occurs, used bit and Data Error bit in the PRD table for which the transfer is being executed are set to 1 and AXI_INT_STA.PRDERR0_x_STA is asserted.

The cases of (6) and (8) mean that read or write specified by PRD Table could not be executed. In those cases, AXI_INT_STA.PRDERR0_x_STA is asserted.

For the case of (7), as far as (8) doesn't occur concurrently, used bit and Data Error bit in PRD table are set to 1 and AXI_INT_STA.PRDERR0_x_STA is asserted similarly to (5).

But in case (8) occurs at the same time, it means that writing-back of PRD table fails and the result of transfer is not stored in PRD table. Peripheral portion terminates the transfer by asserting EPC_D_DBUABRT at Data Interface with Peripheral portion.

It is assumed in the design of PERIPHERAL PORTION that it would not receive an error response on AXI-bus. Make sure to configure the system not to return an error response on AXI bus to PERIPHERAL PORTION.

63.7.5.7 Case of error

There are two kinds of errors in PERIPHERAL PORTION. One is an error due to the mistake in the setting and the other is the transfer error caused by receiving an error response on AXI bus.

But Peripheral portion was designed on the premise that it would not receive an error response (for both of read and write) on AXI bus when it executes DMA transfer, so PERIPHERAL PORTION only reports that the transfer error occurs for debug use. Make sure to configure system so that it doesn't return an error response on AXI bus to Peripheral portion.

In case an error occurs at Peripheral portion asserts EPC_D_DBTABRT at Data Interface, Peripheral portion automatically clears DMA_Ch0_CONx.PRD_ENx for the current PRD table so that the current transfer is terminated, and asserts AXI_INT_STA.PRDERR0_x_STA at the same time.

In case an error occurs at Peripheral portion, the result of the current transfer is not guaranteed. Make sure not to use transferred data when the error occurs.

63.7.5.8 Ordering of transactions

Peripheral portion operates AXI transactions in order. Hence Peripheral portion always uses the same value "H'0" as MAWID[3:0], MWID[3:0] and MARID[3:0].

63.7.5.9 Write Transfer with all zero strobe

Peripheral portion can execute two outstanding transactions and issues two outstanding addresses on AXI address channel checking the max packet size and the rest of buffer assigned by PRD table.

But, in OUT transfer (which requires the write transfer on AXI bus), the received packet might be the short one and its size might be less than both of the max packet size and the rest of buffer. In that case, Peripheral portion might have no more data to be transferred although it has already issued the transfer address on AXI write address channel. For that case, Peripheral portion executes the write transfer with all zero strobe on MWSTRB[7:0] so that no write occurs at target.

Figure 63.31 shows the case that Peripheral portion receives the short packet and it has data to transferred for ADR1 but doesn't for ADR2. Then, Peripheral portion executes the write transfer with all zero strobe on MWSTRB[7:0] for ADR2.

In Figure 63.31 the write transfer with all zero strobe starts from the head of the transfer, but MWSTRB[7:0] might be set to all zero in the middle of transfer depending on the size of the received packet.

Therefore Peripheral portion requires the target on AXI bus to accept the write transfer with all zero strobe and discard the write data for the transfer.

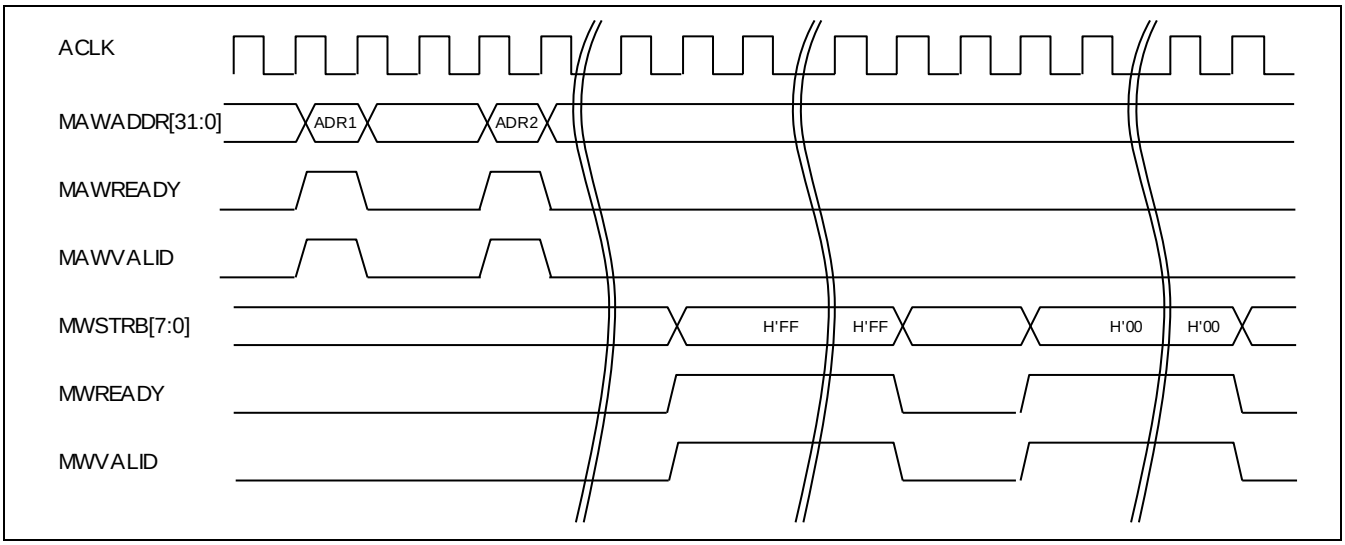

Figure 63.31 write transfer with all zero strobe

63.7.5.10 Interrupts

Pn_PRDEND_STA (n = 1 to 30) in DMA_INT_STA is asserted in the cases below.

1. PRD_ENx in DMA_Ch0_CONx (x = 1 to 4) assigned for PIPE n is cleared due to the completion of transfer. (Completion of transfer means that Lst bit in PRD table is set and data assigned to it has been transferred, the short packet has been received for OUT PIPE, PP bit is cleared in received USB3.0 data packet with non ZLP mode or that an error has occurred in transfer.)
2. PIPE which is not assigned to DMA_Ch0_CONx becomes ready. (It can accept the next packet for IN transfer, or it has new received packet for OUT transfer.)
3. Transfer of descriptor in which Int bit is set is completed.

Especially Pn_PRDEND_STA is asserted in case 2 as follows.

When PIPE n is IN pipe and DMA_Ch0_CON1 (for example) is assigned for the DMA transfer with it, Pn_PRDEND_STA is asserted at the completion of DMA transfer. If multiple pipes are enabled, DMA_Ch0_CON1 is assigned to another PIPE (PIPE m in this example) as soon as DMA transfer with PIPE n is completed. But the transmission of packets has not been completed at PIPEn. Pn_PRDEND_STA is asserted again when no DMA_Ch0_CONx is assigned to PIPE n and it has transmitted the last packet.

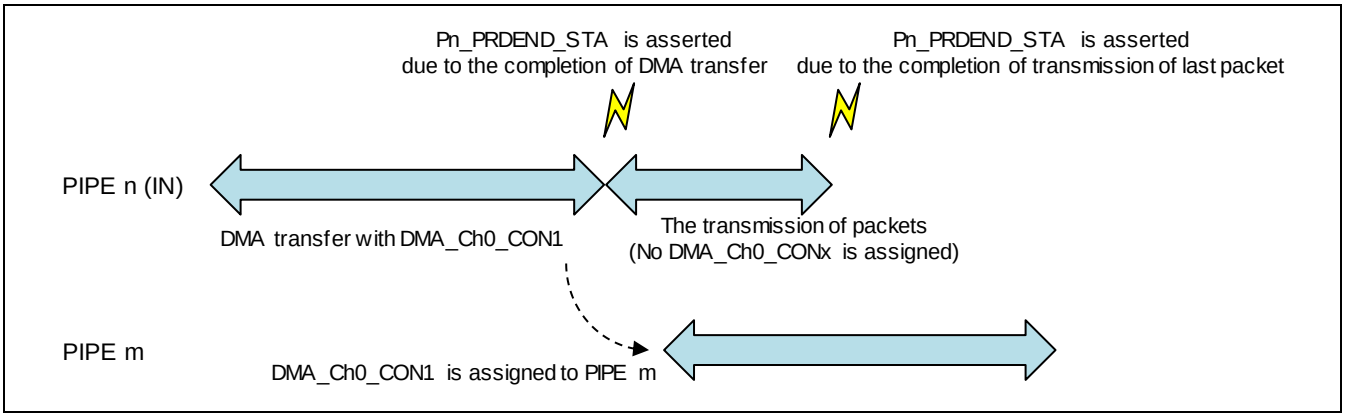

Figure 63.32 the behavior of Pn_PRDEND_STA in IN transfer

When PIPE n is OUT pipe but no DMA_Ch0_CONx is assigned to it, Pn_PRDEND_STA is asserted every time PIPEn receives a packet.

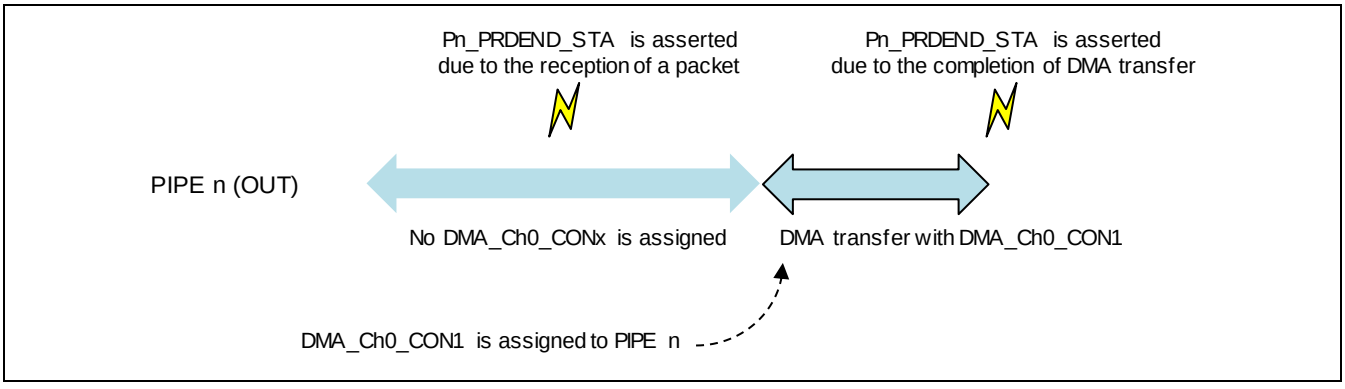

Figure 63.33 the behavior of Pn_PRDEND_STA in OUT transfer

Note that Pn_PRDEND_STA is not asserted if DMA_Ch0_CONx is assigned when the last IN packet has been transmitted or when the OUT packet has been received. As noted above, Pn_PRDEND_STA might be asserted due to the causes except for DMA transfer. When it is required to know only the completion of DMA transfer, see PRD_ENx_CLR_STA in AXI_INT_STA instead.

63.7.6 List of Interrupt factors

The interrupt factors for Peripheral portion are shown below.

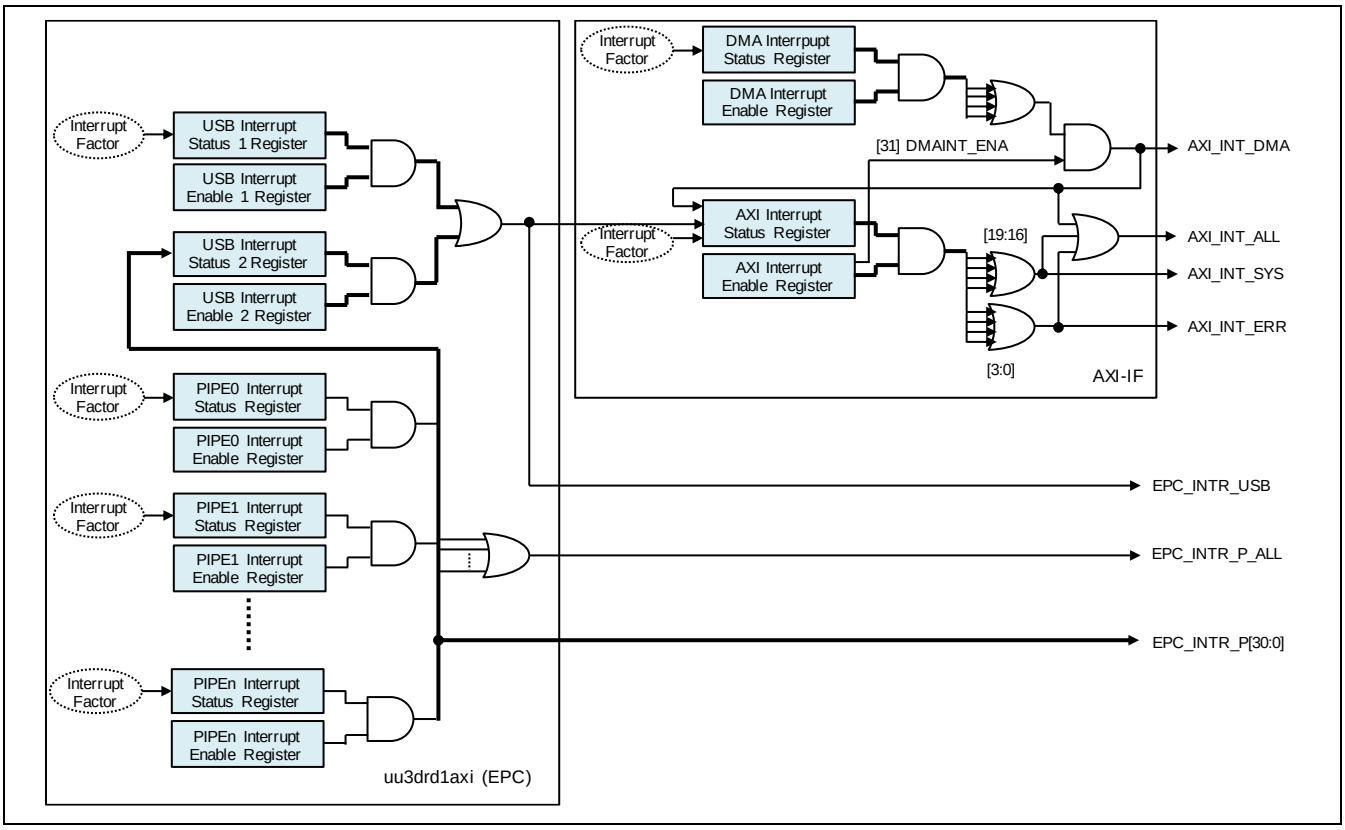

Figure 63.34 The system diagram for the interrupt

Table 63.19 Interrupt factors at USB3.0 Controller Peripheral function: AXI_INT_STA register

Interrupt factors	Descriptions
DMAINT_STA	This factor shows the status of interrupt by DMA transfer
EPCINT_STA	This factor shows the status of interrupt of EPC_INTR_USB.
PRDEN4_CLR_STA	This factor indicates that DMA_CH0_PRD_CON4.PRD_EN4 has been cleared by hardware.
PRDEN3_CLR_STA	This factor indicates that DMA_CH0_PRD_CON3.PRD_EN3 has been cleared by hardware.
PRDEN2_CLR_STA	This factor indicates that DMA_CH0_PRD_CON2.PRD_EN2 has been cleared by hardware.
PRDEN1_CLR_STA	This factor indicates that DMA_CH0_PRD_CON1.PRD_EN1 has been cleared by hardware.
PRDERR0_4_STA	This factor indicates that there was an error in PRD table assigned to DMA_CH0_CON4.
PRDERR0_3_STA	This factor indicates that there was an error in PRD table assigned to DMA_CH0_CON3.
PRDERR0_2_STA	This factor indicates that there was an error in PRD table assigned to DMA_CH0_CON2.
PRDERR0_1_STA	This factor indicates that there was an error in PRD table assigned to DMA_CH0_CON1.

Table 63.20 Interrupt factors at USB3.0 Controller Peripheral function: DMA_INT_STA register

Interrupt factors	Descriptions
P[5-1]_PRDEND_STA	This factor shows the status of the interrupt by DMA transfer for PIPE[5-1].

Table 63.21 Interrupt factors at USB3.0 Controller Peripheral function: USB_INT_STA_1 register

Interrupt factors	Descriptions
B3_PLLWKUP_STA	This factor indicates that PHY30_CLK125_IN was resumed due to PLL wakeup (USB30_CON.B3_PLLWAKE was set or the input signal B3_PLL_WAKEIN is asserted) or U3 Wakeup LFPS from host.
B3_LUPSUCS_STA	This factor indicates that the link of USB3.0 has been established (LTTSM enters U0 state from Polling state).
B3_POLLING_STA	This factor indicates that LTSSM has made the transition to Polling state.
B3_INACTV_STA	This factor indicates that LTSSM has made the transition to Inactive state.
B3_DISABLE_STA	This factor indicates that LTSSM has made the transition to Disabled state.
B3_VNDTST_STA	This factor indicates that Vendor Device Test LMP has been received.
B3_U2INACT_STA	This factor indicates that U2 Inactivity Timeout LMP has been received.
B3_SETLNK_STA	This factor indicates that Set Link Function LMP has been received.
B3_LNKCNG_STA	This factor indicates that LTSSM has made the transition as listed below. U0 -> U1 U0 -> U2 U0 -> U3 U3 -> Recovery -> U0 U2 -> Recovery -> U0 U1 -> Recovery -> U0
B3_WRMRST_STA	This factor indicates that warm reset has been received.
B3_HOTRST_STA	This factor indicates that hot reset has been received.
B3_PSFAIL_STA	This factor indicates that the transition of POWERDOWN mode on USB30_CON.POW_SEL[2:0] failed.
B3_PSSUCS_STA	This factor indicates that the transition of POWERDOWN mode on USB30_CON.POW_SEL[2:0] has been completed successfully.
B3_U12REQ_STA	This factor indicates that PERIPHERAL PORTION received LGO_U1/U2 or when U1/U2_TIMER in SSIF was expired.
B3_TPSUCS_STA	This factor indicates that TP (Device Notification) requested on USB30_CON.B3_TP_SEND has been successfully completed.
B2_LPMRCV_STA	This factor indicates that PERIPHERAL PORTION has received LPM request from USB2.0 host and has returned ACK to it.
B2_USBRST_STA	This factor indicates that USB2.0 bus reset has been received.
B2_L1SPND_STA	This factor indicates that L1 suspend request has been received from USB2.0 host.
B2_L1RSUM_STA	This factor indicates that PLL wakeup has been requested (USB20_CON.B2_SUSPEND = 0 or B2_PLL_WAKEIN = 1) or when the resume request from USB2.0 host has been received (USB_STA.B2_L1RSUM_OUT changes from 0 to 1) during L1 state (USB_STA.B2_L1_SPND_OUT = 1).
B2_SPND_STA	This factor indicates that the suspend request has been received from USB2.0 host and USB_STA.B2_SPND_OUT changes from 0 to 1.
B2_RSUM_STA	This factor indicates that PLL wakeup has been requested (USB20_CON.B2_SUSPEND=0 or B2_PLL_WAKEIN = 1) or when the resume request from USB2.0 host has been received (USB_STA.B2_RSUM_OUT changes from 0 to 1) during L2 state (USB_STA.B2_SPND_OUT = 1) or L3 state (USB30_CON.B3_CONNECT = 0).

Interrupt factors	Descriptions
SPEED_STA	This factor indicates that there was change in the speed mode of USB.
VBUS_CNG_STA	This factor indicates that the level of the input signal “VBUS” changed.

Table 63.22 Interrupt factors: USB_INT_STA_2 register

Interrupt factors	Descriptions
PIPE[5:0]_INT_STA	This factor indicates that an interrupt related to PIPE[5-0] occurred.

Table 63.23 Interrupt factors: P0_INT_STA register

Interrupt factors	Descriptions
P0_STSED_STA	This factor indicates that status stage of control transfer has been completed successfully.
P0_STSST_STA	This factor indicates that status stage of control transfer has been started at PIPE0.
P0_SETUP_STA	This factor indicates that valid setup data has been received at PIPE0.
P0_RCVNL_STA	This factor indicates that null data has been received at PIPE0.
P0_ERDY_STA	This factor indicates that the condition to send ERDY was satisfied at PIPE0.
P0_FLOW_STA	This factor indicates that PIPE0 has entered flow control state.
P0_STALL_STA	This factor indicates that STALL has been sent at PIPE0.
P0_NRDY_STA	This factor indicates that NRDY or NAK has been sent at PIPE0.
P0_BFRDY_STA	In case the direction of transfer is IN (P0_MOD.P0_DIR = 1), the next data can be written to P0_WRITE register. In case the direction of transfer is OUT (P0_MOD.P0_DIR = 0), the next data can be read from P0_READ register.

Table 63.24 Interrupt factors: Pn_INT_STA register

Interrupt factors	Descriptions
Pn_CBW_STA	This factor indicates that CBW has been received at PIPEn and is ready to be read from Pn_READ register.
Pn_STERR_STA	This factor indicates that Stream bulk protocol error has occurred at PIPEn.
Pn_STRMX_STA	This factor indicates that Stream ID in received packet was different from that in Pn_STREAM.Pn_STREAM_C.
Pn_NSTRM_STA	In case the direction of transfer is IN (Pn_MOD.Pn_DIR==1), this factor indicates that ACK_TP(NoStream) has been received at PIPEn. In case the direction of transfer is OUT (Pn_MOD.Pn_DIR==0), this factor indicates that DP(NoStream) has been received at PIPEn.
Pn_PRIME_STA	In case the direction of transfer is IN (Pn_MOD.Pn_DIR==1), this factor indicates that ACK_TP(PRIME) has been received at PIPEn. In case the direction of transfer is OUT (Pn_MOD.Pn_DIR==0), this factor indicates that DP(PRIME) has been received at PIPEn.
Pn_RCVNL_STA	This factor indicates that zero length packet has been received at PIPEn.
Pn_ERDY_STA	This factor indicates that the condition to send ERDY has been satisfied at PIPEn.
Pn_FLOW_STA	This factor indicates that PIPEn has entered flow control state.
Pn_LSTTR_STA	In case the direction of transfer is IN (Pn_MOD.Pn_DIR==1), this factor indicates that the last data of the transfer (short packet, packet for which Pn_LAST was set or packet for which EPC_D_DBWTRANSEND was asserted) has been sent at PIPEn. In case the direction of transfer is OUT(Pn_MOD.Pn_DIR==0), this factor indicates that the last data of the transfer (short packet or packet with PP = 0) has been received at PIPEn.
Pn_STALL_STA	This factor indicates that STALL has been sent at PIPEn.

Interrupt factors	Descriptions
Pn_NRDY_STA	This factor indicates that NRDY or NAK has been sent at PIPEn.
Pn_BFRDY_STA	In case the direction of transfer is IN (Pn_MOD.Pn_DIR==1), the next data can be written to Pn_WRITE register. In case the direction of transfer is OUT (Pn_MOD.Pn_DIR==0), the next data can be read from Pn_READ register.

63.7.7 Zero Length Packet (ZLP)

63.7.7.1 Definition of Zero Length Packet

Zero length packet (ZLP) is the data packet (DP) but it has no data word in it's data payload. ZLP is used to show the boundary of the transfer in some USB device classes, in case that the size of the last data packet equals to the max packet size of the PIPE.

Short packet, which length of data is less than the max packet size of the PIPE, is interpreted as the last packet of transfer in general. For example, it is defined that the size of packet except the last one in bulk transfer should be the max packet size of the PIPE. But it differs how to treat the case that the size of the last packet of transfer equals to the max packet size of the PIPE, depending on USB device class.

It is difficult to know whether the received packet which has the length same as the max packet size is the last one or not for the receiver (host or device). In some USB device classes, ZLP is sent next to show that there is the boundary of transfer. But in Bulk Only Transfer (BOT), ZLP is not used because CBW notifies the amount of transfer in advance. The device might transmit data less than the amount shown in CBW and the size of the last data packet might be the max packet size, but CSW is transferred next even in that case and CSW of 13 bytes is the short packet in bulk transfer. Therefore host can know that the packet just before CSW was the last data packet. In Stream bulk transfer, the packet with PP = 0 to show the end of transfer related the current Stream ID.

See the specification of USB device class to know whether ZLP is really required or not.

63.7.7.2 Transfer of ZLP support mode

PERIPHERAL PORTION has the mode to support ZLP transfer. Set USB_COM_CON.Pn_WDATAIF_NL, USB_COM_CON.Pn_RDATAIF_NL and USB_COM_CON.Pn_LSTTR_PP to 1 in order to use the mode.

63.7.7.3 In the configuration with AXI-IF

In the configuration with AXI-IF, Peripheral portion sends ZLP for OUT transfer and receives

ZLP for IN transfer automatically with the settings for them.

In order to transmit ZLP in ZLP transfer, the software sets ZL bit in PRD table where ZLP is requested to be transmitted in advance. When Peripheral portion receives ZLP in OUT transfer, it sets ZL bit in PRD table where ZLP is received.

USB_COM_CON.Pn_WDATAIF_NL, USB_COM_CON.Pn_RDATAIF_NL and USB_COM_CON.Pn_LSTTR_PP should be set to 1 as noted in section 63.7.7.2.

For IN transfer, with PRD table in which Lst = 1 and ZL = 1, Peripheral portion sends ZLP after the last data packet of the PRD table in order to show the boundary of transfer. With PRD table in which Lst = 0 or ZL = 0, Peripheral portion never sends ZLP.

Therefore, set both of Lst bit and ZL bit to 1 in the PRD table which has the last data packet and requires ZLP after it. In other PRD tables, set both of Lst bit and ZL bit to 0.
Note that the meaning of H'0000 in SIZE field of PRD table differs depending on ZL bit and Lst bit. If ZL = 1 and Lst = 1, H'0000 in SIZE field means that 0 byte transfer is requested by the PRD table. Otherwise, H'0000 means that 64 Kbytes transfer is requested.

If ZLP is required after 64 Kbytes data has been transferred, prepare two PRD tables. The first one has 64 Kbytes data (SIZE field is H'0000) with Lst = 0 and ZL = 0, and the second one has 0 bytes data (SIZE field is H'0000) with Lst = 1 and ZL = 1.

For OUT transfer, the software is never required to set Lst bit and ZL bit in PRD table. When Peripheral portion receives ZLP in OUT transfer, it sets both of Lst bit and ZL bit to 1 in the PRD table. If Peripheral portion has already received some packets before ZLP, Peripheral portion transfers them to system memory where the PRD table designates, then it sets Lst bit and ZL bit in the PRD table.

If Peripheral portion doesn’t receive ZLP but short packet (which length is not 0), it sets Lst bit to 1 but leave ZL bit as 0.

Note that the meaning of H'0000 in SIZE field of PRD table differs depending on ZL bit and Lst bit. If ZL = 1 and Lst = 1, H'0000 in SIZE field means that 0 byte data is contained in the buffer designated by the PRD table. Otherwise, H'0000 means 64 Kbytes data is contained in the buffer.

If ZLP is received after 64Kbytes data has been received, two PRD tables are used. The first one shows SIZE = H'0000, Lst = 0 and ZL = 0, and it means that 64 Kbyte data has been received but ZLP isn’t included. The second one shows SIZE = H'0000, Lst = 1 and ZL = 1, and it means that only ZLP has been received for the PRD table.

63.7.8 Physical Region Descriptor (PRD) Table

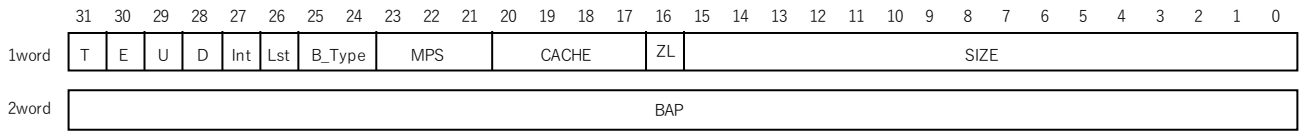
Use Physical Region Descriptor (PRD) Table for source/destination Address and transfer size of DMA Transfer in AXI Master-IF and setting required for applicable DMA Transfer. Creation of PRD Table on memory area and setting address of the created PRD Table shall be done by the Software (FW). And PRD Table shall be created for each PIPE. Make sure to locate PRD Table in the area where the table does not cross over 4KB Address boundary.

Format of PRD Table and the definition of each field are described below.

[PRD Table Format]

Format of PRD Table shall be compliant with ASIC-PF (SS Development Guide) “Descriptor Format A” and it is defined as below. The 3rd word is omitted and the rest of two words will form a descriptor.

PRD Table Format



Details of PRD Table

[1word]

Bit	Field Name	Update	Description
31	T	FW	Type bit that indicates type of descriptor.
		—	0: Buffer Pointer
			1: Link Pointer
30	E	FW	End bit that indicates the End of Descriptor Chain.
		—	Specifies 0 in case of a Link Pointer.
			0: Other than the above.
			1: Indicates the End of Chain.
29	U	—	Used bit that indicates Transfer of the applicable descriptor is completed.
		HW	Specifies 0 in case of PRD Table generated by FW
			0: Indicates incomplete transfer or transfer in progress.
			1: Indicates completion of transfer
28	D	—	Data Error bit that indicates occurrence of an Error during Transfer.
		HW	Specify 0 in case of PRD Table generated by FW.
			0: No Error occurred
			1: Error occurred

Bit	Field Name	Update	Description
27	Int	FW —	Specifies existence of occurrence of Interrupt due to Transfer at applicable descriptor. In case this bit is set to 1, transfer at applicable descriptor is regarded to be completed and DMA_INT_STA.Pn_PRDEND_STA is set to 1. Specify 0 in case of a Link Pointer. 0: Interrupt not occurred 1: Interrupt occurred In case Short Packet is received in OUT Transfer, an interrupt is set as transfer of PRD Table is completed regardless of setting of this bit.
26	Lst	FW —	Specifies the last packet for transfer at applicable descriptor Assert EPC_D_DBWTRANSEND signal when writing the last data in case this bit is set to 1 in WRITE (PIPE for In Transfer) to EPC in order to indicate the last data for Transfer (same Stream ID). Set the interrupt status for EPC, where is Pn_INT_STA.Pn_LSTTR_STA bit, when the last packet including the data asserted EPC_D_DBWRTRANSEND is completed. Specify 0 in case of READ (PIPE for OUT Transfer PIPE) to EPC. This bit is set to 1 by HW when the transfer is completed with asserting EPC_D_DBRTRANSEND at DATA-IF. This bit is specified 0 in case of a Link Pointer. 0: Other than the above 1: Last Packet
25, 24	B_Type	FW —	Indicates burst type. Specifies 00 in case of a Link Pointer. B’00: Fixed Burst B’01: Incrementing burst B’10: *Reserved* B’11: *Reserved*
23 to 21	MPS	FW —	Indicates Max Packet Size / Unit of transfer in Data-IF. Specify 00 in case of a Link Pointer. B’000: 8Byte / B’001: 16Byte / B’010: 32Byte / B’011: 64Byte / B’100: 512Byte / B’101: 1024Byte / others: Reserved
20 to 17	CACHE	FW —	Specify CACHE signal (MARCACHE/MAWCACHE) during DATA Transfer Access.
16	ZL	FW HW	Set this bit to 1 for USB device class which uses ZLP. 0: ZLP is not transferred through Data Interface or on AXI DMA transfer. 1: ZLP is transferred through Data Interface or on AXI DMA transfer Notes: 1 If T bit shows link pointer, set this bit to 0. 2 If the bits are not set to 1 but ZLP is used, it is treated as PRD table format error and AXI_INT_STA.PRDERR0_x_STA.

Bit	Field Name	Update	Description
15 to 0	SIZE	FW	Indicates number of byte to be transferred.
		HW	This is updated to “the number of remaining bytes to transfer” by HW when transfer with EPC in a packet is completed during transfer.
			Set value can be specified to a value between 1 and 64 Kbyte in steps of a byte. Set H'0000 to specify 64 Kbyte. SIZE specified for a descriptor shall be integral multiple of a Packet in USB Transfer. Multiple Descriptors cannot be used to compose 1 USB Packet.
			Transfer is stopped automatically when short Packet is received during OUT (AXI-Write) transfer. Setting values shall be integral multiple of Max Packet Size in USB packet.
			The remain is transmitted as Short Packet in USB Transfer when specified SIZE is not integral multiple of Max Packet Size during In (AXI-Read) Transfer.
			Specify 0 in case of a Link Pointer.

[2word]

Bit	Field Name	Update	Description
31 to 0	BAP	FW	In case Type bit is Buffer Pointer:
		HW	Indicates Storage Address of transfer Data.
			In case Type bit is Link Pointer:
			Indicates address of the next descriptor to be located.
			Make sure that lower three bits should be “0” at the address of the next descriptor to be located.
			In case it is a Descriptor Chain Buffer Pointer, address of the next descriptor shall be located at continuous address. In case Type bit is a Buffer Pointer, address of the next descriptor shall be located at continuous address.
			This is updated by HW when transfer with EPC in a unit of a packet is completed during transfer. The value in this field is invalid if the transfer is stopped due to reception of short packet or occurrence of transfer error.

Int bit is used to generate a PRDEND Interrupt upon completion of transfer of the set descriptor.

This is used to start creation of PRD Table for the next process prior to the completion of current process of PRD Table in cases such as CPU with slow response speed for an Interrupt.

[Setting and validating PRD Table]

FW generates a PRD Table that specifies destination of data transfer and parameters for transfer for each PIPE on memory. PRD Table is valid and Transfer is enabled when address of the generated PRD table, applicable PIPE number, transfer direction of the PIPE in one of the four PRD Table Setting Area Registers provided in AXI-IF and PRD_EN is 1 and EXTPRD_EN is 0 after that

[Set the following register to set PRD Table]

Register	Field	Description
DMA_Ch0_PRD_ADR	PRD_ADR	Specifies the Initial Address of PRD Table.

Register	Field	Description
DMA_Ch0_CON	PIPE_DIR	Specifies transfer direction of the PIPE specified in PIPE_NO.
	PIPE_NO	Specifies PIPE number.
	EXTPRD_NO	This is specified only when setting area to be linked exists.
	EXTPRD_EN	This is set to 1 only when setting area to be linked exists.
	PRD_EN	This is set to 1 to allow (enable) the Transfer that was specified in PRD Table.

63.8 Example of Software flow

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

63.8.1 Outline of software flow

The Software for PERIPHERAL PORTION is described in this section. The flow includes initialization, interrupt handling, control transfer process, bulk transfer process and interrupt transfer process.

Note that the flow described here is an example in general usage of PERIPHERAL PORTION. Modification of the flow or additional operation might be required depending on application in which user's system assumes.

The loop as below is used at some points in the flow and assumes the read polling of register by software. The interrupt notification might be used instead, but note that the setting to enable the interrupt is required in that case.

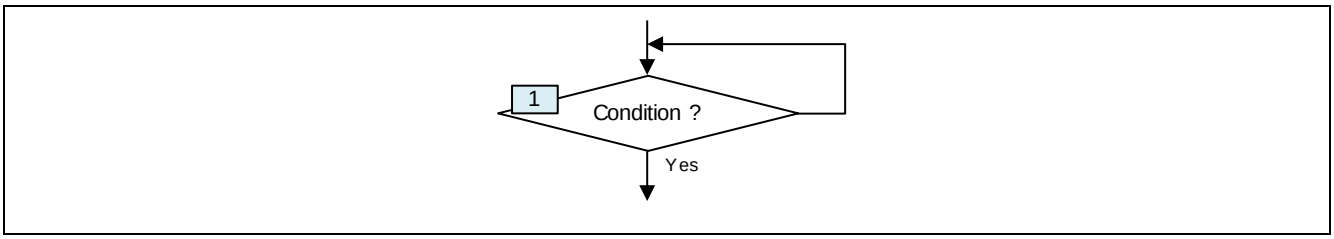


Figure 63.35 The read polling of register by software

In order to access registers related to PIPEn, the index of PIPE should be set in PIPE_COM.PIPE_NUM[4:0] in advance. Note that the setting of the index of PIPE is omitted in each step of this section.

63.8.2 Initialization

The initialization should be completed before the device is used as USB device.

It is recommended that the initialization is done immediately after the power to device is turned on.

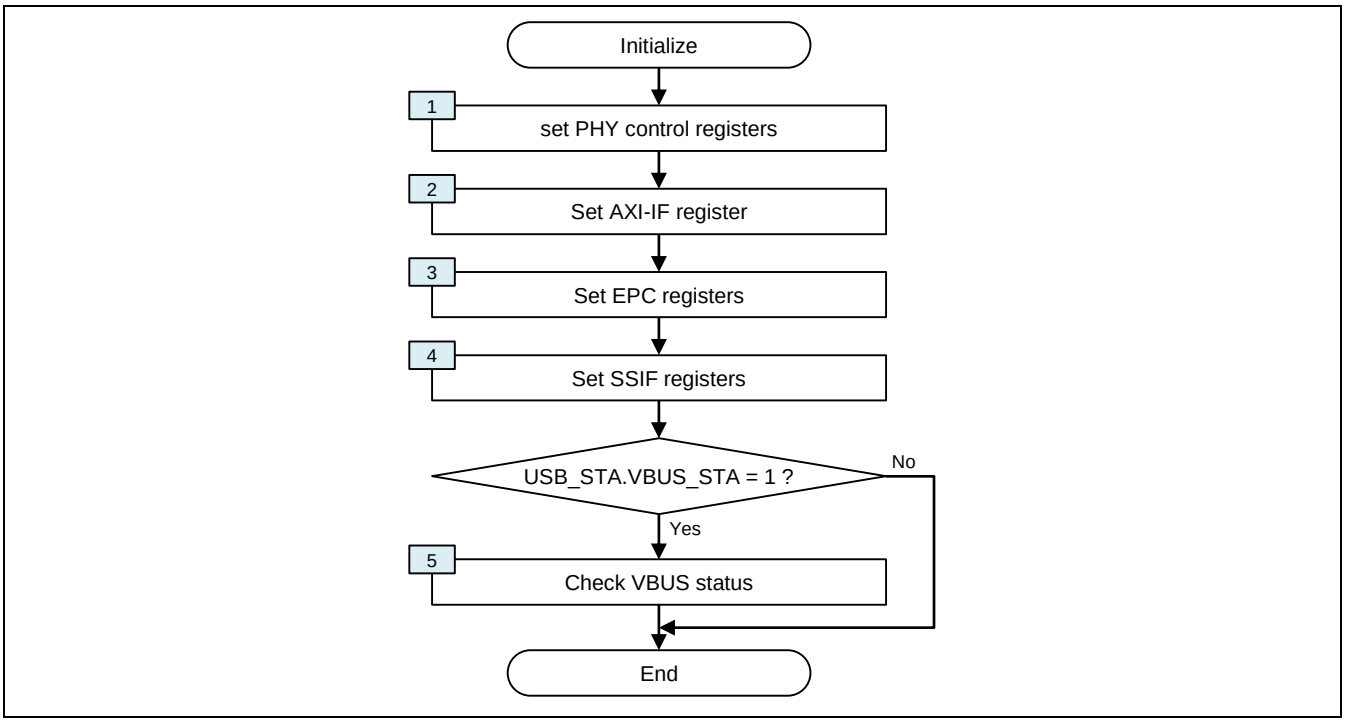

Figure 63.36 Initialization flow

(1) Set PHY register

The setting of Reference clock setting & SSC setting is changed here if default values of the parameters for Reference clock & SSC below are not consistent with the user's system.

- USB3S0_CLK_P/USB3S0_CLK_M used

  USB30_CLKSET0. USB30_FSEL[5:0]: B'10_0111

  USB30_CLKSET1. USB30_PLL_MULTI [7:0]: B'000_0000

  USB30_CLKSET1. USB30_ REF_CLKDIV: B'0

  USB30_CLKSET1. USB30_ REF_USB_SEL: B'1

- USB_XTAL/USB_EXTAL used

  USB30_CLKSET0. USB30_FSEL[5:0]: B'00_0010

  USB30_CLKSET1. USB30_PLL_MULTI [7:0]: B'110_0100

  USB30_CLKSET1. USB30_ REF_CLKDIV: B'1

  USB30_CLKSET1. USB30_ REF_USB_SEL: B'0

- SSC used

  USB30_SSC_SET. SSC_RANGE [2:0]: setting appropriate value for user system

  USB30_SSC_SET. SSC_EN: B'1

- Peripheral function used

  USB30_VBUS_EN. VBUS_EN: B'1

After the above setting,

- Write 0x0010 to USB30_PHY_ENABLE
- Write 0x191A to USB30_CLKSET1
- Wait 10us
- Write 0x190A to USB30_CLKSET1

(2) Set AXI-IF registers

The setting of AXI-Bridge is changed here if default values of the parameters for AXI-bus below are not consistent with the user's system.

- AXI_CON.MST_BSIZE[1:0] (Burst size setting: default value 8 bytes)

(3) Set EPC registers

Set the operation mode and initialize the interrupt status in EPC as follows.

a) USB30_CON register

If U3_POW_SEL[1:0] is required to be changed from default settings, change them here.

b) USB_INT_STA_1 register

Write 1 to all status bits in USB_INT_STA_1 in order to clear them.

c) USB_INT_ENA_1 register

Set VBUS_CNG_ENA to 1 in order to enable VBUS change interrupt.
It is also recommended to enable B3_HOTRST_ENA. See section 63.8.3.5 for details.

(4) Set SSIF registers

The setting of SSIF is changed here if required. But it is recommended to use them with default settings basically.

(5) Check VBUS status

Check whether the status of USB_STA.VBUS_STA has already changed to 1 or not.
If USB_STA.VBUS_STA==1, proceed to the operation of connection.

63.8.3 Interrupt process

When an interrupt is asserted, see the interrupt status register to know what factor causes the interrupt, and then do the operation required.

Examples of the flow for interrupt are shown in this section.

63.8.3.1 Interrupt handler process

The process in interrupt handler when an interrupt is asserted is described here.

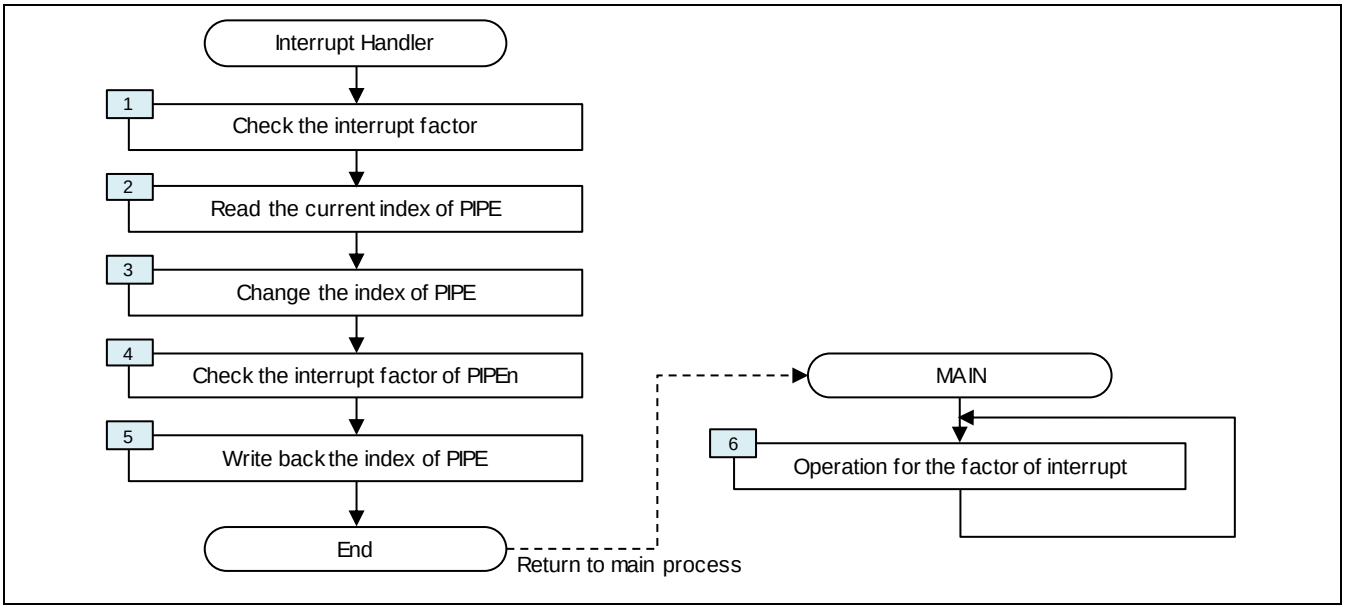

Figure 63.37 Interrupt handler process flow

(1) Check the interrupt factor
See interrupt status register to know what factor is the cause of the interrupt. Then clear the status bit in interrupt status register.
It is assumed here that the interrupt is asserted due to PIPEn event, so registers related to PIPEn are accessed later.
If it is required to remember the interrupt factor in main process, prepare the variable to remember it.

(2) Read the current index of PIPE
The software should read the current index of PIPE and remember it before it changes the index of PIPE in PIPE_COM.PIPE_NUM[4:0] due to the interrupt asserted by PIPEn event and the succeeding operation for PIPEn.
The saved index of PIPE is written back at (5) if required.

(3) Change the index of PIPE
Change the index of PIPE in PIPE_COM.PIPE_NUM[4:0] to that of PIPE which generates the interrupt.

- PIPE_COM.PIPE_NUM[4:0] = the index of PIPE

(4) Check the interrupt factor of PIPEn
See the interrupt status register for PIPEn (Pn_INT_STA) to know what factor at PIPEn is the cause of the interrupt.
Note that Pn_INT_STA register shows the interrupt status of PIPE which is designated by the index of PIPE in PIPE_COM.PIPE_NUM[4:0].
Then clear the status bit in interrupt status register.
If it is required to remember the interrupt factor in main process, prepare the variable to remember it.

(5) Write back the index of PIPE
When the software exits the interrupt handler, write back the saved index of PIPE at (2) to PIPE_COM.PIPE_NUM[4:0] if required.
- PIPE_COM.PIPE_NUM[4:0] = the saved index of PIPE at (2)

(6) Operation for the factor of interrupt
The firmware does the operation required for the factor of interrupt after it returns to main process. In order to remember the factor, use the variable as noted at (1) and (4). After completing the operation, initialize the variable.

Especially note that it is prohibited to change the index of PIPE until read of the whole packet from P0_READ/Pn_READ or write of it to P0_WRITE/Pn_WRITE is completed.
If the interrupt due to PIPEn event is asserted (it can be known by USB_INT_STA_2 register) but read of the whole packet from P0_READ/Pn_READ or write of it to P0_WRITE/Pn_WRITE has been started, wait for the completion of read or write of the packet. Then change PIPE_COM.PIPE_NUM[4:0] to see the factor of interrupt at PIPEn.
See section 63.9.2 for details.

63.8.3.2 USB Connection

The operation required for USB connection is described here.

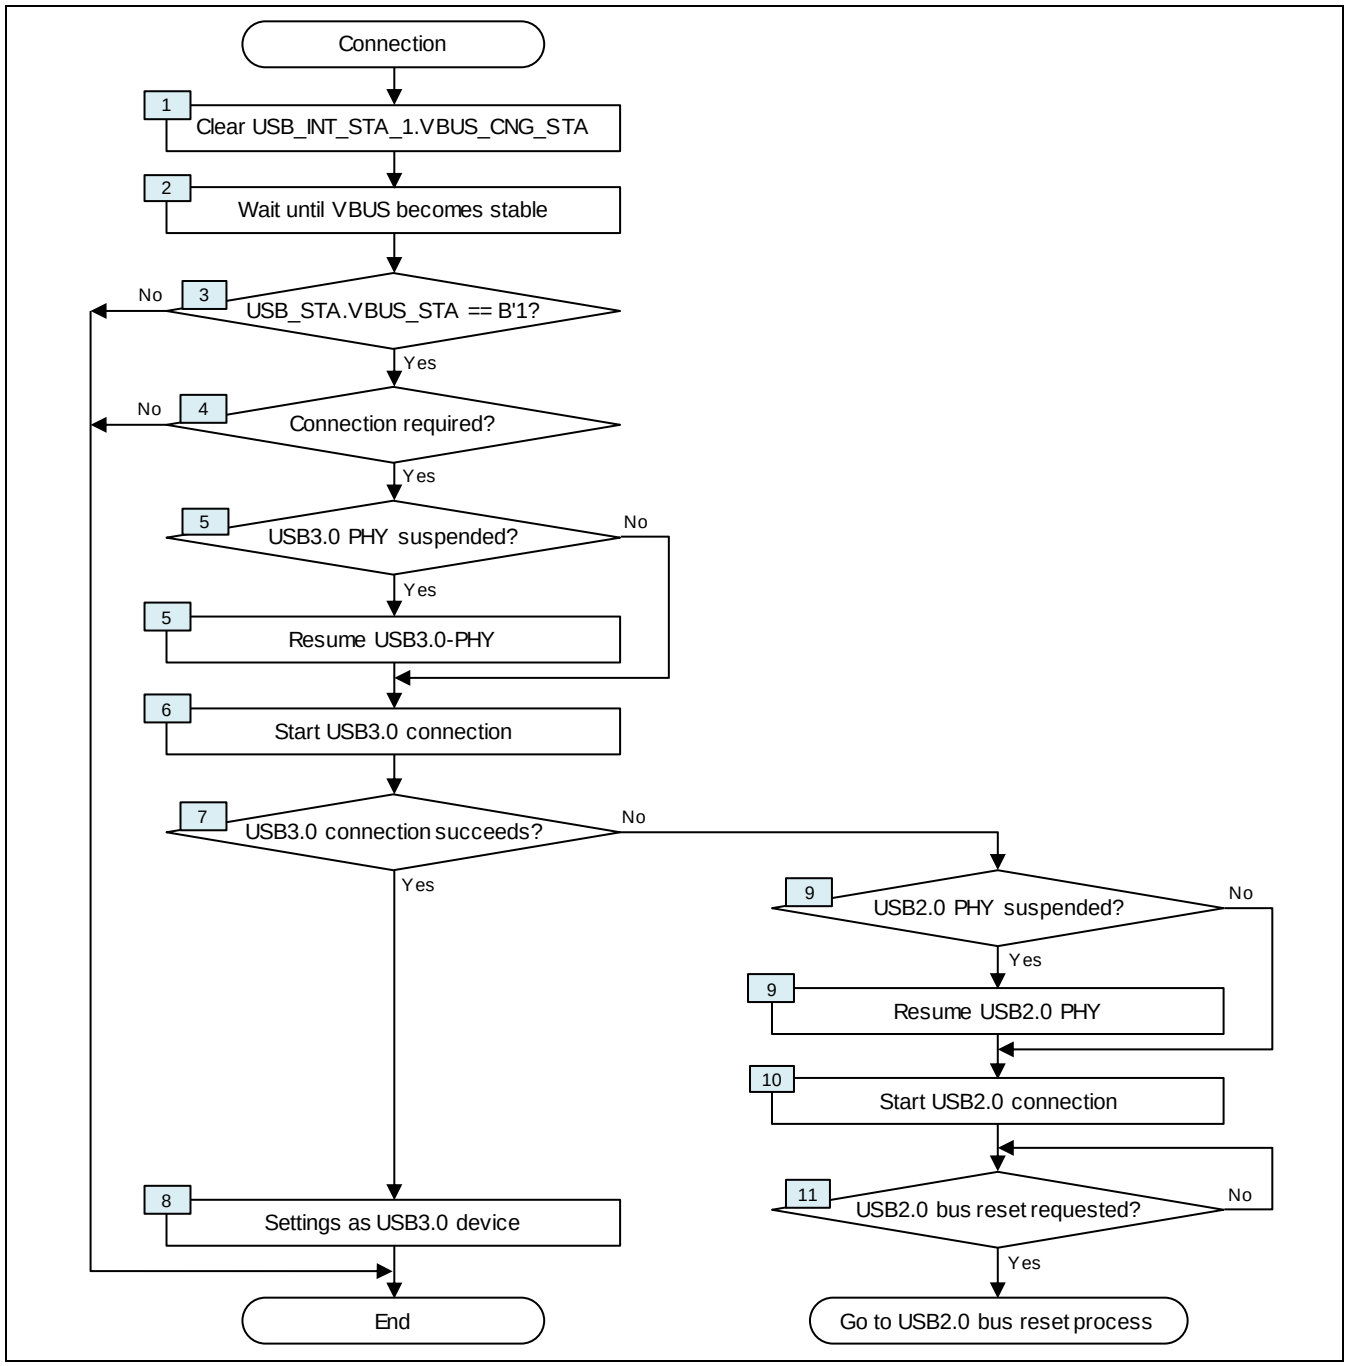

Figure 63.38 USB connection flow

(1) Clear USB_INT_STA_1.VBUS_CNG_STA
When VBUS status changes, USB_INT_STA_1.VBUS_CNG_STA is asserted. It is notified on an interrupt if enabled. If it is asserted, write 1 to USB_INT_STA_1.VBUS_CNG_STA to clear.

- USB_INT_STA_1.VBUS_CNG_STA=1 (Clearing the event that the VBUS status is changed)

(2) Wait until VBUS becomes stable
In this subsection the device is assumed to be in disconnected state first. Therefore, it is required to check VBUS status in order to know if the device is really connected or not, because the change of VBUS status might be caused by noise.

To know VBUS status, USB_STA.VBUS_STA is available. If it shows 1, VBUS voltage level is valid and it means that the device is connected at present.
But VBUS voltage level is supposed to be unstable due to chattering just after the device is connected to host or hub. VBUS level will swing between 1 and 0 (therefore, USB_STA.VBUS_STA will also swing) for a while. During the chattering time, it is difficult to know the status of USB connection. Therefore, it is required to wait for VBUS to become stable. Wait for several dozens of milli-second in order to remove the influence of chattering of VBUS level.

If USB_INT_ENA_1.VBUS_CNG_ENA is enabled during the chattering time, there might be many interrupts caused by the swing of VBUS level. Disable USB_INT_ENA_1.VBUS_CNG_ENA to prevent that the software is annoyed at the swing of VBUS level for the chattering time.

- USB_INT_ENA_1.VBUS_CNG_ENA = 0 (The change of VBUS is masked)

(3) Is USB_STA.VBUS_STA== 1?
Check USB_STA.VBUS_STA to know whether the interrupt is caused by the change of VBUS level or merely noise. If USB_STA.VBUS_STA== 1, it means new USB connection. But if it shows 0, the interrupt detected at (1) would be caused by noise.

[Note]
If you find frequently that your device is unconnected even when you have confirmed USB_STA.VBUS_STA ==1 at this point, increase the wait time at (2). In that case, it might take more time to stabilize VBUS level in your system.

(4) Is connection required?
If device requires to be connected, proceed to (5) to request the connection.
It is possible to insert the grace time here before the connection. The software can use the grace time for the preparation of the connection or other use.

(5) Resume USB3.0-PHY
If USB3.0-PHY is in the power down state and PLL is suspended, resume USB3.0-PHY so that it provides USB3.0 clock.
See section 63.8.8.6 for details.

(6) Start the operation for USB3.0 connection
Start the connecting operation as USB3.0 device when it is confirmed that device is connected to host.

- USB30_CON.B3_CONNECT = 1 (Starting the connection process for SS)
- USB_COM_CON.EP0_EN = 1 (PIPE0 is enabled)
- USB_COM_CON.SPD_MODE = 0 (SS mode is requested)
- SSIFLINKSET3.SSIF_NUM_RDET[3:0] = H'8 (The number of trial for Rx.Detect = 8)
- USB_COM_CON.RX_DETECTION = 1 (RxDetect is started)
- USB_INT_ENA_1.B3_LUPSUCS_ENA = 1 (Interrupt due to the success of link up is enabled)
- USB_INT_ENA_1.B3_DISABLE_ENA= 1 (Interrupt due to the failure of link up is enabled)

Besides, if USB_INT_ENA_1.SPEED_ENA is enabled, the interrupt that SPEED state of USB is changed is asserted after LTSSM enters U0 as SS device or bus reset and chirp are completed as HS or FS device.

- USB_INT_ENA_1. SPEED_ENA = 1 (Interrupt of SPEED state is enabled)

(7) Does USB3.0 connection succeed?
As the result of the trial for USB3.0 connection, one of USB_INT_STA_1.B3_LUPSUCS_STA or USB_INT_STA_1.B3_DISABLE_STA is asserted. USB_INT_STA_1.B3_LUPSUCS_STA means that the link up process of LTSSM has been successfully done and LTSSM is in U0. USB_INT_STA_1.B3_DISABLE_STA means that the link up process of LTSSM has failed and LTSSM is in SS.Disabled. When they are asserted, an interrupt is generated if enabled.

- Check USB_INT_STA_1.B3_LUPSUCS_STA== 1 or USB_INT_STA_1.B3_DISABLE_STA== 1

After the confirmation above, write 1 to USB_INT_STA_1.B3_LUPSUCS_STA or USB_INT_STA_1.B3_DISABLE_STA to clear them.

- Write 1 to USB_INT_STA_1.B3_LUPSUCS_STA if asserted (Clearing the event that the link up has succeeded)
- Write 1 to USB_INT_STA_1.B3_DISABLE_STA if asserted (Clearing the event that USB3.0 connection has failed)

If USB_INT_STA_1.B3_LUPSUCS_STA is asserted, it means USB3.0 connection is successful, proceed to (8).
If USB_INT_STA_1.B3_DISABLE_STA is asserted, it means USB3.0 connection has failed, proceed to (9).

(8) Transition to default state
After the connecting operation has been successfully completed, enable the detection of control transfer at PIPE0 (endpoint 0). At the same time, the interrupts required for the operation mode should be enabled. An example for those cases are shown below. If there are other interrupts required for the usage of core, enable them as well.

- USB_INT_ENA_2.PIPE0_INT_ENA = 1 (Interrupt at PIPE0 is enabled)
- All bits in P0_INT_ENA register should be enabled (All interrupt factors for PIPE0 are enabled)

If the interrupt due to the change of USB SPPED state is enabled at (6), the interrupt is asserted when USB3.0 or USB2.0 connection is established. See USB_STA.SPEED[1:0] to know which speed the device is acting as. Then set the bits below according to the speed state.

In this state, the device is acting as USB3.0 device.
- USB_INT_ENA_1.B3_HOTRST_ENA = 1 (Interrupt due to hot reset is enabled)
- USB_INT_ENA_1.B3_WRMRST_ENA = 1 (Interrupt due to warm reset is enabled)

(9) Resume USB2.0-PHY
If USB2.0-PHY is in the power down state and PLL is suspended, resume USB2.0-PHY so that it provides USB2.0 clock.
See section 63.8.8.10 for details.

(10) Start USB2.0 connection
Start the connecting operation as USB2.0 device. Note that USB30_CON.B3_CONNECT is still 1. USB3.0 connection might be tried again after USB2.0 bus reset.
- USB_COM_CON.EP0_EN = 1 (PIPE0 is enabled: this field is already enabled at (6))
- USB_COM_CON_SPD_MODE = 1 (USB2.0 mode is requested)
- USB20_CON.B2_PUE = 1 (Pull up on D+ is enabled)
- USB20_CON.B2_CONNECT = 1 (Starting the connection process for USB3.0)

(11) Is USB2.0 bus reset requested?
When USB2.0 bus reset comes, go to USB2.0 bus reset process. See section 63.8.3.6 for details.

63.8.3.3 USB Disconnection

The operation required for USB disconnection is described here.

(1) Is USB_STA.VBUS_STA== 0?
If you find that USB_STA.VBUS_STA==B'0 (it notifies on USB_INT_STA_1.VBUS_CNG_STA for example), the device is disconnected.

(2) Initialize the settings
If the device is disconnected, initialize the settings below.
- USB20_CON.B2_PUE = 0 (D+ pull up is disabled)
- USB20_CON.B2_CONNECT = 0 (the request of connection as HS or FS device is disabled)
- USB30_CON.B3_CONNECT = 0 (the request of connection as SS device is disabled)
- USB_COM_CON.COF = 0 (the device is in unconfigured state)

PIPEs should be initialized as well.
- USB_COM_CON.PIPE_CLR = 1 (PIPE is initialized)
 * Make sure that USB_COM_CON.PIPE_CLR returns to 0 after setting USB_COM_CON.PIPE_CLR = 1.

(3) Place PHYs in low power states
It is recommended to place USB3.0-PHY and USB2.0-PHY in low power state and PLLs in them are suspended in order to reduce the power consumption.
If you stop USB3.0-PHY(PLL), refer to section 63.8.8.1 (3), (4), (5). In this case, “U3 state” should be replaced with “disconnected state(SS.Disabled)”. Note that the values of USB30_CON.POW_SEL[2:0] are different in U3 and disconnected state. See section 63.2.2.20 for details.
If you stop USB2.0-PHY(PLL), refer to section 63.8.8.7 (2).

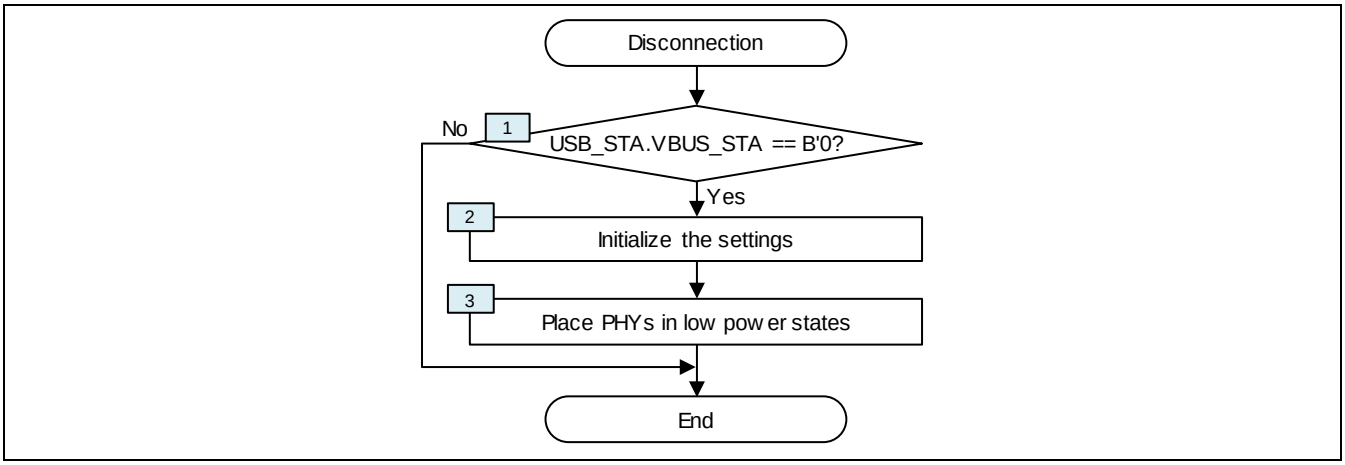

Figure 63.39 USB disconnection flow

63.8.3.4 Warm Reset Process

The operation required when warm reset is detected is described here.

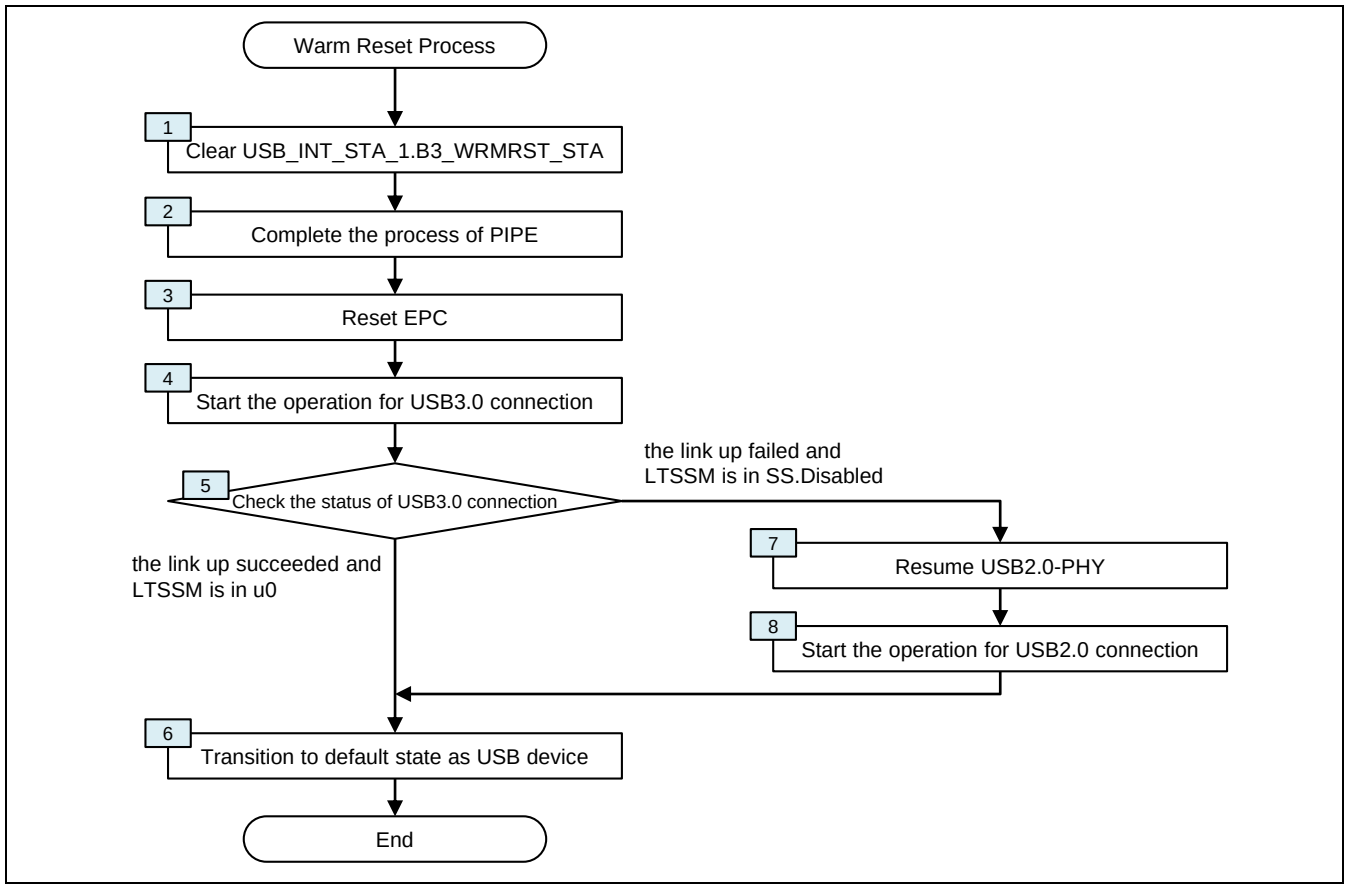

Figure 63.40 warm reset process flow

(1) Clear USB_INT_STA_1.B3_WRMRST_STA
When an interrupt is asserted and USB_INT_STA_1.B3_WRMRST_STA is set to 1, it means that PERIPHERAL PORTION receives warm reset. Write 1 to USB_INT_STA_1.B3_WRMRST_STA in order to clear it.
- Interrupt due to USB_INT_STA_1.B3_WRMRST_STA is generated
- Check that USB_INT_STA_1.B3_WRMRST_STA == 1
- USB_INT_STA_1.B3_WRMRST_STA = 1 (Clearing the event that warm reset is asserted)

(2) Complete the process of PIPE
Basically, as warm reset is requested when the device is just connected or when host and the device can't communicate, it is unlikely that the device is executing data transfer when warm reset comes.
But if it is doing, stop the process of data transfer if it is being executed.
In the configuration with AXI-IF, AXI_COM.MST_WAIT0 can be used to suspend the transfer.

- AXI_CON.MST_WAIT0 = 1 (DMA transfer at USB3.0 Controller is requested to be suspended)

See AXI_STA.DMA_TRANS0 to know whether the transfer is really suspended or not. If the transfer is suspended, then clear DMA_Ch0_CONx.PRD_ENx to 0.
- DMA_Ch0_CONx.PRD_ENx = 0 (DMA transfer in USB3.0 Controller is disabled)

In the configuration without AXI-IF, stop reading from or writing to PERIPHERAL PORTION through Data

Interface. In that case, since the transfer through Data Interface is executed in a unit of a packet, so reading or writing of the current packet should be completed. Then stop reading or writing for the next packet.

(3) Reset EPC portion
Set the registers as follows in order to initialize EPC. In addition to the operations, clear all interrupt statuses.

- USB_COM_CON.CONF = 0
- USB_COM_CON.EP0_EN = 0
- USB_COM_CON.PIPE_CLR = 1 (PIPE is initialized)
 * Make sure that USB_COM_CON.PIPE_CLR returns to 0 after setting USB_COM_CON.PIPE_CLR = 1.
- Write 1 to all interrupt status bits in order to clear them

(4) Start the operation for USB3.0 connection
Start the connecting operation as USB3.0 device.

- SSIFLINKSET3.SSIF_NUM_RDET[3:0] = H'8 (The number of trial of Rx.Detect = 8)
- USB_COM_CON.EP0_EN = 1
- USB_COM_CON.SPD_MODE = 0
- USB30_CON.B3_CONNECT = 1 (Starting the connection process for USB3.0)
- USB_INT_ENA_1. SPEED_ENA = 1 (Interrupt of SPEED state is enabled)

If USB3.0 connection is established (the device works as USB3.0 device) before warm reset comes, the fields already has the values above. But SSIFLINKSET3.SSIF_NUM_RDET[3:0] might be changed. Set the field again to make sure.

(5) Check the status of USB3.0 connection
Check the status of connection process as USB3.0 device on the bits below.
If USB_INT_STA_1.B3_LUPSUCS_STA is asserted, USB3.0 connection is completed successfully. Clear the bit and proceed to (6).
If USB_INT_STA_1.B3_DISABLE_STA is asserted, the link up process as USB3.0 device has failed. Clear the bit and proceed to (7).
- Interrupt due to USB_INT_STA_1.B3_LUPSUCS_STA or USB_INT_STA_1.B3_DISABLE_STA is asserted
- Check whether USB_INT_STA_1.B3_LUPSUCS_STA == 1 or not (The link up succeeded or not)
- Check whether USB_INT_STA_1.B3_DISABLE_STA == 1 or not (The link up failed or not)
- Write 1 to the asserted bit to clear (Clearing the event that the link up succeeded or failed)

(6) Transition to default state as USB device
After the connecting operation has been successfully done, enable the detection of control transfer at PIPE0 (endpoint 0). At the same time, the interrupts required for the operation mode should be enabled. Examples for those cases are shown below. If there are other interrupts required for the usage of core, enable them as well.
- USB_INT_ENA_2.PIPE0_INT_ENA = 1 (Interrupt at PIPE0 is enabled)
- All bits in P0_INT_ENA register should be enabled (All interrupt factors for PIPE0 are enabled)

If the interrupt due to the change of USB SPPED state is enabled at (3), the interrupt is asserted when USB3.0 or USB2.0 connection is established. See USB_STA.SPEED[1:0] to know which speed the device is acting as. Then set the bits according to SPEED state as follows.

[when acting as USB3.0 device]
- USB_INT_ENA_1.B3_HOTRST_ENA = 1 (Interrupt due to hot reset is enabled)
- USB_INT_ENA_1.B3_WRMRST_ENA = 1 (Interrupt due to warm reset is enabled)

[when acting as USB2.0 device]
- USB_INT_ENA_1.B2_SPND_ENA = 1 (Interrupt due to USB2.0 suspend is enabled)
- USB_INT_ENA_1.B2_L1SPND_ENA = 1 (Interrupt due to L1 suspend is enabled)

- USB_INT_ENA_1.B2_USBRST_ENA = 1 (Interrupt due to USB2.0 bus reset is enabled)

(7) Resume USB2.0-PHY
If USB20 PHY is in the power down state and PLL is suspended, resume PLL so that it provides USB2.0 clock.

(8) Start the operation for USB2.0 connection
Start the connecting operation as USB2.0 device when USB3.0 connection is failed at (6).

- USB_COM_CON.EP0_EN = 1
- USB_COM_CON.SPD_MODE = 1
- USB20_CON.B2_PUE = B'1 (Pull up on D+ is enabled)
- USB20_CON.B2_CONNECT = 1 (Starting the connection process for USB2.0)

If device is acting as USB2.0 device and USB3.0- PHY is expected to be in low power state, set it in low power state here. But note that USB2.0 bus reset will come when the operation for USB2.0 connection is started and it is required to try USB3.0 connection again collaterally. It means that USB3.0-PHY can’t be placed in low power state before USB2.0 connection is established. Make sure that the device is acting as USB2.0 device and the sequence of USB2.0 bus reset has already been done before setting USB3.0-PHY in low power state.

63.8.3.5 Hot Reset Process

The operation required when hot reset is detected is described here.

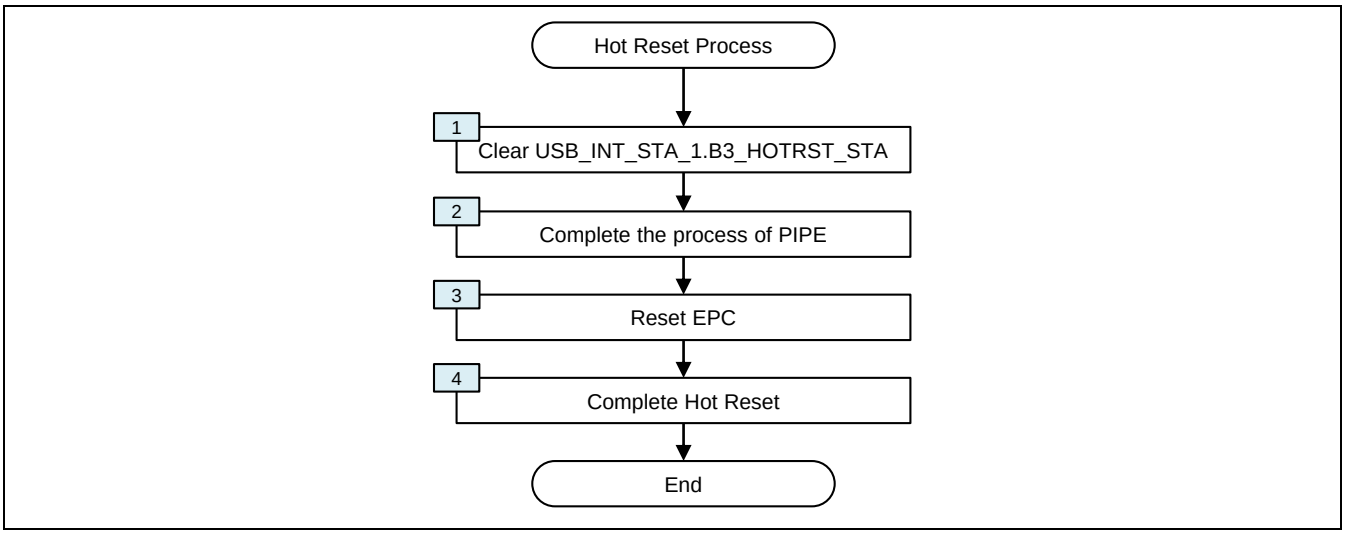

Figure 63.41 hot reset process flow

(1) Clear USB_INT_STA_1.B3_HOTRST_STA
When an interrupt is asserted and USB_INT_STA_1.B3_HOTRST_STA is set to 1, it means that PERIPHERAL PORTION receives hot reset. Write 1 to USB_INT_STA_1.B3_HOTRST_STA in order to clear it.

- Interrupt due to USB_INT_STA_1.B3_HOTRST_STA is generated
- Check that USB_INT_STA_1.B3_HOTRST_STA == 1
- USB_INT_STA_1.B3_HOTRST_STA = 1 (Clearing the event that hot reset is asserted)

(2) Complete the process of PIPE
Since hot reset comes during the training sequence, it is unlikely that the device is executing data transfer when hot reset comes.
But if it is doing, stop the process of data transfer if it is being executed.
In the configuration with AXI-IF, AXI_COM.MST_WAIT0 can be used to suspend the transfer.

- AXI_CON.MST_WAIT0 = 1 (DMA transfer at Peripheral portion is requested to be suspended)

See AXI_STA.DMA_TRANS0 to know whether the transfer is really suspended or not. If the transfer is suspended, then clear DMA_Ch0_CONx.PRD_ENx to 0.

- DMA_Ch0_CONx.PRD_ENx = 0 (DMA transfer in Peripheral portion is disabled)

In the configuration without AXI-IF, stop reading from or writing to PERIPHERAL PORTION through Data Interface. In that case, since the transfer through Data Interface is executed in a unit of a packet, so reading or writing of the current packet should be completed. Then stop reading or writing for the next packet.

(3) Reset EPC portion
Set the registers as follows in order to initialize EPC. In addition to the operations, clear all interrupt statuses.
- USB_COM_CON.CONF = 0
- USB_COM_CON.EP0_EN = 0
- USB_COM_CON.PIPE_CLR = 1 (PIPE is initialized)
* Make sure that USB_COM_CON.PIPE_CLR returns to 0 after setting USB_COM_CON.PIPE_CLR = 1.
- Write 1 to all interrupt status bits in order to clear them

(4) Complete Hot Reset
Set the bit below to complete hot reset.

- USB_COM_CON.EP0_EN = 1
- USB30_CON.B3_HOTRST_CMP = 1

By setting USB30_CON.B3_HOTRST_CMP= 1, LTSSM state of PERIPHERAL PORTION transits from HotReset.Active to HotReset.Exit.
Setting B3_HOTRST_CMP= 1 allows the device to transit to HotReset.Exit from HotReset.Active. This process should be completed within 12 ms from detecting the start of HotReset at (1)

[Note]

The function of hot reset of device is tested in TD.7.28 of link layer test for compliance. The notations for the test are described here.
The downstream port can initiate a hot reset. When it transmits TS2 ordered sets with Reset bit asserted, the device shall respond by sending TS2 ordered sets with Reset bit asserted. When the device completes the operation for reset, it sends TS2 ordered set with Reset bit deasserted. The downstream port shall respond by sending TS2 ordered sets with Reset bit deasserted. Once both ports receive the TS2 ordered sets with Reset bit deasserted, it means the completion of hot reset and they shall exit from the hot reset state.

Note that PERIPHERAL PORTION automatically starts to transmit TS2 ordered sets with Reset bit asserted when it receives TS2 ordered sets with Reset bit asserted. (that is, hot reset requested from downstream port.)

But it is required to set USB30_CON.B3_HOTRST_CMP in order to return TS2 ordered sets with Reset bit deasserted, if PERIPHERAL PORTION enters the state it returns TS2 ordered set with Reset bit asserted once. If there is any operation required for reset, it should be done before USB30_CON.B3_HOTRST_CMP is set. It is notified on USB_INT_STA_1.B3_HOTRST_STA that PERIPHERAL PORTION receives TS2 ordered sets with Reset bit asserted and starts to respond to them.

If the device doesn’t return TS2 ordered sets with Reset bit asserted and hot reset isn’t completed with tHotResetActiveTimeout (=12 ms), the device fails in the test of TD.7.28.

If the device including PERIPHERAL PORTION never deasserts Reset bit in TS2 ordered set, the software may not recognize that USB_INT_STA_1.B3_HOTRST_STA is asserted. In the test of TD.7.28, TS2 ordered sets with Reset bit asserted may come immediately after the device is connected to the downstream port. That case doesn’t occur in normal operation. If the software masks interrupts except that due to the change of VBUS (USB_INT_STA_1.VBUS_CNG_STA) immediately after the device is connected, the software may not be able to know USB_INT_STA_1.B3_HOTRST_STA asserted. It is recommended to enable interrupts due to USB_INT_STA_1.VBUS_CNG_STA and USB_INT_STA_1.B3_HOTRST_STA just after the device is connected.

63.8.3.6 USB2.0 Bus Reset Process

The operation required when USB2.0 bus reset is detected is described here.

There are two cases assumed as that USB2.0 bus reset comes.

- Device is just connected but fails in USB3.0 connection. USB2.0 connection is in progress.
- Device is working in HS or FS but host requests USB2.0 bus reset for some reason.
  This case also means device has failed in USB3.0 connection once.

That is, USB2.0 bus reset doesn't come when device works in SS, but it comes when device works in HS or FS.

USB2.0 bus reset means not only the reset as USB2.0 device but also the retry of USB3.0 connection for USB3.0 device. See section 63.7.3 for the description of USB3.0 specification.

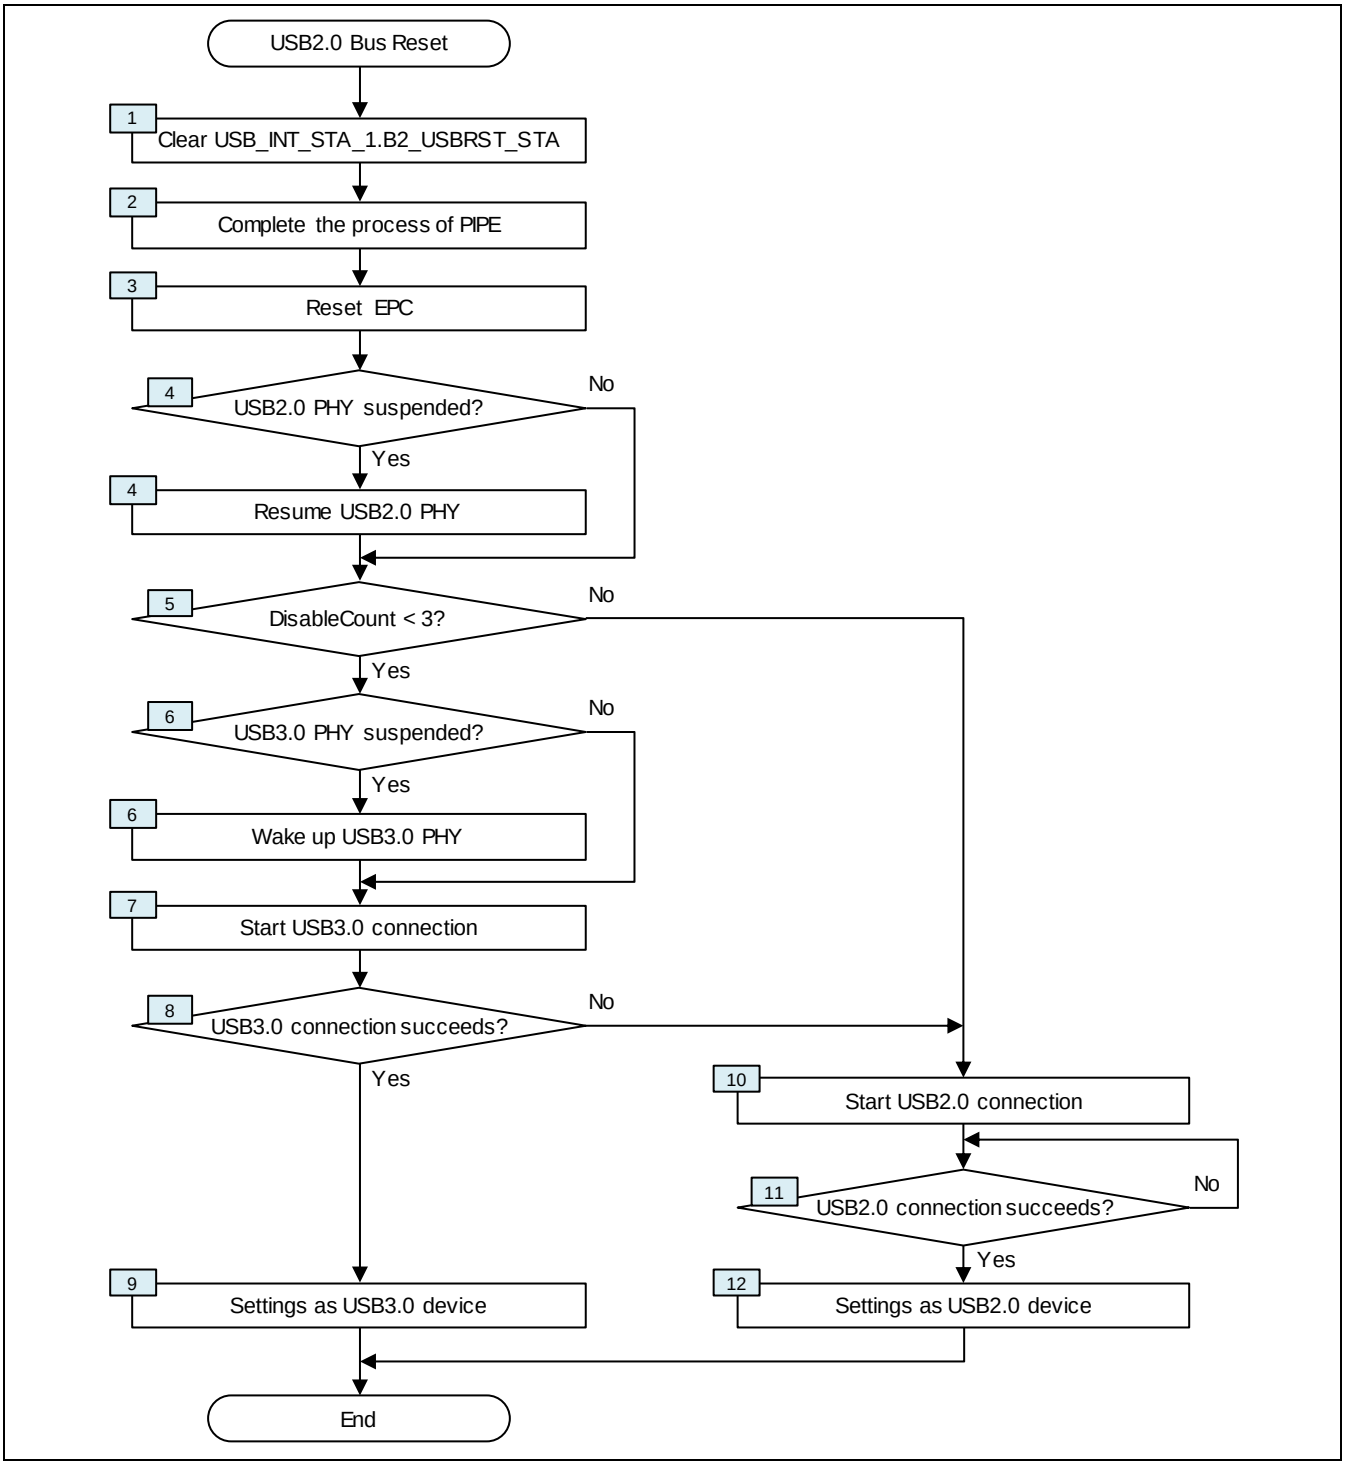

Figure 63.42 USB2.0 Bus Reset (switching from USB2.0 to USB3.0) Flow

The software is required to prepare the variable “DisabledCount” with this flow. The variable means the number of failure in link up. The initial value of DisabledCount is 0 and it is initialized to 0 when one of the following conditions is satisfied.

- VBUS is disabled (No power is provided from VBUS)

- Port configuration exchange completes successfully.
- Power is removed.

Furthermore, Being requested USB2.0 bus reset means that the device has already pulled up D+ (as HS or FS device) and has been detected by host. It is assumed that the software has already set USB20_CON.B2_CONNECT = 1 when USB2.0 bus reset comes.

(1) Clear USB_INT_STA_1.B2_USBRST_STA
When an interrupt is asserted and USB_INT_STA_1.B2_USBRST_STA is set to 1, it means that PERIPHERAL PORTION receives USB2.0 bus reset. Write 1 to USB_INT_STA_1.B2_USBRST_STA in order to clear it.

(2) Complete the process of PIPE
Basically, as USB2.0 bus reset is requested when the device is just connected or when host and the device can’t communicate, it is unlikely that the device is executing data transfer when bus reset comes.
But if it is doing, stop the process of data transfer if it is being executed.
In the configuration with AXI-IF, AXI_COM.MST_WAIT0 can be used to suspend the transfer.

- AXI_CON.MST_WAIT0 = 1 (DMA transfer at Peripheral portion is requested to be suspended)

See AXI_STA.DMA_TRANS0 to know whether the transfer is really suspended or not. If the transfer is suspended, then clear DMA_Ch0_CONx.PRD_ENx to 0.

- DMA_Ch0_CONx.PRD_ENx = 0 (DMA transfer in Peripheral portion is disabled)

In the configuration without AXI-IF, stop reading from or writing to PERIPHERAL PORTION through Data Interface. In that case, since the transfer through Data Interface is executed in a unit of a packet, so reading or writing of the current packet should be completed. Then stop reading or writing for the next packet.

(3) Reset EPC portion
Set the registers as follows in order to initialize EPC. In addition to the operations, clear all interrupt statuses.
- USB_COM_CON.CONF = 0
- USB_COM_CON.EP0_EN = 0
- USB_COM_CON.PIPE_CLR = 1 (PIPE is initialized)
* Make sure that USB_COM_CON.PIPE_CLR returns to 0 after setting USB_COM_CON.PIPE_CLR = 1.
- USB20_CON.B2_TSTMOD[2:0] = H'0 (if test mode is set)
- USB20_CON.B2_TSTMOD_EN = 0 (if test mode is set)
- Write 1 to all interrupt status bits in order to clear them

(4) Resume USB2.0-PHY
It is assumed that the device works in HS or FS, but the device might be in suspended state and PLL in USB2.0-PHY might be stopped when USB2.0 bus reset comes.
In that case resume USB2.0-PHY so that it provides USB2.0 clock. USB3.0 connection might be requested depending on the value of DisabledCount, but the pull up of D+ for USB2.0 connection is still valid and USB2.0 connection is tried immediately when USB3.0 connection fails. That is, USB2.0-PHY clock is required regardless of the value of DisabledCount.

(5) Is DisabledCount<3?
If DisabledCount < 3, it means the device state is in USDPORT.Powered on due to USB2.0 bus reset and the device requests USB3.0 connection. Proceed to (6).
If DisabledCount==3, it means the device state is in USDPORT.Disabled_Error and the device doesn't request USB3.0 connection. Proceed to (10).

(6) Resume USB3.0-PHY
If USB3.0-PHY is in the power down state and PLL is suspended, resume USB3.0-PHY so that it provides USB3.0 clock.

(7) Start USB3.0 connection
As DisbledCount<3, USB3.0 connection is tried again.
If USB2.0 bus reset is the first one just after the device is connected but fails in USB3.0 connection, Most of the fields below has already been set at (6) in section 63.8.3.2. In that case, the setting s for USB2.0 connection at (10) in section 63.8.3.2 should be still active as they are because USB2.0 connection might be required when USB3.0 connection fails.

- USB30_CON.B3_CONNECT = 1 (Starting the connection process for USB3.0)
- USB_COM_CON.EP0_EN = 1 (PIPE0 is enabled)
- USB_COM_CON.SPD_MODE = 0 (USB3.0 mode is requested)
- SSIFLINKSET3.SSIF_NUM_RDET[3:0] = H'1 (The number of trial for Rx.Detect = 1)
- USB_COM_CON.RX_DETECTION = 1 (RxDetect is started)
- USB_INT_ENA_1.B3_LUPSUCS_ENA = 1 (Interrupt due to the success of link up is enabled)
- USB_INT_ENA_1.B3_DISABLE_ENA= 1 (Interrupt due to the failure of link up is enabled)
- USB_INT_ENA_1. SPEED_ENA = 1 (Interrupt of SPEED state is enabled)

The difference with (6) in section 63.8.3.2 is that the SSIFLINKSET3.SSIF_NUM_RDET[3:0] = H'1 although it is set to H'8 at (6) in section 63.8.3.2. It means that the device can do only one trial of Rx detection.

(8) Does USB3.0 connection succeed?
As the result of the trial for USB3.0 connection, one of USB_INT_STA_1.B3_LUPSUCS_STA or USB_INT_STA_1.B3_DISABLE_STA is asserted. USB_INT_STA_1.B3_LUPSUCS_STA means that the link up process of LTSSM has been successfully done and LTSSM is in U0. USB_INT_STA_1.B3_DISABLE_STA means that the link up process of LTSSM has failed and LTSSM is in SS.Disabled. When they are asserted, an interrupt is generated if enabled.

- Check USB_INT_STA_1.B3_LUPSUCS_STA== 1 or USB_INT_STA_1.B3_DISABLE_STA== 1

After the confirmation above, write 1 to USB_INT_STA_1.B3_LUPSUCS_STA or USB_INT_STA_1.B3_DISABLE_STA to clear them.

- Write 1 to USB_INT_STA_1.B3_LUPSUCS_STA if asserted (Clearing the event that the link up has succeeded)
- Write 1 to USB_INT_STA_1.B3_DISABLE_STA if asserted (Clearing the event that USB3.0 connection has failed)

If USB_INT_STA_1.B3_LUPSUCS_STA is asserted, it means USB3.0 connection is successful, proceed to (9).
If USB_INT_STA_1.B3_DISABLE_STA is asserted, it means USB3.0 connection has failed, proceed to (10).

(9) Settings as USB3.0 device
After the connecting operation as SS device has been successfully completed, disable USB2.0 connection. It is defined in USB3.0 specification that USB2.0 connection should be disabled within tUSB2SwitchDisconnect (= 1ms) after Far End Receiver Termination is detected and LTSSM enters Polling.
- USB20_CON.B2_CONNECT = 0 (USB2.0 connection is disabled)
- USB20_CON.B2_PUE = 0 (Pull up of D+ is disabled)

Then enable the detection of control transfer at PIPE0 (endpoint 0). At the same time, the interrupts required for the operation mode should be enabled. An example for that cases are shown below. If there is another interrupt required for the usage of core, enable it as well.

- USB_INT_ENA_2.PIPE0_INT_ENA = 1 (Interrupt at PIPE0 is enabled)
- All bits in P0_INT_ENA register should be enabled (All interrupt factors for PIPE0 are enabled)

As the device is working as SS device, interrupts due to hot reset or warm reset shall be enabled.

- USB_INT_ENA_1.B3_HOTRST_ENA = 1 (Interrupt due to hot reset is enabled)
- USB_INT_ENA_1.B3_WRMRST_ENA = 1 (Interrupt due to warm reset is enabled)

When the port configuration is completed, DisabledCount is reset to 0.

If USB2.0 clock is not needed, USB2.0-PHY can be suspended. See section 63.8.8.7 for details.

(10) Start USB2.0 connection
Since USB3.0 connection has failed, disable USB3.0 connection.
- USB30_CON.B3_CONNECT = 0
- DisabledCount++

Then, start USB2.0 connection.
The most of the fields below has already set, but USB_COM_CON.SPD_MODE is set for USB3.0 connection at (7), so it should be changed for USB2.0 connection.

- USB_COM_CON.EP0_EN = 1 (PIPE0 is enabled: this field is already enabled at (6))
- USB_COM_CON.SPD_MODE = 1 (USB2.0 mode is requested)
- USB20_CON.B2_PUE = 1 (Pull up on D+ is enabled)
- USB20_CON.B2_CONNECT = 1 (Starting the connection process for USB3.0)
- USB_INT_ENA_1. SPEED_ENA = 1 (Interrupt of SPEED state is enabled)

(11) Does USB2.0 connection succeed?
After USB2.0 bus reset and chirp, the device works as HS or FS device. For USB2.0 connection, there is no link training as that in USB3.0 connection, so it is assumed to be always completed successfully.

(12) Setting as USB2.0 device
After the connecting operation as HS or FS has been successfully done, enable the detection of control transfer at PIPE0 (endpoint 0). At the same time, the interrupts required for the operation mode should be enabled. Examples for those cases are shown below. If there are other interrupts required for the usage of core, enable them as well.

- USB_INT_ENA_2.PIPE0_INT_ENA = 1 (Interrupt at PIPE0 is enabled)
- All bits in P0_INT_ENA register should be enabled (All interrupt factors for PIPE0 are enabled)

If the interrupt due to the change of USB SPPED state is enabled at (10), the interrupt is asserted when USB2.0 connection is established. See USB_STA.SPEED[1:0] to know which speed the device is acting as. Then set the bits according to SPEED state as follows.

[when acting as USB2.0 device]
- USB_INT_ENA_1.B2_SPND_ENA = 1 (Interrupt due to USB2.0 suspend is enabled)
- USB_INT_ENA_1.B2_L1SPND_ENA = 1 (Interrupt due to L1 suspend is enabled)
- USB_INT_ENA_1.B2_USBRST_ENA = 1 (Interrupt due to USB2.0 bus reset is enabled)

63.8.4 Control Transfer

The operation for control transfer is described here.

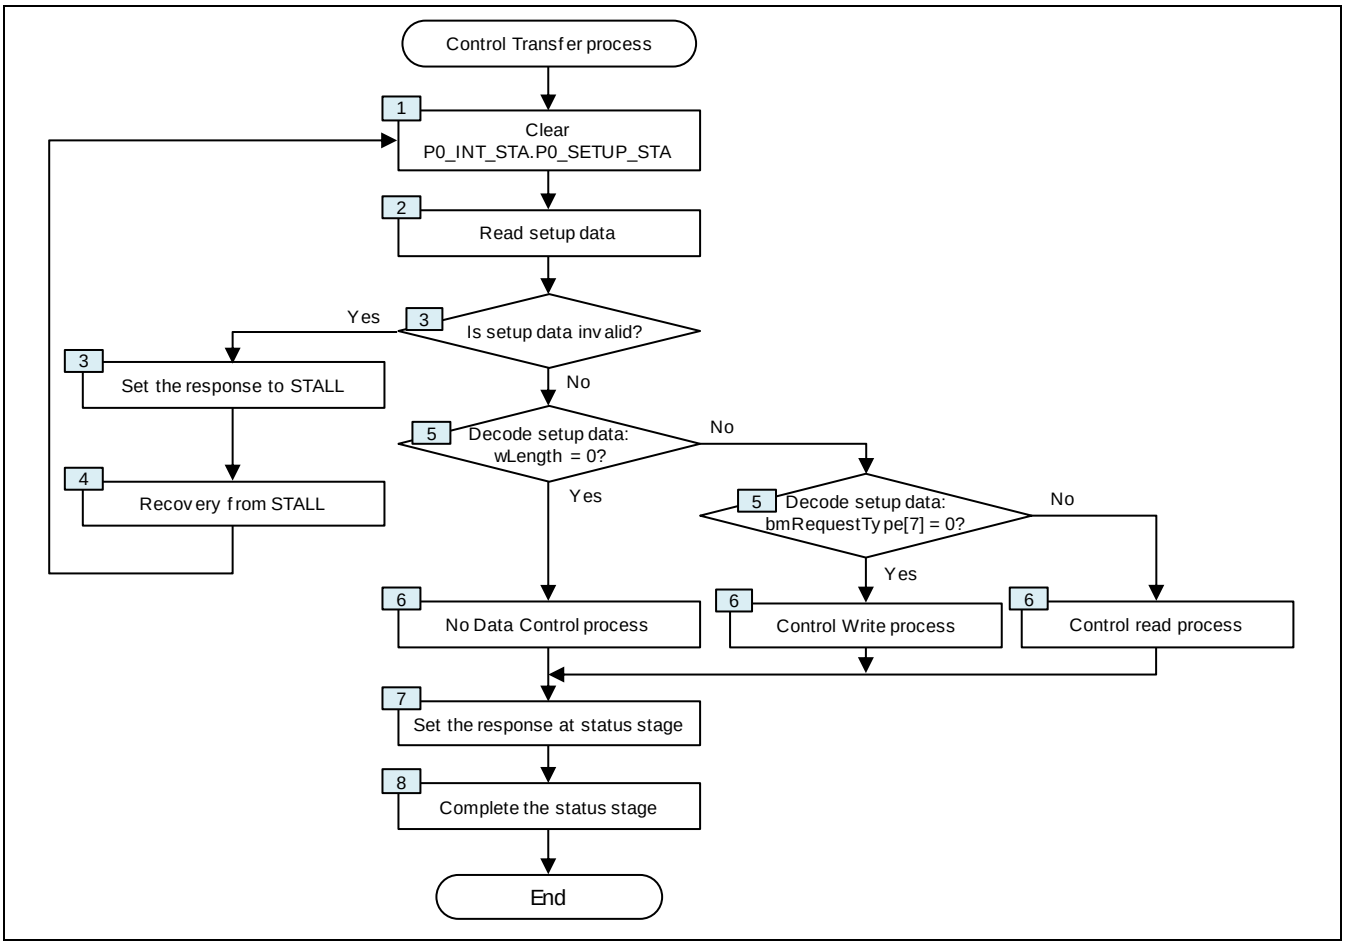

Figure 63.43 control transfer process flow

(1) Clear P0_INT_STA.P0_SETUP_STA
When an interrupt is asserted and P0_INT_STA.P0_SETUP_STA is set to 1, it means that PERIPHERAL PORTION has received setup data. Write 1 to P0_INT_STA.P0_SETUP_STA in order to clear it.

- Interrupt due to P0_INT_STA.P0_SETUP_STA is generated
- Check that P0_INT_STA.P0_SETUP_STA== 1
- P0_INT_STA.P0_SETUP_STA = 1 (Clearing the event setup data has been received)

In case the status bits related to control transfer are set, they should be cleared as follows.
- P0_INT_STA.P0_STSST_STA = 1
- P0_INT_STA.P0_STSED_STA = 1
- P0_INT_STA.P0_RCVNL_STA = 1
- P0_INT_STA.P0_ERDY_STA = 1
- P0_INT_STA.P0_FLOW_STA = 1
- P0_INT_STA.P0_STALL_STA = 1
- P0_INT_STA.P0_NRDY_STA = 1

The data buffer for PIPE0 should also be cleared just in case data of previous transfer is left in the buffer.
- P0_CON.P0_BCLR = 1 (Clearing data buffer for PIPE0)

(2) Read setup data
Read setup data from STUP_DAT_0 and STUP_DAT_1 registers.

(3) Is setup data invalid?
In case that setup data is invalid, respond with STALL. Set P0_ST_RES[1:0], P0_OT_RES[1:0] and P0_IN_RES[1:0] in P0_CON register to return STALL response in that case.

- P0_CON.P0_RES_WEN = 1
- P0_CON.P0_ST_RES[1:0] = B'10 (forced STALL response)
- P0_CON.P0_OT_RES[1:0] = B'10 (forced STALL response)
- P0_CON.P0_IN_RES[1:0] = B'10 (forced STALL response)

With the settings above, PERIPHERAL PORTION returns STALL for all requests (IN, OUT or STATUS) to PIPE0. Whenever PERIPHERAL PORTION responds with STALL, P0_INT_STA.P0_STALL_STA is asserted. Since USB device is not required to change the response from PIPE0 until new setup data comes to PIPE0 as noted in (5) or any reset comes in that case, an interrupt due to P0_INT_STA.P0_STALL_STA can be ignored (that is, it can be masked).

(4) Recovery from STALL
If host wants to recovery the status, it will send ClearFeature (ENDPOINT_HALT) or other request. The device should initialize the response for it.
When host sends new setup data including it requests ClearFeature (ENDPOINT_HALT), P0_INT_STA.P0_SETUP_STA will be asserted again.
When the assertion of P0_INT_STA.P0_SETUP_STA is detected (it is notified on an interrupt if enabled), PERIPHERAL PORTION automatically sets P0_CON.P0_ST_RES[1:0], P0_CON.P0_OT_RES[1:0] and P0_CON.P0_IN_RES[1:0] to B'00 (NRDY/NAK response). Note that it might take time to decide and prepare a response here. Hence it is assumed that the response is changed to normal one after the decision and the preparation. If it doesn't take time, normal responses can be set here.

- New setup data is received. (It is notified on the assertion of P0_INT_STA.P0_SETUP_STA.)
(- PERIPHERAL PORTION automatically sets P0_CON.P0_*_RES[1:0] to B'00, but the software can change them to normal response.)

Then, go back to (1).

(5) Decode setup data
Decode the content of setup data which is read at (2).
If wLength = 0, no data control process is being requested.
If wLength is not 0 and bmRequestType[7] is 0, control write data process is being requested. Otherwise control read process is being requested.

(6) No Data Control, Control Write or Control Read process
Refer each subsection as follows.
a) No Data Control process: Refer to section 63.8.4.1
b) Control Write process: Refer to section 63.8.4.2
c) Control Read process: Refer to section 63.8.4.3

(7) Set the response at status stage
From (7) to (8) the settings for status stage are described. For the operations required in each process before status stage, refer section 63.8.9. Basically the process requested by setup data should be finished before the device completes the status stage. The status stage might be started before the completion of the process, but the device can put off the completion of the status stage by returning NRDY or NAK.

Set P0_CON.P0_ST_RES[1:0] as follows.
- P0_CON.P0_RES_WEN = 1

- P0_CON.P0_ST_RES[1:0] = B'01 (Normal response)

For P0_CON.P0_OT_RES[1:0] and P0_CON.P0_IN_RES[1:0], keep the value set at (6) in case of Control Write process or Control Read process. In case of No Data Control process, they should be set to forced STALL response at the same time as the setting of P0_CON.P0_ST_RES[1:0].

- P0_CON.P0_OT_RES[1:0] = B'10 (STALL response)
- P0_CON.P0_IN_RES[1:0] = B'10 (STALL response)

(8) Complete Status Stage
Wait for the interrupt due to P0_INT_STA.P0_STSED_STA, which shows PERIPHERAL PORTION completes the status stage of the control transfer. Confirm P0_INT_STA.P0_STSED_STA is asserted, and then write 1 to it to clear.

- Interrupt due to P0_INT_STA.P0_STSED_STA is generated
- Check that P0_INT_STA.P0_STSED_STA== 1
- P0_INT_STA.P0_STSED_STA = 1 (Clearing the event that the status stage of control transfer has been completed.)

Note: In the specification of USB, it is defined that the sequence of control transfer should be initialized when new setup data is received during control transfer. Device should stop the operation for previous setup data and switch to the operation of new setup data. That case seldom occurs, but the consideration of it is required.

63.8.4.1 No Data Control Process

The operation for no data control transfer is described here.

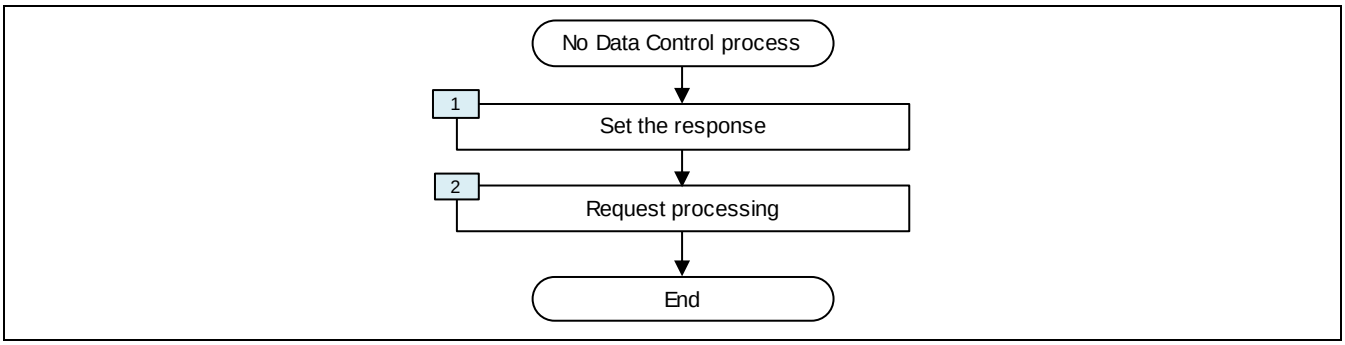

Figure 63.44 no data control transfer process flow

(1) Set the response
After decoding setup data, set the response for the request.

- P0_MOD.P0_DIR = 0 (Direction = OUT)

Select NRDY/NAK response for the status stage until the operation at (2) is completed. If the operation is not needed, PERIPHERAL PORTION can respond with ACK immediately. The final response at the status stage is selected at (7) in the flow of section 63.8.4.
As no data is sent or received in this flow, select STALL response for IN and OUT transfer request. All of the settings below are for P0_CON register and it allows only 32-bit access, so note that they should be done in one word access.

- P0_CON.P0_RES_WEN = 1
- P0_CON.P0_ST_RES[1:0] =B'00 (NRDY/NAK response. ACK response is also selectable.)
- P0_CON.P0_OT_RES[1:0] =B'10 (STALL response)

- P0_CON.P0_IN_RES[1:0] =B'10 (STALL response)

(2) Request processing
If any operation for the request is required, do it here.
See section 63.8.9 for the operations of major device requests.

63.8.4.2 Control Write Process

The operation for control writer transfer is described here.

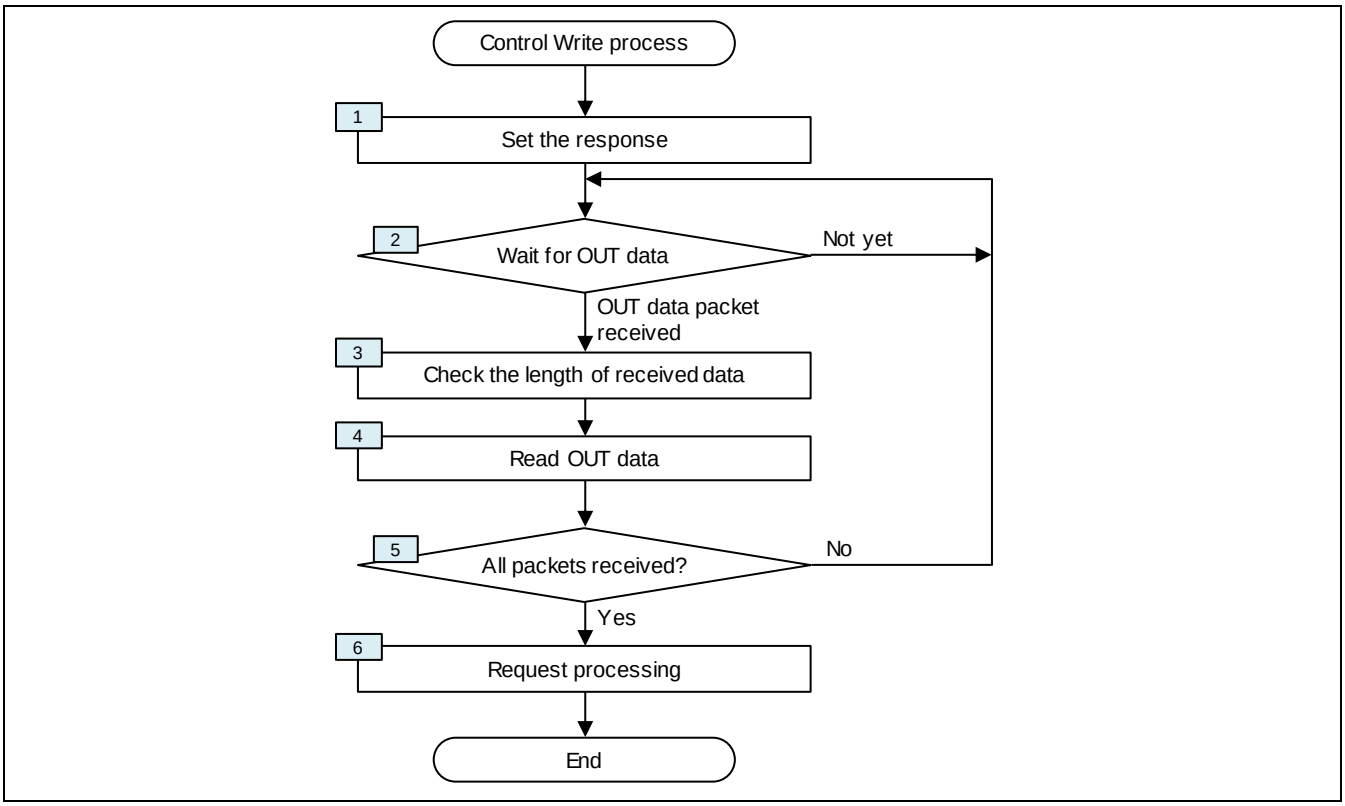

Figure 63.45 control write process flow

(1) Set the response
After decoding setup data, set the response for the request.
As control write transfer is requested here, select OUT as the direction of transfer.
Set NRDY/NAK response for the status stage since the data stage has not been finished yet. Set normal response for OUT and STALL response for IN.

- P0_MOD.P0_DIR = 0 (Direction = OUT)
- P0_CON.P0_RES_WEN = 1
- P0_CON.P0_ST_RES[1:0] = B'00 (NRDY/NAK response)
- P0_CON.P0_OT_RES[1:0] = B'01 (normal response)
- P0_CON.P0_IN_RES[1:0] = B'10 (STALL response)

(2) Wait for OUT data
For control write transfer, the software reads each packet in data stage of the transfer through P0_READ register.
When OUT data packet to PIPE0 Is received, an interrupt due to P0_INT_STA.P0_BFRDY_STA is asserted. In that case, write 1 to P0_INT_STA.P0_BFRDY_STA to clear.

- Interrupt due to P0_INT_STA.P0_BFRDY_STA is generated
- Check that P0_INT_STA.P0_BFRDY_STA== 1
- P0_INT_STA.P0_BFRDY_STA = 1 (Clearing the event that OUT data has been received at PIPE0)

When receiving OUT data packet, P0_STA.P0_BUFSTS is also asserted. The meaning of the bit is OUT data packet is ready to be read from P0_READ register. Polling P0_STA.P0_BUFSTS is available to know that OUT data packet has been received for the software as well.

(3) Check the length of received data
Read the following field to know the length of received data.

- Read P0_LNG.P0_LENGTH[9:0] (This field shows the number of bytes of received data)

(4) Read OUT data
Read OUT data through P0_READ register. Note that OUT data in control transfer can't be read from Data Interface of Peripheral portion or can't be transferred by AXI DMA transfer.
P0_READ register should be read in a unit of 32-bit. P0_READ register is updated and the next 32-bit word of received data is shown in P0_READ register every time it is read. The length of received data is known at (3) and the number of read from P0_READ register can be calculated from the length. The number of read = the length divided by 4, round-up is required if there is any residue. If there is residue, it also means the last 32-bit word read has one or more unnecessary bytes. In that case, discard unnecessary bytes.

(5) Are all packets received?
If wLength shown in setup data is more than the max packet size in control transfer, it means two or more OUT data packets would come. In that case, repeat the steps from (2) to (4) for the number of packets.

After all of OUT packets have been received and read, set the registers as follows. Note P0_CON register should be written in a unit of 32-bit and other fields should hold its value. That is, read-modify-write will be required.
- P0_CON.P0_RES_WEN = 1
- P0_CON.P0_OT_RES[1:0] = B'10 (STALL response)

(6) Request processing
If any operation for the request is required, do it here.
See section 63.8.9 for the operations of major device requests.

63.8.4.3 Control Read Process

The operation for control read transfer is described here.

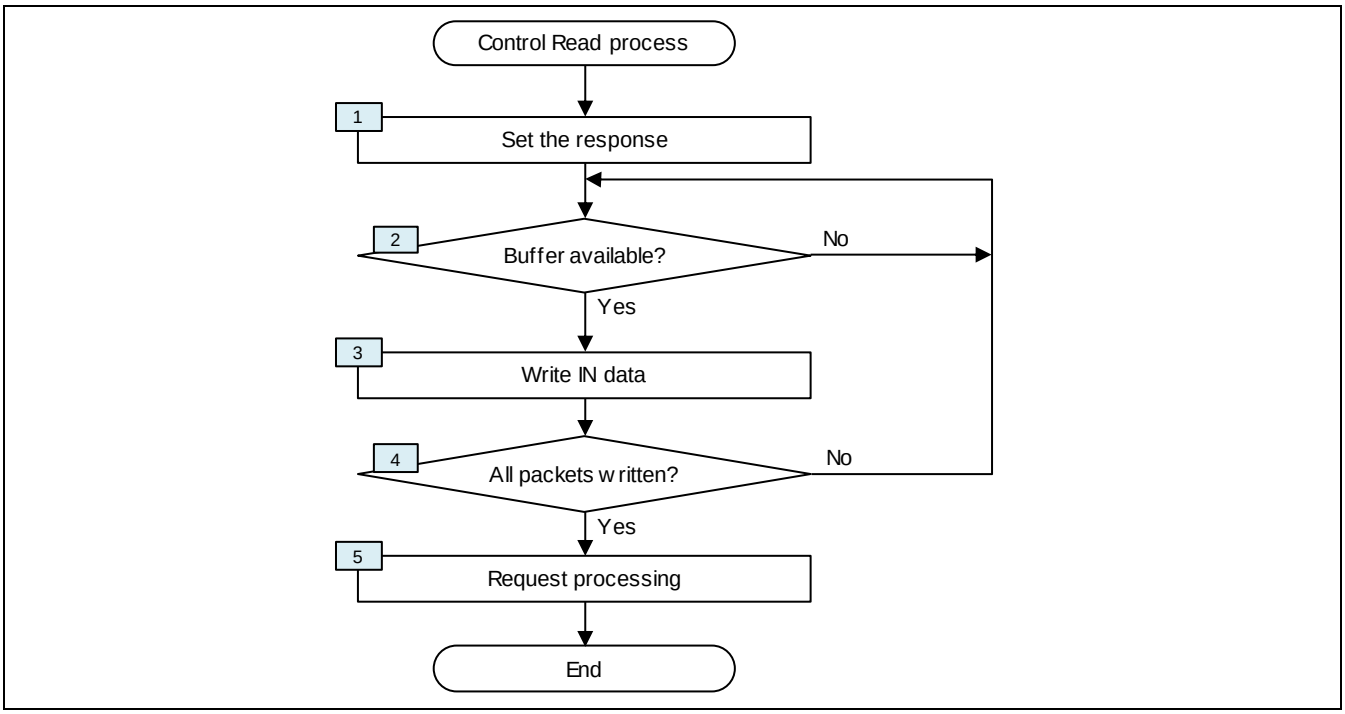

Figure 63.46 control read process flow

(1) Set the response
After decoding setup data, set the response for the request.
As control read transfer is requested here, select IN as the direction of transfer.
Set NRDY/NAK response for the status stage since the data stage has not been finished yet. Set normal response for IN and STALL response for OUT.

- P0_MOD.P0_DIR = 1 (Direction = IN)
- P0_CON.P0_RES_WEN = 1
- P0_CON.P0_ST_RES[1:0] = B'00 (NRDY/NAK response)
- P0_CON.P0_OT_RES[1:0] = B'10 (STALL response)
- P0_CON.P0_IN_RES[1:0] = B'01 (Normal response)

(2) Check if buffer is available
For control read transfer, the software writes each packet in data stage of the transfer through P0_WRITE register. But if there is no space available in the buffer for PIPE0, it can't write. P0_STA.P0_BUFSTS shows if there is available space in the buffer. See the bit before writing IN data packet to P0_WRITE register.

- Check whether P0_STA.P0_BUFSTS == 1 or not

If P0_STA.P0_BUFSTS is 0 and there is no available space in the buffer currently, Wait until P0_STA.P0_BUFSTS becomes 1 or an interrupt due to P0_INT_STA.P0_BFRDY_STA is asserted. When IN is selected as the direction of PIPE0 (that is, P0_MOD.P0_DIR=1), P0_INT_STA.P0_BFRDY_STA is asserted when the buffer for PIPE0 becomes available for new write data.
Therefore, the software can know the timing the buffer for PIPE0 prepares new available space by polling P0_STA.P0_BUFSTS or an interrupt due to P0_INT_STA.P0_BFRDY_STA.
But, Note that P0_INT_STA.P0_BFRDY_STA is not asserted just after reset (hardware reset,

USB_COM_CON.PIPE_CLR, P0_CON.P0_BCLR and P0_CON.P0_CLR) and when the software writes the first packet. In that case, since the buffer has available space just after reset, so the software can write the packet without being notified on an interrupt due to P0_INT_STA.P0_BFRDY_STA. The software still can see P0_STA.P0_BUFSTS in that case.

(3) Write IN data

Write IN data through P0_WRITE register. Note that IN data in control transfer can't be written through Data Interface of Peripheral portion or can't be transferred by AXI DMA transfer.

P0_WRITE register should be written in a unit of 32-bit. The number of write can be calculated as the number of write = the length divided by 4, round-up is required if there is any residue. The written words are concatenated as one packet.

When the length of packet is not multiples of 32-bit, the last word has unnecessary bytes. The last written word should be also written as a 32-bit word. The number of valid bytes in the last word is set in P0_CON.P0_BYTE_EN. Unnecessary bytes in the last word are discarded.

To send the packet, set the registers as follows after the last word has been written.

- P0_CON.P0_SEND = 1
- P0_CON.P0_BYTE_EN[1:0] = B'xx (the number of valid byes in last written word)

(4) Are all packets written?

If wlength shown in setup data is more than the max packet size in control transfer, it means two or more IN data packets are required. In that case, repeat the steps from (2) to (3) for the number of packets.

After all of IN packets have been sent, set the registers as follows. Note P0_CON register should be written in a unit of 32-bit and other fields should hold its value. That is, read-modify-write will be required.

- P0_CON.P0_RES_WEN = 1
- P0_CON.P0_IN_RES[1:0] = B'01 (STALL response)

(5) Request processing

If any operation for the request is required, do it here.

See section 63.8.9 for the operations of major device requests.

63.8.5 Bulk Transfer

The operation for bulk transfer is described here.

PIPEs other than PIPE0 (PIPE0 is used only for control transfer) can be used for bulk transfer. The settings for bulk transfer are shown below.

- PIPE_COM.PIPE_NUM[4:0] = the index of PIPE used for the current bulk transfer
- PIPE_MOD.Pn_EPNUM[3:0] = the endpoint number of the PIPE
- PIPE_MOD.Pn_TYPE[1:0] = B'10 (bulk transfer)
- PIPE_MOD.DIR = the direction of transfer
- PIPE_MOD.Pn_STREAM = whether the PIPE is used for Stream bulk transfer or not
- PIPE_MOD.Pn_BOT = whether the PIPE uses BOT or not
- PIPE_MOD.Pn_ERDY_CON[1:0] = threshold to send ERDY
- PIPE_RAMMAP.Pn_BASEAD[13:0] = the base address of buffer assigned for the PIPE
- PIPE_RAMMAP.Pn_RAMIF[1:0] = the index of RAM interface of the PIPE
- PIPE_RAMMAP.Pn_MPKT[10:0] = 1024bytes for SS, 512 bytes for HS or 64 bytes for FS
- PIPE_RAMMAP.Pn_RAMAREA = the size of RAM area assigned for the PIPE
- Pn_CON.Pn_DATAIF_EN = whether Data Interface of Peripheral portion is used or not.
- Pn_CON.Pn_EN = 1 (the PIPE is enabled)

These settings are done just after Set Configuration is completed and the device enters configured state. But if the device has only single configuration for each PIPE, these settings can be done after the device is turned on.

63.8.5.1 Bulk-IN Process

The normal bulk IN process is described here. See section 63.8.5.3 for Stream bulk process.

In this subsection the process to write bulk IN packet through Pn_WRITE register is described. DMA transfer as the master function of Peripheral portion is available in the configuration with AXI-IF. See section 63.8.7 for the process using DMA transfer.

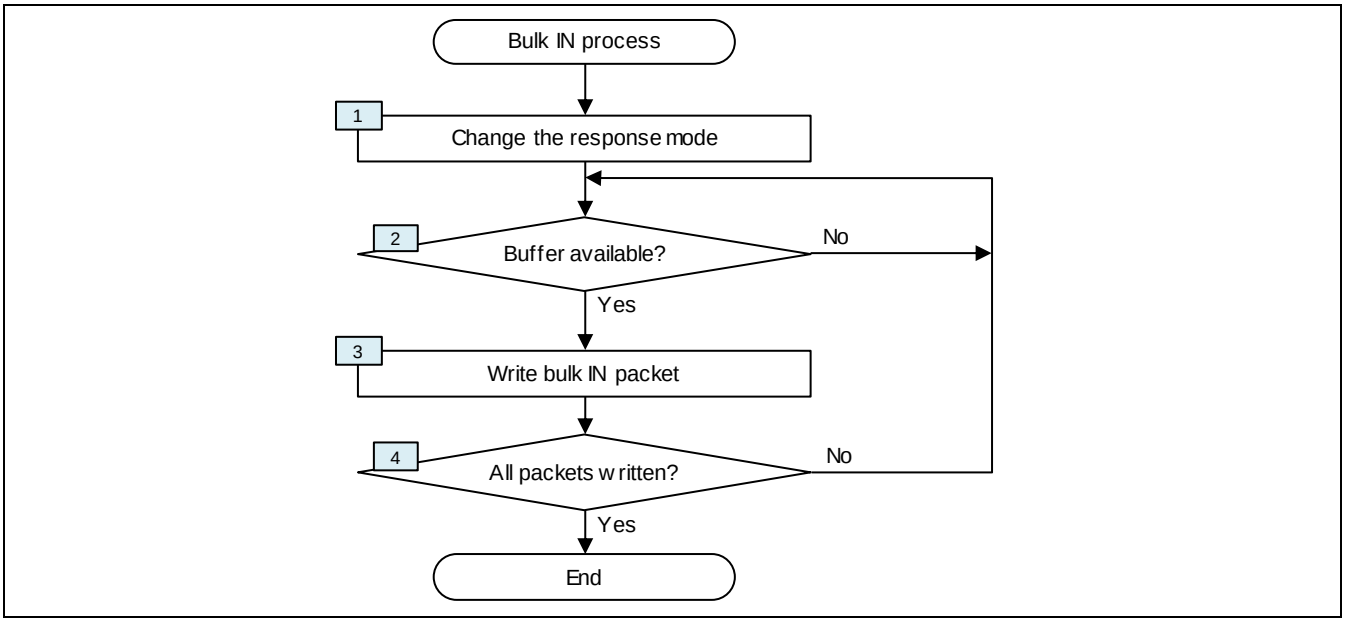

Figure 63.47 bulk IN process flow

(1) Change the response mode of the bulk IN PIPE
Change the response mode of the bulk IN PIPE to normal response so that the PIPE can transmit data.

- Pn_CON.Pn_RES_WEN = 1
- Pn_CON.Pn_RES[1:0] = B'01 (Normal response)

(2) Check if buffer is available
Check if buffer for the bulk IN PIPE is available before writing bulk IN packet. Pn_STA.Pn_BUFSTS shows if the buffer is available or not.

- Check whether Pn_STA.Pn_BUFSTS == 1 or not

If Pn_STA.Pn_BUFSTS is 0 and there is no available space in the buffer currently, Wait until Pn_STA.Pn_BUFSTS becomes 1 or an interrupt due to Pn_INT_STA.Pn_BFRDY_STA is asserted. When IN is selected as the direction of the bulk PIPE (that is, Pn_MOD.Pn_DIR = 1), Pn_INT_STA.Pn_BFRDY_STA is asserted when the buffer of the PIPE becomes available for new write data.
Therefore, the software can know the timing the buffer of the PIPE prepares new available space by polling Pn_STA.Pn_BUFSTS or an interrupt due to Pn_INT_STA.Pn_BFRDY_STA.
But, Note that Pn_INT_STA.Pn_BFRDY_STA is not asserted just after reset (hardware reset, USB_COM_CON.PIPE_CLR, Pn_CON.Pn_BCLR and Pn_CON.Pn_CLR) and when the software writes the first packet. In that case, since the buffer has available space just after reset, so the software can write the packet without being notified on an interrupt due to Pn_INT_STA.Pn_BFRDY_STA. The software still can see Pn_STA.Pn_BUFSTS in that case.

(3) Write bulk IN packet
Write bulk IN packet to be transmitted to the buffer. Bulk IN data is written in a unit of packet and the buffer can't accept data across the max packet size defined in PIPE_RAMMAP.Pn_MPKT[10:0].

[writing through Pn_WRITE register]

a-1) Write data through Pn_WRITE register. Since only 32-bit access is allowed to the register, data should be written in a unit of 32-bit. The number of write can be calculated as the number of write = the length divided by 4, round-up is required if there is any residue. The written words are concatenated as one packet.
When the length of packet is not multiples of 32-bit, the last written word may have unnecessary bytes.
The last word should be also written as a 32-bit word. The number of valid bytes in the last word is set in Pn_CON.Pn_BYTE_EN[1:0]. Unnecessary bytes in the last word are discarded.

a-2) Set fields as follows to send the packet. Since only 32-bit access is allowed to Pn_CON register, all fields below should be set in one word access.
- Pn_CON.Pn_SEND = 1
- Pn_CON.Pn_BYTE_EN[1:0] = B'xx (the number of valid byes in last written word)
- In case of the last packet of data group, set Pn_CON.Pn_LAST = 1

(4) Are all packets written?
If it is required to send two or more packets, repeat the steps from (2) to (3).

Note: When the information of a certain PIPE is read from or write to PIPEn registers, PIPE_COM.PIPE_NUM[4:0] should have the index of the PIPE.

63.8.5.2 Bulk-OUT Process

The normal Bulk-OUT process is described here. See section 63.8.5.3 for Stream bulk process.

In this subsection the process to read bulk OUT packet through Pn_READ register is described. DMA transfer as the master function of Peripheral portion is available in the configuration with AXI-IF. See section 63.8.7 for the process using DMA transfer.

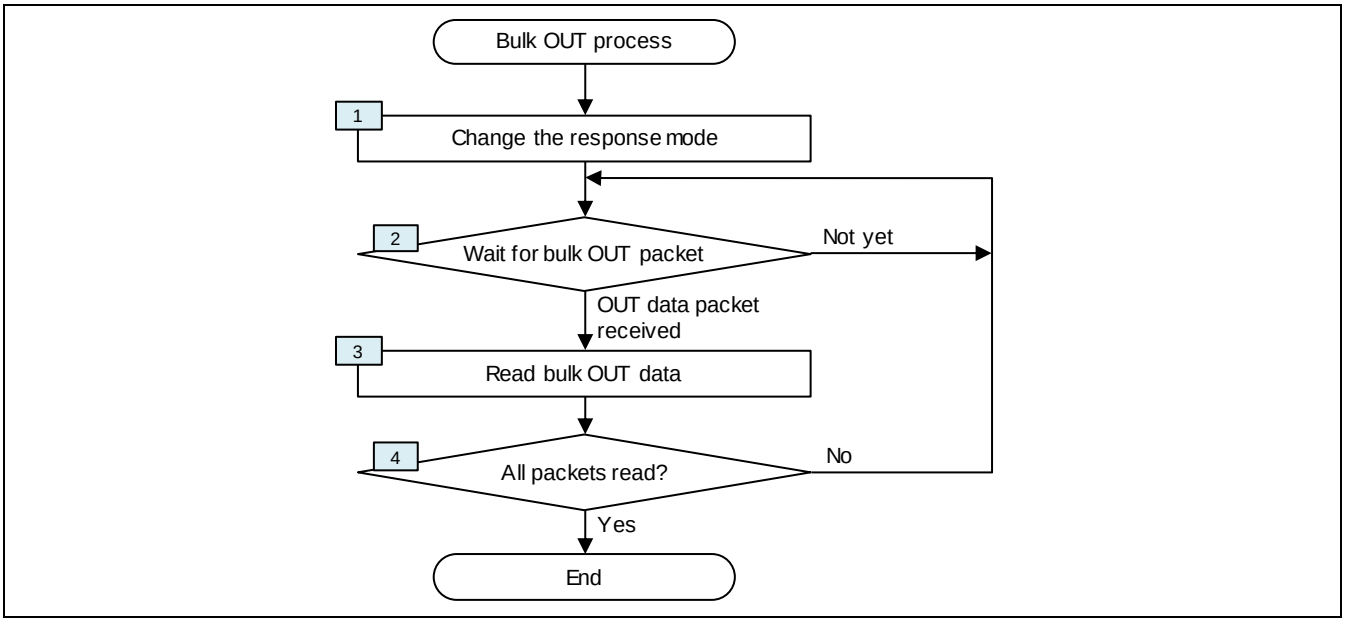

Figure 63.48 bulk OUT process flow

(1) Change the response mode of the bulk OUT PIPE
Change the response mode of the bulk OUT PIPE to normal response so that the PIPE can receive data.

- Pn_CON.Pn_RES_WEN = 1
- Pn_CON.Pn_RES[1:0] = B'01 (Normal response)

(2) Wait for bulk OUT data
When bulk OUT data to the PIPE is received, an interrupt due to Pn_INT_STA.Pn_BFRDY_STA is asserted. In that case, write 1 to Pn_INT_STA.Pn_BFRDY_STA to clear.

- Interrupt due to Pn_INT_STA.Pn_BFRDY_STA asserted
- Check whether Pn_INT_STA.Pn_BFRDY_STA == 1 or not.
- Pn_INT_STA.Pn_BFRDY_STA = 1 (clearing the event that OUT data is received at the PIPE)

When receiving OUT data packet, Pn_STA.Pn_BUFSTS is also asserted. The meaning of the bit is bulk OUT data packet is ready to be read from Pn_READ register. Polling Pn_STA.Pn_BUFSTS is available to know that OUT data packet has been received for the software as well.

(3) Read bulk OUT packet

Read bulk OUT packet from the buffer. Bulk OUT data is read in a unit of packet and the buffer can't be read across the max packet size defined in PIPE_RAMMAP.Pn_MPKT[10:0].

[reading through Pn_READ register]

a-1) Read Pn_LNG register in order to know the length of received data

a-2) Read received packet through Pn_READ register.

Pn_READ register should be read in a unit of 32-bit. Pn_READ register is updated and the next 32-bit word of received data is shown in Pn_READ register every time it is read. The length of received data is known at a-1) and the number of read from Pn_READ register can be calculated from the length. The number of read = the length divided by 4, round-up is required if there is any residue. If there is residue, it also means the last 32-bit word read has one or more unnecessary bytes. In that case, discard unnecessary bytes.

(4) Are all packets read?

If the bulk OUT PIPE has more packets to be read, repeat the steps from (2) to (3).
Pn_INT_STA.Pn_LSTTR_STA is asserted when the last packet (short packet or packet with PP = 0) is received.

When a short packet or a packet with PP = 0 (PP is used only in USB3.0) is received, PERIPHERAL PORTION recognizes it is the last packet of the current transfer. It returns ACK with NumP = 0 to host after receiving the packet. ACK with NumP = 0 means that the device can't receive any more packet currently. The device should send ERDY when it wants to resume the transfer. When the last packet (short packet or packet with PP = 0) has been read to AXI-Bus and the buffer of the PIPE has available space, PERIPHERAL PORTION automatically send ERDY to request the resume of transfer.
Note that PERIPHERAL PORTION may return ACK with NumP = 0 even when the received packet is not the last packet if it has no available buffer at that time. But when PERIPHERAL PORTION gets available space in the buffer of the PIPE, it automatically sends ERDY to resume the transfer for the PIPE.

Note: When the information of a certain PIPE is read from or write to PIPEn registers, PIPE_COM.PIPE_NUM[4:0] should have the index of the PIPE.

63.8.5.3 Stream Bulk Process

The process of stream bulk, especially UASP (USB Attached SCSI protocol) application as an example is described here.

(1) PIPE structure of UASP

UASP assumes 4 pipe models, not including control pipe (PIPE0). The pipes are Command (OUT), Status (IN), Data-in (IN) and Data-out (OUT).
UAS driver sends a command through host stack to Command pipe, device receives it and returns the status or the result for the command from Status pipe. Device receives OUT packet at Data-out pipe or returns IN packet from Data-In pipe, if required.

Stream protocol is used for the parallel operation for commands. Device can receive multiple commands to Command pipe at once. It returns statuses from Status pipe or IN packets from Data-in pipe, or receives OUT packets to Data-out pipe, in “out-of-order” way. Each command has a Stream ID as a tag, and Stream protocol is used for the tagging.
Note Status pipe, Data-in pipe and Data-out pipe are Stream bulk pipes but Command pipe is not. Stream ID is provided in CIU (Command IU) which is received at Command pipe.

(2) Basic Stream Bulk IN process

The basic process of Stream bulk IN is described here.
Stream bulk IN pipe should have PIPE_MOD.Pn_STREAM = 1 as noted in the first part of section 63.8.5.

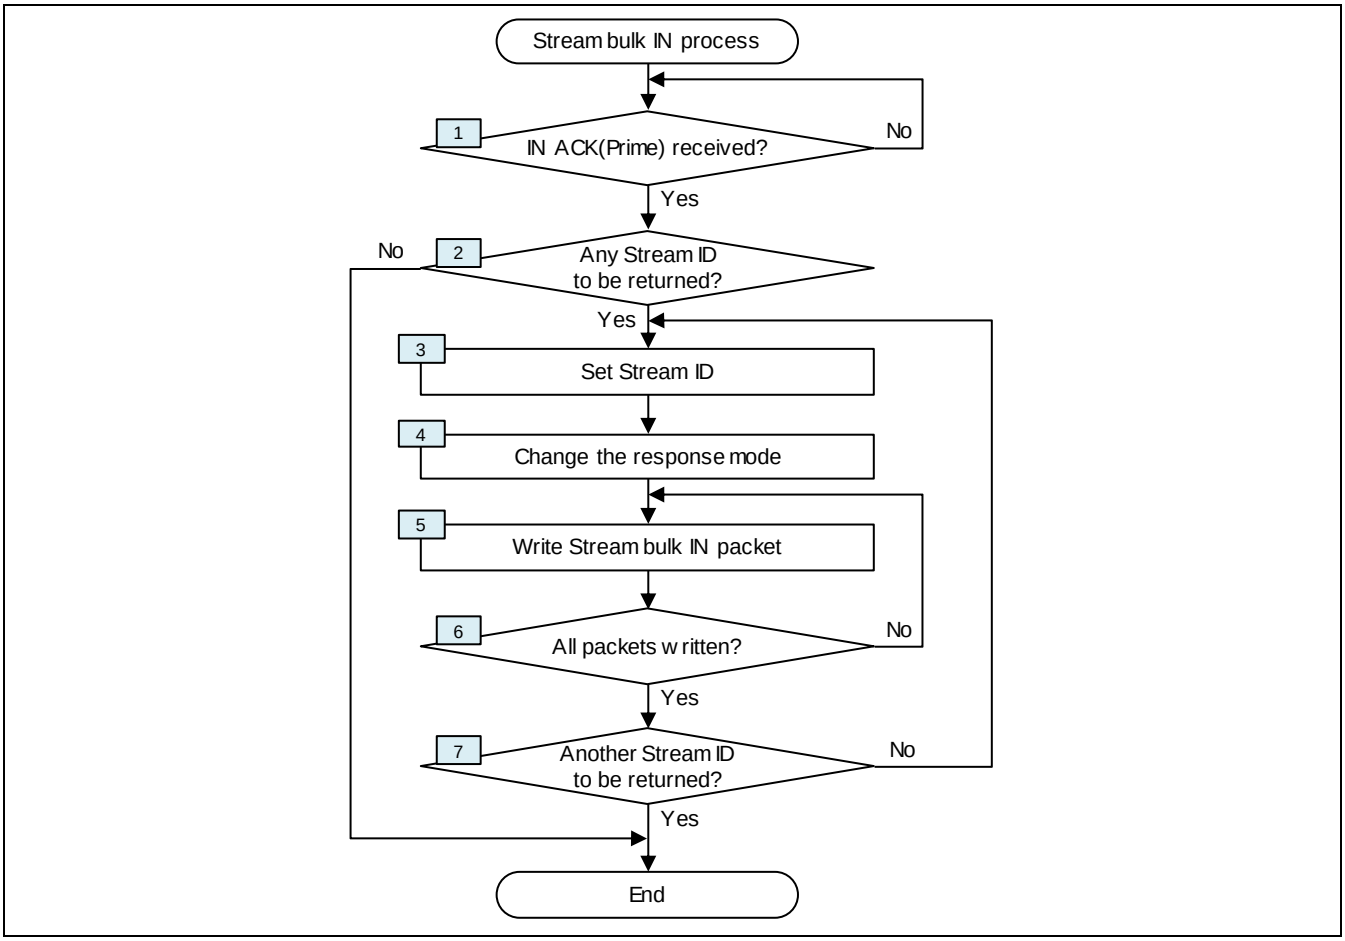

Figure 63.49 Basic Stream bulk IN process flow

(1) Is IN ACK(Prime) received?
IN ACK(Prime) is used to inform device that one or more streams are added to the IN pipe and transfer for it will be started. In case Stream Bulk IN pipe receives IN ACK(Prime), it always responds with NRDY(Prime). Receiving IN ACK(Prime) means the pipe transits to Prime Pipe state of Stream Bulk state machine, and sending NRDY(Prime) means it goes back to Idle state.
PERIPHERAL PORTION automatically changes the setting of Pn_CON.Pn_RES[1:0] of the IN pipe to return NRDY (= B'00) and sends NRDY(Prime) to host.
The reception of IN ACK(Prime) is notified on the assertion of Pn_INT_STA.Pn_PRIME_STA. An interrupt due to it is asserted if enabled.

- Interrupt due to Pn_INT_STA.Pn_PRIME_STA is asserted, if enabled.
- Check that Pn_INT_STA.Pn_PRIME_STA == 1

After the confirmation above, clear Pn_INT_STA.Pn_PRIME_STA.

- Pn_INT_STA.Pn_PRIME_STA = 1 (Clearing the event that IN ACK(Prime) is received)

Then, the IN pipe is required to prepare to transfer Stream Bulk IN data.

(2) Is there any Stream ID to be returned?
The data returned from Stream bulk IN pipe should be tagged by Stream ID. The ID is notified in the command from host in advance. In UASP, CIU (Command IU) is sent to Command pipe and the command ID in CIU is used as Stream ID.
If device has received multiple commands, it should decide which command is processed first. In UASP, the operation for Stream is closely related to NCQ (native command queuing) of storage. Stream bulk IN pipe returns data in the order the storage returns.
If there is any Stream ID to be returned, proceed to (3).

(3) Set Stream ID
Set Stream ID of data which is to be returned next to Pn_STREAM.Pn_STREAM_C[15:0].

- Pn_STREAM.Pn_STREAM_C[15:0] = CStream (The curren stream ID)

(4) Change the response mode of Stream bulk IN pipe
As the IN pipe returned NRDY at (1), so it is in the flow control state. The response mode of the IN pipe was changed to “forced NRDY or NAK response” (= B'00).
Change the response mode of the IN pipe to normal response mode.

- Pn_CON.Pn_RES_WEN = 1
- pn_CON.Pn_RES[1:0] = B'01 (Normal response)

(5) Write Stream bulk IN packet
Write Stream bulk IN packet to be transmitted to the buffer. This step is same as that for normal bulk IN.
Stream bulk IN data is written in a unit of packet and the buffer can’t accept data across the max packet size defined in PIPE_RAMMAP.Pn_MPKT[10:0].
It is also required to see whether there is available space in the buffer or not on Pn_INT_STA.Pn_BFRDY_STA or Pn_STA.Pn_BUFSTS. See section 63.8.5.1 for details.

[writing through Pn_WRITE register]

a-1) Write data through Pn_WRITE register. Since only 32-bit access is allowed to the register, data should be written in a unit of 32-bit. The number of write can be calculated as the number of write = the length divided by 4, round-up is required if there is any residue. The written words are concatenated as one packet.
When the length of packet is not multiples of 32-bit, the last written word has unnecessary bytes.

The last word should be also written as a 32-bit word. The number of valid bytes in the last word is set in Pn_CON.Pn_BYTE_EN[1:0]. Unnecessary bytes in the last word are discarded.

a-2) Set fields as follows to send the packet. Since only 32-bit access is allowed to Pn_CON register, all fields below should be set in one word access.

- Pn_CON.Pn_SEND = 1
- Pn_CON.Pn_BYTE_EN[1:0] = B'xx (The number of valid byes in last written word)
- In case of the last packet of data group, set Pn_CON.Pn_LAST = 1

See section 63.8.7 for details.

When the first packet for the Stream ID (= CStream) is written to buffer, PERIPHERAL PORTION returns ERDY(CStream) to host. This means not only the exit from flow control state but the selection of Stream from device. If host agrees the selection, it sends IN ACK(CStream) to start transfer for the Stream ID.

(6) Are all packets written?
If it is required to send two or more packets, repeat the step of (5).
When the last packet for the Stream ID is written, make sure to indicate that on Pn_CON.Pn_LAST (in case data is written through pn_WRITE register), Lst bit in PRD table (with AXI-IF).

(7) Is there another Stream ID to be returned?
When the last packet written at (6) is sent to host, EOB (end of burst) bit in it is set to 1 so that it shows the packet is the last one in the burst. Host will send ACK(NumP = 0) as the response to the packet with EOB = 1. This means the IN pipe enters flow control state again.
If there is another Stream ID to be returned, repeat the steps from (2) to (6).
Note that PERIPHERAL PORTION might set EOB = 1 in the packet which is not the last one for the Stream ID (= CStream) in case that the preparation of data is delayed and there is no packet in buffer to be sent next to the current packet. In that case, actually EOB is set to 1 in the packet and the IN pipe is considered as being in the flow control state, but no additional operation is required by the softrware. When the next packet is written in buffer, the IN pipe sends ERDY(CStream) automatically. This means not only the exit from the flow control state but the selection of CStream again. The IN transfer for CStream will be started.

Note: When the information of a certain PIPE is read from or write to PIPEn registers, PIPE_COM.PIPE_NUM[4:0] should have the index of the PIPE.

Note: It is possible for host to send ACK (Stream x) and initiates the selection of the Stream. But, basically, to decrease the size of buffer and increase the performance of device, it is desirable that device decides what Stream is processed next seeing its status and initiates the selection of stream. Beside, device can’t send data related to the Stream ID which is not prepared yet. Therefore, PERIPHERAL PORTION responds with NRDY if Stream x doesn’t equal to the Stream ID in Pn_STREAM.Pn_STREAM_C[15:0]. PERIPHERAL PORTION asserts Pn_INT_STA.Pn_STRMX_STA in case Stream ID in the received packet is not same as that in Pn_STREAM.Pn_STREAM_C[15:0], Prime nor NoStream. In that case, the Stream ID requested in the received packet is shown in Pn_NRDYSTRM register.
It is possible to give priority to the Stream ID requested from host by checking Pn_NRDYSTRM register, but it is assumed here that device requests another Stream ID which it decided to process.
Especially, READ READY IU and WRITE READY IU are defined to show which stream (command) is processed next from device in UASP. ERDY(Stream) is used in Super Speed Stream Bulk of UASP just as the substitution of them. Therefore the device initiates the selection of stream in this flow.

Note: From the definition in USB3.0 specification, device which selects the Stream by returning ERDY (Stream) may receive ACK (No Stream) from host. ACK (No Stream) means the rejection from host for proposed Stream ID in ERDY. In such case, device should consider the Stream as “Not Ready”, and may select another Stream.
It depends on the application whether No Stream is really used or not.

(3) Basic Stream Bulk OUT process

The basic process of Stream bulk OUT is described here.
Stream bulk OUT pipe should have PIPE_MOD.Pn_STREAM = 1 as noted in the first part of section 63.8.5.

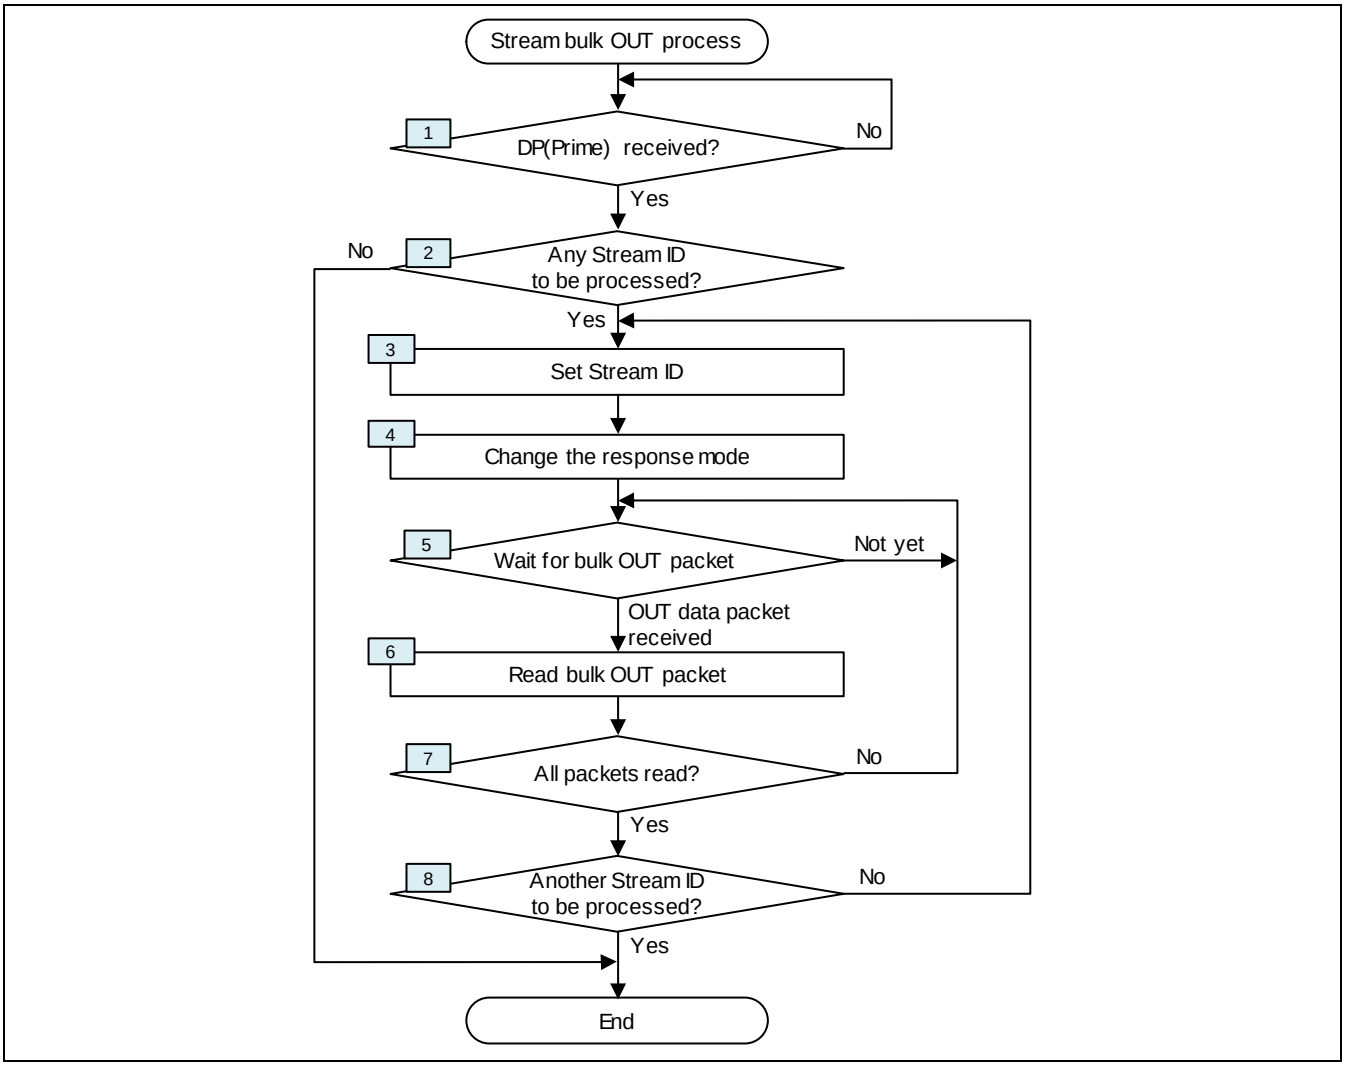

Figure 63.50 Basic Stream bulk OUT process flow

(1) Is DP(Prime) received?
DP(Prime) is used to inform device that one or more streams are added to the OUT pipe and transfer for it will be started. In case Stream Bulk OUT pipe receives DP(Prime), it always responds with NRDY(Prime). Receiving DP(Prime) means the pipe is requested to enter Prime Pipe state of Stream Bulk state machine, and sending NRDY(Prime) means it goes back to Idle state.
PERIPHERAL PORTION automatically changes the setting of Pn_CON.Pn_RES[1:0] of the OUT pipe to return NRDY (= B'00) and sends NRDY(Prime) to host.
The reception of DP(Prime) is notified on the assertion of Pn_INT_STA.Pn_PRIME_STA. An interrupt due to it is asserted if enabled.

- Interrupt due to Pn_INT_STA.Pn_PRIME_STA is asserted, if enabled.
- Check that Pn_INT_STA.Pn_PRIME_STA == 1

After the confirmation above, clear Pn_INT_STA.Pn_PRIME_STA.
- Pn_INT_STA.Pn_PRIME_STA = 1 (Clearing the event that DP (Prime) is received)
Then, the OUT pipe is required to prepare to transfer Stream Bulk OUT data.

(2) Is there any Stream ID to be processed
The data received at Stream bulk OUT pipe should be tagged by Stream ID. The ID is notified in the command from host in advance. In UASP, CIU (Command IU) is sent to Command pipe and the command ID in CIU is used as Stream ID.
If device has received multiple commands, it should decide which command is processed. In UASP, the operation for Stream is closely related to NCQ (native command queuing) of storage. Stream bulk OUT pipe processes the stream in the order the storage specifies
If there is any Stream ID to be processed, proceed to (3).

(3) Set Stream ID
Set Stream ID of the Stream which is processed next to Pn_STREAM.Pn_STREAM_C[15:0].

- Pn_STREAM.Pn_STREAM_C[15:0] = CStream (The curren stream ID)

(4) Change the response mode of Stream bulk OUT pipe
As the OUT pipe returned NRDY at (1), so it is in the flow control state. The response mode of the OUT pipe was changed to “forced NRDY or NAK response” (=B'00).
Change the response mode of the OUT pipe to normal response mode.

- Pn_CON.Pn_RES_WEN = 1
- pn_CON.Pn_RES[1:0] = B'01 (Normal response)

After the setting above, ERDY (CStream) is sent from the OUT pipe to host. This means not only the exit from flow control state but the selection of Stream from device. If host agrees the selection, it start the transfer for the stream and sends DP (CStream).

(5) Wait for bulk OUT data
When bulk OUT data to the OUT PIPE is received, an interrupt due to Pn_INT_STA.Pn_BFRDY_STA is asserted. In that case, write 1 to Pn_INT_STA.Pn_BFRDY_STA to clear. This step is same as that for normal bulk OUT.

- Interrupt due to Pn_INT_STA.Pn_BFRDY_STA asserted
- Check pn_INT_STA.Pn_BFRDY_STA == 1 or not.
- Pn_INT_STA.Pn_BFRDY_STA = 1 (Clearing the event that OUT data is received at the PIPE)

When receiving OUT data packet, Pn_STA.Pn_BUFSTS is also asserted. The meaning of the bit is bulk OUT data packet is ready to be read from Pn_READ register. The software can poll Pn_STA.Pn_BUFSTS to know that OUT data packet has been received for the software as well.

(6) Read bulk OUT packet
Read bulk OUT packet from the buffer. Bulk OUT data is read in a unit of packet and the buffer can’t be read across the max packet size defined in PIPE_RAMMAP.Pn_MPKT[10:0]. This step is same as that for normal bulk OUT.

a-1) Read Pn_LNG.Pn_LENGTH[15:0] in order to know the length of received data
a-2) Read received packet through Pn_READ register.
Pn_READ register should be read in a unit of 32-bit. Pn_READ register is updated and the next 32-bit word of received data is shown in Pn_READ register every time it is read. The length of received data is known at a-1) and the number of read from Pn_READ register can be calculated from the length. The number of read = the length divided by 4, round-up is required if there is any residue. If there is residue, it also means the last 32-bit word read has one or more unnecessary bytes. In that case, discard unnecessary bytes.

See section 63.8.7 for details.

(7) Are all packets read?
If the bulk OUT PIPE has more packets to be read, repeat the steps from (5) to (6).
Pn_INT_STA.Pn_LSTTR_STA is asserted when the last packet (short packet or packet with PP = 0) is received.

(8) Is there another Stream ID to be processed?
When the last packet is received at (7), PERIPHERAL PORTION returns ACK with NumP = 0. This means the OUT pipe enters flow control state again.
If there is another Stream ID to be returned, repeat the steps from (2) to (7). Note that Pn_CON.Pn_RES[1:0] was changed to B'00 (NAK/NRDY response) when the PIPE received the last packet and returned ACK with NumP = 0. Pn_CON.Pn_RES[1:0] is changed to B'01 (normal response) at (4) again, and the PIPE transmits ERDY to resume the transfer.
It is also noted that PERIPHERAL PORTION might return ACK with NumP = 0 for the packet which is not the last one for the Stream ID (= CStream) in case that there is no available space in the buffer for the PIPE currently. In that case, actually NumP is set to 0 in the ACK packet and the OUT pipe is considered as being in the flow control state, but no additional operation is required for the software. When the received packet is transferred to system memory and PERIPHERAL PORTION gets available space in the buffer, the OUT pipe sends ERDY(CStream) automatically. This means not only the exit from the flow control state but the selection of CStream again. The OUT transfer for CStream will be started.

Note: When the information of a certain PIPE is read from or write to PIPEn registers, PIPE_COM.PIPE_NUM[4:0] should have the index of the PIPE.

Note: It is possible for host to send ACK (Stream x) and initiates the selection of the Stream. But, basically, to decrease the size of buffer and increase the performance of device, it is desirable that device decides what Stream is processed first seeing its status and initiates the selection of stream. Beside, device can’t send for Stream ID which is not available yet. Therefore, PERIPHERAL PORTION responds with NRDY if Stream x doesn’t equal to the Stream ID in Pn_STREAM.Pn_STREAM_C[15:0]. PERIPHERAL PORTION asserts Pn_INT_STA.Pn_STRMX_STA in case Stream ID in the received packet doesn’t equal to that in Pn_STREAM.Pn_STREAM_C[15:0], Prime nor NoStream. In that case, the Stream ID contained in the received packet is shown in Pn_NRDYSTRM register.
It is possible to give priority to the Stream ID requested from host by checking Pn_NRDYSTRM register, but it is assumed here that device requests another Stream ID it decided to process.
Especially, READ READY IU and WRITE READY IU are defined to select which stream (command) is processed next from device in UASP. ERDY(Stream) used in super speed Stream Bulk of UASP is alternative of them. So the device initiates the selection of stream in UASP.

Note: From the definition in USB3.0 specification, device selects the Stream by returning ERDY (Stream) may receive ACK (No Stream) from host. ACK (No Stream) means the rejection from host for proposed Stream ID in ERDY. In such case, device should consider the Stream as “Not Ready”, and may select another Stream.
It depends on the application whether No Stream is really used or not.

63.8.5.4 SuperSpeed UASP Non-Data Transfer

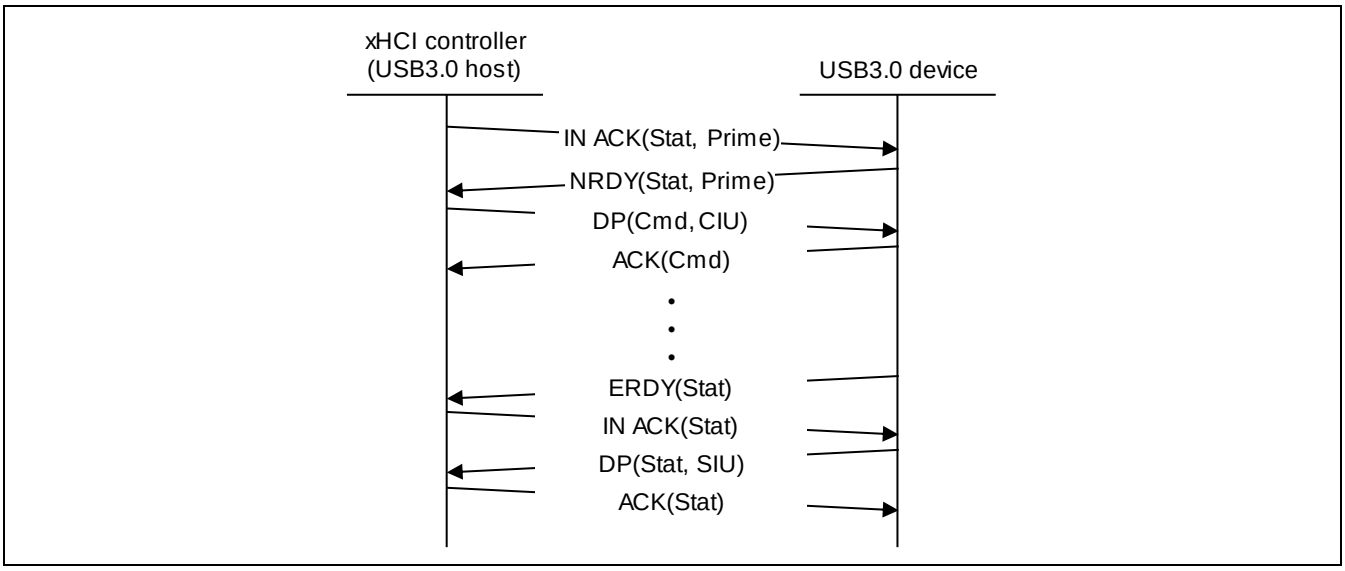

Figure 63.51 Example SuperSpeed UASP Non-Data Transfer

Figure 63.51 shows the part between USB3.0 host and USB3.0 device of Figure 6 in UASP specification Rev.1.0. The example is called as “Non-Data Transfer” but the status PIPE is working as the Stream bulk IN PIPE.
In this case, IN ACK(Stat, Prime) comes to the status PIPE first, then the status PIPE returns NRDY(Stat, Prime).
The some operation is requested on DP(Cmd, CIU) to the command PIPE. The command ID in CIU is used as Stream ID later. When the operation is completed, SIU as the result of the operation is returned from the status PIPE.
Pn_CON.Pn_RES[1:0] is set to B'01 (normal response) at (4) of section 63.8.5.3 (2). When SIU is written to buffer of the status PIPE and it is ready to be transmitted, ERDY(Stat) is sent in order to resume the transfer. IN ACK(Stat) comes to the status PIPE, it sends DP(Stat, SIU) and DP(Stat, SIU) is acknowledged by ACK(Stat).

63.8.5.5 SuperSpeed UASP Data-IN transfer

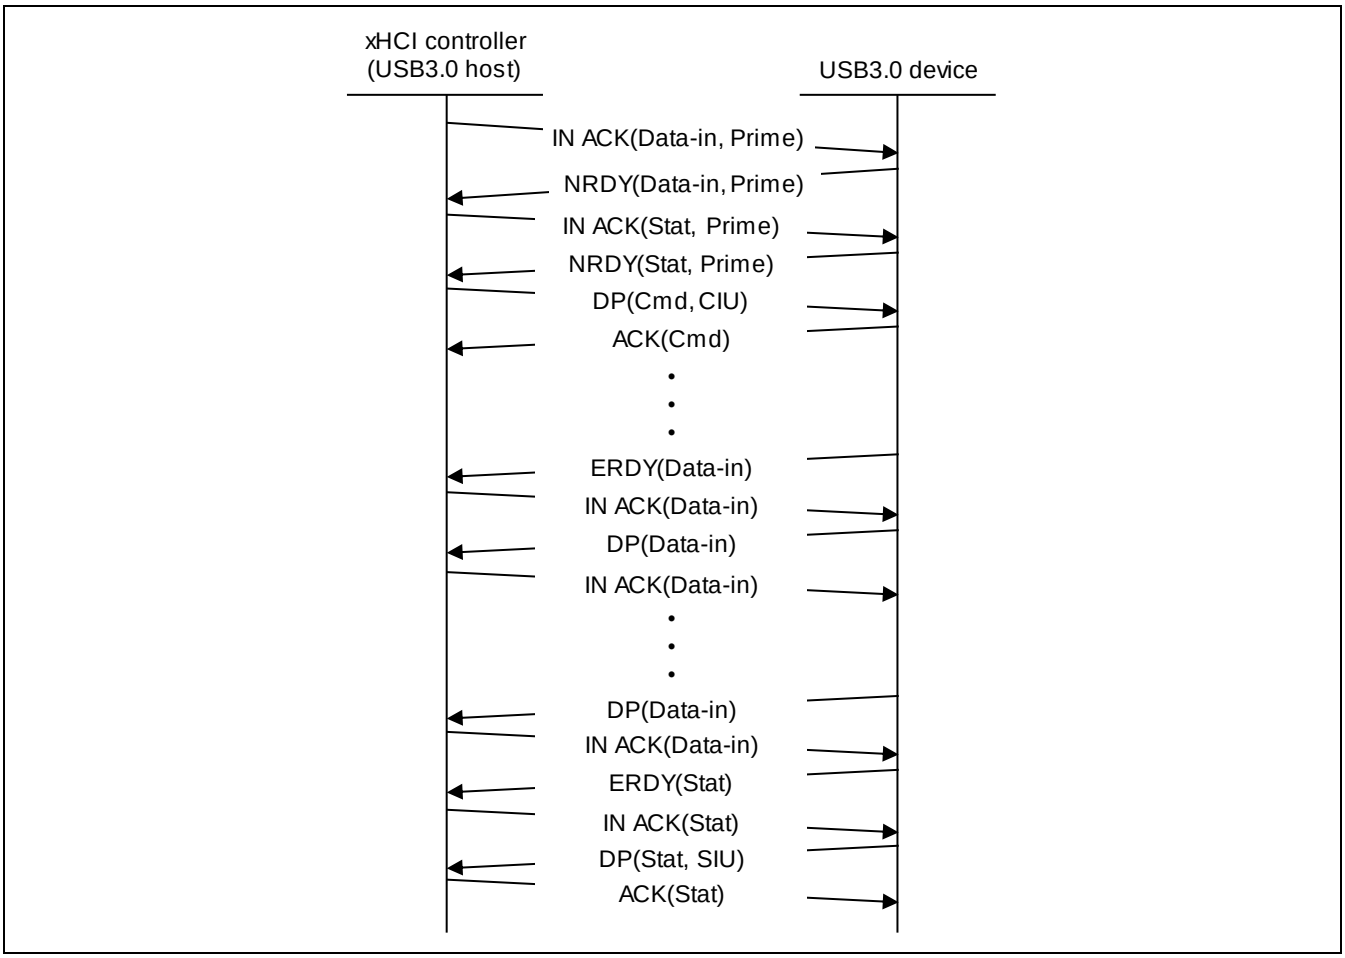

Figure 63.52 Example SuperSpeed UASP Data-IN transfer

Figure 63.52 shows the part between USB3.0 host and USB3.0 device of Figure 7 in UASP specification Rev.1.0.

In this case, the Data-in PIPE and the status PIPE are working as Stream bulk IN PIPE.

To set each PIPE in Prime Pipe state, IN ACK (Data-in, Prime) and IN ACK (Stat, Prime) comes. Both PIPEs return NRDY (Prime) to them and go back to Idle state.

The bulk IN operation is requested on DP (Cmd, CIU) to the command PIPE. The command ID in CIU is used as Stream ID later.

If Pn_CON.Pn_RES[1:0] of the Data-in PIPE is already set to B'01 (normal response), the Data-in PIPE sends ERDY (Data-in) when IN data becomes ready to be transmitted from it. The data transfer from the Data-in PIPE is started by receiving IN ACK (Data-in).
All data transfers from Data-in PIPE are completed, SIU is made as the result of the operation.
If Pn_CON.Pn_RES[1:0] of the status PIPE is already set to B'01 (normal response), the status PIPE sends ERDY (Stat) when SIU is written to buffer and is ready to be transmitted from it. The SIU is sent as DP (Stat, SIU) when IN ACK (Stat) comes.

63.8.5.6 SuperSpeed UASP Data-OUT transfer

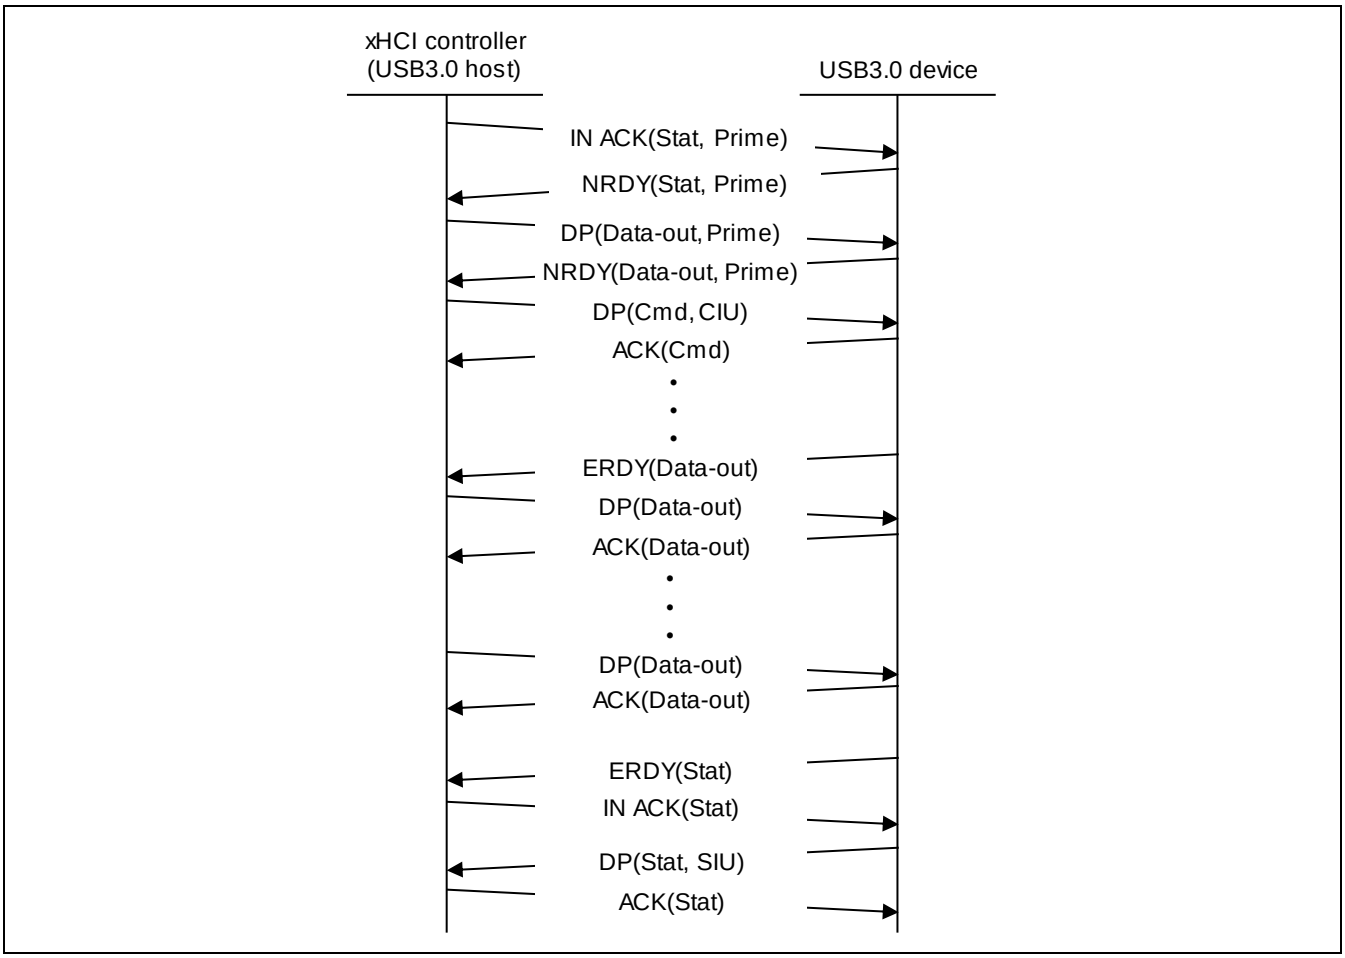

Figure 63.53 Example SuperSpeed UASP Data-OUT transfer

Figure 63.53 shows the part between USB3.0 host and USB3.0 device of Figure 8 in UASP specification Rev.1.0.

In this case, the status PIPE is working as Stream bulk IN PIPE, and the Data-OUT PIPE is working as Stream bulk OUT PIPE.
To set each PIPE in Prime Pipe state, IN ACK (Stat, Prime) and DP (Data-out, Prime) comes. Both PIPEs return NRDY(Prime) to them and go back to Idle state.

The bulk IN operation is requested on DP (Cmd, CIU) to the command PIPE. The command ID in CIU is used as Stream ID later.

When Pn_CON.Pn_RES[1:0] of the Data-out PIPE is changed from B'00 to B'01 (normal response, note that Pn_CON.Pn_RES[1:0] is set to B'00 once for Stream bulk PIPE when it receives DP (Prime) or ACK (Prime)), the Data-out PIPE sends ERDY (Data-out) if it has available space in buffer. The data transfer to the Data-out PIPE is started.
All data tnrasfers to Data-out PIPE are completed, SIU is made as the result of the operation.
If Pn_CON.Pn_RES[1:0] of the status PIPE is already set to B'01 (normal response), the status PIPE sends ERDY (Stat) when SIU is written to buffer and is ready to be transmitted from it. The SIU is sent as DP (Stat, SIU) when IN ACK (Stat) comes.

63.8.6 Interrupt Transfer

Interrupt Transfer process is described here.

PIPEs other than PIPE0 (PIPE0 is used only for control transfer) can be used for interrupt transfer. The settings for interrupt transfer are shown below.

- PIPE_COM.PIPE_NUM[4:0] = the index of PIPE used for the current interrupt transfer
- PIPE_MOD.Pn_EPNUM[3:0] = the endpoint number of the PIPE
- PIPE_MOD.Pn_TYPE[1:0] = B'11 (interrupt transfer)
- PIPE_MOD.DIR = the direction of transfer
- PIPE_RAMMAP.Pn_BASEAD[13:0] = the base address of buffer assigned for the PIPE
- PIPE_RAMMAP.Pn_RAMIF[1:0] = the index of RAM interface of the PIPE
- PIPE_RAMMAP.Pn_MPKT[10:0] = the max packet size of the PIPE
- PIPE_RAMMAP.Pn_RAMAREA = the size of RAM area assigned for the PIPE
- Pn_CON.Pn_DATAIF_EN = whether Data Interface of the controller is used or not.
- Pn_CON.Pn_EN = 1 (the PIPE is enabled)

These settings are done just after Set Configuration is completed and the device enters configured state. But if the device has only single configuration for each PIPE, these settings can be done after the device is turned on.

63.8.6.1 Interrupt IN Transfer

In this subsection it is assumed that interrupt transfer is used to return small data periodically, so the process to write through Pn_WRITE register is described here.

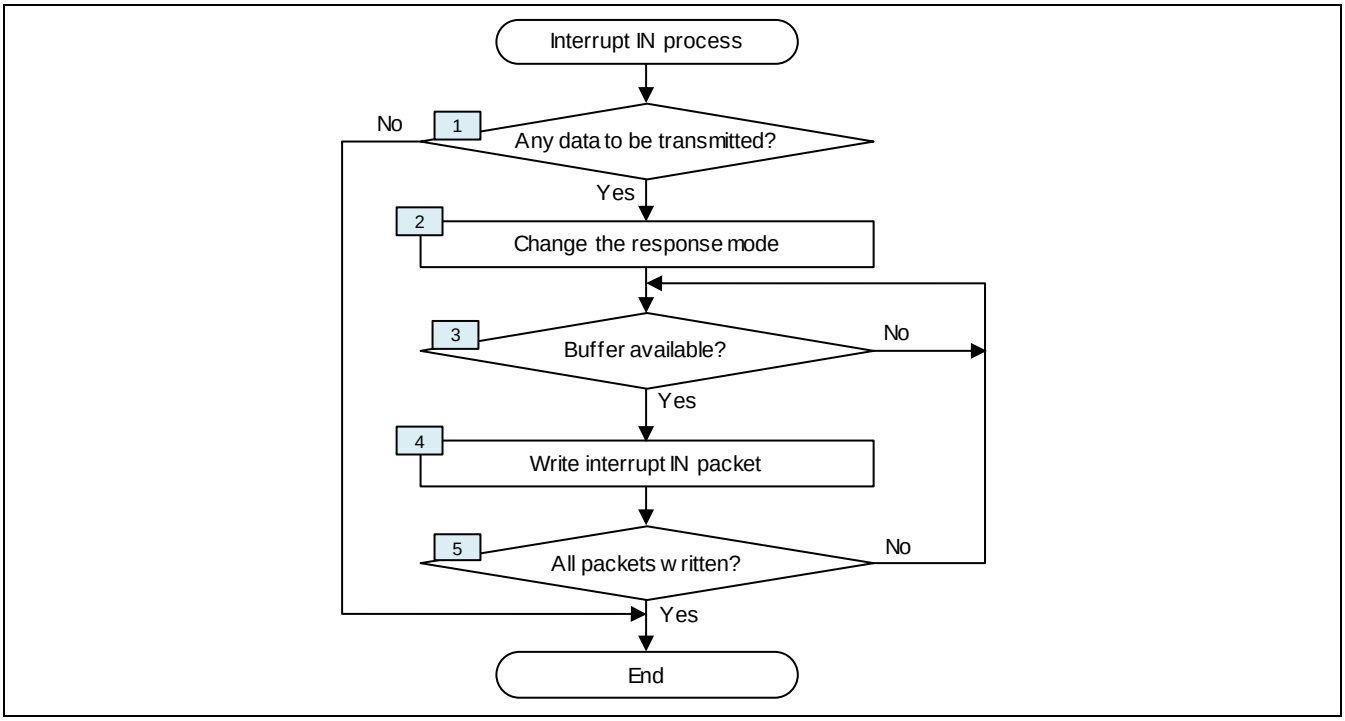

Figure 63.54 Interrupt IN process flow

(1) Is there any data to be transmitted?
Check if there is any data to be transmitted from interrupt IN PIPE.
If not, set Pn_CON.Pn_RES[1:0] = B'00 so that the PIPE returns NRDY or NAK for IN request. When Pn_CON.Pn_RES[1:0] already has the value, leave it as it is.

- Pn_CON.Pn_RES_WEN = 1
- Pn_CON.Pn_RES[1:0] = B'00 (NRDY/NAK response)

If there is, proceed to (2).

(2) Change the response mode of the interrupt IN PIPE
As it is confirmed that there is data to be transmitted at (1), change the response mode of the interrupt IN PIPE to enable the transmission of a packet.

- Pn_CON.Pn_RES_WEN = 1
- Pn_CON.Pn_RES[1:0] = B'01 (normal response)

(3) Check if buffer is available
Check if buffer for the interrupt IN PIPE is available before writing interrupt IN packet. Pn_STA.Pn_BUFSTS shows if the buffer is available or not.

- Check whether Pn_STA.Pn_BUFSTS == 1 or not

If Pn_STA.Pn_BUFSTS is 0 and there is no available space in the buffer currently, Wait until Pn_STA.Pn_BUFSTS becomes 1 or an interrupt due to Pn_INT_STA.Pn_BFRDY_STA is asserted. When IN is

selected as the direction of the interrupt PIPE (that is, Pn_MOD.Pn_DIR==1), Pn_INT_STA.Pn_BFRDY_STA is asserted when the buffer for the PIPE becomes available for new write data.
Therefore, the software can know the timing the buffer of the PIPE prepares new available space by polling Pn_STA.Pn_BUFSTS or an interrupt due to Pn_INT_STA.Pn_BFRDY_STA.

(4) Write interrupt IN packet
Write interrupt IN packet to be transmitted to the buffer. Interrupt IN data is written in a unit of packet and the buffer can't accept data across the max packet size defined in PIPE_RAMMAP.Pn_MPKT[10:0].

[writing through Pn_WRITE register]

a-1) Write data through Pn_WRITE register. Since only 32-bit access is allowed to the register, data should be written in a unit of 32-bit. The number of write can be calculated as the number of write = the length divided by 4, round-up is required if there is any residue. The written words are concatenated as one packet.
When the length of packet is not multiples of 32-bit, the last written word has unnecessary bytes.
The last word should be also written as a 32-bit word. The number of valid bytes in the last word is set in Pn_CON.Pn_BYTE_EN[1:0]. Unnecessary bytes in the last word are discarded.

a-2) Set fields as follows to send the packet. Since only 32-bit access is allowed to Pn_CON register, all fields below should be set in one word access.
- Pn_CON.Pn_SEND = 1
- Pn_CON.Pn_BYTE_EN[1:0] = B'xx (The number of valid byes in last written word)
- In case of the last packet of data group, set Pn_CON.Pn_LAST = 1

(5) Are all packets written?
If it is required to send two or more packets, repeat the steps from (3) to (4).

Note: When the information of a certain PIPE is read from or write to PIPEn registers, PIPE_COM.PIPE_NUM[4:0] should have the index of the PIPE.

63.8.7 DMA Transfer

63.8.7.1 Settings for DMA transfer

Data transfer using DMA in Peripheral portion is described here.

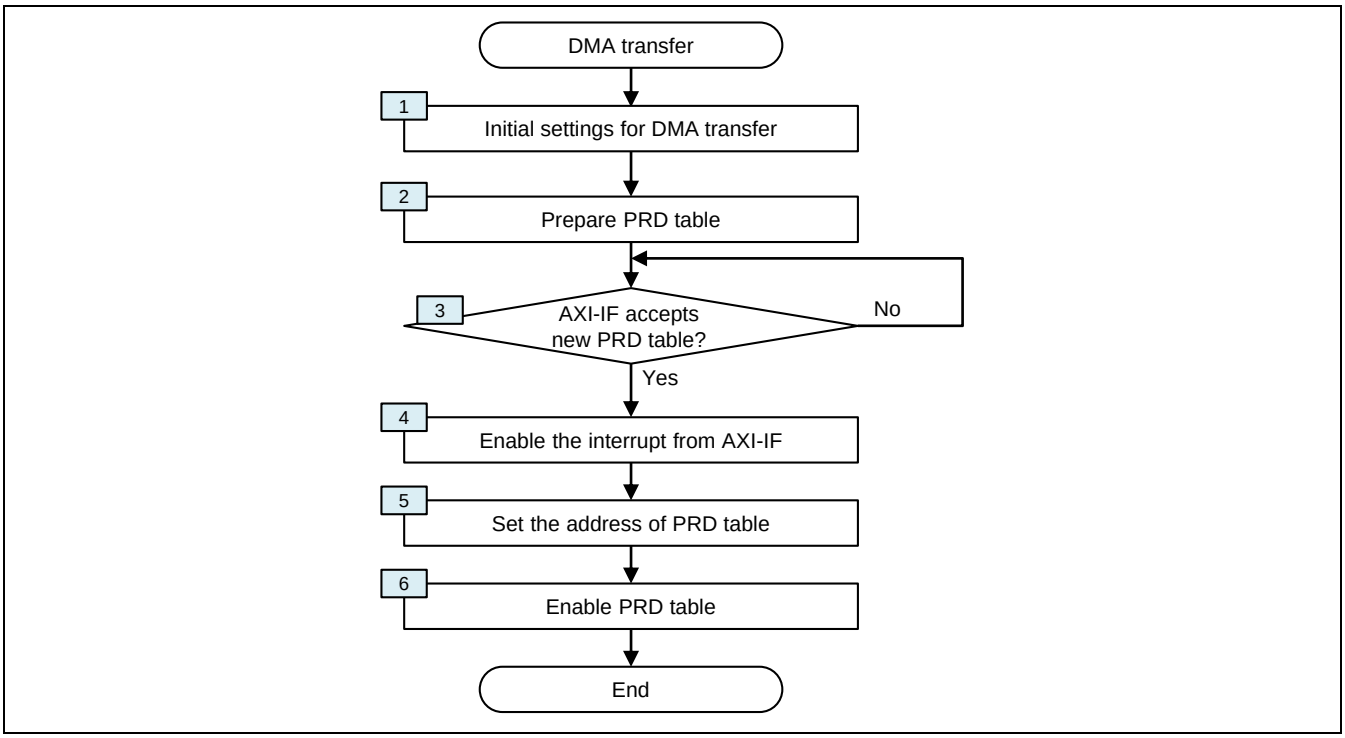

Figure 63.55 Transfer Setting Flow

(1) Initial settings for DMA transfer
Change the response mode of the PIPE to enable data transfer.
Since USB3.0 Controller uses EPC_D_Pn_DATAEN[30:1] to see if the PIPE is ready for the transfer or not, Pn_CON.Pn_DATAIF_EN should be enabled.

- Pn_CON.Pn_RES_WEN = 1
- Pn_CON.Pn_RES[1:0] = B'00 (NRDY/NAK response)
- Pn_CON.Pn_DATAIF_EN = 1

(2) Prepare PRD table
Prepare PRD table in system memory following the format defined in section 63.7.8.

(3) Can Peripheral portion accept new PRD table?
Peripheral portion handles up to 4 PRD tables concurrently. If the number of PRD tables running in Peripheral portion is less than 4, new PRD table can be set for Peripheral portion. The “PRD table running” means here that PRD table is assigned to one of DMA_Ch0_PRD_ADRx register and DMA_Ch0_CONx.PRD_ENx is enabled for it.
If there is any DMA_Ch0_CONx in which PRD_ENx is disabled (= 0), new transfer can be assigned to it.
If there is no DMA_Ch0_CONx with PRD_ENx = 0, wait for the completion of one of PRD tables running.

(4) Enable interrupt from AXI-IF
Enable the assertion of an interrupt from Peripheral portion if it is disabled, and clear the interrupt status registers. But the status register might have the interrupt status of completed transfer, and it is also possible that the concurrent transfer is finished and set its status in registers just when the software clears them for new transfer. Make sure not to clear statuses of other PIPE or other DMA_Ch0_CONx when clearing the status of PIPE and

DMA_Ch0_CONx to be used. The bits in status register have “write 1 to clear” function, which means it is not cleared when writing 0. Write 1 just to the bit to be cleared.

- DMA_INT_STA.Pxx_PRDEND_STA = 1 (The status of the PIPE to be used is cleared)
- AXI_INT_STA.PRDENx_CLR_STA = 1 (The status of DMA_Ch0_CONx to be used is cleared)
- AXI_INT_STA.PRDERR0_x_STA = 1 (The error status of DMA_Ch0_CONx to be used is cleared)

After clearing the interrupt status, enable the interrupt for the PIPE and DMA_Ch0_CONx to be used.
- AXI_INT_ENA.DMA_INT_ENA = 1
- AXI_INT_ENA.PRDENx_CLR_ENA = 1
- AXI_INT_ENA.PRDERR0_x_STA = 1

(5) Set the address of PRD table
Set the address of PRD table generated at (2) in DMA_Ch0_PRD_ADRx register. If the transfer consists of some PRD tables, set the address of the first PRD table.

- DMA_Ch0_PRD_ADRx = the address of PRD table

(6) Enable PRD table
Set the information of PRD table to DMA_Ch0_CONx register, and enable it on DMA_Ch0_PRD_CONx.PRD_ENx. The fields below can be set in one word access.

- DMA_Ch0_PRD_CONx.PIPE_DIRx = the direction of the PIPE
- DMA_Ch0_PRD_CONx.PIPE_NOx = the index of the PIPE
- DMA_Ch0_PRD_CONx.PRD_ENx = 1

In case the transfer of new PRD table is expected to wait for the completion of one of the concurrent transfer and be executed after it, use DMA_Ch0_PRD_CONx.EXTPRD_ENx. See section 63.7.5 for details of DMA_Ch0_PRD_CONx.EXTPRD_ENx.

- DMA_Ch0_PRD_CONx.EXTPRD_NOx = the index of DMA_Ch0_PRD_CONy which completion of transfer new PRD table is waiting for.
- DMA_Ch0_PRD_CONx.EXTPRD_ENx = 1 (the use of EXTPRD_EN is enabled)

Note that EXTPRD_ENx is not cleared if PRD_ENy of DMA_Ch0_PRD_CONy which completion is waited for is already 0. That is, EXTPRD_ENx can’t be used for DMA_Ch0_PRD_CONy which has already cleared its enable bit (PRD_ENy). Make sure that PRD_ENy is still 1 and the related transfer is still being executed when EXTPRD_EN is associated. When you find PRD_ENy is already cleared to 0, don’t use EXTPRD_EN. In that case, there is no need to wait for the completion of DMA_Ch0_PRD_CONy since it has already been finished.

63.8.8 Power Management

63.8.8.1 Suspend in USB3.0 (transition of state from U0 to U3)

The process to transit to U3 state of LTSSM in USB3.0 specification is described here.

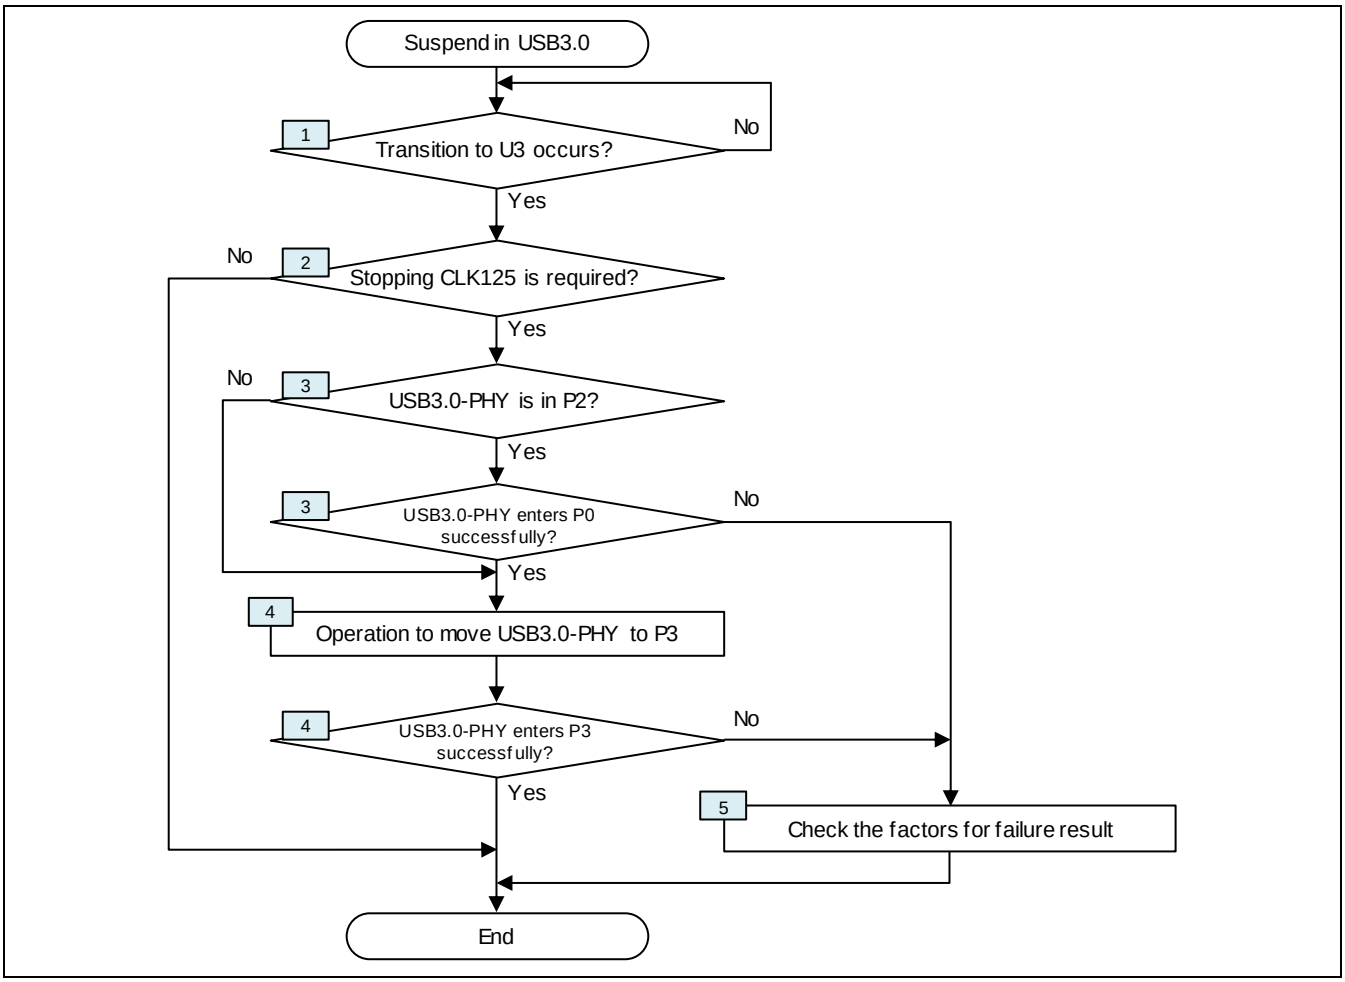

Figure 63.56 Suspend in USB3.0 flow

(1) Transition to U3 is informed

It is defined that only a downstream port (host or hub) can initiated U3 entry and an upstream port can't reject it in USB3.0 specification. The downstream port initiates U3 entry by sending LGO_U3.

When the controller receives LGO_U3, it accepts it and executes the transition to U3 inside. At this time, USB_INT_STA_1.B3_LNKCNG_STA is asserted since the change of the link status occurs. The current status of LTSSM can be known by seeing PORTSC.PLS[3:0].

Check whether the transition to U3 is requested or not when LTSSM is in U0 state and USB_INT_STA_1.B3_LNKCNG_STA is asserted. If LTSSM has changed to U3 state, the transition to U3 has been requested from downstream port.

- Interrupt due to USB_INT_STA_1.B3_LNKCNG_STA is generated
- Check whether PORTSC.PLS[3:0] shows U3 or not.

Note that there is another possibility that disconnection or error occurs as the factor of the change of the link status. In such case, follow the flows noted in other sections.

After confirming the factor of the change, clear USB_INT_STA_1.B3_LNKCNG_STA. Then, proceed to (2).
- USB_INT_STA_1.B3_LNKCNG_STA = 1 (Clearing the event that the link has changed)

(2) Is stopping USB3.0-PHY clock required?
LTSSM in Peripheral portion has transited to U3 at (1), but USB3.0-PHY is in P0 or P2 state of USB3.0-PHY state since only P0 or P2 can be selected as the setting of USB30_CON.U3_POW_SEL[1:0]. Note the difference between U0/U1/U2/U3 and P0/P1/P2/P3. Ux is the power management states in LTSSM. Px is the power management states for USB3.0-PHY and the upper layer. USB30_CON.U3_POW_SEL[1:0] defines the PHY state in which USB3.0-PHY is placed when the transition to U3 is requested in LTSSM. P3 is defined as the state in which the clock is suspended. The reason why P3 is not selected as the setting of USB30_CON.U3_POW_SEL[1:0] is that it may cause issues if the clock from USB3.0-PHY is stopped suddenly.

If USB3.0-PHY is not required to be placed in P3 when the upper layer is in U3 state, no additional operation is required here. If it is required, proceed to (3).

(3) Is USB3.0-PHY placed in P2?
As noted above, P0 or P2 can be selected as USB3.0-PHY state on USB30_CON.U3_POW_SEL[1:0] when LTSSM of upper layer enters U3. If USB3.0-PHY is in P2 at present and expected to enter P3, it should be move to P0 once before it is operated to enter P3.

- USB30_CON.POW_SEL_WEN = 1
- USB30_CON.POW_SEL[2:0] = B'110 (the transition from P2 to P0 is requested when LTSSM is in U3)

When the transition to P0 requested has been done, an interrupt due to the transition is asserted. Since there is no reason to fail in the transition, so USB3.0-PHY surely enters P0, but confirm the result of the transition.

- Interrupt due to the transition asserted
- Check whether USB_INT_STA_1.B3_PSSUCS_STA is asserted or not. If it is asserted, the transition has been done successfully. Clear it after the confirmation.
- If USB_INT_STA_1.B3_PSSUCS_STA is not asserted, check whether USB_INT_STA_1.B3_PSFAIL_STA is asserted or not. If it is asserted, the presumed factors are explained at (5).

If USB30_CON.U3_POW_SEL[1:0]==B'00 (P0) and USB3.0-PHY is placed in P0 when LTSSM enters U3, this operation is not required.

Hence, USB3.0-PHY is P0 at present.

(4) Operation to move USB3.0-PHY to P3
Set USB30_CON.POWSEL[2:0] to place USB3.0-PHY in P3.

- USB30_CON.POW_SEL_WEN = 1
- USB30_CON.POWSEL[2:0] = B'101 (the transition from P0 to P3 is requested when LTSSM is in U3)

When the transition to P3 requested has been done, an interrupt due to the transition is asserted. Since there is no reason to fail in the transition, so USB3.0-PHY surely enters P3, but confirm the result of the transition.

- Interrupt due to the transition asserted
- Check whether USB_INT_STA_1.B3_PSSUCS_STA is asserted or not. If it is asserted, the transition has been done successfully. Clear it after the confirmation.
- If USB_INT_STA_1.B3_PSSUCS_STA is not asserted, check whether USB_INT_STA_1.B3_PSFAIL_STA is asserted or not. If it is asserted, the presumed factors are explained at (5).

(5) Check the factors for failure result
If case the transition of power state noted here failed, the presumed factors are as follows.
(1) the disconnection has occurred and LTSSM transits to SS.Disabled.
(2) U3Wakeup LFPS from host has come and LTSSM has started the transition to U0.
(3) the warm reset from host has come

See the statuses below to know whether the factors above occur or not.
- USB_INT_STA_1.B3_DISABLE_STA = 1 (if (1) occurred)
- PORTSC.PLS[3:0] = H'0 (if (2) occurred)
- USB_INT_STA_1.B3_WRMRST_STA = 1 (if (3) occurred)

If (1) occurs, see section 63.8.3.3 for the disconnection process.
If (2) occurs, see section 63.8.8.2 for the resume process from U3.
If (3) occurs, see section 63.8.3.4 for the warm reset process.

In case the transition of power state failed but the factors above has not caused it, fatal error might occur in the system.

63.8.8.2 Resume in USB3.0 (from U3 to U0: Initiated by host)

The process for the transition to U0 initiated by host in USB3.0 is described here.

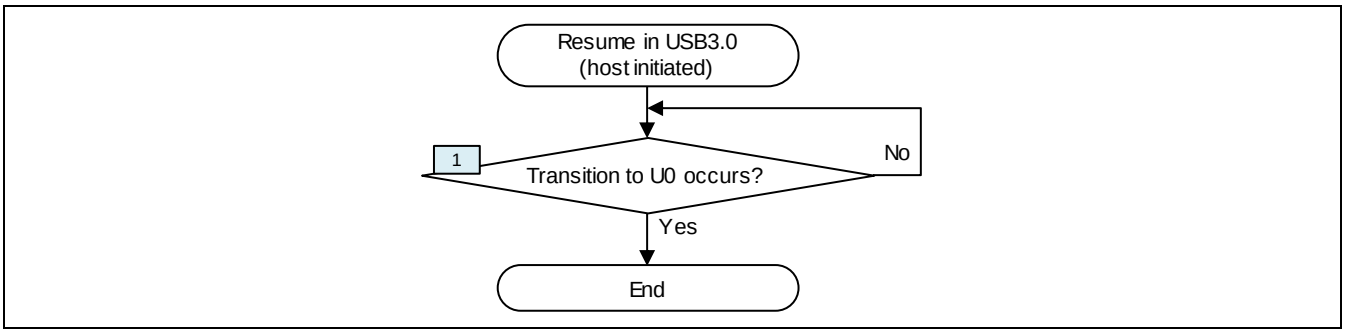

Figure 63.57 Resume in USB3.0 (host initiated) flow

(1) Does the transition to U0 occur?
In case Peripheral portion is in U3 and receives U3Wakeup LFPS from host, it automatically responds to the LFPS and go back to U0. At this time, USB3.0-PHY is moved back to P0 as well.
The event is notified on the assertion of USB_INT_STA_1.B3_LNKCNG_STA. An interrupt due to the bit is asserted if enabled.

- Interrupt due to USB_INT_STA_1.B3_LNKCNG_STA is asserted, if enabled
- Check that USB_INT_STA_1.B3_LNKCNG_STA == 1
- Check that PORTSC.PLS[3:0] shows U0 (= H'0)

After the confirmation above, clear USB_INT_STA_1.B3_LNKCNG_STA.

- USB_INT_STA_1.B3_LNKCNG_STA = 1 (clearing the event of the link change)

If USB3.0-PHY is placed in P3 following the flow in section 63.8.8.1 and the clock from it is stopped in U3, the clock is also resumed as USB3.0-PHY goes back to P0. USB_INT_STA_1.B3_PLLWKUP_STA is asserted in that case. If it is asserted, clear it.

- USB_INT_STA_1.B3_PLLWKUP_STA = 1 (clearing the event of USB3.0 PLL Wakeup)

63.8.8.3 Resume in USB3.0 (from U3 to U0: Initiated by device)

The process for the transition to U0 initiated by device in USB3.0 is described here.

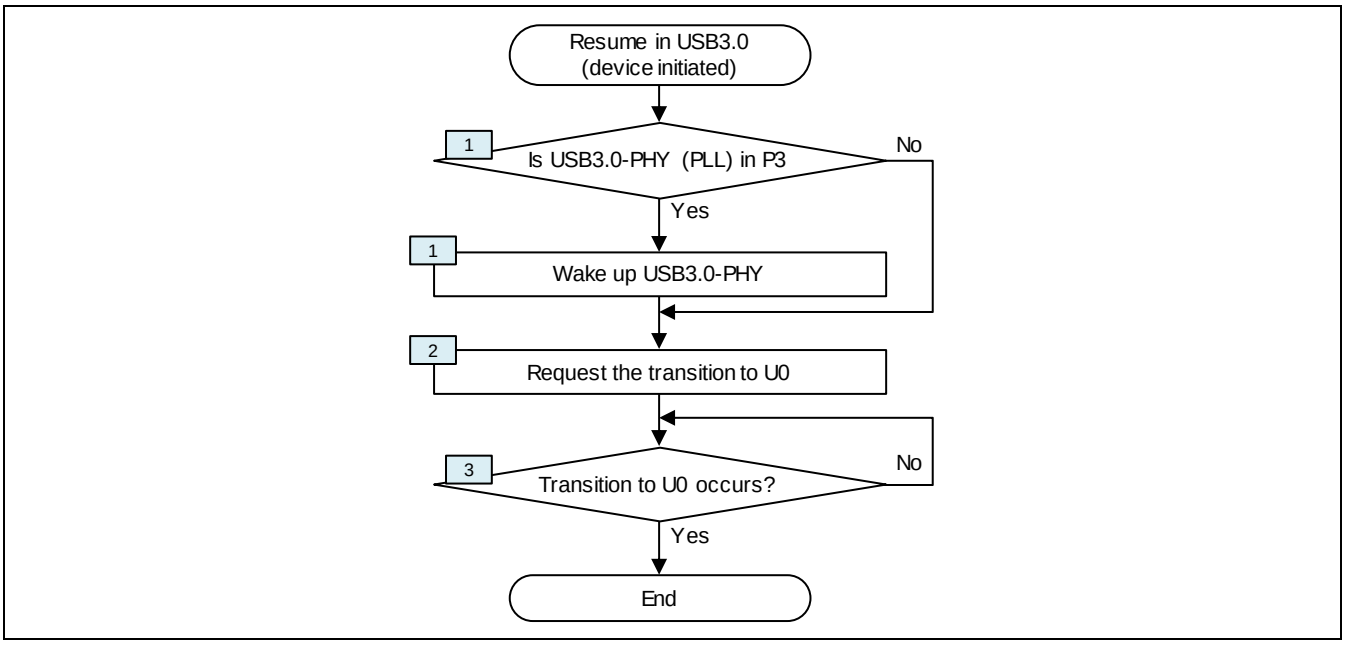

Figure 63.58 Resume in USB3.0 (device initiated) flow

(1) Is USB3.0-PHY in P3?
If USB3.0-PHY is placed in P3 following the flow in section 63.8.8.1 and the clock from it is stopped in U3, it is required to wake up USB3.0-PHY since the clock from USB3.0-PHY should be provided for the operations here. See section 63.8.8.6 for the process of wakeup of USB3.0-PHY.

If USB3.0-PHY is P0 or P2 and the clock from it is being provided, it is not required to wake up USB3.0-PHY.

(2) Request the transition to U0
Request the transition to U0 in LTSSM as follows.

- PORTSC.LWS = 1
- PORTSC.PLS[3:0] = H'0 (U0 state is requested)

(3) Does the transition to U0 occur?
With the request to transit to U0, Peripheral portion asserts U3Wakeup LFPS to host. When host responds to the LFPS and LFPS handshake is established, Peripheral portion has transited to U0.
At that time, USB_INT_STA_1.B3_LNKCNG_STA is asserted and an interrupt due to it is caused if enabled.

- Interrupt due to USB_INT_STA_1.B3_LNKCNG_STA is asserted, if enabled
- Check that USB_INT_STA_1.B3_LNKCNG_STA == 1
- Check that PORTSC.PLS[3:0] shows U0 (= H'0)

After the confirmation above, clear USB_INT_STA_1.B3_LNKCNG_STA.

- USB_INT_STA_1.B3_LNKCNG_STA = 1 (Clearing the event of the link change)

63.8.8.4 Function Suspend

The process for function suspend in USB3.0 is described here.

The function suspend is defined for SuperSpeed device and functions are placed into function suspend on the reception of Set Feature(FUNCTION_SUSPEND). Since function has one or more interfaces, what function is selected to be suspend is recognized by seeing what interface receives the request. If the function has multiple interfaces, the request comes to the first interface of the function.

Note that the specification defines about the function suspend as follows.

— A function may be placed into function suspend independently of other functions within the device.
— A device may be transitioned into device suspend regardless of the function suspend state of any function within the device.
— Function suspend state is retained while in device suspend and throughout the device suspend entry and exit processes.

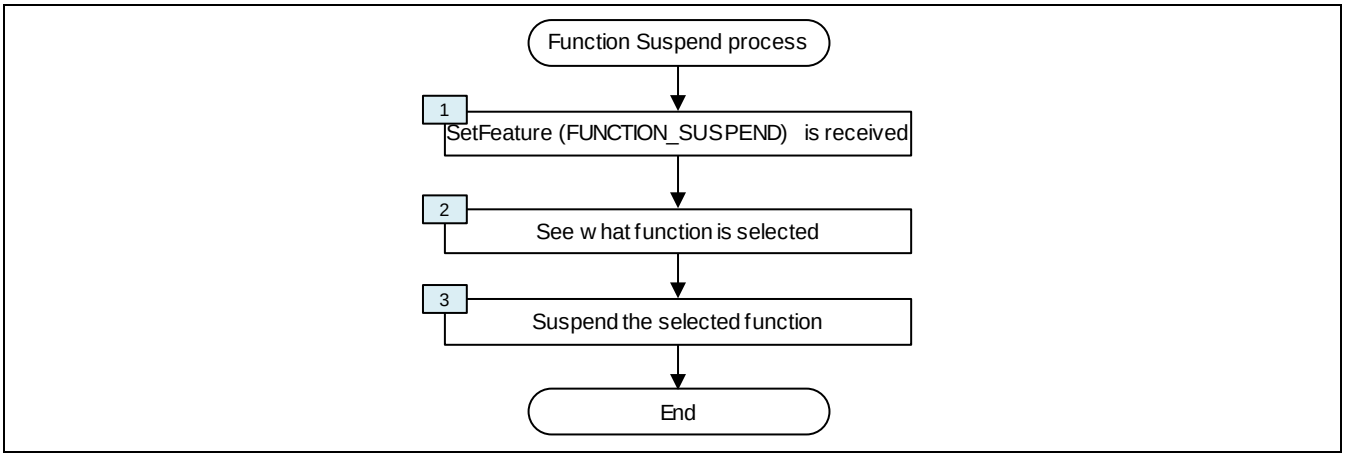

Figure 63.59 Function Suspend process

(1) Set Feature(FUNCTION_SUSPEND) is received
In case Set Feature(FUNCTION_SUSPEND) comes, the function suspend is requested. The function suspend is requested only vie Set Feature(FUNCTION_SUSPEND).

(2) See what function is selected
See what function within the device is selected. The interface number of the function is specified in the lower byte of wIndex. If the function has multiple interfaces, the lower byte of wIndex shall be the first interface of the function.
Bit 0 in the upper byte of wIndex shows which of normal state (= 0) or suspended state (= 1) is requested. When bit 0 is 1 and the function has been enabled, the selected function is requested to suspend. When bit 0 is 0 and the function has been suspended, the selected function is requested to exit from suspended state.
Bit 1 in the upper byte for wIndex shows whether the function remote wakeup is enabled or not.

(3) Suspend the selected function
Suspend the function which is selected at (2).
If the function can't be suspended, the device may be allowed to return STALL response to Set Feature (FUNCTION_SUSPEND).

63.8.8.5 Function Remote Wakeup

The process of function remote wakeup is described here.
The function remote wakeup is defined for SS device and DEVICE_REMOTE_WAKEUP is not supported by SuperSpeed device.

As a function may be suspended independently of other functions, the link is still in U0 state even when one or more functions are suspended. In case the suspended function within the device requires to be woken up and the link is U0 state, the device simply sends Function Remote Wakeup Notification. In case the function is requesting the remote wake up but the link is in the low power state (U1, U2 or U3), resume the link to U0 state first and then sends Function Remote Wakeup Notification.

The function shows whether it supports the function remote wakeup or not in the response to Get Status from the interface which belongs to the function.
It is also required that Function Remote Wake is enabled to request the function remote wakeup from the device. Function Remote Wake is disabled (= 0) in the default state and set when Set Feature (FUNCTION_SUSPEND) is received and bit 1 of the upper byte of wIndex in setup data is 1. The current status of Function Remote Wake is shown in the response to GetStatus from the interface which belongs to the function.

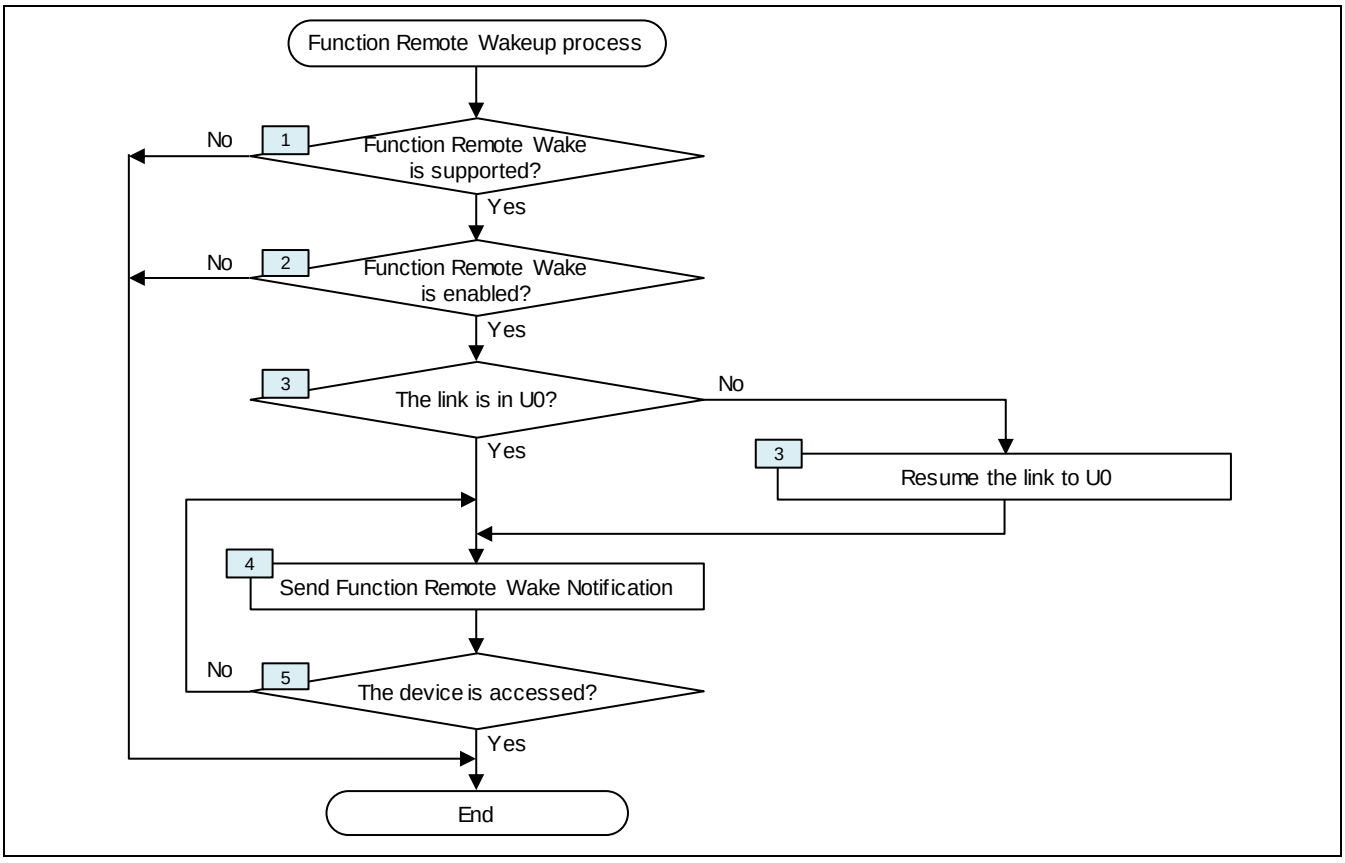

Figure 63.60 Function Remote Wakeup process

(1) Is Function Remote Wake supported?
If the function within the device doesn't support Function Remote Wake, it can't request the function remote wakeup. The function shows whether it supports Function Remote Wake or not in the response to Get Status from the interface which belongs to the function. See section 63.8.9.5 for details.

(2) Is Function Remote Wake enabled?
If Function Remote Wake is disabled for the function within the device, it can't request the function remote wakeup. The current status of Function Remote Wake is shown in the response to Get Status from the interface which belongs to the function. See section 63.8.9.5 for details.

(3) The link is in U0 state?
To send Function Remote Wake Notification, the link is required to be in U0 state.
If PERIPHERAL PORTION is in U1 or U2 state, it automatically goes back to U0 state when Notification written in USB3_TP_DAT_x register is sent. Therefore, the software need not mind the link status except the case the link is U3. Proceed to (4).
If PERIPHERAL PORTION is in U3 state, it is required to exit from the state first. See 63.8.8.6 for the process of resume in USB3.0.

(4) Send Function Remote Wake Notification
If the link is in U0 state, then send Function Remote Wake Notification.

- Write Function Remote Wake Notification to USB3_TPDAT_x (x=0,1,2) registers
- USB30_CON.B3_TP_SEND = 1 (Notification in USB3_TPDAT_x (x=0,1,2) registers is sent)

(5) Is the device accessed?
If tNotification (= 2500ms) has passed and the device has not been accessed yet from the time Function Remote Wake Notification was sent, it is required to send Function Remote Wake Notification again. The device should send the notification until the function is resumed.
When Set Feature(FUNCTION_SUSPEND) with bit 0 = 1 in the upper byte of wIndex comes, the function is resumed.

63.8.8.6 USB3.0-PHY (PLL) Wakeup Process

The process to wake up USB3.0-PHY (PLL) in case it is suspended is described here.

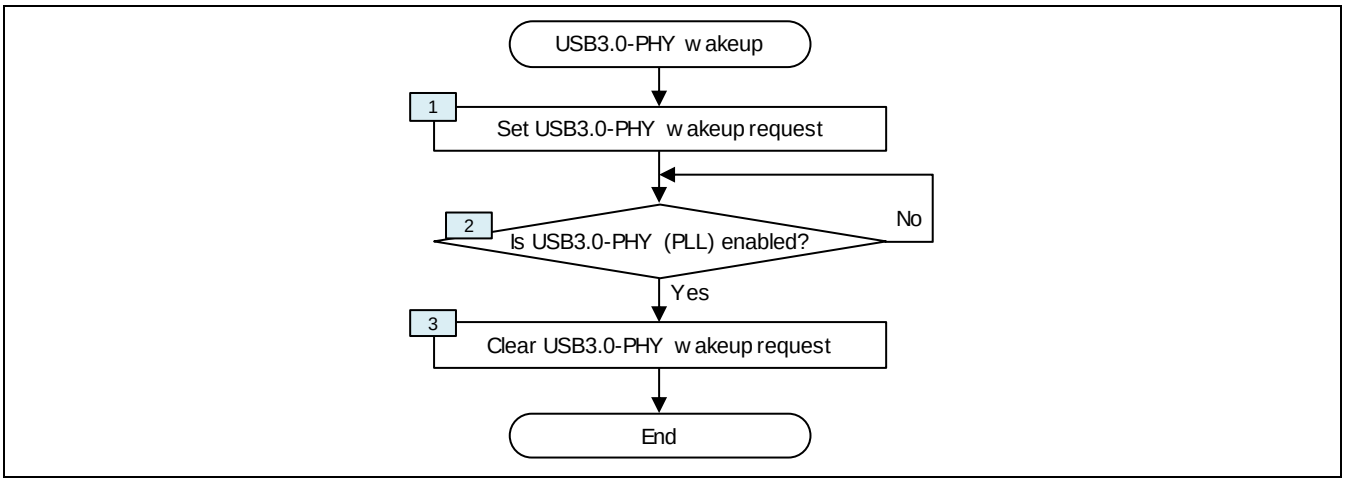

Figure 63.61 USB3.0-PHY (PLL) wakeup process flow

(1) Set USB3.0-PHY wakeup request
There are 2 ways to request USB3.0-PHY to wake up.
The first way is to set USB30_CON.B3_PLLWAKE.

[In case register is used]
- USB30_CON.B3_PLLWAKE = 1

(2) Is USB3.0-PHY (PLL) enabled?
Responding to the wake up request at (1), USB3.0-PHY (PLL) becomes enabled.
At that time, USB_INT_STA_1.B3_PLLWKUP_STA is asserted and an interrupt due to it is generated if enabled.

- Interrupt due to USB_INT_STA_1.B3_PLLWKUP_STA is generated
- Check that USB_INT_STA_1.B3_PLLWKUP_STA==1

After the confirmation above, clear USB_INT_STA_1.B3_PLLWKUP_STA.

- USB_INT_STA_1.B3_PLLWKUP_STA = 1 (Clearing the event of USB3.0 PLL Wakeup)

(3) Clear USB3.0-PHY wakeup request
After the resume of USB3.0-PHY is confirmed at (2), clear USB3.0-PHY wakeup request set in (1).

[In case register is used]
- USB30_CON.B3_PLLWAKE = 0

[In case input signal is used]
- B3_PLL_WAKEIN = 0

63.8.8.7 Suspend in USB2.0

The process when the state transition to suspend in USB2.0 occurs is described here.

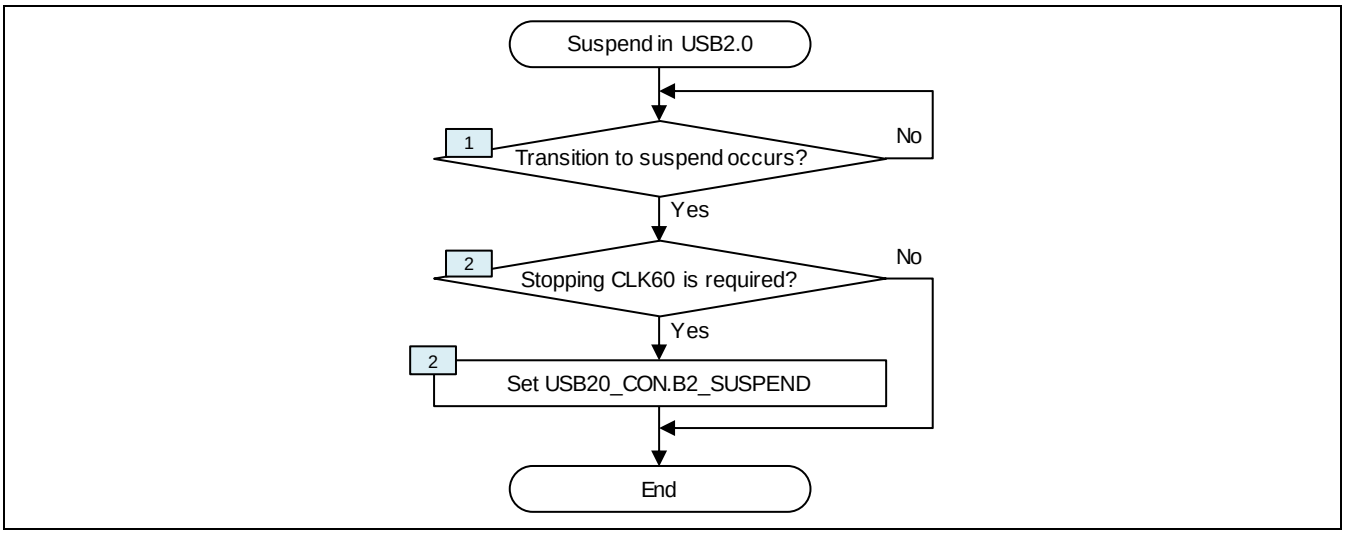

Figure 63.62 Suspend in USB2.0 process flow

(1) Does the transition to suspend occur?
In USB2.0 (HS/FS) host requests device to make a transition to suspended state by sending no signal to it for a certain period. Device transits to suspended state when it detects constant idle state on USB bus for more than 3.0ms.
When the controller works as HS or FS device and finds constant idle state on USB bus and make the transition to suspended state, it asserts USB_INT_STA_1.B2_SPND_STA. An interrupt due to it is generated if enabled.

- Interrupt due to USB_INT_STA_1.B2_SPND_STA is generated, if enabled
- Check whether USB_INT_STA_1.B2_SPND_STA==1 or not.

After the confirmation above, clear USB_INT_STA_1.B2_SPND_STA.

- USB_INT_STA_1.B2_SPND_STA = 1 (Clearing the event of entering USB2.0 suspension)

(2) Is stopping USB2.0-PHY clock required?
PLL in USB2.0-PHY is still running even when the controller enters the suspended state of USB2.0. In order to stop PLL in USB2.0-PHY, set USB20_CON.B2_SUSPEND

- USB20_CON.B2_SUSPEND = 1 (Clock from USB2.0-PHY is stopped)

If it is not required to stop the clock from USB2.0-PHY, no operation is needed here.

63.8.8.8 Resume in USB2.0 (Initiated by host)

The process to resume in USB2.0 initiated by host is described here.

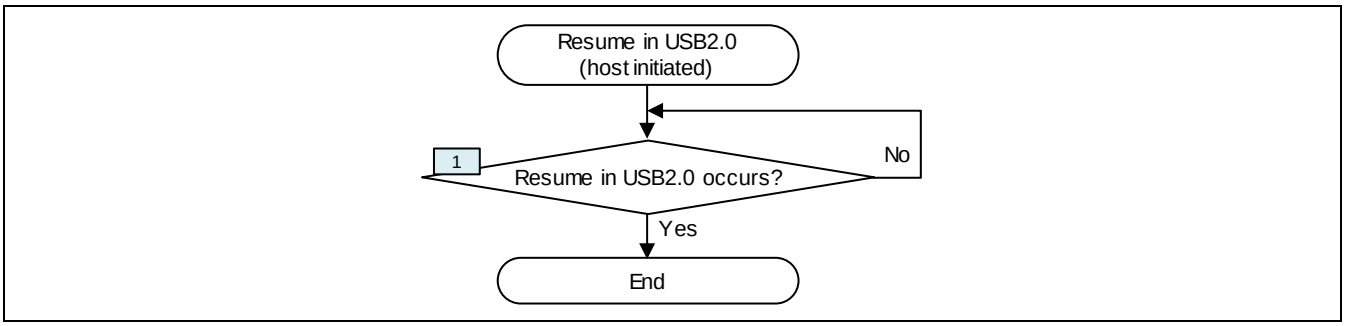

Figure 63.63 Resume in USB2.0 (Initiated by host) process flow

(1) Does the resume in USB2.0 occur?
In case Peripheral portion is in suspended state and receives the resume signal from host, it responds to it end exits from the suspended state automatically.
At that time Peripheral portion asserts USB_INT_STA_1.B2_RSUM_STA or USB_INT_STA_1.B2_L1RSUM_STA depending on the low power state it stayed in. An interrupt due to them is generated if enabled.

- Interrupt due to USB_INT_STA_1.B2_RSUM_STA or USB_INT_STA_1.B2_L1RSUM_STA is generated, if enabled.
- Check whether USB_INT_STA_1.B2_RSUM_STA or USB_INT_STA_1.B2_L1RSUM_STA==1 or not.

After the confirmation above, clear the status bit asserted.

- USB_INT_STA_1.B2_RSUM_STA = 1 (In case of resume from suspend)
- USB_INT_STA_1.B2_L1RSUM_STA = 1 (In case of resume from sleep)

If USB2.0 PLL is stopped in the suspend state, it is also resumed when Peripheral portion exits from the suspend state.

63.8.8.9 Resume in USB2.0 (Initiated by device)

The process to resume in USB2.0 initiated by device is described here.

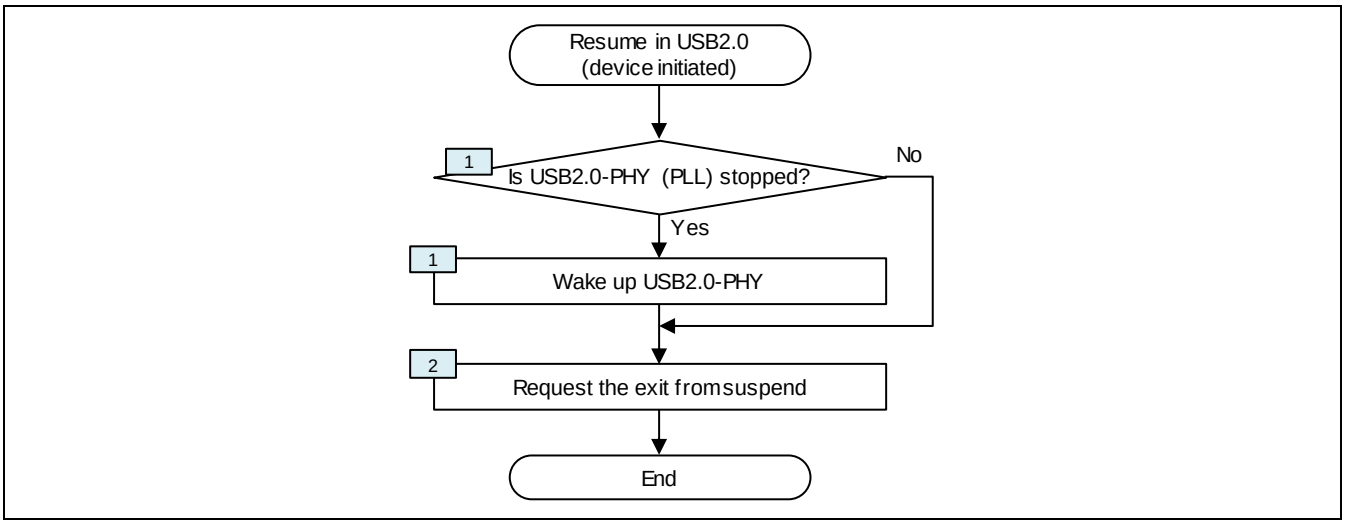

Figure 63.64 Resume in USB2.0 (Initiated by device) process flow

(1) Is the clock from USB2.0-PHY stopped?
If the clock from USB2.0-PHY is stopped following the flow in section 63.8.8.7, it is required to wake up USB2.0-PHY since the clock form USB2.0-PHY should be provided for the operations here.
See section 63.8.8.10 for the process to wakeup of USB2.0-PHY.

(2) Request the exit from the suspended state
Request to exit from the suspended state by setting as follows.

- USB20_CON.B2_RSUM_IN = 1 (resume request)

If PLL in USB2.0-PHY is not stopped in suspended state, that is, if USB20_CON.B2_SUSPEND is not set to 1 in suspended state, USB_INT_STA_1.B2_RSUM_STA or USB_INT_STA_1.B2_L1RSUM_STA may be asserted when downstream port responds to the resume request and bus activity comes back.
But, if it is stopped, they are not asserted here because they are asserted when USB20_CON.B2_SUSPEND is cleared so they would have already been asserted at (1).
In either case host should responds to the resume request from the device and bus becomes active again, so the device is required only to wait for the resume of transfer.

63.8.8.10 USB2.0 PHY (PLL) Wakeup Process

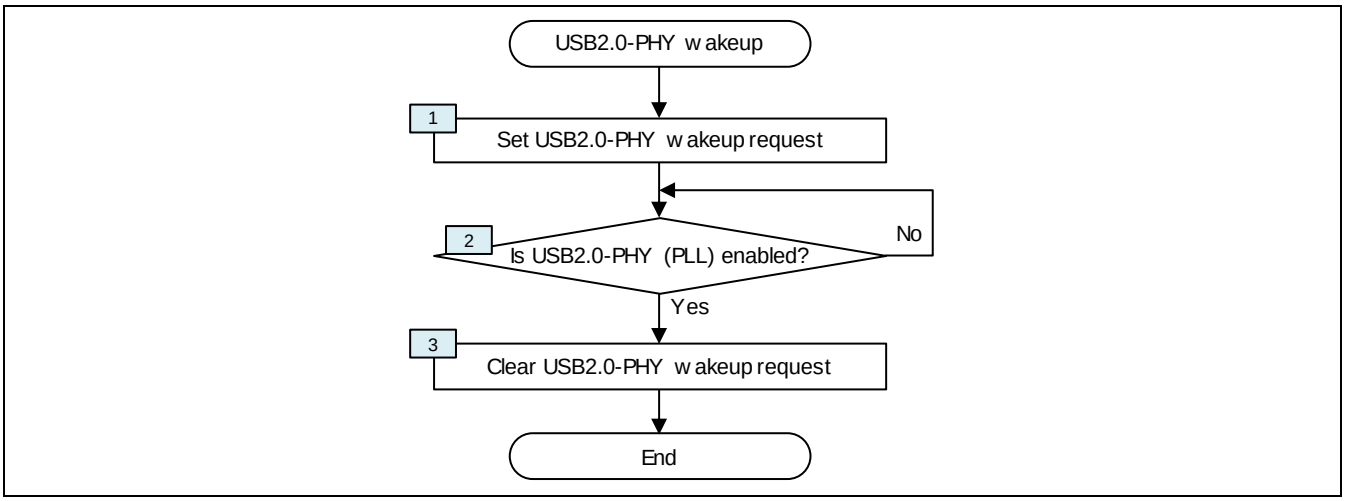

Figure 63.65 USB2.0-PHY (PLL) wakeup process flow

(1) Set USB2.0-PHY wakeup request
There are 2 ways to request USB2.0-PHY to wake up.
The first way is to clear USB20_CON.B2_SUSPEND.

[In case register is used]
- USB20_CON.B2_SUSPEND = 0 (Clearing the value set in section 63.8.8.7)

(2) Is USB2.0-PHY (PLL) enabled?
Responding to the wake up request at (1), USB2.0-PHY (PLL) becomes enabled.
At that time, USB_INT_STA_1.B2_RSUM_STA is generated and an interrupt due to it is caused if enabled.

- Interrupt due to USB_INT_STA_1.B2_RSUM_STA is generated
- Check that USB_INT_STA_1.B2_RSUM_STA==1

After the confirmation above, clear USB_INT_STA_1.B2_RSUM_STA.

- USB_INT_STA_1.B2_RSUM_STA = 1 (Clearing the event of USB2.0 PLL Wakeup)

If PERIPHERAL PORTION was in L1 state, USB_INT_STA_1.B2_L1RSUM_STA is asserted instead.

(3) Clear USB2.0-PHY wakeup request
After the resume of USB2.0-PHY is confirmed at (2), clear B2_PLL_WAKEIN input signal if used.
If USB20_CON.B2_SUSPEND is used to place USB2.0-PHY in suspended state, USB20_CON.B2_SUSPEND is automatically cleared.

[In case input signal is used]
- B2_PLL_WAKEIN = 0

63.8.8.11 Process of transition from U0 to U1/U2 in USB3.0 (Initiated by device)

With the settings as follows, PERIPHERAL PORTION automatically controls the transition from U0 to U1/U2 by sending LGO_U1/LGO_U2 request or by responding to LGO_U1/LGO_U2 request from host.

- PORTPMSC.U1_TIMEOUT[15:0] = U1 timeout value defined by user
- PORTPMSC.U2_TIMEOUT[15:0] = U2 timeout value in received U2 Inactivity Timeout LMP
- SSIFCMD.SSIF_URES[1:0] = B'00 (LAU responses to LGO_U1/LGO_U2 are allowed)
- SSIFCMD.SSIF_UREQ[1:0] = B'00 (sending LGO_U1/LGO_U2 by timeout is allowed)

PERIPHERAL PORTION controls the exit from U1/U2 state when it has any available data to be transmitted in buffer or when host requests wakeup as well. No additional operation by the software is required for the cases.

But there might be a case the software requests the transition to U1/U2 state at any point it wants. The process for such case is described here. But note that U1 timeout value can be defined by user, so consider it first to change the value of PORTPMSC.U1_TIMEOUT[15:0] in case LGO_U1 is required to be sent.

The process of Sleep (U1/U2) transition in USB3.0 when the device initiates at any timing is explained. This process flow is for usage when the device initiates LGO_U1/LGO_U2 at any time, and the timer which determine the duration for no data on the bus may be set in PORTPMSC.U1_TIMEOUT. The device can issue LGO_U1 after the timeout of timer.

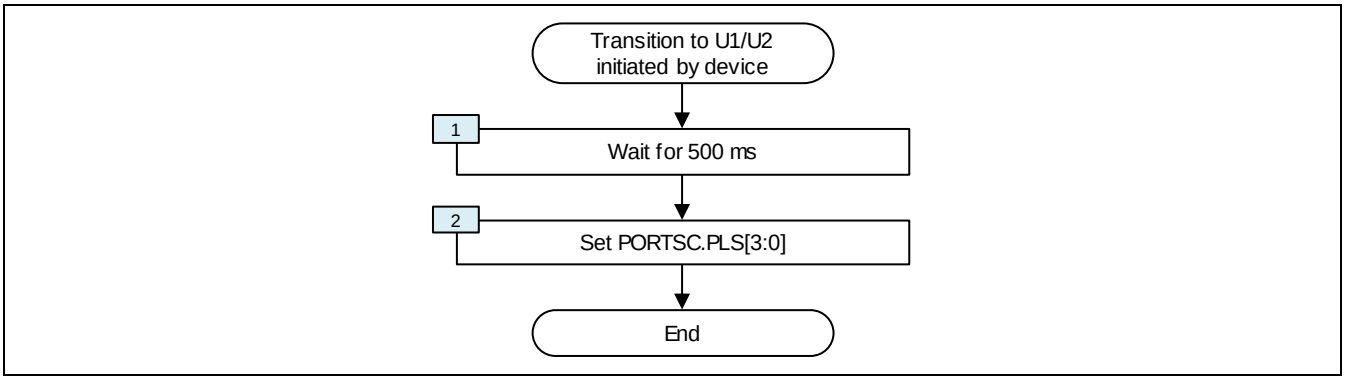

Figure 63.66 Transition to U1/U2 (Initiated by device) process flow

(1) Wait for 500ms

In C.3.2.2 and C3.2.1 of USB3.0 specification, it is defined that the link should be kept in U0 after device has sent ERDY until host sends a request in response to the ERDY or until tERDYtimeout (= 500ms) occurs.
Since PERIPHERAL PORTION sends ERDY automatically depending on the status of buffer, so it might be difficult to know when it has sent ERDY exactly.
If the software doesn't assure when the last ERDY has been sent, wait for 500ms from the point. If no response from host comes, it can request the transition to U1/U2 state. Note that PERIPHERAL PORTION might send ERDY again depending on the process of transfer if the response from host comes before the timeout.
If the software assures when the last ERDY has been sent and 500ms has passed, it can request the transition to U1/U2 immediately. The triggers to send ERDY for PERIPHERAL PORTION are :

1) IN packet is written to buffer
2) Pn_CON.Pn_RES[1:0] is changed to normal response (= B'01)
3) buffer for OUT endpoint was full once but becomes available
4) buffer for OUT endpoint had the last packet of transfer (short packet or packet with PP = 0) but it has been transferred to system memory.

If these triggers has not occurred for 500ms, it can be said that 500ms has passed at least from the last ERDY the device has sent.

(2) Set PORTSC.PLS[3:0]

The software can requests the transition to U1 or U2 by setting PORTSC.PLS[3:0]. It is also required to set SSIFCMD.SSIF_UDIR[1:0] to enable the function.

- SSIFCMD.SSIF_UDIR[1:0] = B'00 (If only one of LGO_U1 or LGO_U2 is requested, unused bit doesn't require to be enabled.)
- PORTSC.PLS[3:0] = H'1 (If the transition to U1 is requested)
  H'2 (If the transition to U2 is requested)

With the operations above, PERIPHERAL PORTION sends LGO_U1 or LGO_U2 to request the transition to U1 or U2. If host accepts it, the link make a transition to the low power state.
When LTSSM in PERIPHERAL PORTION enters U1 or U2, USB_INT_STA_1.B3_LNKCNG_STA is asserted. An interrupt due to it is generated if enabled. PORTSC.PLS[3:0] shows the current state of LTSSM.

- Interrupt due to USB_INT_STA_1.B3_LNKCNG_STA is asserted
- Check that USB_INT_STA_1.B3_LNKCNG==1
- Check that PORTSC.PLS[3:0] shows the requested state (U1 or U2).

Note that PORTSC.PLS[3:0] might show another state if the link transits to U1/U2 but host requests the exit form the state soon.
If host doesn't accept the request, USB_INT_STA_1.B3_LNKCNG_STA is not asserted. In case the software can't detect the assertion of the bit even when it waits for a certain time, it should consider the possibility that host rejected the request. The software can send the same request again, but host might intend new transfer, so the software had better the state of PERIPHERAL PORTION in U0 for the moment.

After the confirmation above, write 1 to USB_INT_STA_1.B3_LNKCNG_STA to clear.

- USB_INT_STA_1.B3_LNKCNG_STA = 1 (Clearing the event that the link status is changed)

63.8.9 Device Requests

This section describes the operations required for USB device requests.

63.8.9.1 Clear Feature

This request is used to clear or disable a specific feature.

In case the recipient is device and the device works in SS, U1_ENABLE, U2_ENABLE and LTM_ENABLE are defined as feature selectors.

(a) When Clear Feature(U1_ENABLE) comes, disable the initiation of U1 entry of PERIPHERAL PORTION as follows. Note that U1_ENABLE enables or disables only the initiation of U1 entry but the device is still allowed to accept LGO_U1 from downstream port and enters U1 state regardless of the feature.
- SSIFCMD.SSIF_UDIR[0] = 1 (The initiation of LGO_U1 due to direct request is disabled.)
- SSIFCMD.SSIF_UREQ[0] = 1 (The initiation of LGO_U1 due to timeout is disabled.)

(b) When Clear Feature(U2_ENABLE) comes, disable the initiation of U2 entry of PERIPHERAL PORTION as follows. Note that U2_ENABLE enables or disables only the initiation of U2 entry but the device is still allowed to accept LGO_U2 from downstream port and enters U2 state regardless of the feature.
- SSIFCMD.SSIF_UDIR[1] = 1 (The initiation of LGO_U2 due to direct request is disabled.)
- SSIFCMD.SSIF_UREQ[1] = 1 (The initiation of LGO_U2 due to timeout is disabled.)

(c) When Clear Feature(LTM_ENABLE) comes, disable the transmission of LTM (Latency Tolerance Message). Note that SS device must support U1 and U2 features, but LTM feature is optional. SS device shows whether it supports LTM feature or not on LTM capable bit in SuperSpeed USB Device Capabilities Descriptor.

In case the recipient is device and the device works in HS or FS, DEVICE_REMOTE_WAKEUP and TEST_MODE are defined as feature selectors.

(d) When Clear Feature(DEVICE_REMOTE_WAKEUP) comes, disable the remote wakeup function of the device.

(e) When TEST_MODE feature is enabled, the device is in test mode. But it is defined that the power cycle is used for the device to exit from test mode and Clear Feature(TEST_MODE) doesn't clear the feature.

For FUNCTION_SUSPEND, Clear Feature is not used to change the feature. Only Set Feature(FUNCTION_SUSPEND) is used to change the feature.

In case the recipient is endpoint, ENDPOINT_HALT is defined as feature selector. All of SS, HS and FS devices support the feature.

(f) When Clear Feature (ENDPOINT_HALT) comes, it means the reset of Halt feature and the initialization of the endpoint.
At first, set Pn_CON.Pn_CLR and wait for Pn_CON.Pn_CLR to return to 0.
- Pn_CON.Pn_CLR = 1 (Initialization of the endpoint (pipe) is required.)
- Wait for Pn_CON.Pn_CLR==0

After Pn_CON.Pn_CLR==0, set enable bits below again.
- Pn_CON.Pn_EN = 1 (The endpoint (pipe) is enabled)
- Pn_CON.Pn_DATAIF_EN = 1 (EPC_D_Pn_DATAEN[30:1] is enabled for the endpoint)

Then, set Pn_CON.Pn_RES[1:0] = B'01 so that the endpoint responds in normal state.
- Pn_CON.Pn_RES[1:0] = B'01 (Normal response)

It is not recommended that the endpoint 0 (PIPE0) supports function STALL for HS and FS device. It is also defined that SS device doesn't support the feature. If the device doesn't support Halt feature for the endpoint 0, it

executes the control transfer of Clear Feature(ENDPOINT_HALT) for the endpoint 0 normally but can ignore the request.

It is noted in section 63.8.9.5 how each feature is controlled as the status of the device.

63.8.9.2 Get Configuration

This request returns the current device configuration value.
In case this request is received, return the current configuration value. It has been selected with Set Configuration. If not, return the initial value (= zero).

63.8.9.3 Get Descriptor

This request returns the specified descriptor if the descriptor exists.
The length of transfer is specified in wLength of setup data. In case the size of the descriptor equals to or is smaller than the value in wLength, transmit all of the descriptor from the beginning to the end. In case the size of the descriptor is larger than the value in wLength, transmit a part of the descriptor from the beginning to the length specified in wLength. Each packet transporting the descriptor should equal to or smaller than the max packet size defined for each speed mode (512byte for SS, 64byte for HS and 8/16/32/64byte for FS). If the size of the last packet equals to the max packet size defined, zero length packet should follow it.

63.8.9.4 Get Interface

This request returns the selected alternate setting of the specified interface.

In case this request is received, return the current alternate setting of the interface. It has been selected with Set Interface. If not, return the initial value (= zero).

63.8.9.5 Get Status

This request returns status for the specified recipient.

In case the recipient is device, the information returned for this request as SuperSpeed device is shown in Figure 63.67.

D7	D6	D5	D4	D3	D2	D1	D0
Reserved (Reset to Zero)			LTM Enable	U2 Enable	U1 Enable	Remote Wakeup	Self-Powered
D15	D14	D13	D12	D11	D10	D9	D8
Reserved (Reset to Zero)							

Figure 63.67 Information as SS device in case the recipient is device

D0: This bit shows whether the device is self-powered or not.

D1: This bit shows whether the device supports Remote Wakeup or not.
SuperSpeed device is defined to set this bit to 0 and use Function Remote Wakeup instead.

D2: This bit shows whether the device is currently enabled to initiate U1 entry or not. If this bit is 0, the device is disabled to initiate U1 entry. Regardless of whether this bit is set or not, the device can accept the request for U1 entry from downstream port and enter U1 state.
This bit is set to 1 on the reception of Set Feature(U1_ENABLE) and set to 0 on the reception of Clear Feature(U1_ENABLE). This bit is reset to 0 when the device is reset.

D3: This bit shows whether the device is currently enabled to initiate U2 entry or not. If this bit is 0, the device is disabled to initiate U2 entry. Regardless of whether this bit is set or not, the device can accept the request for U2 entry from downstream port and enter U2 state.
This bit is set to 1 on the reception of Set Feature(U2_ENABLE) and set to 0 on the reception of Clear Feature(U2_ENABLE). This bit is reset to 0 when the device is reset.

D4: This bit shows whether the device is currently enabled to send LTM (Latency Tolerance Message) or not. If this bit is 0, the device is disabled to send LTM.

This bit is set to 1 on the reception of Set Feature(LTM_ENABLE) and set to 0 on the reception of Clear Feature(LTM_ENABLE). This bit is reset to 0 when the device is reset.

In case the recipient is device, the information returned for this request as HighSpeed or FullSpeed device is shown in Figure 63.68.

D7	D6	D5	D4	D3	D2	D1	D0
Reserved (Reset to Zero)						Remote Wakeup	Self-Powered
D15	D14	D13	D12	D11	D10	D9	D8
Reserved (Reset to Zero)							

Figure 63.68 Information as HS/FS device in case the recipient is device

D0: This bit shows whether the device is self-powered or not.

D1: This bit shows whether the device supports Remote Wakeup or not.
The default value is 0. The value is modified on the reception of Set Feature(DEVICE_REMOTE_WAKEUP) or Clear Feature(DEVICE_REMOT_WAKEUP). When Set Feature(DEVICE_REMOTE_WAKEUP) is received, the status of this bit is changed to 1. When Clear Feature(DEVIE_REMOT_WAKEUP) is received, the status of this bit is changed to 0.
When this feature is enabled, device can request the remote wakeup in suspended state.
This bit is reset to 0 when the device is reset.

In case the recipient is interface, the information returned for this request as SuperSpeed device is shown in Figure 63.69.

D7	D6	D5	D4	D3	D2	D1	D0
Reserved (Reset to Zero)						Function Remote Wakeup	Function Remote Wakeup Capable
D15	D14	D13	D12	D11	D10	D9	D8
Reserved (Reset to Zero)							

Figure 63.69 Information as SS device in case the recipient is interface

D0: This bit shows whether the interface supports Function Remote Wakeup Capable or not.
Note that Function Remote Wakeup function is used instead of Remote Wakeup function in SuperSpeed device. If the device doesn't support Function Remote Wakeup, it can't request the remote wakeup in suspended state (U3).

D1: This bit shows whether the function is currently enabled to request the remote wakeup or not.
The definition of function depends on the specification of device.
The default value is 0. The value is modified on the reception of Set Feature(FUNCTION_SUSPEND). When Set Feature(FUNCTION_SUSPEND) is received and bit 1 in the upper byte of wIndex is 1, Function Remote Wake is enabled and the status of this bit is changed to 1. When Set Feature(FUNCTION_SUSPEND) is received and bit1 in the upper byte of wIndex is 0, Function Remote Wake is disabled and the status of this bit is changed to 0.
When this feature is enabled, device can request the remote wakeup for the suspended function.
This bit is reset to 0 when the device is reset.

In case the recipient is interface, the information returned for this request as HighSpeed or FullSpeed device is shown in Figure 63.70. All fields are reserved.

Figure 63.70 Information as HS/FS device in case the recipient is interface

In case the recipient is endpoint, the information returned for this request as SuperSpeed, HighSpeed or FullSpeed device is shown in Figure 63.71.

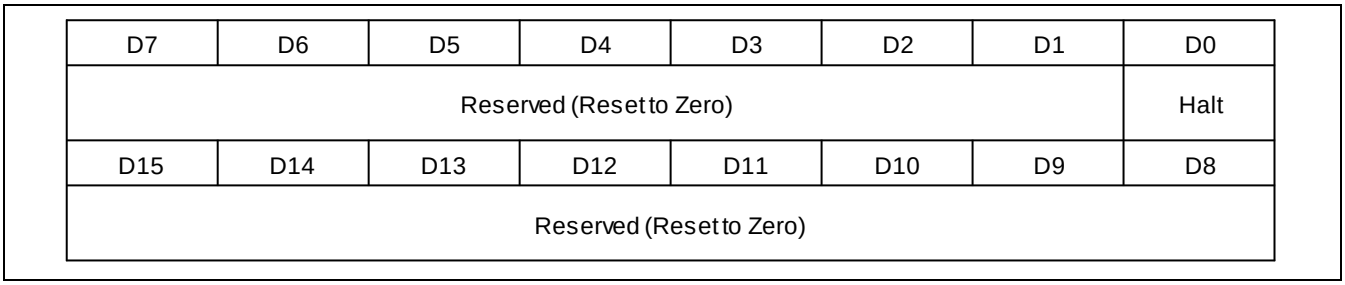

Figure 63.71 Information as SS/HS/FS device in case the recipient is endpoint

D0: This bit shows the current status of Halt feature of the endpoint. If the endpoint is currently halted, the Halt feature is set to 1.
The Halt feature is required to be implemented for all interrupt and bulk endpoints.
The Halt feature might be set due to the internal status of device (when unsupported request comes, for example), or it might be set by Set Feature(ENDPOINT_HALT).
During the feature is set to 1, the endpoint should return STALL response to any request. To return STALL response, set Pn_CON.Pn_RES[1:0] = B'10.
- Pn_CON.Pn_RES[1:0] = B'10 (STALL response)

The Halt feature is cleared on the reception of ClearFeature(ENDPOINT_HALT), SetConfiguration and SetInterface. Note that the sequence number in SS and data toggle in HS/FS is initialized on those requests. The feature might be cleared due to the internal status of device (when the cause of error is removed, for example).
When the Halt feature is reset, the endpoint changed it status not to return STALL response. Set Pn_CON.Pn_RES[1:0] = B'01 to request the endpoint to respond in the normal mode.
- Pn_CON.Pn_RES[1:0] = B'01 (Normal response)

SS device doesn’t support function STALL on control endpoint.

63.8.9.6 Set Address

This request sets the device address for all future device accesses. The address is shown in wValue field of setup data.
In case this request is received, read the address in wValue field of setup data. But the device can't update its address to the value given on Set Address until it completes the control transfer of Set Address, since it is defined in USB specification that stages after the initial setup packet assume the same device address as the setup packet.
Write the address given on Set Address to the field below before completing the status stage of the control transfer of Set Address. (That is, write the address to the field below, then P0_CON.P0_ST_RES[1:0] to normal response.)
The hardware of PERIPHERAL PORTION updates the field to new address after it completes the status stage of the control transfer of Set Address.

— USB_COM_CON.DEV_ADDR[6:0] = the value in wValue field of setup packet.

Set Address 0 has the special meaning to initialize the settings in the device. See Table 9-9 in USB3.0 specification.

63.8.9.7 Set Configuration

This request sets the device configuration. The configuration value selected is shown in lower byte of wValue field of setup data.

The configuration value shall be zero or the value shown in the configuration descriptor.

(1) In case the configuration value matches the value shown in the configuration descriptor, do the operations as follows before the status stage of the control transfer is completed.
- Configure PERIPHERAL PORTION to follow the configuration selected.
- USB_COM_CON.CONF = 1 (PERIPHERAL PORTION is in configured state)

Remember the configuration value since Get Configuration might be requested later.
Then, complete the status stage of the control transfer by setting P0_CON.P0_ST_RES[1:0] = B'01 (normal response).

(2) In case the configuration value is zero, it means that the device is requested to go back to address state. Do the operation as follows before the status stage of the control transfer is completed.
- USB_COM_CON.CONF = 0 (PERIPHERAL PORTION is not in configured state)

The buffer of each PIPE should be initialized as well. Do the operation noted in (f) of section 63.8.9.1 for PIPEs those have been used in configured state.

Note that the clocks to Data-IN RAMs or Data-OUT RAM is suspended with the setting above. (They are suspended in unconfigured state.) In that case, the clocks to Register RAM and EP0 RAM are still running.
Remember the configuration value since Get Configuration might be requested later.
Then, complete the status stage of the control transfer by setting P0_CON.P0_ST_RES[1:0] = B'01 (normal response).

63.8.9.8 Set Descriptor

This request is optional and may be used to update existing descriptors or new descriptors may be added.
If this request is not defined in the specification of device or the class specification which the device supports, this request is not required to be implemented.
When SetDescriptor comes, update the specified descriptor.

63.8.9.9 Set Feature

This request is used to set or enable a specific feature.

In case the recipient is device and the device works in SS, U1_ENABLE, U2_ENABLE and LTM_ENABLE are defined as feature selectors.

(a) When Set Feature(U1_ENABLE) comes, enable the initiation of U1 entry of PERIPHERAL PORTION as follows. Note that U1_ENABLE enables or disables only the initiation of U1 entry but the device is still allowed to accept LGO_U1 from downstream port and enters U1 state regardless of the feature.
- SSIFCMD.SSIF_UDIR[0] = 0 (The initiation of LGO_U1 due to direct request is enabled.)
- SSIFCMD.SSIF_UREQ[0] = 0 (The initiation of LGO_U1 due to timeout is enabled.)
- PORTPMSC.U1_TIMEOUT = U1 timeout value defined by user

(b) When Set Feature(U2_ENABLE) comes, enable the initiation of U2 entry of PERIPHERAL PORTION as follows. Note that U2_ENABLE enables or disables only the initiation of U2 entry but the device is still allowed to accept LGO_U2 from downstream port and enters U2 state regardless of the feature.
- SSIFCMD.SSIF_UDIR[1] = 0 (The initiation of LGO_U2 due to direct request is enabled.)
- SSIFCMD.SSIF_UREQ[1] = 0 (The initiation of LGO_U2 due to timeout is enabled.)
- PORTPMSC.U2_TIMEOUT = U2 timeout value in received U2 Inactivity Timeout LMP

(c) When Set Feature(LTM_ENABLE) comes, enable the transmission of LTM (Latency Tolerance Message). Note that SS device must support U1 and U2 features, but LTM feature is optional. SS device shows whether it supports LTM feature or not on LTM capable bit in SuperSpeed USB Device Capabilities Descriptor.

In case the recipient is device and the device works in HS or FS, DEVICE_REMOTE_WAKEUP and TEST_MODE are defined as feature selectors.

(d) When Clear Feature(DEVICE_REMOTE_WAKEUP) comes, enable the remote wakeup function of the device. When requesting the remote wakeup, see the flow in section 63.8.8.9.

(e) When TEST_MODE feature is enabled, the device is in test mode. The upper byte of wIndex of setup data specifies test mode selector and it is defined in Table 9-7 of USB2.0 specification.
PERIPHERAL PORTION has the function for TEST_MODE with the setting of USB20_CON.B2_TSTMOD [2:0] and USB20_CON.B2_TSTMOD_EN. When Set Feature (TEST_MODE) comes, set USB20_CON.B2_TSTMOD[2:0] and USB20_CON.B2_TSTMOD_EN according to the test mode selector specified.

In case the recipient is interface and the device works in SS, FUNCTION_SUSPEND is defined as feature selector.

(f) The function within the device shows whether it supports Function Remote Wakeup function or not in Function Remote Wakeup Capable bit in Figure 63.69. When the function supports Function Remote Wake and Set Feature(FUNCTION_SUSPEND) is received and the bit 1 in the upper byte of wIndex is 1, enable Function Remote Wake. When the function supports Function Remote Wake and Set Feature(FUNCTION_SUSPEND) is received and the bit 1 in the upper byte of wIndex is 0, disable Function Remote Wake.
To request the function remote wakeup, See section 63.8.8.5.

In case the recipient is endpoint, ENDPOINT_HALT is defined as feature selector. All of SS, HS and FS devices support the feature.

(g) When Set Feature(ENDPOINT_HALT) comes, set Pn_CON.Pn_RES[1:0] = B'10 to return STALL response from the endpoint.
- Pn_CON.Pn_RES[1:0] = B'10 (STALL response)

Note that the state machine of Stream bulk transits to Disabled state by receiving Set Feature(ENDPOINT_HALT).

If the endpoint works as the Stream bulk one, disable all transfers on the reception of Set Feature(ENDPOINT_HALT).

It is not recommended that the endpoint 0 supports function STALL for HS and FS device. It is also defined that SS device doesn't support the feature. If the device doesn't support Halt feature for the endpoint 0, it executes the control transfer of Set Feature(ENDPOINT_HALT) for the endpoint 0 normally but can ignore the request.

It is noted in section 63.8.9.5 how each feature is controlled as the status of the device.

63.8.9.10 Set Interface

This request allows host to select an alternate setting of the specified interface.
In case this request is received, configure PERIPHERAL PORTION to follow the configuration of interface selected.

— Configure PERIPHERAL PORTION to follow the configuration of interface selected

As Set Interface means the initialization of selected interface as well, it is recommended to initialize the PIPEs related to the interface using Pn_CON.Pn_CLR. The operations as follows are required for all PIPEs related to the interface.

— -Pn_CON.Pn_CLR = 1 (Initialization of PIPE)
— Wait for Pn_CON.Pn_CLR returns to 0
— Pn_CON.Pn_EN = 1 (Enabling the PIPE again)
— Pn_CON.Pn_DATAIF_EN = 1 (Enabling data interface for the PIPE again.)

Remember the alternate setting of the interface since Get Interface might be requested later.

63.8.9.11 Set Isochronous Delay

This request informs the device of the delay from the time host transmits a packet to the time it is received by the device.

As PERIPHERAL PORTION doesn't support Isochronous transfer, so there is no function to use the value received on this request.
From the viewpoint of implementation the device can return STALL response in order to show it doesn't support this request, or can ignore the request although it responds correctly to the control transfer of this request.

63.8.9.12 Set SEL

This request is valid when the device works in SS and sets both the U1 and U2 System Exit Latency and the U1 or U2 exit latency for all the links between a device and a root port on the host.
When Set SEL comes, update BELT (Best Effort Latency Tolerance) value referring the information provided on this request, if required.

63.8.9.13 Synch Frame

This request is used to set and then report an endpoint's synchronization frame.

As PERIPHERAL PORTION doesn't support Isochronous transfer, so there is no function to use the value received on this request.
From the viewpoint of implementation the device can return STALL response in order to show it doesn't support this request, or can ignore the request although it responds correctly to the control transfer of this request.

63.8.10 BOT Control

Bulk Only Transport (BOT) is defined as one of transfer methods in mass storage class. An example of BOT operation is described here.

63.8.10.1 Overall

BOT consists of two bulk endpoints as its name suggests.

- Bulk OUT PIPE (for the reception of CBW or OUT data)
- Bulk IN PIPE (for the transmission of CSW or IN data)

In BOT protocol, Command Block Wrapper (CBW) is sent to request an operation in advance of IN or OUT data transfers, and Command Status Wrapper (CSW) is sent to notify the result of the operation after the IN or OUT data transfers. There are some commands which don't require the data transfers. For such command, only CBW and CSW are exchanged.

63.8.10.2 BOT assistance mode

PERIPHERAL PORTION has BOT assistance mode. The mode is available when Pn_MOD.Pn_BOT is set to 1 for OUT PIPE in BOT.
In BOT assistance mode, PERIPHERAL PORTION notifies the reception of CBW by asserting Pn_INT_STA.Pn_CBW_STA. If an interrupt due to the bit is enabled, the interrupt is generated.

PERIPHERAL PORTION interprets the received packet as CBW when both of two conditions below are satisfied for the packet.

- The length of the packet is 31bytes.
- The first 4bytes of the packet (dCBWSignature) equals to 43425355h.

In this mode, Pn_CON.Pn_DATAIF_EN of the OUT PIPE that receives CBW is disabled (reset to 0) every time CBW (the packet which satisfies two conditions above) is received. As the result, CBW is not transferred through Data Interface or on AXI DMA transfer. Pn_CON.Pn_DATAIF_EN of IN PIPE is not changed.

CBW can be transferred through Data Interface or on AXI DMA transfer if Pn_CON.Pn_DATAIF_EN is set to 1 again, but it is recommended to read CBW through Pn_READ register because the software should read and decode it for BOT operation.

As CBW is a short packet in bulk transfer, the OUT PIPE in BOT enters flow control after the reception of CBW if it works as USB3.0 device. When CBW has been read through Pn_READ register (or when it has been transferred through Data Interface or on AXI DMA transfer), PERIPHERAL PORTION returns ERDY from the OUT PIPE automatically. But if OUT data transfer is requested, make sure to set Pn_CON.Pn_DATAIF_EN to 1 after CBW has been read or transferred.

If BOT assistance mode is not used (Pn_MOD.Pn_BOT = 0) for BOT transfer, the OUT PIPE in BOT doesn't distinguish CBW and CBW is transferred as one of short packets on AXI DMA transfer. In that case Pn_CON.Pn_DATAIF_EN is not disabled and Pn_INT_STA.Pn_CBW_STA is not asserted on the reception of CBW.
(PERIPHERAL PORTION doesn't know that the packet is CBW.)

The software is required to find CBW in system memory (where the received packet is transferred to) when a short packet is received.

63.8.10.3 BOT Process

It is assumed that BOT assistance mode in section 63.8.10.2 and the flow of BOT process with the mode is described here.
Make sure to set Pn_MOD.Pn_BOT = 1.

As noted above, one bulk OUT PIPE and one bulk IN PIPE are required for BOT. For the settings of bulk OUT PIPE, see section 63.8.5.2. For the settings of bulk IN PIPE, see section 63.8.5.1.
As the preparation of BOT, enable an interrupt due to Pn_INT_STA.Pn_CBW_STA of the OUT PIPE. That is, set Pn_INT_ENA.Pn_CBW_ENA of bulk OUT PIPE to 1.
- Pn_INT_ENA.Pn_CBW_ENA= 1 (Interrupt due to Pn_INT_STA.Pn_CBW_STA is enabled)

(1) Is CBW received?
When CBW is received, Pn_INT_STA.Pn_CBW_STA is asserted and an interrupt due to it is generated.

- Interrupt due to Pn_INT_STA.Pn_CBW_STA is asserted
- Check that Pn_INT_STA.Pn_CBW_STA == 1

After the confirmation above, clear Pn_INT_STA.Pn_CBW_STA.

- Pn_INT_STA.Pn_CBW_STA = 1 (Clearing the event of the reception of CBW)

(2) Read CBW
Read CBW through Pn_READ register.

(3) Decode CBW
Decode the content of CBW which is read at (2).
If any operation other than data transfer is requested, do it here.

(4) Which direction of transfer is requested?
If OUT transfer is requested, proceed to (5).
If IN transfer is requested, proceed to (6).
If No data transfer is requested, proceed to (7).

(5) Read OUT data
It is assumed here that OUT data received is transferred through Data Interface or on AXI DMA transfer. Set Pn_CON.Pn_DATAIF_EN = 1 since it is reset to 0 at the reception of CBW.
For bulk OUT transfer, see section 63.8.5.2. If two or more packets are received, repeat the flow shown there.
Proceed to (7).

(6) Write IN data
It is assumed here that IN data to be transmitted is transferred through Data Interface or on AXI DMA transfer. Pn_CON.Pn_DATAIF_EN of IN PIPE is not changed on the reception of CBW.
For bulk IN transfer, see section 63.8.5.1. If two or more packets are to be transmitted, repeat the flow shown there.
Proceed to (7).

(7) Send CSW
It is assumed here that the software prepares CSW and writes it through Pn_WRITE register.
Before writing CSW to the buffer of the IN PIPE, confirm that the buffer has available space.

- Check that Pn_STA.Pn_BUFSTS== 1 for bulk IN PIPE in order to confirm that the buffer for the PIPE is available.

If the buffer has available space for CSW, write CSW through Pn_WRITE register. Since the size of CSW is 13 bytes, the access to Pn_WRITE register is required 4 times. The last write word has only 1 valid byte.

- Write CSW to Pn_WRITE register. 4 write accesses are required for 13 bytes of CSW.

After CSW has been written to Pn_WRITE register, send CSW as follows. As only 32-bit access is allowed to the register, both fields should be set in one word access.

-Pn_CON.Pn_SEND = 1
-Pn_CON.Pn_BYTE_EN[1:0] = B'01 (The last word has only 1 valid byte.)

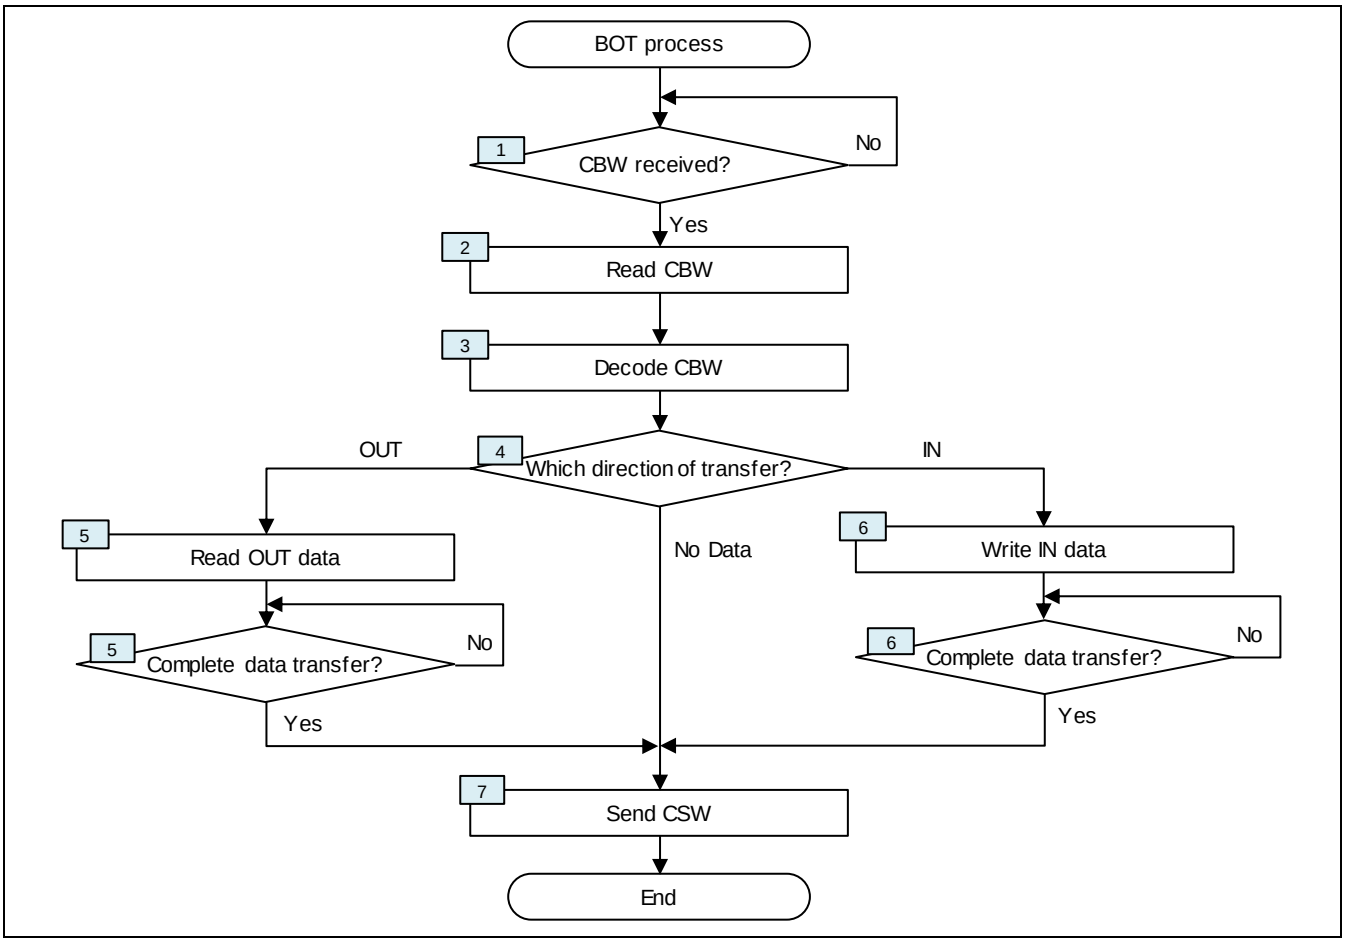

Figure 63.72 BOT process flow

63.9 Instructions and Directions for Use

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

Instructions and directions for using Peripheral Core is described in this section.

63.9.1 Method of Specifying RAM Mapping

Peripheral core has configurable EPC data buffer RAM to be allocated for each PIPE.

Table 63.25 Number of SRAMs

	Usage	Bit Width	Number of words	Quantity	Total size per channel
1.	For data buffer EP0 (PIPE0)	64 bit	64	1	512byte
2.	For data buffer IN PIPE	64 bit	2048	4	64kbyte
3.	For data buffer OUT PIPE	64 bit	2048	4	64kbyte

Setting Example)

Number of PIPEs: 2 PIPEs for each of IN/OUT. (Total: 4 PIPEs)

Pn_RAMAREA: (PIPE1/OUT) 4k Byte (4 Block)

(PIPE2/IN) 4k Byte (4 Block)

(PIPE3/OUT) 2k Byte (2 Block)

(PIPE4/IN) 2k Byte (2 Block)

Quantity of SRAM to be connected: For IN PIPE = 1, For OUT PIPE = 1

⇨ (4k + 2k) for each of IN/OUT / 8 Byte = 768 word

63.9.2 Example of Setting

The buffer space for each PIPE in EPC is set by 63.2.2.55 PIPEn Mode Setting Register (Pn_MOD). The buffer size for each PIPE is specified in Pn_RAMAREA[2:0], and it is specified 1Block (1KByte) size per one packet in USB transaction regardless Max_Packet_Size at Pn_MPKT. Thus regarding to Pn_BASEAD[13:0] which specify Base_Address, the lower 7 bits need to be set to all 0 and specified its size as 1KB unit.

Following notice is the key to use RAM field efficiently.

- Set the PIPE which Max_Packet_Size is 1Kbyte at the top of each RAM (IN/OUT separately)
- Set the PIPE which Max_Packet_Size is less than 1Kbyte at the end of RAM as much as possible
- Note that the space other than 1Block occupied 1 packet size is required 1Kbyte for each, when the PIPE which Max_Packet_Size is less than 1Kbyte and Pn_RAMAREA is set to the value other than B'00 (1Block).

Example)

Table 63.26 Specifications of PIPEs

	Endpoint Index	Direction of Transfer	Endpoint Type	Max Burst Size	Max Packet Size
PIPE1	Endpoint 1	IN	BULK	4	1024 Byte
PIPE2	Endpoint 2	OUT	BULK	4	1024 Byte
PIPE3	Endpoint 3	IN	BULK	2	1024 Byte
PIPE4	Endpoint 4	OUT	BULK	2	1024 Byte
PIPE5	Endpoint 5	IN	INTERRUPT	1	512 Byte

Table 63.27 SRAM interfaces and sizes of SRAMs

RAM-IF Index/ IN or OUT	RAM Size	
0/IN	64bit × 576word	(4KByte + 512Byte)
1/IN	64bit × 264word	(2KByte)
2/IN	None	—
3/IN	None	—
0/OUT	64bit × 512word	(4KByte)
1/OUT	64bit × 256word	(2KByte)
2/OUT	None	—
3/OUT	None	—

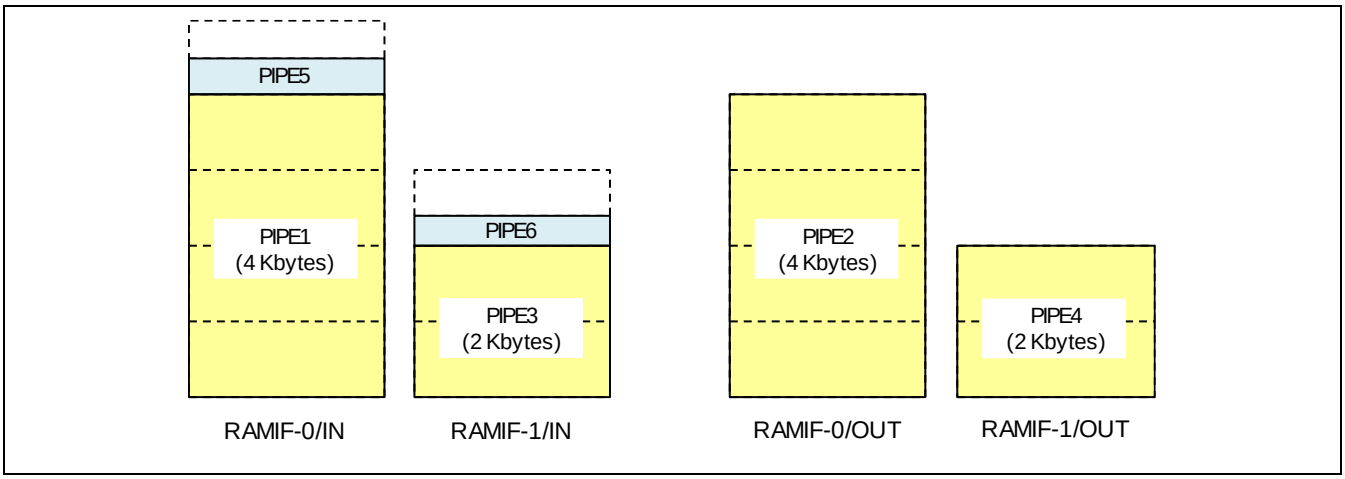

Figure 63.73 RAM Mapping Diagram for Example

63.9.3 Register Access

P0_READ, P0_WRITE, Pn_READ and Pn_WRITE registers are used to read or write a packet to each PIPE through these registers.

But as noted in the subsection of each register, it is prohibited to access to other Px_yyy (x = 0 to 15, yyy = register name) registers before whole of a packet has been read or written through the register which is currently used. Px_yyy registers. The packet might not be read or written correctly otherwise.

It is also prohibited to change the targeted PIPE of Pn_yyy registers on PIPE_COM.PIPE_NUM[4:0] before read or write of a packet has been completed to the PIPE currently selected.

When P0_WRITE or Pn_WRITE register is used, it is required to send the packet which has been written by setting P0_CON.P0_SEND or Pn_CON.Pn_SEND before the access to other Px_yyy registers.

Make sure to complete read or write of a packet before the access to other Px_yyy registers, once it is started.

If Px_yyy register is read or written in an interrupt routine, it might violate the notation without awareness. To avoid the case, mask the interrupt related to the routine during read or write of a packet, or never access to Px_yyy registers in an interrupt service.

The lists of registers prohibited to access during P0_READ or Pn_READ register is used are as follows.

Prohibited to access during P0_READ register is used	P0_WRITE, Pn_READ, Pn_WRITE, Pn_STA, Pn_LNG, Pn_RSVPKT
Prohibited to access during Pn_READ register is used	P0_READ, P0_WRITE, P0_STA, P0_LNG, Pn_WRITE

The lists of registers prohibited to access during P0_WRITE or Pn_WRITE register is used are as follows.

Prohibited Registers for accessing in case of P0_WRITE	P0_READ, Pn_READ, Pn_WRITE, Pn_STA, Pn_LNG, Pn_RSVPKT
Prohibited Registers for accessing in case of Pn_WRITE	P0_READ, P0_WRITE, P0_STA, P0_LNG, Pn_READ

64. RCLK Watchdog Timer (RWDT)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

64.1 Overview

This LSI includes the RCLK watchdog timer (RWDT).

This LSI can be reset by the overflow of the counter when the value of the counter has not been updated because of a system runaway.

The RWDT is a single-channel timer that uses the RCLK as an input and can be used as a watchdog timer. RCLK is a clock, which is generated by the clock pulse generator (CPG).

Frequency of RCLK:

— RZ/G2H: Select from 32.89kHz and 32.55kHz
— RZ/G2M V1.3: Select from 32.89kHz and 32.55kHz
— RZ/G2M V3.0: Select from 32.89kHz and 32.55kHz
— RZ/G2N: Select from 32.89kHz and 32.55kHz .
— RZ/G2E: Select from 31.3 kHz and 32.8 kHz.

64.1.1 Features

- One channel is provided.
- Can be used as a watchdog timer. Reset is generated when the counter overflows.
- A counter input clock can be chosen from:
  Clocks (RCLK/1 to RCLK/ (128 × 60 × 30)) that are obtained by dividing the RCLK.

64.1.2 Block Diagram

Figure 64.1 shows block diagrams of the RWDT.

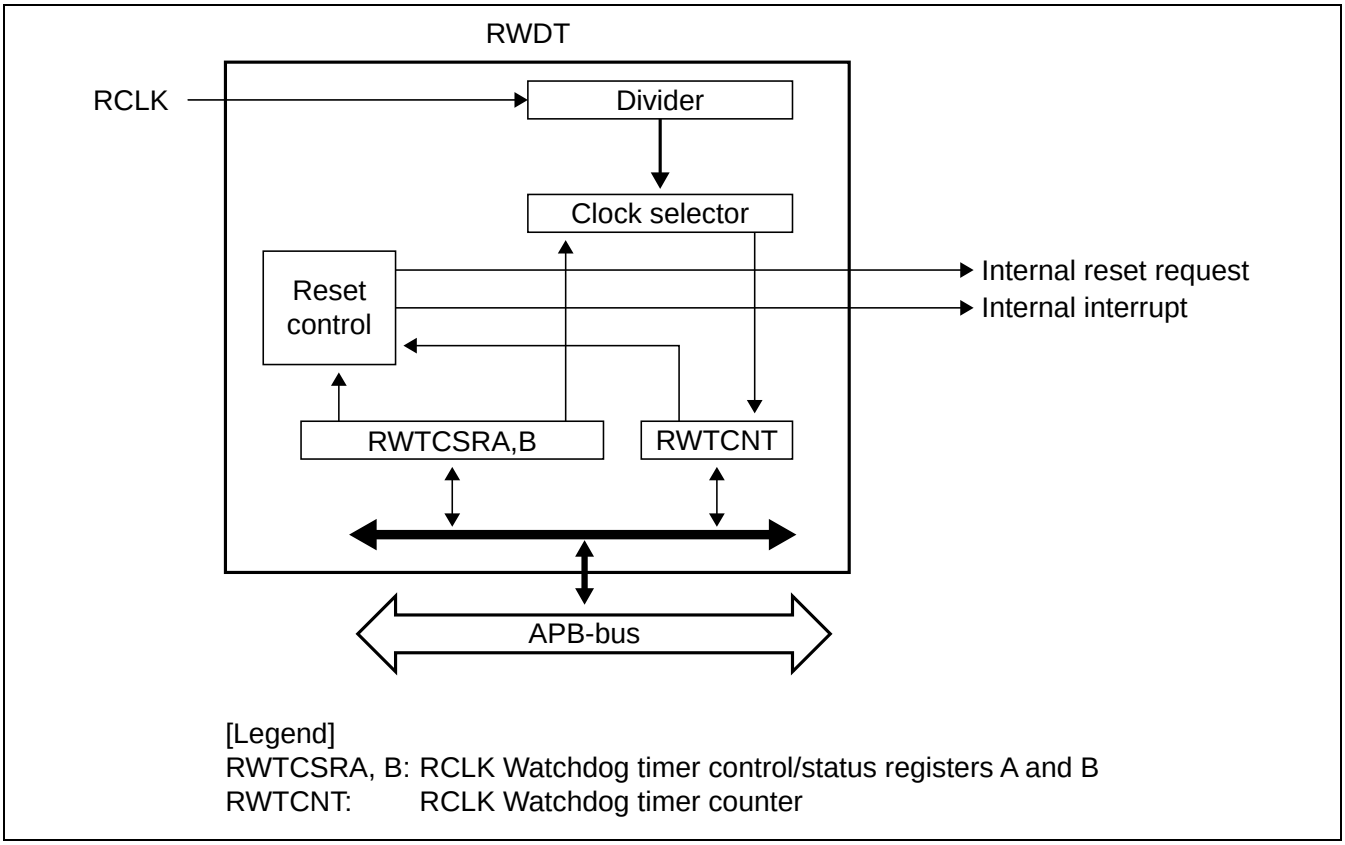

Figure 64.1 Block Diagram of RWDT

64.1.3 Register Configuration

Table 64.1 shows the RWDT register configuration. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined. Table 64.2 shows the register state in each processing mode.

Table 64.1 Register Configuration of RWDT

					Second Generation RZ/G Series Products			
Name	**Abbreviation**	**R/W**	**Address**	**Access Size**	**RZ/G2H**	**RZ/G2M V1.3 RZ/G2M V3.0**	**RZ/G2N**	**RZ/G2E**
RCLK watchdog timer counter	RWTCNT	R/W	H'E602_0000	16/32*1	√	√	√	√
RCLK watchdog timer control/status register A	RWTCSRA	R/W*3	H'E602_0004	8/32*2	√	√	√	√
RCLK watchdog timer control/status register B	RWTCSRB	R/W	H'E602_0008	8/32*2	√	√	√	√

Notes: 1. Write is performed in 32 bits and read in 16 bits. Operation cannot be guaranteed if the register is not written as a longword (32bits) and not read as a word (16bits).
2. Write is performed in 32 bits and read in 8 bits. Operation cannot be guaranteed if the register is not written as a longword (32bits) and not read as a byte (8bits).
3. Except for bit [4] that is R/WC0 register.

Note: * Section 65. System Watchdog Timer (SWDT) and RWDT overflow reset.

64.2 Register Description

[Legend for Register Description]

Initial value: Register value after a reset.

—: Undefined value

R/W: Bit or field is readable and writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R: Read-only. The write value should always be initial value.

—/WB: Write-only. The read value is initial value.

64.2.1 RCLK Watchdog Timer Counter (RWTCNT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

RWTCNT is a 16-bit readable/writable register that increments on the selected clock. When an overflow occurs, it generates a Reset. The RWTCNT counter is initialized to H'0000 by a power-on reset and RWDT software reset.

Use a long word access to write to the RWTCNT counter, with H'5A5A in the upper byte. Use a word access to read RWTCNT.

64.2.2 RCLK Watchdog Timer Control/Status Register A (RWTCSRA)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

RWTCSRA is an 8-bit readable/writable register composed of bits to select the clock used for the count, overflow flag, and enable bit.

Use a long word access to write to RWTCSRA, with H'A5_A5A5 in the upper byte. Use a byte access to read RWTCSRA.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CODE_VAL2[23:8]

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	CODE_VAL2 [23:0]	H'00_0000	—/WB	Code value 2 When writing this register, write H'A5_A5A5 to this bit field. When reading, these bits are always read as 0.
7	TME	B'0	R/W	Starts and stops timer operation. 0: Timer disabled: Count-up stops and RWTCNT value is retained 1: Timer enabled
6	—	B'0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	WRFLG	B'0	R	Write Status Flag When this bit is 1, write access to RWTCNT is prohibited. If it isn't maintained, operation isn't secured. This bit indicates the period that the writing to RWTCNT is masked for synchronization after the writing to RWTCNT Confirm that this flag is 0 when RWTCNT is written to continuously.
4	WOVF	B'0	R/WC0	Indicates that the RWTCNT has overflowed. This bit isn't initialized by a generated reset by an overflow of RWDT and section 65. System Watchdog Timer (SWDT). Write 0 to this bit before using the RWDT. 0: No overflow 1: RWTCNT has overflowed Note: Only 0 can be written to clear the flag.
3	WOVFE	B'1	R/W	Overflow Interrupt Disable/Enable 0: Disables interrupts due to overflow 1: Enables interrupts due to overflow

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	CKS0[2:0]	B’111	R/W	RTC Clock Select These bits select the clock to be used for the RWTCNT count from the eight types obtainable by dividing the RCLK. The overflow period that is shown inside the parenthesis in the table is the value when the RCLK is 32.768 kHz. B’000: RCLK (RWTCNT: H’0000 = 2.0 s (RWTCNT: H'FF00 = 7.8 ms)) B’001: RCLK/4 (RWTCNT: H’0000 = 8.0 s (RWTCNT: H'FF00 = 31.3 ms)) B’010: RCLK/16 (RWTCNT: H’0000 = 32.0 s (RWTCNT: H'FF00 = 125.0 ms)) B’011: RCLK/32 (RWTCNT: H’0000 = 64.0 s (RWTCNT: H'FF00 = 250.0 ms)) B’100: RCLK/64 (RWTCNT: H’0000 = 128.0 s (RWTCNT: H'FF00 = 500.0 ms)) B’101: RCLK/128 (RWTCNT: H’0000 = 256.0 s (RWTCNT: H'FF00 = 1.0 s)) B’110: RCLK/1024 (RWTCNT: H’0000 = 2048.0 s (RWTCNT: H'FF00 = 8.0 s)) B’111: RCLK select expanded mode The clock cycle varies depending on the CKS1 bit in RWTCSRB. If RWTCSRB.CKS1[3:0] is H’0, division ratio is RCLK/4096 and values of overflow time is RWTCNT: H’0000 = 8192.0 s (RWTCNT: H'FF00 = 32.0 s). If RWTCSRB.CKS1[3:0] is other than H’0, values of overflow time is calculated with formula in chapter 64.3.4. Note. These overflow periods are calculated from the rounded value of RCLK = 32.768 kHz as example.

Note: If bits CKS0 [2:0] are modified when the RWDT is operating, the up-count may not be performed correctly. Ensure that the bits CKS0 [2:0] are modified only when the RWDT is not operating.

64.2.3 RCLK Watchdog Timer Control/Status Register B (RWTCSRB)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

RWTCSRB is an 8-bit readable/writable register composed of bits to select the clock used for the count.

Use a word access to write to RWTCSRB, with H'A5_A5A5 in the upper byte. Use a byte access to read RWTCSRB.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

H'B	Prohibited (Prohibited)	14080 s (55 s)	Prohibited (Prohibited)	Prohibited (Prohibited)
H'C	Prohibited (Prohibited)	15360 s (60 s)	Prohibited (Prohibited)	Prohibited (Prohibited)
from H'D	Prohibited (Prohibited)	Prohibited (Prohibited)	Prohibited (Prohibited)	Prohibited (Prohibited)

Note. These overflow periods are calculated from the rounded value of RCLK = 32.768 kHz as example.

Note: If the CKS1 [5] to CKS1 [0] bits are modified when the RWDT is running, the up-count may not be performed correctly. Ensure that these bits are modified only when the RWDT is not running.

64.2.4 Notes on Register Access

RWTCSRA: Bits TME, CKS0

RWTCSRB: Bits CKS1

After writing a value in this register, it is possible to read that value 2 cycles in counter input clock (RCLK) after writing has finished. And 2 cycles of RCLK need to be inputted until the set-up value is reflected.

RWTCNT: Bits 15 to 0

After writing a value in this register, it is possible to read that value 2 cycles in counter input clock (RCLK) after writing has finished. And 2 cycles of RCLK need to be inputted until the set-up value is reflected. Writing to this register, once started, is protected from further write operations until the writing operation has been completed. Read RWTCSRA. If WRFLG is 0, the next value can be written in RWTCNT.

The writing procedure to RWTCNT, RWTCSRA, and RWTCSRB differs from that of other registers with the purpose of preventing an unintended write. The procedure for writing to these registers is given below.

Writing to RWTCNT, RWTCSRA, and RWTCSRB:

- These registers must be written by a long word transfer instruction. They cannot be written by a byte or word transfer instruction.
- When writing to RWTCNT, set the upper byte to H'5A5A and transfer the lower byte as the write data. When writing to RWTCSRA and RWTCSRB, set the upper byte to H'A5_A5A5 and transfer the lower byte as the write data.

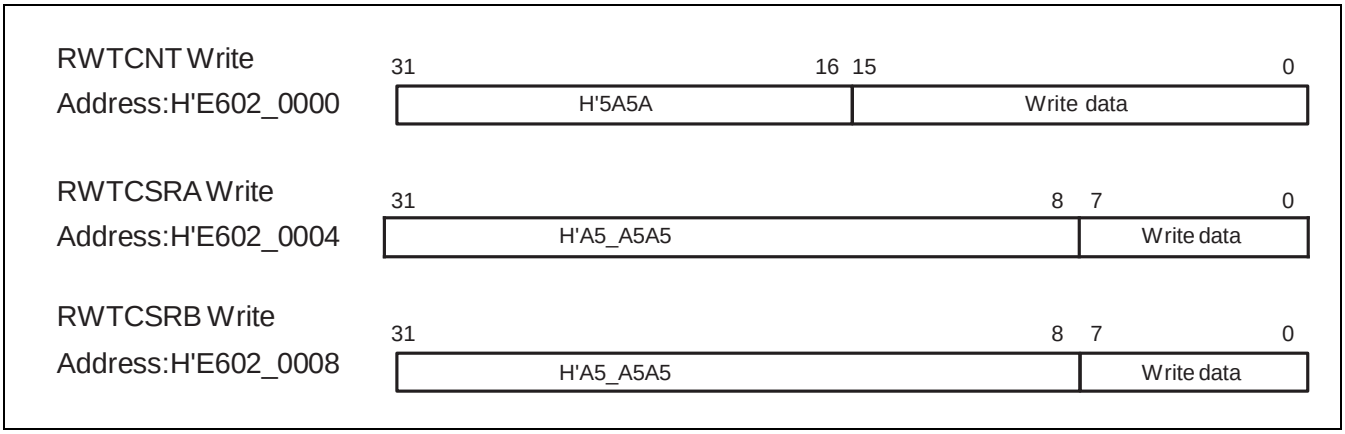

Figure 64.2 Writing to RWTCNT, RWTCSRA, and RWTCSRB

64.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

64.3.1 Control of System Runaway

After a reset, RWDT is disabled. When the counter overflow occurs after the counter starts, an internal reset is again generated. By this function, a reset can be automatically generated even when this LSI has caused a system runaway. While this LSI is operating correctly, write H'0000 (or the set value) to RWTCNT periodically so that RWTCNT does not overflow.

Take the following steps to use the RWDT.

1. Clear the TME bit in RWTCSRA to 0 to temporarily stop counting.
   (Confirm that RCLK was input more than 2 cycles in case RWTCNT is not initialized)
2. Write H'0000 or the set value in RWTCNT
3. Clear the WOVF bit in RWTCSRA to 0.
4. Set the kind of count clock to the CKS0 [2:0] bits in RWTCSRA, and CKS1 [5:0] bits in RWTCSRB.
5. Confirm that RWTCSRA.WRFLG becomes 0.
   If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the TME bit in RWTCSRA to 1.
   (TME and CKS0 can't be set at the same time. When setting that at the same time, behavior isn't guaranteed.)
7. While this LSI is operating correctly, write H'0000 (or the set value) to RWTCNT periodically so that RWTCNT does not overflow.
8. When RWTCNT overflows, Reset is generated because the RWDT sets the WOVF flag in RWTCSRA to 1. At this time, RWTCNT, RWTCSRA (excluding the WOVF bit), and RWTCSRB are initialized.

Execute a power-on reset or a software reset at that time and initialize RWDT.

When not initializing and using RWDT, behavior isn't guaranteed.

64.3.2 Module Stop

A setup of a stop of the Clock by a Module Stop signal is possible when RWDT is an idle state. The Idle state of RWDT is when the condition of following all was satisfied.

- When RWTCSRA.TME bit is 0
- When RWTCSRA.WRFLG is 0
- When 3 or more cycles have passed in RCLK since the last Register access

64.3.3 Debugging Operation

When debugging the CPU core, stop counting up RWTCNT and retain the value of RWTCNT.

64.3.4 Formula to calculate overflow time

This is the formula to calculate the overflow time for RWDT when choosing Expanded Mode.

Overflow time = 128 × T_RCLK × opset_val × (65536 – RWTCNT)

T_RCLK: is the period of RCLK clock.

RWTCNT: is value of RWTCNT in decade.

opset_val: refer table below.

CKS1[5:0]	opset_val	CKS1[5:0]	opset_val	CKS1[5:0]	opset_val	CKS1[5:0]	opset_val
H'00	32	H'10	32	H'20	32	H'30	32
H'01	1	H'11	5	H'21	60	H'31	300
H'02	2	H'12	10	H'22	120	H'32	600

65. System Watchdog Timer (SWDT)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

65.1 Overview

This LSI includes the System Watchdog Timer (SWDT).
This LSI can be reset by the overflow of the counter when the value of the counter has not been updated because of a system runaway.
The System Watchdog timer is a single-channel timer that uses the OSCCLK as an input clock and can be used as a watchdog timer. OSCCLK is a clock which is generated by CPG.

65.1.1 Features

- One channel is provided.
- Can be used as a watchdog timer. A reset is generated when the counter overflows.

65.1.2 Block Diagram

Figure 65.1 shows a block diagram of the System Watchdog Timer.

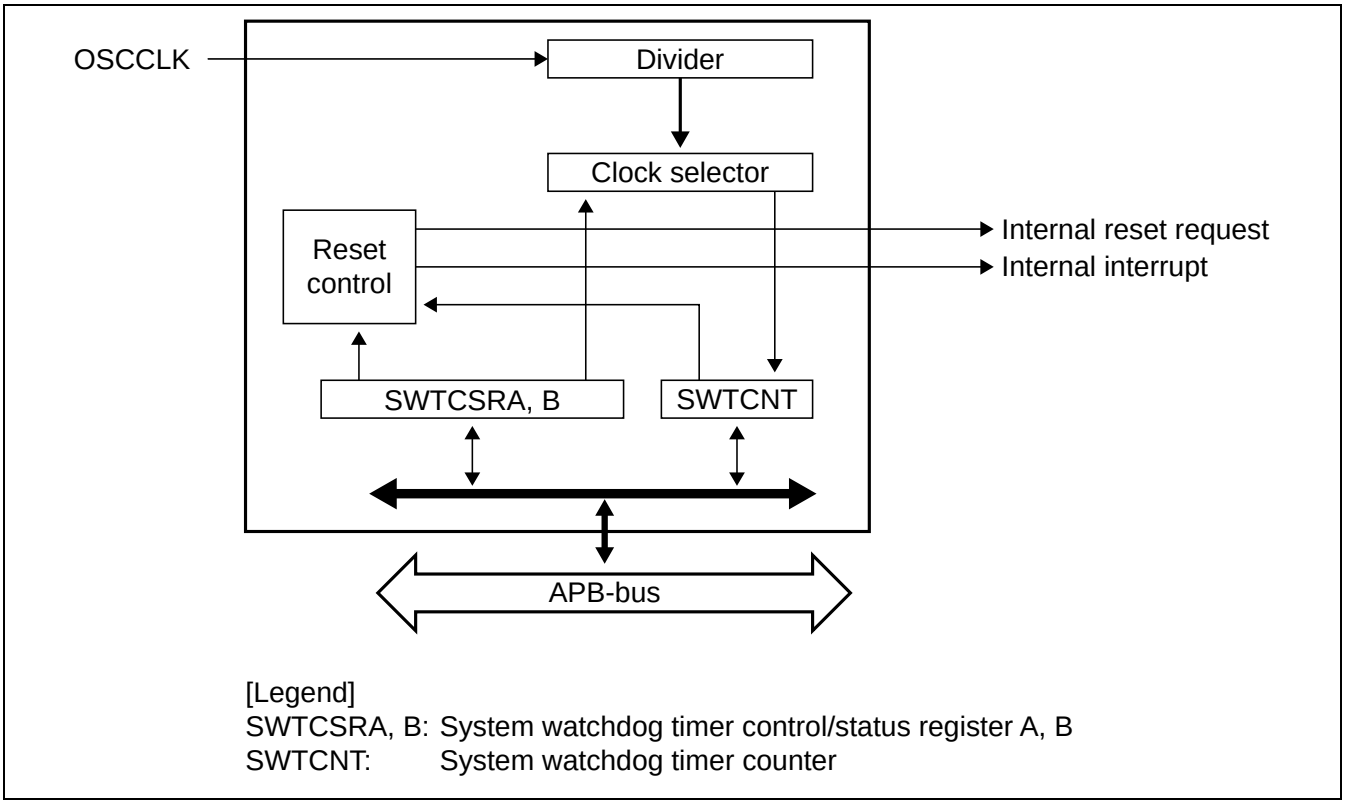

Figure 65.1 Block Diagram of System Watchdog Timer

65.1.3 Register Configuration

Table 65.1 shows the System Watchdog Timer register configuration. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined.

Table 65.2 shows the register state in each processing mode.

Table 65.1 Register Configuration of System Watchdog Timer

					Second Generation RZ/G Series Products

65.2 Register Description

[Legend for Register Description]

Initial value: Register value after a reset.

—: Undefined value

R/W: Bit or field is readable and writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R: Read-only. The write value should always be initial value.

—/WB: Write-only. The read value is initial value.

65.2.1 System Watchdog Timer Counter (SWTCNT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SWTCNT is a 16-bit readable/writable register that increments on the selected clock. When an overflow occurs, it generates a reset. The SWTCNT counter is initialized to H'F488 by a power-on reset.

Use a long word access to write to the SWTCNT counter, with H'5A5A in the upper byte. Use a word access to read SWTCNT.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CODE_VAL1[15:0]

65.2.2 System Watchdog Timer Control/Status Register A (SWTCSRA)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SWTCSRA is an 8-bit readable/writable register composed of bits to select the clock used for the count, overflow flag, and enable bit.

Use a long word access to write to SWTCSRA, with H'A5_A5A5 in the upper byte. Use a byte access to read SWTCSRA.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CODE_VAL2[23:8]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB	—/WB

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	CODE_VAL2 [23:0]	H’00_0000	—/WB	Code value 2 When writing this register, write H’A5_A5A5 to this bit field. When reading, these bits are always read as 0.
7	TME	B’1	R/W	Starts and stops timer operation. 0: Timer disabled: Count-up stops and SWTCNT value is retained 1: Timer enabled
6	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	WRFLG	B’0	R	Write Status Flag When this bit is 1, write access to SWTCNT is prohibited. If it isn't maintained, operation isn't secured. This bit indicates the period that the writing to SWTCNT is masked for synchronization after the writing to SWTCNT Confirm that this flag is 0 when SWTCNT is written to continuously.
4	WOVF	B’0	R/WC0	Indicates that the SWTCNT has overflowed. This bit isn't initialized by a generated reset by an overflow of section 64. RCLK Watchdog Timer (RWDT) and System Watchdog Timer. Write 0 to this bit before using the System Watchdog Timer. 0: No overflow 1: SWTCNT has overflowed Note: Only 0 can be written to clear the flag.
3	WOVFE	B’1	R/W	Overflow Interrupt Disable/Enable 0: Disables interrupts due to overflow 1: Enables interrupts due to overflow

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	CKS0[2:0]	B’111	R/W	RTC Clock Select These bits select the clock to be used for the SWTCNT count from the eight types obtainable by dividing the OSCCLK. The overflow period that is shown inside the parenthesis in the table is the value when the OSCCLK is 131.578 kHz. B’000: OSCCLK (SWTCNT: H’0000 = 498 ms (SWTCNT: H’FBFC = 7.8 ms)) B’001: OSCCLK /4 (SWTCNT: H’0000 = 2.0 s (SWTCNT: H’FBFC = 31.3 ms)) B’010: OSCCLK /16 (SWTCNT: H’0000 = 8.0 s (SWTCNT: H’FBFC = 125.0 ms)) B’011: OSCCLK /32 (SWTCNT: H’0000 = 16 s (SWTCNT: H’FBFC = 250.0 ms)) B’100: OSCCLK /64 (SWTCNT: H’0000 = 32 s (SWTCNT: H’FBFC = 500.0 ms)) B’101: OSCCLK /128 (SWTCNT: H’0000 = 64 s (SWTCNT: H’FBFC = 1.0 s)) B’110: OSCCLK /1024 (SWTCNT: H’0000 = 510.0 s (SWTCNT: H’FBFC = 8.0 s)) B’111: OSCCLK select expanded mode The clock cycle varies depending on the CKS1 bit in SWTCSRB. If SWTCSRB.CKS1[3:0] is H’0, division ratio is OSCCLK/4096 and values of overflow time is SWTCNT: H’0000 = 2040.0 s (SWTCNT: H’FBFC = 32.0 s). If SWTCSRB.CKS1[3:0] is other than H’0, values of overflow time is calculated with formula in chapter 65.3.3. Note: These overflow periods are calculated from the rounded value of OSCCLK = 131.578 kHz.

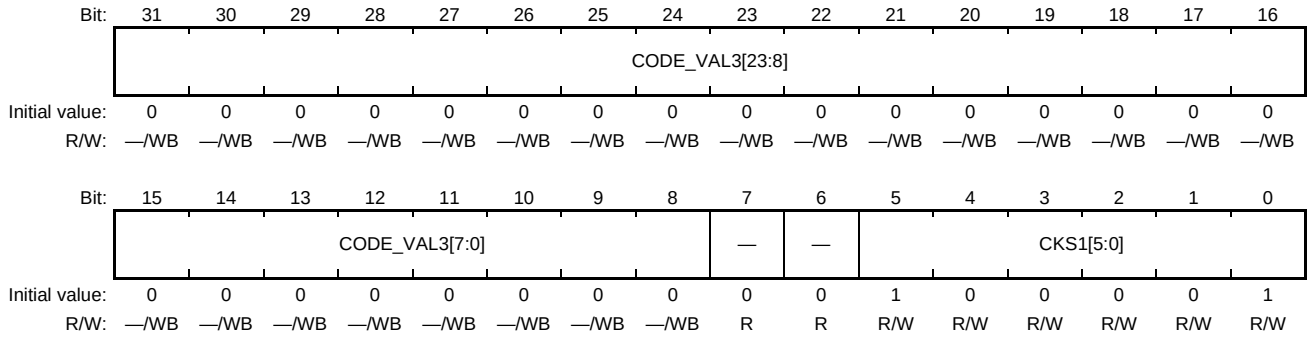
Note: If bits CKS0 [2:0] are modified when the System Watchdog Timer is operating, the up-count may not be performed correctly. Ensure that the bits CKS0 [2:0] are modified only when the System Watchdog Timer is not operating.

65.2.3 System Watchdog Timer Control/Status Register B (SWTCSRB)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

SWTCSRB is an 8-bit readable/writable register composed of bits to select the clock used for the count.

Use a word access to write to SWTCSRB, with H'A5_A5A5 in the upper byte. Use a byte access to read SWTCSRB.



Bit	Bit Name	Initial Value	R/W	Description
31 to 8	CODE_ VAL3[23:0]	H’00_0000	—/WB	Code value 3 When writing this register, write H’A5_A5A5 to this bit field. When reading, these bits are always read as 0.
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5 to 0	CKS1[5:0]	B’10_0001	R/W	OSCCLK Select for OSCCLK Select Expanded Mode Selects the clock used for the SWTCNT count when the CKS0 bit in SWTCSRA is B'111. The following table shows the time values used to cause an overflow from the counter H'0F13 (Overflow from counter H'FBFC). Assuming the overflow cycle in the table is calculated for the case when the OSCCLK is 131.578 kHz. For more values of overflow time, refer to chapter 65.3.3

CKS1[5:4] / CKS1[3:0]	B'00	B'01	B'10	B'11
H'0	1920 s (32 s)			
H'1	60 s (1 s)	5 min (5 s)	60 min (1 min)	300 min (5 min)

from H'D	Prohibited (Prohibited)	Prohibited (Prohibited)	Prohibited (Prohibited)	Prohibited (Prohibited)

Note: If the CKS1 [5] to CKS1 [0] bits are modified when the System Watchdog Timer is running, the up-count may not be performed correctly. Ensure that these bits are modified only when the System Watchdog Timer is not running.

65.2.4 Notes on Register Access

SWTCSRA: Bits TME, CKS0

SWTCSRB: Bits CKS1

After writing a value in this register, it is possible to read that value 2 cycles in counter input clock (OSCCLK) after writing has finished. And 2 cycles of OSCCLK need to be inputted until the set-up value is reflected.

SWTCNT: Bits 15 to 0

After writing a value in this register, it is possible to read that value 2 cycles in counter input clock (OSCCLK) after writing has finished. And 2 cycles of OSCCLK need to be inputted until the set-up value is reflected. Writing to this register, once started, is protected from further write operations until the writing operation has been completed. Read SWTCSRA. If WRFLG is 0, the next value can be written in SWTCNT.

The writing procedure to SWTCNT, SWTCSRA, and SWTCSRB differs from that of other registers with the purpose of preventing an unintended write. The procedure for writing to these registers is given below.

Writing to SWTCNT, SWTCSRA, and SWTCSRB

- These registers must be written by a long word transfer instruction. They cannot be written by a byte or word transfer instruction.
- When writing to SWTCNT, set the upper byte to H'5A5A and transfer the lower byte as the write data. When writing to SWTCSRA and SWTCSRB, set the upper byte to H'A5_A5A5 and transfer the lower byte as the write data.

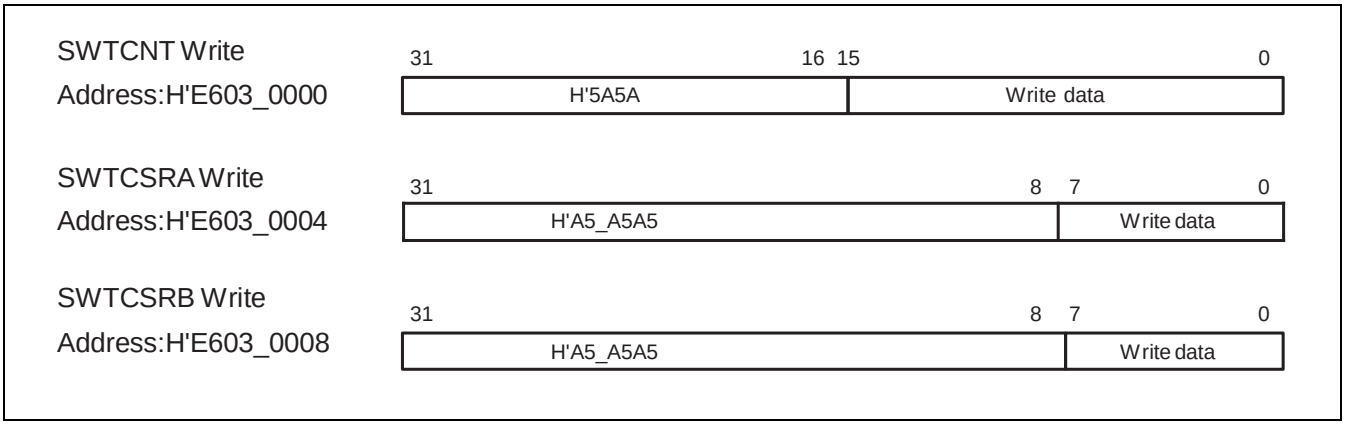

Figure 65.2 Writing to SWTCNT, SWTCSRA, and SWTCSRB

65.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

65.3.1 Control of System Runaway

After a reset, System Watchdog Timer is enabled. When the counter overflow occurs after the counter starts, an internal reset is again generated. By this function, a reset can be automatically generated even when this LSI has caused a system runaway. While this LSI is operating correctly, write H'0000 (or the set value) to SWTCNT periodically so that SWTCNT does not overflow.

Take the following steps to use the System Watchdog Timer.

1. Clear the TME bit in SWTCSRA to 0 to temporarily stop counting.
   (Confirm that OSCCLK was input more than 2 cycles in case SWTCNT is not initialized)
2. Write H'0000 or the set value in SWTCNT
3. Clear the WOVF bit in SWTCSRA to 0.
4. Set the kind of count clock to the CKS0 [2:0] bits in SWTCSRA, and CKS1 [5:0] bits in SWTCSRB.
5. Confirm that SWTCSRA.WRFLG becomes 0.
   If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the TME bit in SWTCSRA to 1.
   (TME and CKS0 can't be set at the same time. When setting that at the same time, behavior isn't guaranteed.)
7. While this LSI is operating correctly, write H'0000 (or the set value) to SWTCNT periodically so that SWTCNT does not overflow.
8. When SWTCNT overflows, Reset is generated because the System Watchdog Timer sets the WOVF flag in SWTCSRA to 1. At this time, SWTCNT, SWTCSRA (excluding the WOVF bit), and SWTCSRB are initialized.

Execute a power-on reset or a software reset at that time and initialize System Watchdog Timer.

When not initializing and using System Watchdog Timer, behavior isn't guaranteed.

65.3.2 Debugging Operation

When debugging the CPU core, stop counting up SWTCNT and retain the value of SWTCNT.

65.3.3 Formula to calculate overflow time

This is the formula to calculate the overflow time for SWDT when choosing Expanded Mode.

Overflow time = 128 × T_OSCCLK × opset_val × (65536 – SWTCNT)

T_OSCCLK: is the period of OSCCLK clock.

SWTCNT: is value of SWTCNT in decade.

opset_val: refer to table below.

CKS1[5:0]	opset_val	CKS1[5:0]	opset_val	CKS1[5:0]	opset_val	CKS1[5:0]	opset_val
H'00	32	H'10	32	H'20	32	H'30	32
H'01	1	H'11	5	H'21	60	H'31	300

66. 16-Bit Timer Pulse Unit (TPU)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

66.1 Overview

This LSI has a 16-bit timer pulse unit (TPU), which consists of four 16-bit timers.

Internal clock:

— RZ/G2H: S3D4ϕ
— RZ/G2M V1.3: S3D4ϕ
— RZ/G2M V3.0: S3D4ϕ
— RZ/G2N: S3D4ϕ
— RZ/G2E: S3D4Cϕ

66.1.1 Features

The TPU has the following features.

- Four timers are incorporated.
- Four pulse outputs are possible.
- Each timer of the TPU has four general registers (TGRA, TGRB, TGRC, and TGRD) for each timer. TGRA enables an output compare setting. TGRB, TGRC and TGRD in each timer can be used as timer-counter clearing registers. TGRC and TGRD can also be used as buffer registers.
- The following operations can be set for each timer.
  Waveform output on compare match: output of a 0 or 1 or toggling of output is selectable.
  Counter clearing operation: Counters can be cleared in response to a compare match.
  PWM mode allows the output of a PWM waveform with any duty cycle.
  The four outputs can be used to produce PWM output in up to four phases.
- A stepping motor control mode is available for timer 0.
- Buffer operation can be set for each timer.
- Automatic rewriting of values in output compare registers is possible.
- One interrupt request from TPU
  Enabling or disabling of compare match and counter overflows as interrupt sources can be set independently for each timer.
  In stepping motor control mode, enabling or disabling of state transitions, requests for data, and overflows of data as interrupt sources is possible for timer 0.

Table 66.1 shows the TPU functions.

Table 66.1 TPU Functions

66.1.4 Register Configuration

Table 66.3 shows the TPU register configuration. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined. Access the register as a word (16 bits). Operation cannot be guaranteed if the register is not accessed as a word.

Table 66.4 shows the register states in each operating mode.

66.2 Register Description

Registers in the TPU are allocated to and arranged in the address space of the internal bus.

Legend for Register Description

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R: Read-only. When the bit is reserved, the write value should always be 0. Writing 1 to these bits can cause a malfunction of TPU.

—/W: Write-only. The read value is undefined.

66.2.1 Timer Control Register (TCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TCR is provided for each of timers 0 to 3 and is used to control TCNT. TCR is initialized to H'0000 by a reset.

Writing to TCR is only allowed only when TCNT is stopped.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CCLR[2:0]			CKEG[1:0]		TPSC[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
7 to 5	CCLR[2:0]	B’000	R/W	Counter Clear Specify the TCNT clearing source. B’000: TCNT clearing disabled B’001: TCNT cleared in response to TGRA compare match B’010: TCNT cleared in response to TGRB compare match B’011: Setting prohibited B’100: TCNT clearing disabled B’101: TCNT cleared in response to TGRC compare match B’110: TCNT cleared in response to TGRD compare match B’111: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
4, 3	CKEG[1:0]	B’00	R/W	Clock Edge Select the input clock edge for counting up. Counting of both edges by the internal clock has the same effect as halving the cycle of the input clock (e.g., the rate of counting both edges of Internal clock/4 is same as the rate of counting rising edges of Internal clock/2). When the phase coefficient mode is selected, this setting is ignored. B’00: Count rising edges B’01: Count falling edges* 1X: Count both edges* [Legend] X: Don't care Note: * If the input clock is Internal clock/1, the timer does not operate with this setting.
2 to 0	TPSC[2:0]	B’000	R/W	Timer Prescaler Select the clock for counting by TCNT. The clock source can be selected independently for each timer. Table 66.5 shows the clock sources that can be set for each timer. For more information on count clock selection, see Table 66.6.

Table 66.5 TPU Clock Sources

	Internal Clock

Table 66.6 Count Clock Selection by the TPSC [2:0] Bits

Timer	TPSC[2]	TPSC[1]	TPSC[0]	Description
0 to 3	B’0	B’0	B’0	Internal clock /1 (initial value)
			B’1	Internal clock /4
		B’1	B’0	Internal clock /16
			B’1	Internal clock /64
	B’1	*	*	Setting prohibited

[Legend]
*: Don't care.

66.2.2 Timer Mode Register (TMDR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TMDR is provided for each of timers 0 to 3, and is used to specify the operating mode of the corresponding timer. TMDR is initialized to H'0000 by a reset.

Writing to TMDR is only allowed when TCNT is stopped.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	BFWT	BFB	BFA	—	MD[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
6	BFWT	B'0	R/W	Buffer Write Timing Specifies when to update TGRA and TGRB when TGRC and TGRD are in use as compare match buffers. When TGRC and TGRD are not in use as compare match buffer registers, this has no effect. 0: TGRA and TGRB are rewritten on a compare match with the counters. 1: TGRA and TGRB are rewritten on clearing of the counter.
5	BFB	B'0	R/W	Buffer Operation B Specifies operation mode of TGRB. 0: TGRB is in normal operation. 1: TGRB and TGRD are used for buffered operation.
4	BFA	B'0	R/W	Buffer Operation A Specifies operation mode of TGRA. 0: TGRA normal operation. 1: TGRA and TGRC are used for buffered operation.
3	—	B'0	R	Reserved This bit is always read as 0 and cannot be modified.
2 to 0	MD[2:0]	B'000	R/W	Timer Operating Mode Specifies the timer operating mode. B'000: Normal operation B'001: Setting prohibited B'010: PWM mode B'011 to B'111: Setting prohibited

66.2.3 Timer I/O Control Register (TIOR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TIOR is provided for each of timers 0 to 3, and is used to control the corresponding TPU0TO0 to TPU0TO3 pins. TIOR is initialized to H'0000 by a reset.

Writing to TIOR is only allowed when TCNT is stopped. Note that the setting of TMDR may affect TIOR.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	IOA[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
2 to 0	IOA[2:0]	B'000	R/W	I/O Control Bits IOA2 to IOA0 specify the functions of TGRA and the TPU0TO0 to TPU0TO3 pins. For details, see Table 66.7.

Table 66.7 Settings for Bits IOA [2:0], Initial States of Pins TPU0TO0 to TPU0TO3, and Results of Matching with TGRA

Timer	IOA[2]	IOA[1]	IOA[0]	Description	
0 to 3	B'0	B'0	B'0	Always output 0 (initial value)	
			B'1	Initial output from the TPU0TO0 to TPU0TO3 pins is 0	Output 0 on compare match with TGRA.*
		B'1	B'0		Output 1 on compare match with TGRA.
			B'1		Toggle output on compare match with TGRA.*
	B'1	B'0	B'0	Always output 1	
			B'1	Initial output from the TPU0TO0 to TPU0TO3 pins is 1	Output 0 on compare match with TGRA.
		B'1	B'0		Output 1 on compare match with TGRA.*
			B'1		Toggle output on compare match with TGRA.*

Note: * This setting is prohibited in PWM mode.

66.2.4 Timer Interrupt Enable Register (TIER)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TIER is provided for each of timers 0 to 3 and is used to enable or disable the sources of interrupt requests for the corresponding timer. TIER is initialized to H'0000 by a reset. Bits 8 to 13 are only present in timer 0.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	TMDOFE	TMDRFE	TMS1ER	TMS1ET	TMS1EA	TMS1ES	—	—	—	TC1EV	TG1ED	TG1EC	TG1EB	TG1EA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
13	TMDOFE	B'0	R/W	Motor Control Data Transfer Overflow Detection Enable This bit enables or disables interrupt request in response to the state of the TMDOFS flag in the stepping motor control mode of timer 0. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. 0: Interrupt request in response to the TMDOFS flag disabled 1: Interrupt request in response to the TMDOFS flag enabled
12	TMDRFE	B'0	R/W	Motor Control Data Transfer Request Detection Enable This bit enables or disables interrupt request in response to the state of the TMDRFS flag in the stepping motor control mode of timer 0. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. 0: Interrupt request in response to the TMDRFS flag disabled 1: Interrupt request in response to the TMDRFS flag enabled
11	TMS1ER	B'0	R/W	Motor Control Deceleration Transition Detection Enable This bit enables or disables interrupt request in response to the state of the TMCFR flag in the stepping motor control mode of timer 0. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. 0: Interrupt request in response to the TMCFR flag disabled 1: Interrupt request in response to the TMCFR flag enabled
10	TMS1ET	B'0	R/W	Motor Control Normal Transition Detection Enable This bit enables or disables interrupt request in response to the state of the TMCFT flag in the stepping motor control mode of timer 0. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. 0: Interrupt request in response to the TMCFT flag disabled 1: Interrupt request in response to the TMCFT flag enabled

Bit	Bit Name	Initial Value	R/W	Description
9	TMS1EA	B'0	R/W	Motor Control Acceleration Transition Detection Enable This bit enables or disables interrupt request in response to the state of the TMCFA flag in the stepping motor control mode of timer 0. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. 0: Interrupt request in response to the TMCFA flag disabled 1: Interrupt request in response to the TMCFA flag enabled
8	TMS1ES	B'0	R/W	Motor Control Stop Transition Detection Enable This bit enables or disables interrupt request in response to the state of the TMCFS flag in the stepping motor control mode of timer 0, This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. 0: Interrupt request in response to the TMCFS flag disabled 1: Interrupt request in response to the TMCFS flag enabled
7 to 5	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
4	TC1EV	B'0	R/W	Overflow Interrupt Enable This bit enables or disables the interrupt request in response to the state of the TCFV flag. 0: Interrupt request in response to the TCFV flag disabled 1: Interrupt request in response to the TCFV flag enabled
3	TG1ED	B'0	R/W	TGR Interrupt Enable D. This bit enables or disables interrupt request in response to the state of the TGFD bit. 0: Interrupt request in response to the TGFD bit disabled 1: Interrupt request in response to the TGFD bit enabled
2	TG1EC	B'0	R/W	TGR Interrupt Enable C This bit enables or disables interrupt request in response to the state of the TGFC bit. 0: Interrupt request in response to the TGFC bit disabled 1: Interrupt request in response to the TGFC bit enabled
1	TG1EB	B'0	R/W	TGR Interrupt Enable B This bit enables or disables interrupt request in response to the state of the TGFB bit. 0: Interrupt request in response to the TGFB bit disabled 1: Interrupt request in response to the TGFB bit enabled
0	TG1EA	B'0	R/W	TGR Interrupt Enable A This bit enables or disables interrupt request in response to the state of the TGFA bit. 0: Interrupt request in response to the TGFA bit disabled 1: Interrupt request in response to the TGFA bit enabled

66.2.5 Timer Status Registers (TSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TSR is provided for each of timers 0 to 3 and indicates the state of the corresponding timer. TSR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	TMDOFS	TMDRFS	TMCFR	TMCFT	TMCFA	TMCFS	—	—	—	TCFV	TGFD	TGFC	TGFB	TGFA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0	R	R	R	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
13	TMDOFS	B'0	R/WC0	Motor Control Data Transfer Overflow Detection This flag indicates that a data transfer overflow has been detected in the stepping motor control mode of timer 0. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. [Clearing condition] Writing 0 to the TMDOFS bit after reading the TMDOFS bit while TMDOFS is set to 1 [Setting condition] When the DMA transfer overflow occurs
12	TMDRFS	B'0	R/WC0	Motor Control Data Transfer Request Detection This flag indicates that a data transfer request interrupt has been detected in the stepping motor control mode of timer 0. If DMA transfer is not in use, data are written to TGRD0 in response to this interrupt. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. [Clearing condition] Writing 0 to the TMDRFS bit after reading the TMDRFS bit while TMDRFS is set to 1 [Setting condition] When data transfer request occurs
11	TMCFR	B'0	R/WC0	Motor Control Deceleration Transition Detection This flag indicates that the current sequence state of timer 0 in the stepping motor control mode is the deceleration state. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. [Clearing condition] Writing 0 to the TMCFR bit after reading TMCFR bit = 1 [Setting condition] When the sequence state is shifted to the deceleration state

Bit	Bit Name	Initial Value	R/W	Description
10	TMCFT	B'0	R/WC0	Motor Control Normal Transition Detection This flag indicates that the current sequence state of timer 0 in the stepping motor control mode is the normal state. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. [Clearing condition] Writing 0 to the TMCFT bit after reading TMCFT bit = 1 [Setting condition] When the sequence state is shifted to the normal state
9	TMCFA	B'0	R/WC0	Motor Control Acceleration Transition Detection This flag indicates that the current sequence state of timer 0 in the stepping motor control mode is the acceleration state. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. [Clearing condition] Writing 0 to the TMCFA bit after reading TMCFA bit = 1 [Setting condition] When the sequence state is shifted to the acceleration state
8	TMCFS	B'0	R/WC0	Motor Control Stop Transition Detection This flag indicates that the current sequence state of timer 0 in the stepping motor control mode is the stop state. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. [Clearing condition] Writing 0 to the TMCFS bit after reading TMCFS bit = 1 [Setting condition] When the sequence state is shifted to the stop state
7 to 5	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
4	TCFV	B'0	R/WC0	Overflow This flag indicates that TCNT has overflowed. [Clearing condition] Writing 0 to the TCFV bit after reading TCFV bit = 1 [Setting condition] When the value of TCNT overflows (when its value changes from H'FFFF to H'0000)
3	TGFD	B'0	R/WC0	Compare Flag D This flag indicates that the values of TCNT and TGRD have matched (a compare match). [Clearing condition] Writing 0 to the TGFD bit after reading TGFD bit = 1 [Setting condition] When the values of TCNT and TGRD have matched
2	TGFC	B'0	R/WC0	Compare Flag C This flag indicates that the values of TCNT and TGRC have matched (a compare match). [Clearing condition] Writing 0 to the TGFC bit after reading TGFC bit = 1 [Setting condition] When the values of TCNT and TGRC have matched

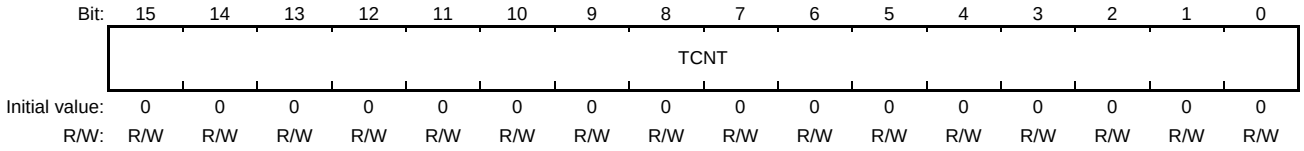
Bit	Bit Name	Initial Value	R/W	Description
1	TGFB	B'0	R/WC0	Compare Flag B This flag indicates that the values of TCNT and TGRB have matched (a compare match). [Clearing condition] Writing 0 to the TGFB bit after reading TGFB bit = 1 [Setting condition] When the values of TCNT and TGRB have matched
0	TGFA	B'0	R/WC0	Output Compare Flag A This flag indicates that the values of TCNT and TGRA have matched (a compare match). [Clearing condition] Writing 0 to the TGFA bit after reading TGFA bit = 1 [Setting condition] When the values of TCNT and TGRA are matched

66.2.6 Timer Counter (TCNT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TCNT is a 16-bit counter, and is provided for each of timers 0 to 3.

TCNT is initialized to H'0000 by a reset.



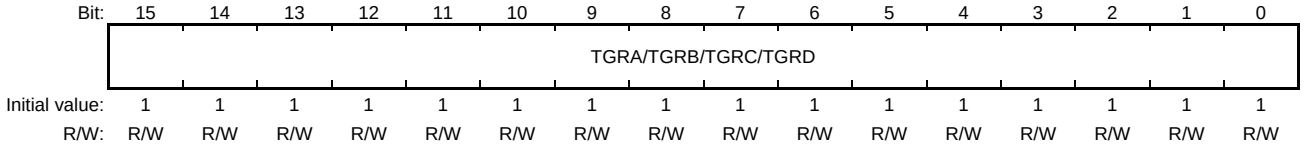
Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TCNT	H'0000	R/W	Timer Counter Bits

66.2.7 Timer General Register A to D (TGRA/TGRB/TGRC/TGRD)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TGRA, TGRB, TGRC and TGRD are 16 bits general registers that are provided for each of timers 0 to 3. TGRC and TGRD can be designated for operation as buffer registers*. TGR is initialized to H'FFFF by a reset.

Note: * The combinations of TGR registers and buffer registers are TGRA with TGRC and TGRB with TGRD.



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TGRA/TGRB/ TGRC/TGRD	H’FFFF	R/W	Timer General Register Bits

66.2.8 Timer Start Register (TSTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TSTR is used to start or stop the timer counter (TCNT) of timers 0 to 3.

TSTR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	TMST	CST3	CST2	CST1	CST0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
4	TMST	B’0	R/W	Motor Control Sequence Start Selects whether to start or stop the motor control sequence. This bit is cleared to 0 when the timer has shifted to the stop state after motor control operation was started. 0: Stops motor control sequence 1: Starts motor control sequence
3	CST3	B’0	R/W	Counter Start Selects whether to start or stop the TCNT3 operation. 0: Stops the TCNT3 counting operation 1: Starts the TCNT3 counting operation
2	CST2	B’0	R/W	Counter Start Selects whether to start or stop the TCNT2 operation. 0: Stops the TCNT2 counting operation 1: Starts the TCNT2 counting operation
1	CST1	B’0	R/W	Counter Start Selects whether to start or stop the TCNT1 operation. 0: Stops the TCNT1 counting operation 1: Starts the TCNT1 counting operation
0	CST0	B’0	R/W	Counter Start Selects whether to start or stop the TCNT0 operation. 0: Stops the TCNT0 counting operation 1: Starts the TCNT0 counting operation

66.2.9 Motor Control Setting Register (TMIR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TMIR is used to configure operation in the motor control mode.

TMIR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	TDMAE	MTRPAT DOWN	MTRPATKIND [1:0]		MTRON
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
4	TDMAE	B’0	R/W	Selection of DMA Use Selects whether to use DMA for step interval input (writing to TGRD0) in the motor control mode. 0: DMA is not used. 1: DMA is used.
3	MTRPAT DOWN	B’0	R/W	Operation and Stop Patterns Transition Ascending/Descending Select Selects the direction of transitions within operation and stop patterns as ascending or descending in the motor control mode. 0: Ascending 1: Descending
2, 1	MTRPAT KIND[1:0|	B’00	R/W	Operation and Stop Pattern Type Select Selects the number of patterns in the cycles of stop and start patterns in the motor control mode. B’00: Four B’01: Eight B’10: Setting prohibited B’11: Setting prohibited
0	MTRON	B’0	R/W	TPU Mode/Stepping Motor Control Mode Select 0: TPU mode 1: Stepping motor control mode Note: This bit also controls a selecting signal to switch TPU0TO0 to TPU0TO3 outputs. Set this bit to 1 after making initial settings for the pattern cycle. Do not modify this bit during the counter operation.

66.2.10 Motor Deceleration (Stop) Transition Register (TMRR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TMRR is used to place timer 0 in to the deceleration state from the normal state, in the motor control mode.

TMRR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	REDUON0	REDUON
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 2	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
1	REDUON0	B’0	R/W	This bit is used to force a transition of timer 0 to the deceleration (or stop) state from the normal state in motor control mode. Note that the state transition only proceeds when pattern 0 is the currently specified pattern. Setting this bit has no effect if timer 0 is not in the normal state. This bit is automatically cleared to 0 when the state of timer 0 shifts to the stop state. 0: No operation 1: Timer 0 is forcibly placed in the deceleration (or stop) state from the normal state.
0	REDUON	B’0	R/W	This bit is used to force a transition of timer 0 to the deceleration (or stop) state from the normal state in motor control mode. Setting this bit has no effect if timer 0 is not in the normal state. This bit is automatically cleared to 0 when the state of timer 0 shifts to the stop state. 0: No operation 1: Timer 0 is forcibly placed in the deceleration (or stop) state from the normal state.

66.2.11 Motor Control Status Register (TMSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TMSR is a read-only register that indicates the sequence state in motor control mode.

TMSR is initialized to H'0001 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	SITR	SITT	SITA	SITS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
3	SITR	B'0	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is deceleration. 0: The sequence state is not deceleration.
2	SITT	B'0	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is normal. 0: The sequence state is not normal.
1	SITA	B'0	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is acceleration. 0: The sequence state is not acceleration.
0	SITS	B'1	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is stop. 0: The sequence state is not stop.

66.2.12 Motor Operation Pattern Storing Register 0 (TMMPR0)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TMMPR0 is used to set motor operation patterns [3] to [0] in motor control mode.

TMMPR0 is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

66.2.16 Motor Output Pattern Storing Register (TMOPR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TMOPR is used to specify the motor output pattern in motor control mode. When read, it indicates the pattern currently being output. Writing to this register while the sequence is in the stop state leads to output of the pattern with the corresponding number. TMOPR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	NOWPAT[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
2 to 0	NOWPAT [2:0]	B'000	R/W	In motor control mode, Reading: The pattern number currently being output is read. Writing: If the sequence is in the stop state, the pattern corresponding to the written pattern number is output.

66.2.17 Motor Acceleration Step Count Register (TMASR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TMASR is used to set the number of steps in the acceleration state of motor control mode. TMASR is initialized to H'0000 by a reset.

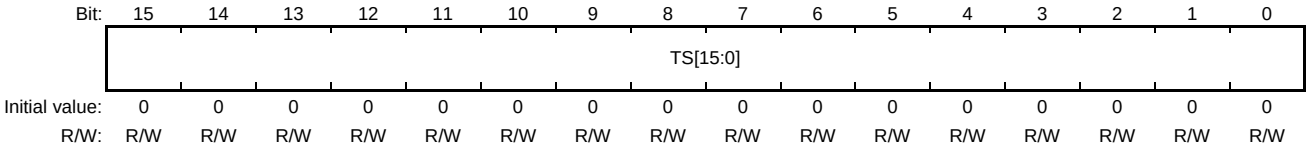
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AS[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	AS[15:0]	H'0000	R/W	Specify the number of steps in the acceleration state of motor control mode. When the setting is H'0000, the acceleration state is skipped.

66.2.18 Motor Normal the Number of Steps Register (TMTSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TMTSR is used to set the number of steps in the normal state of motor control mode. TMTSR is initialized to H'0000 by a reset.

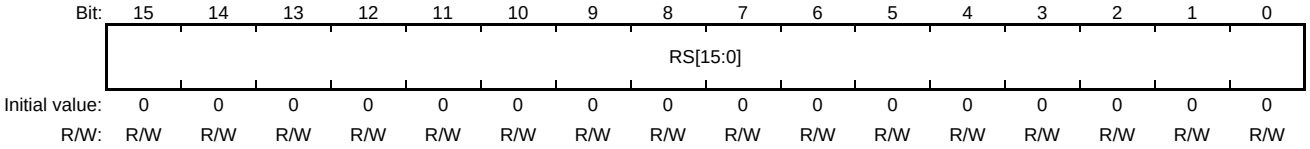


Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TS[15:0]	H'0000	R/W	Specify the number of steps in the normal state of motor control mode. When the setting is H'0000, the normal state is maintained until 1 is written to the REDUON0 bit or REDUON bit in TMRR.

66.2.19 Motor Deceleration the Number of Steps Register (TMRSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TMRSR is used to set the number of steps in the deceleration state of motor control mode. TMRSR is initialized to H'0000 by a reset.



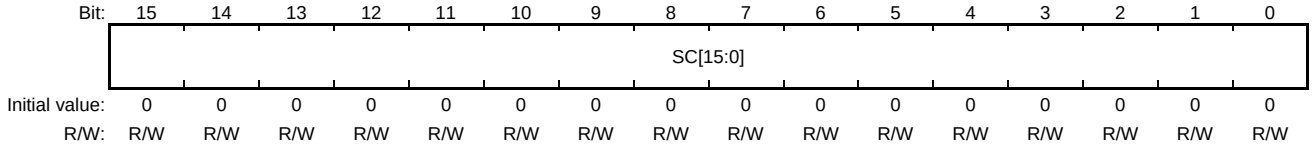
Bit	Bit Name	Initial Value	R/W	Description
15 to 0	RS[15:0]	H'0000	R/W	Specify the number of steps in the deceleration state of motor control mode. When the setting is H'0000, the deceleration state is skipped.

66.2.20 Motor Control Sequence Counter Register (TMSCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TMSCR indicates or controls the value of the sequence counter in motor control mode. Writing to this register is only allowed when the motor control mode is in use and the current state is the normal state.

TMSCR is initialized to H'0000 by a reset.

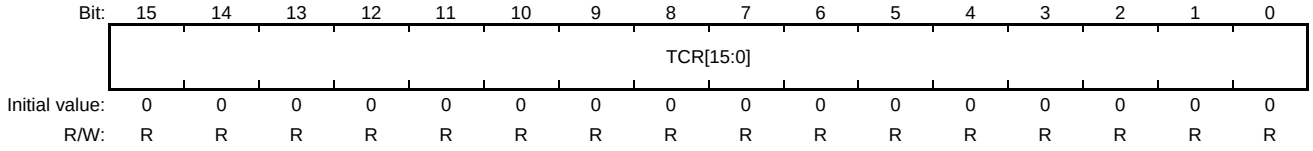


Bit	Bit Name	Initial Value	R/W	Description
15 to 0	SC[15:0]	H'0000	R/W	Value of Sequence Counter in Motor Control Mode Reading: The value of the sequence counter is read. Writing: Writing is only allowed in the normal state. The written value is directly stored in the sequence counter.

66.2.21 Motor Control Normal Counter Register (TMTCR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TMTCR is a read-only register that indicates the number of steps in the normal state of motor control mode. TMTCR is initialized to H'0000 by a reset.



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TCR[15:0]	H'0000	R	Indicate the number of steps in the normal state of motor control mode.

66.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

66.3.1 Overview

An overview of operation in the various modes is given below.

(1) Ordinary Operation

Each timer has TCNT and TGR registers. TCNT counts up, and is capable of free-running operation and counting to define periods corresponding to register settings.

(a) Buffered Operation

When a compare match occurs, the buffer register value in the corresponding timer is transferred to TGR. Either a compare match or clearing of the counter can be selected as the trigger that defines the timing of updating from a buffer register.

(b) PWM Mode

In PWM mode, a PWM waveform is output. The duty cycle can be set by TGR. PWM waveforms with duty cycles in the range from 0 to 100% can be output in accord with the settings of TGRA and TGRB.

(c) Stepping Motor Control Mode

Pre-defined patterns can be output from TPU0TO3 to TPU0TO0 by placing timer 0 to stepping motor control mode.

66.3.2 Basic Functions

(1) Counter Operation

When a bit from among CST3 to CST0 in TSTR is set to 1, the TCNT for the corresponding timer starts counting. A TCNT can operate as a free-running counter, periodic counter, and so on.

(a) Example of Procedure for Setting up Counter Operations

Figure 66.2 shows an example of the procedure for setting up counter operation.

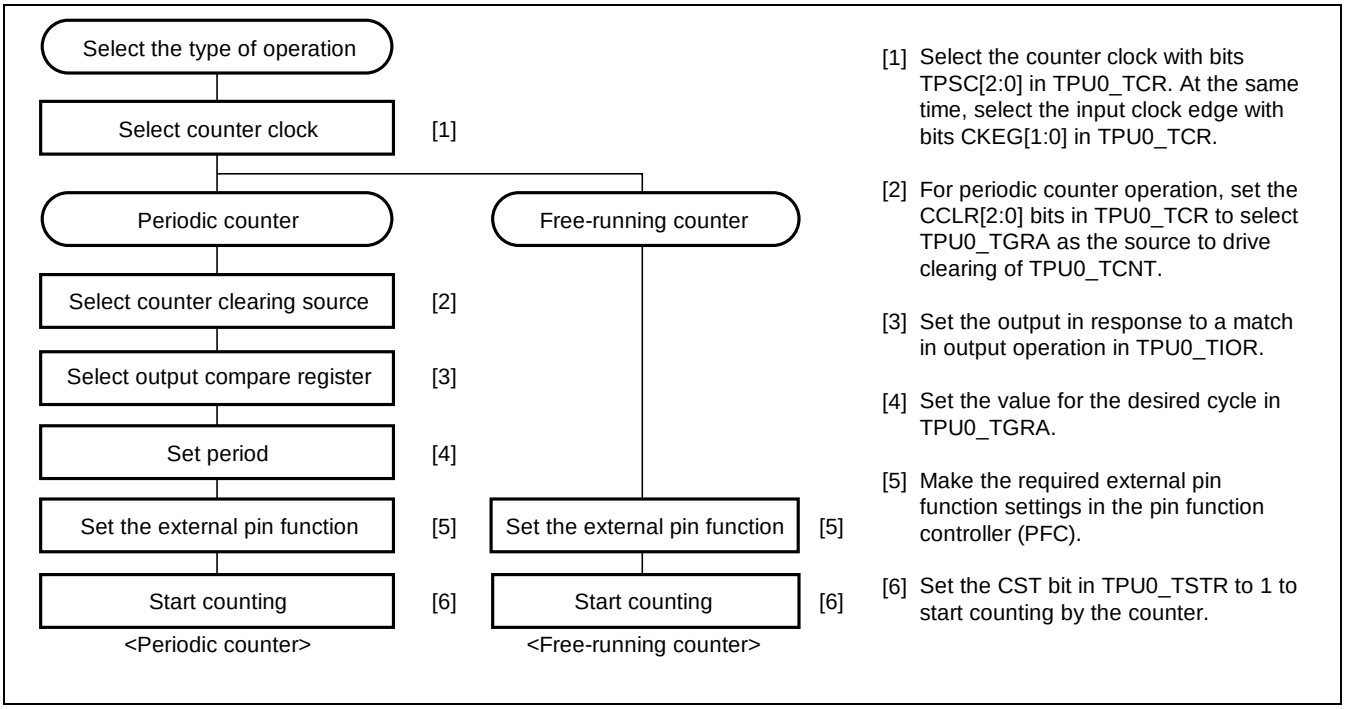


Figure 66.2 Example of Procedure for Setting up Counter Operation

(b) Free-Running Counter Operation and Periodic Counter Operation

Immediately after a reset, the TCNT counters are all designated as free-running counters. When the relevant bit in TSTR is set to 1, the corresponding TCNT starts counting up as a free-running counter. When TCNT has overflowed (when its value changes from H'FFFF to H'0000), the TCFV bit in TSR is set to 1. After it overflows, TCNT starts counting up again from H'0000.

Figure 66.3 illustrates free-running counter operation.

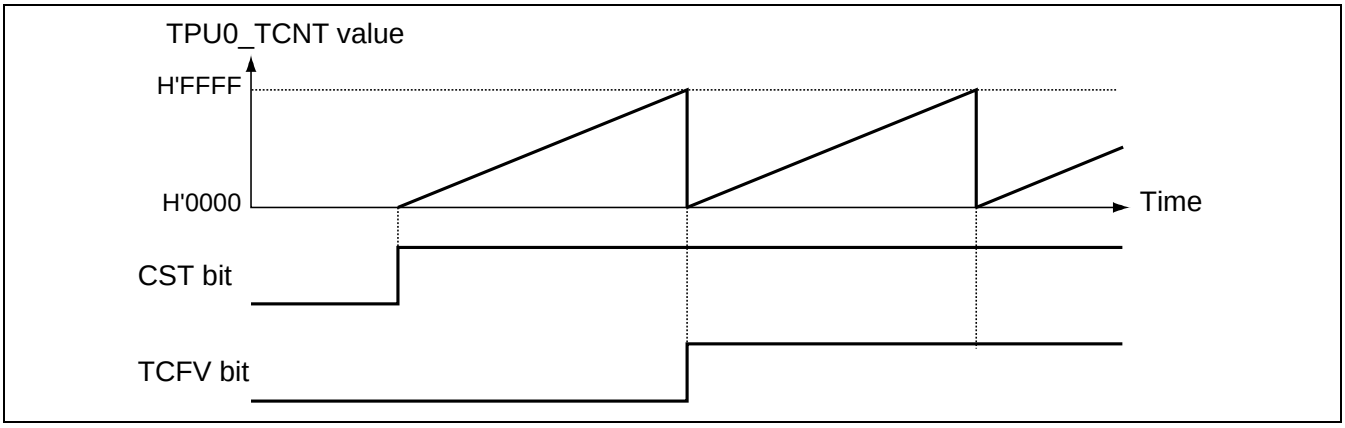

Figure 66.3 Free-Running Counter Operation

When a compare match is selected as the source to drive clearing of TCNT, the TCNT counter for the relevant timer operates as a periodic counter (counting a period defined by a general register). The TGR register for setting the period is designated as the output compare register, and counter clearing in response to a compare match is selected by means of bits CCLR[2:0] in TCR. After the settings have been made, TCNT starts counting as a periodic counter when the corresponding bit in TSTR is set to 1. When the counted value matches the value in the selected TGR, the TGF bit in TSR is set to 1 and TCNT is cleared to H'0000.

After a compare match, TCNT starts counting up again from H'0000.

Figure 66.4 illustrates periodic counter operation.

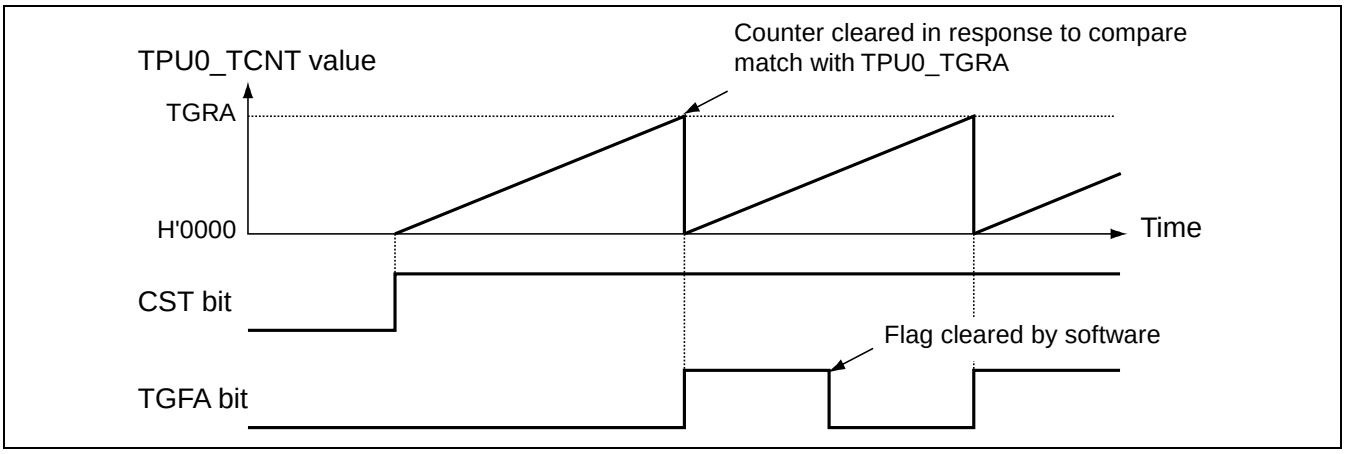

Figure 66.4 Periodic Counter Operation

(2) Waveform Output by Compare Match

The TPU can be set for the output of logical 0 or 1, or toggling of the output on the output pin in response to a compare match with TGRA.

(a) Example of Procedure for Setting up Waveform Output under Compare Match Control

Figure 66.5 shows an example of the procedure for setting up waveform output under compare match control.

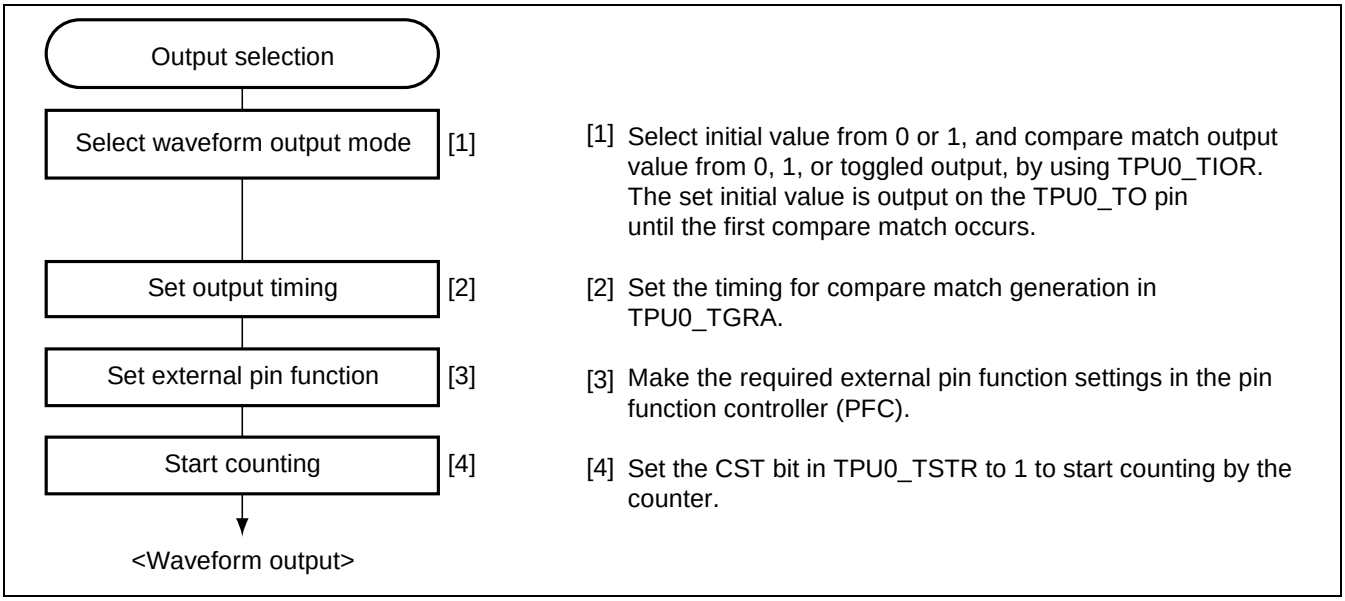

Figure 66.5 Example of Procedure for Setting up Waveform Output under Compare Match Control

(b) Examples of Waveform Output Operation

Figure 66.6 shows an example of the output of 0 or 1.

In this example, TCNT has been designated as a free-running counter, and settings have been made so that 1 or 0 is output in response to compare match A. When the set level is the same as the level on the pin, the level on the pin does not change.

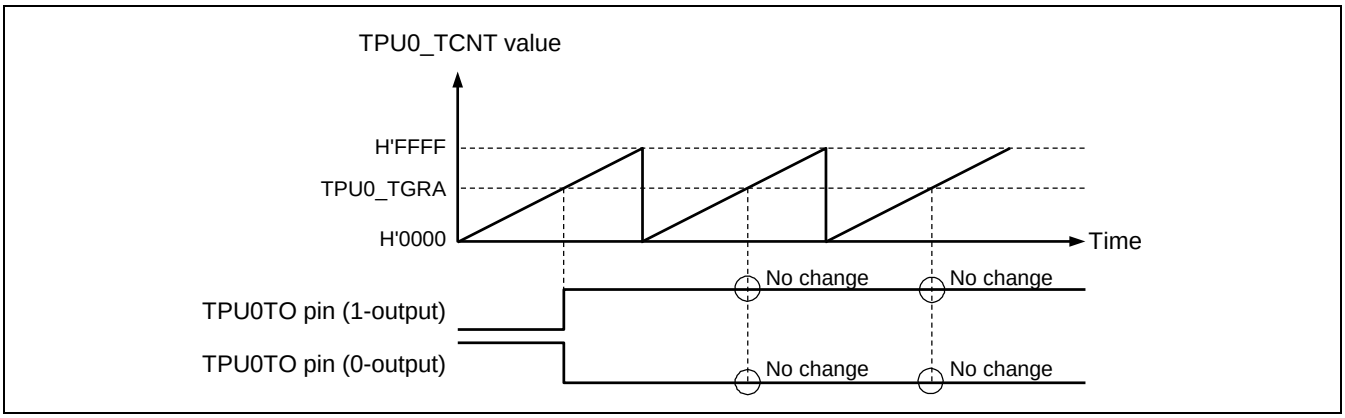

Figure 66.6 Example of Output of 0 or 1

Figure 66.7 shows an example of toggled output.

In this example, TCNT has been designated as a periodic counter (with counter clearing handled by compare match B), and settings have been made so that the output is toggled in response to compare match A.

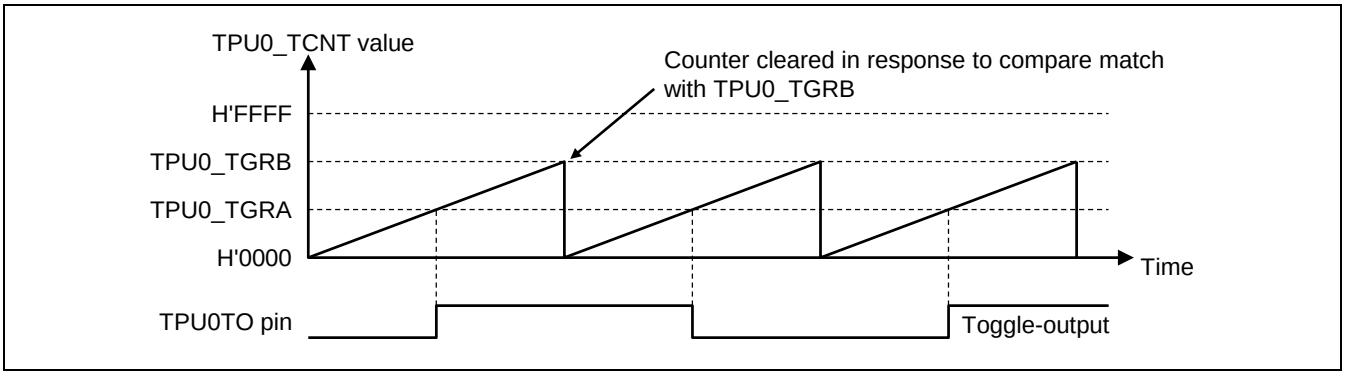

Figure 66.7 Example of Toggled Output Operation

66.3.3 Buffered Operation

TGRC and TGRD can be used as buffer registers.

Table 66.8 shows the register combinations used in buffered operation.

Table 66.8 Register Combinations in Buffered Operation

Timer General Register	Buffer Register
TGRA	TGRC
TGRB	TGRD

When a compare match occurs, the value in the buffer register for the corresponding timer is transferred to the timer general register. Either a compare match or clearing of the counter can be selected as the trigger that defines the timing of updating from a buffer register.

This operation is illustrated in Figure 66.8.

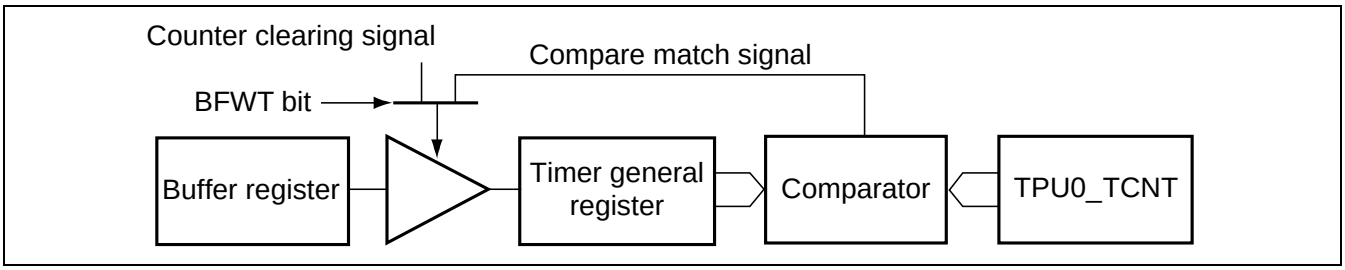

Figure 66.8 Buffered Compare Match Operation

(1) Example of Procedure for Setting up Buffered Operation

Figure 66.9 shows an example of the procedure for setting up buffered operation.

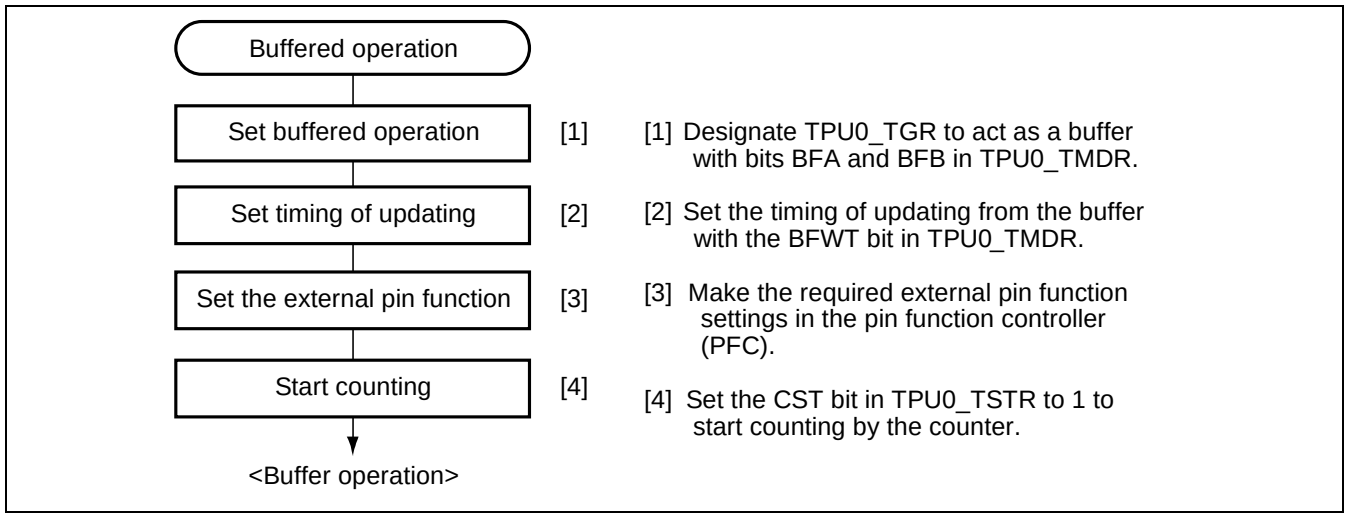

Figure 66.9 Example of Procedure for Setting up Buffered Operation

(2) Examples of Buffered Operation

Figure 66.10 shows an example of operation in which PWM mode has been designated for timer 0, and buffered operation has been designated for TGRA and TGRC. The settings used in this example are for clearing of TCNT in response to compare match B, output of 1 (on the TPU0TO0 to 3 for the selected timer) on compare match A, output of 0 as the initial value by clearing the counter, and the timing for updating from the buffer register as clearing of the counter.

When compare match A occurs, the output changes. When counter clearing is generated by a match with TGRB, the output changes and the value in buffer register TGRC is simultaneously transferred to the timer general register TGRA. This operation is repeated every time compare match A occurs.

For details on the PWM mode, see section 66.3.4, PWM Mode.

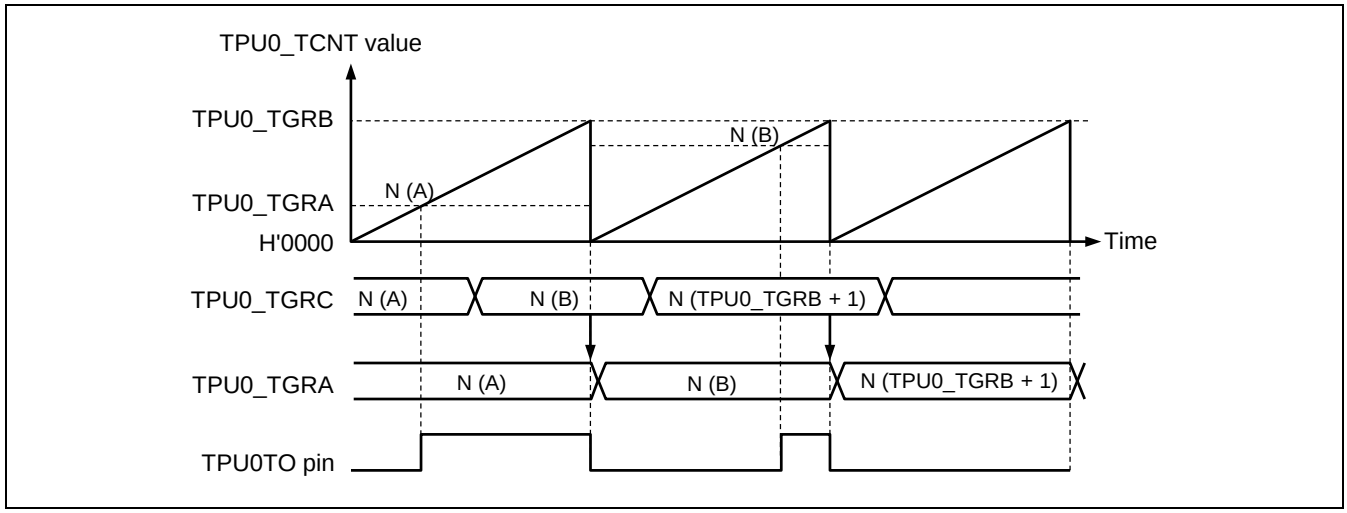

Figure 66.10 Example of Buffer Operation

66.3.4 PWM Mode

In PWM mode, PWM waveforms are output from the output pins. The output of 0 or 1 can be selected as the response to a compare match with the given TGRA.

Designating TGRB compare match as the counter clearing source enables setting of the overall cycle in that register. All timers can be independently placed in PWM mode.

PWM output is generated from the output pins by using TGRA and TGRB to control the duty cycle and period, respectively. The initial output specified by TIOR is output on the output pin by counter clearing in response to a compare match with the period register. Be sure to set TIOR so that the initial output level is different from the compare match output. Selecting the same level or toggled output leads to no operation.

Conditions for 0% and 100% duty cycles are shown below.

- 0% duty cycle: The setting of the duty-cycle register (TGRA) being equal to that of the period register plus one (TGRB + 1)
- 100% duty cycle: The setting of the duty-cycle register (TGRA) being 0

(1) Example of Procedure for Setting up PWM Mode Operation

Figure 66.11 shows an example of the procedure for setting up the PWM mode operation.

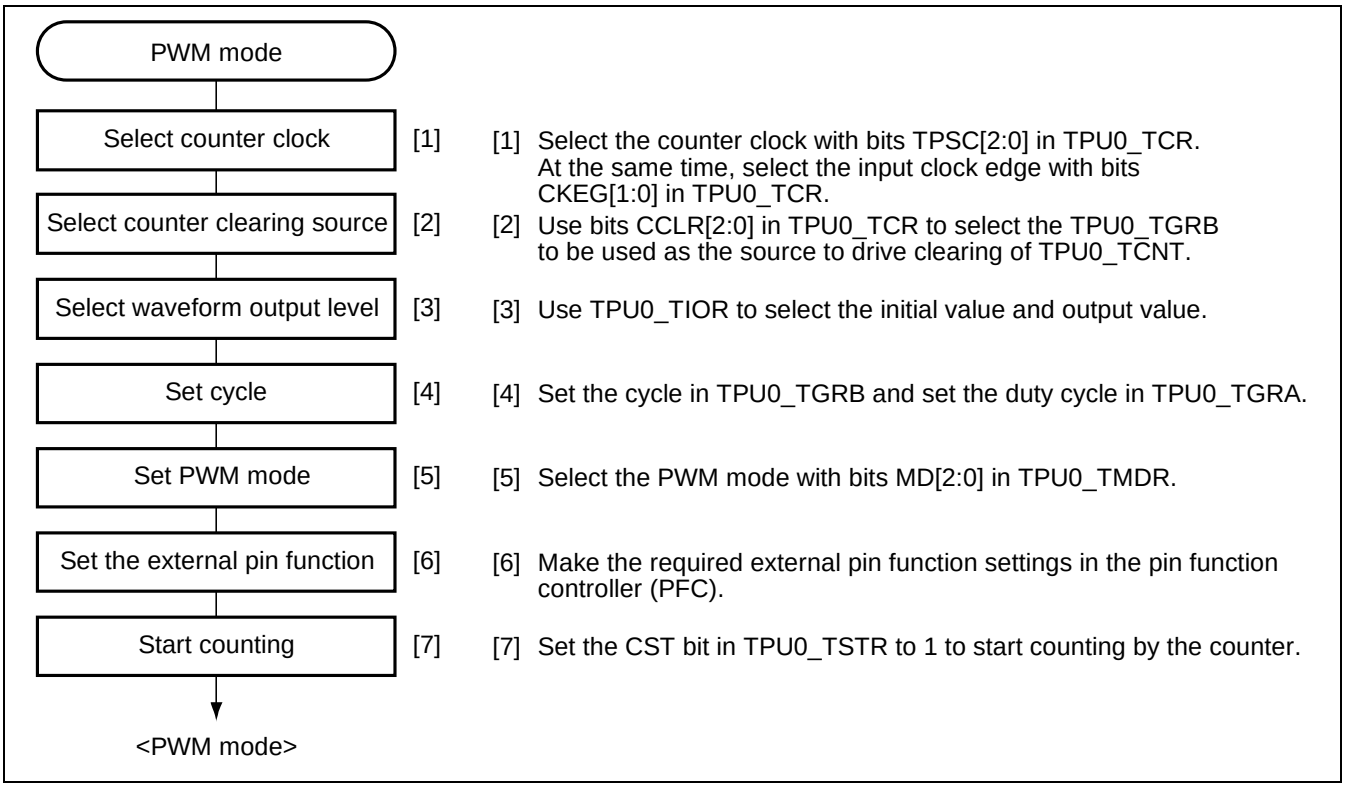

Figure 66.11 Example of Procedure for Setting up PWM Mode Operation

(2) Examples of PWM Mode Operation

Figure 66.12 shows an example of PWM mode operation.

In this example, compare match with TGRB is set as the source to drive clearing of TCNT, 0 is set as the initial output value for TGRA, and 1 is set as the output value on a compare match with TGRA.

In this case, the value set in TGRB defines the cycle time (period), and the value set in TGRA defines the duty cycle.

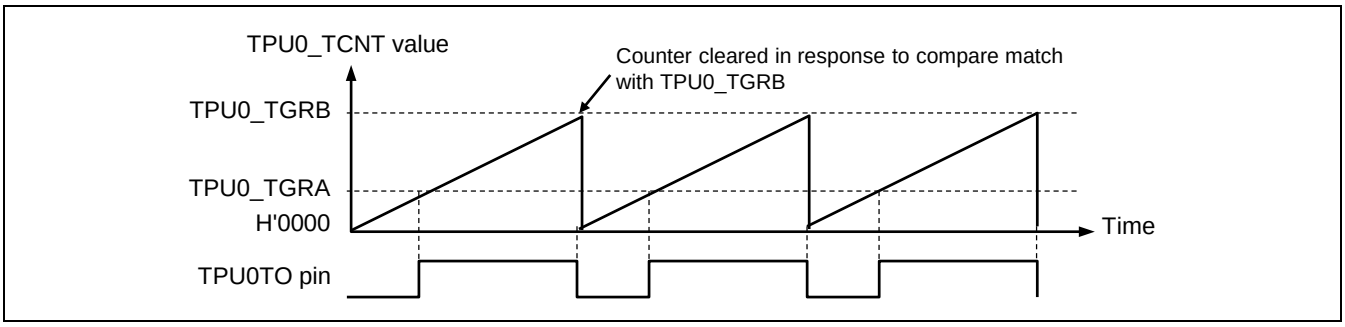

Figure 66.12 Example of PWM Mode Operation (1)

Figure 66.13 shows an example of PWM waveform output with 0% and 100% duty cycles in PWM mode.

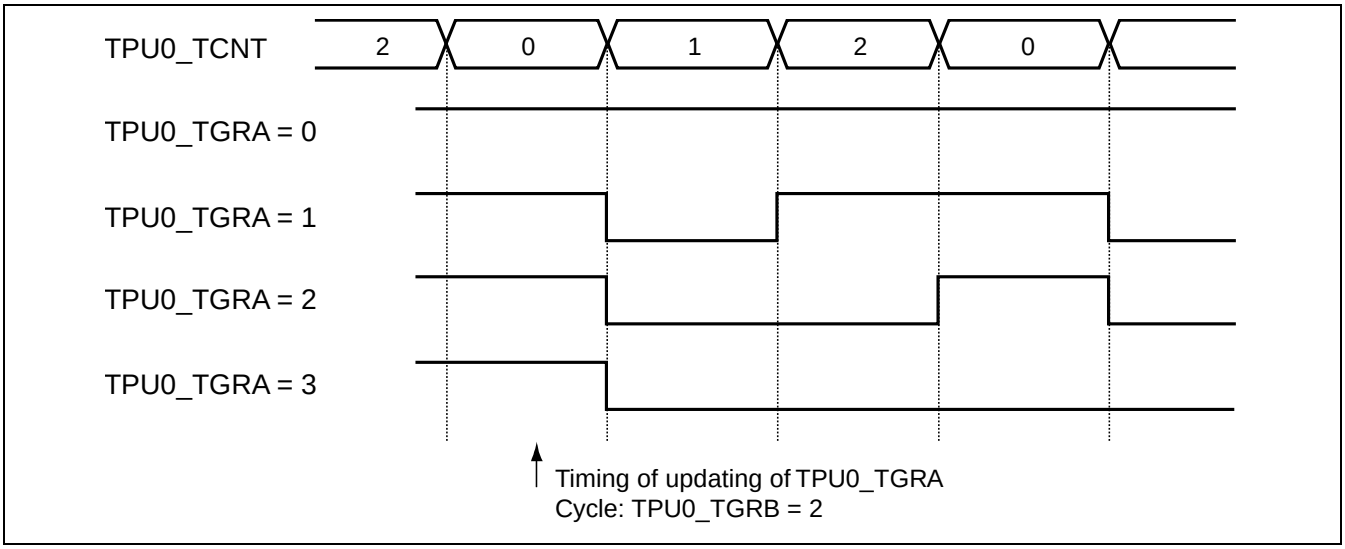

Figure 66.13 Example of PWM Mode Operation (2)

66.3.5 Stepping-Motor Control Mode

(1) Features of Stepping-Motor Control Mode

- This mode is for the output of signals for stepping-motor control on four pins and is only available for timer 0.
- States of the output pins change in response to compare matches with the counter of timer 0.
- By using the DMAC or an interrupt to rewrite the values of the compare-match registers, the intervals between transitions of the states of the output pins can be specified as desired.
- Specified patterns are output on the output pins.
- Four or eight patterns can be selected.
- The pattern-number counter is incremented or decremented by 1 on every compare match with the counter on timer 0. When the pattern-number counter overflows in normal mode, its value returns to 0. When the pattern-number counter underflows, its value becomes 3 (for a four-pattern cycle) or 7 (for an eight-pattern cycle).
- Patterns consist of stop patterns and operating patterns. Operating patterns are output while the counter is running, and stop patterns are output while the counter is stopped.
- While the counter is running, operation is in three states (the acceleration, deceleration, and normal states). Only for acceleration and deceleration, the interval between changes of pattern can be controlled.
- The acceleration or deceleration state can be skipped by writing H'0000 to TMASR and TMRSR.
- TMRR can be used to force a transition from the normal to the deceleration state.

(2) Glossary

Sequence State: The four states in the sequence, i.e. the acceleration, normal, deceleration, and stop states

Sequence Counter: Counter to control transitions to next sequence states
The sequence counter is decremented with every compare match with the counter of timer 0 and, when the value reaches 1, the control state will make the transition to the next state in the sequence on a further compare match with the counter of timer 0.

Auto Mode: Mode of operation when a value other than H'0000 has been written to TMTSR
The number of pattern transitions in the normal state corresponding to the setting of TMTSR, and this is followed by an automatic transition to the deceleration state (or, if TMRSR = H'0000, a transition to the stop state).

Manual Mode: Mode of operation when H'0000 has been written to TMTSR. In this case, the transition from the normal to the deceleration state (or the stop state if TMRSR = H'0000) is not made unless 1 is written to the REDUON0 and REDUON bits in TMRR.

Pulse Mode: Mode of operation when H'0000 has been written to TMASR and TMRSR. Operation is only in the normal state, so the output pattern is changed with a constant interval.

Step: The pattern is changed with every compare match with the counter of timer 0. Step refers to the interval of time between the change to one pattern and the change to the next.

Operation Pattern: The four-bit patterns for output from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the acceleration, normal, and deceleration states. 8 types of Operation Pattern are set by TMMPR0 and TMMPR1. “[ ]” in Figure 66.14, 66.16, 66.18, 66.20 to 66.23 and Table 66.12 means 8 types of Operation Pattern set by TMMPR0 and TMMPR1.

Stop Pattern: The four-bit patterns for output from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the stop state. 8 types of Operation Pattern are set by TMSPR0 and TMSPR1. “( )” in Figure 66.14, 66.16, 66.18, 66.20 to 66.23 and Table 66.12 means 8 types of Operation Pattern set by TMMPR0 and TMMPR1.

(3) Setting up Basic Motor Control Operation

An example of operation in stepping motor control is shown in Figure 66.14.

Stepping-motor control mode allows the output of patterns with a variable step interval.

“( )” in Figure 66.14 means Stop Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the stop state set by TMSPR0 and TMSPR1.

“[ ]” in Figure 66.14 means Operation Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the acceleration, normal, and deceleration states set by TMMPR0 and TMMPR1.

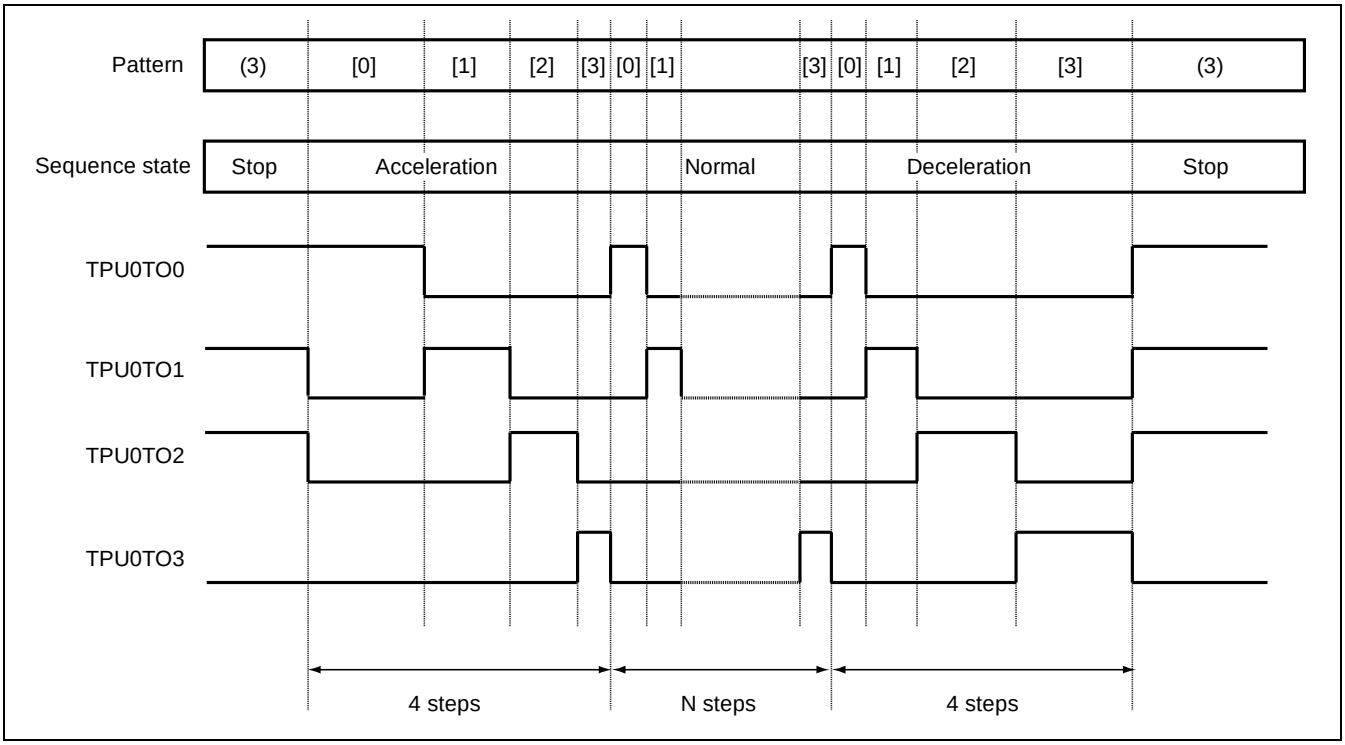

Figure 66.14 Example of Stepping-Motor Control

(a) Compare Match Settings for Timer 0

For stepping motor control, set TCR0 and TMDR0 as follows:

Table 66.9 Compare Match Settings for Timer 0

Register	Setting	Description
TCR0	B'0000_0000_0100_0xxx	CCLR[2:0] bits = B'010 CKEG[1:0] bits = B'00 TPSC[2:0] bits = B'xxx (optional)
TMDR0	B'0000_0000_0110_0000	BFWT bit = 1 BFB bit = 1 BFA bit = 0 MD[2:0] bits = B'000

[Legend]
x: Don't care.

With the above settings, TGRD0 is used as a buffer register for TGRB0, and the contents of the general register are rewritten when the timer counter is cleared. The step interval can be changed by using DMA transfer or interrupt control to write a desired value to TGRD0.

The TPSC [2:0] bits in TCR0 are for a timer prescaler setting. The step interval is calculated from the following formula.

[Calculation example for RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N]

With Internal clock at 66.66 MHz, B'011 as the value of TPSC[2:0] in TCR0, H'1425 as the value of TGRD0, the result is 15.02 ns × 64 × 5157 (H'1425) = 4,955,675.7 ns ≅ 5.0 ms. That is, the pattern will change after approximately 5.0 ms.

[Calculation example for RZ/G2E]

With Internal clock at 62.5 MHz, B'011 as the value of TPSC[2:0] in TCR0, H'1425 as the value of TGRD0, the result is 16.0 ns × 64 × 5157 (H'1425) = 5,280,768 ns ≅ 5.3 ms. That is, the pattern will change after approximately 5.3 ms.

(b) Sequence State and the Number of Steps

In stepping-motor control mode, operation is in three states (acceleration, normal, and deceleration) while the counter is running. In the acceleration and deceleration states, the step interval can be changed. Accordingly, the value of TGRD0 must be changed the same number of times as the patterns are changed.

In the normal state, the step interval cannot be changed. So, TGRD0 is only set once for a period in the normal state.

The numbers of steps in the acceleration, normal, and deceleration states are set in TMASR, TMTSR, and TMRSR, respectively. If H'0000 is written to TMASR or TMRSR, the corresponding state is skipped. Furthermore, the manual mode can be selected by writing H'0000 to TMTSR. In this mode, the transition from normal mode can only be initiated by changing the value in TMRR.

Table 66.10 gives descriptions of the sequence states and Figure 66.15 shows the transitions between sequence states.

Table 66.10 Description of Sequence States

		Description	
Start/Stop	**State**	**Step Interval**	**Definition in TGRD0**
Start	Acceleration	Variable	The number of steps specified for this state
	Normal	Fixed	Only once
	Deceleration	Variable	The number of steps specified for this state
Stop	Stop	—	—

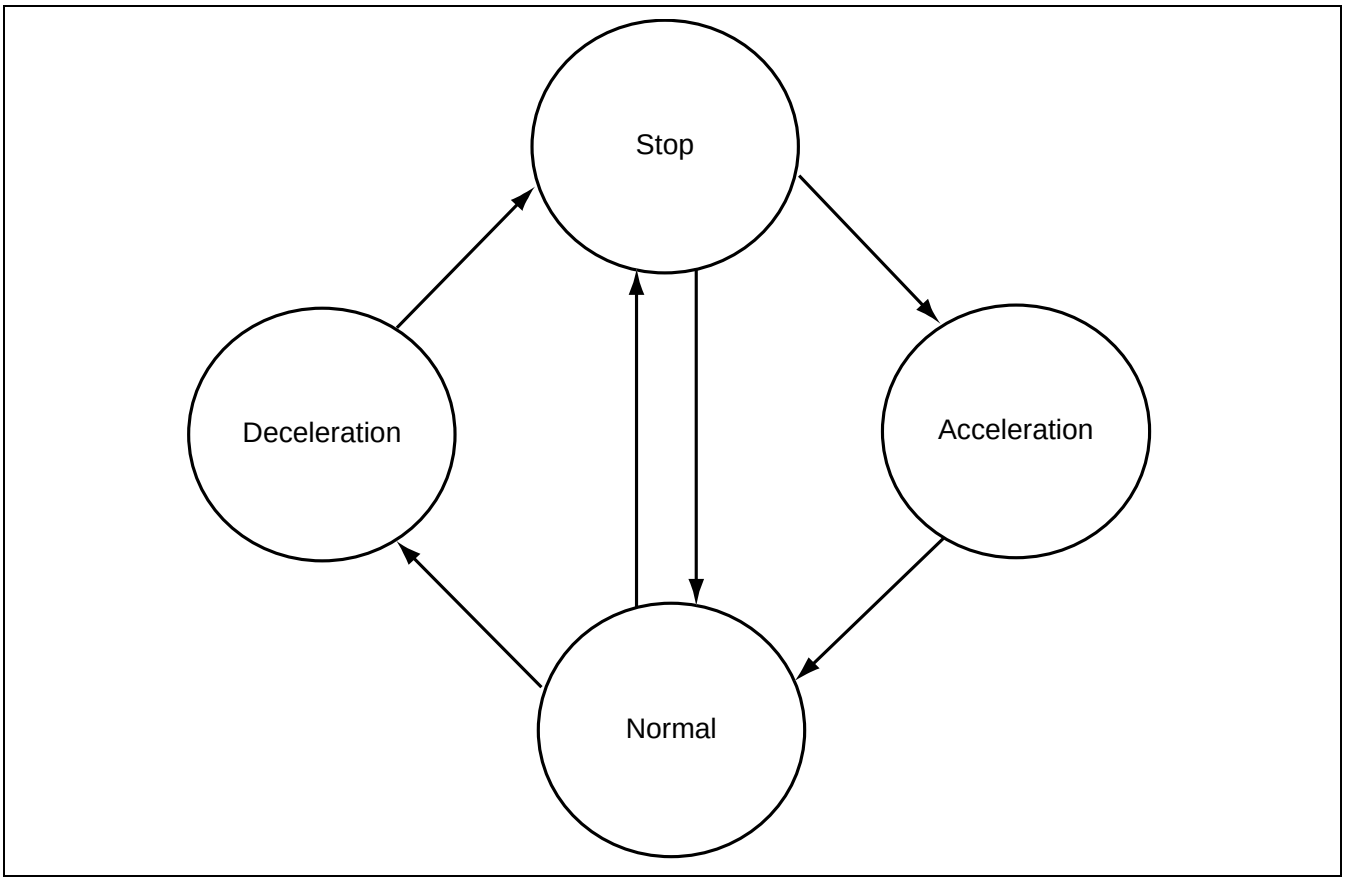

Figure 66.15 Sequence State Transition

(c) Setting of the Step Interval

Direct memory access or interrupt-driven transfer can be used to set the step interval

- DMA transfer

Setting the TDMAE bit in TMIR to 1 selects the use of DMA transfer to modify the step interval.

The number of requests for DMA transfer is given by TMASR + 1 (to transfer the step interval for the normal state) + TMRSR. The step intervals must be defined in sequence from the address indicated by the DMA source address register. Figure 66.16 shows an example of timing in operation with DMA transfer requests used to set the step intervals. “( )” in Figure 66.16 means Stop Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the stop state set by TMSPR0 and TMSPR1. “[ ]” in Figure 66.16 means Operation Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the acceleration, normal, and deceleration states set by TMMPR0 and TMMPR1. Figure 66.17 shows the corresponding definitions of step intervals in the address map.

Table 66.11 lists an example of the DMA settings.

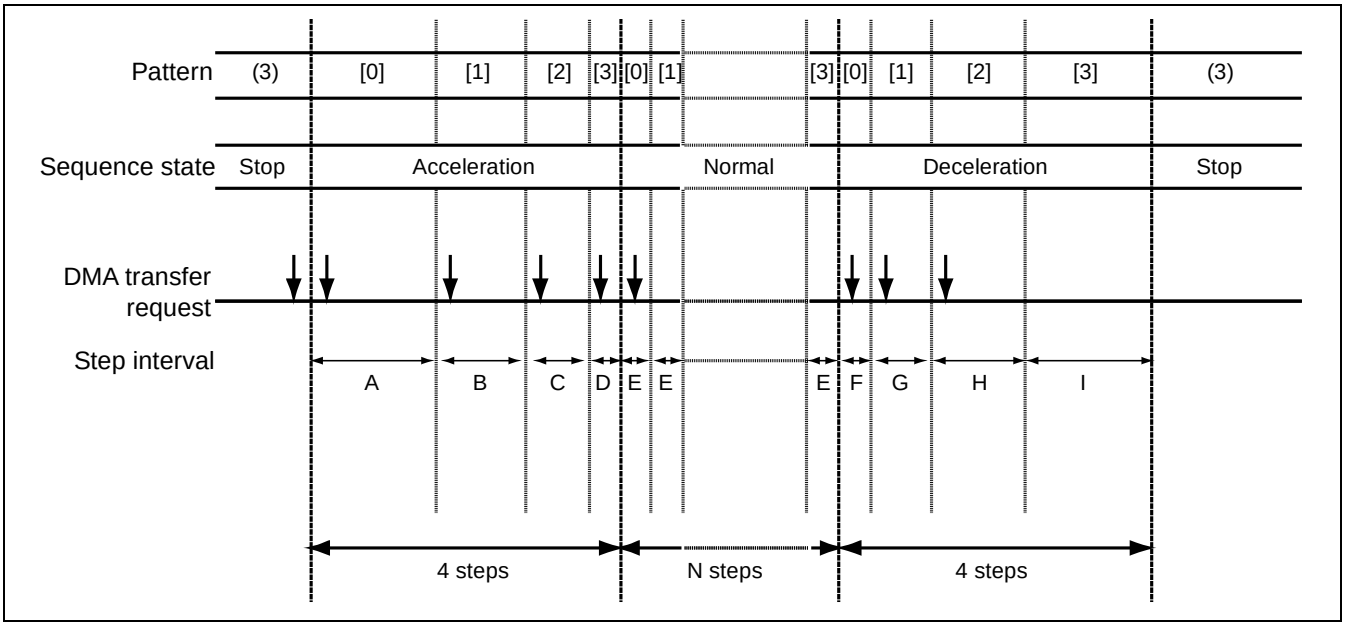

Figure 66.16 Operation with DMA Transfer Requests Used to Adjust the Step Interval

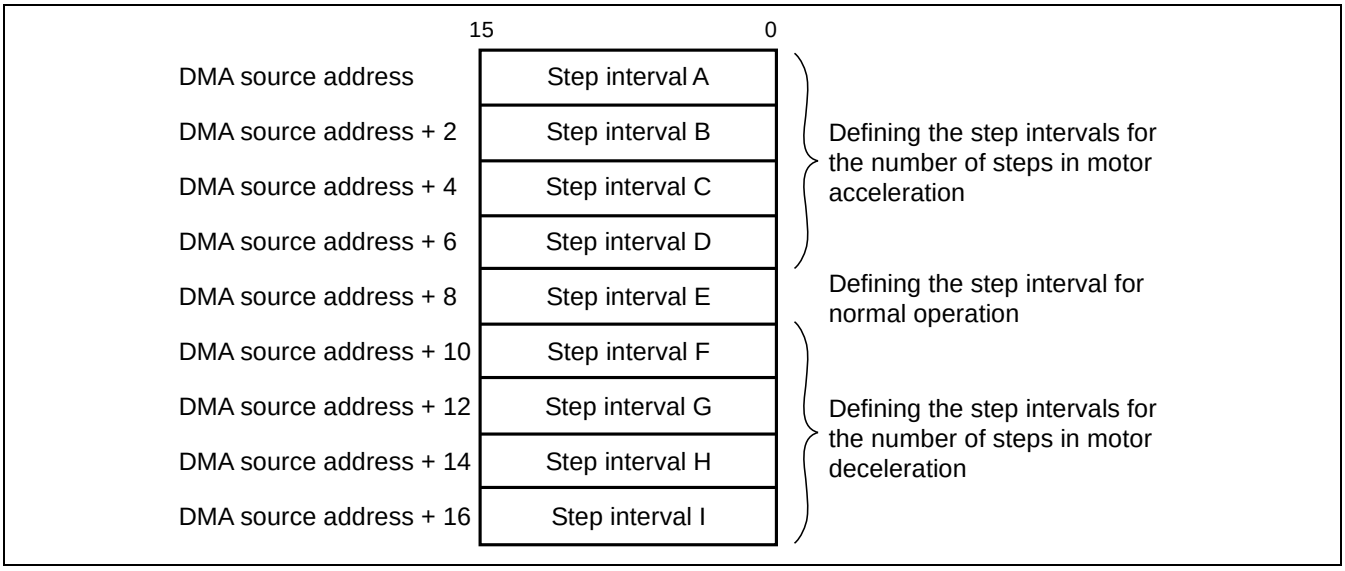

Figure 66.17 Address Map of Step Interval Definitions for the Example of Operation

Table 66.11 DMA Settings

DMA Register	Setting	Description
DMA source address register	H'XXXX_XXXX	Address where the table of step intervals starts
DMA destination address register	H'E6E8_0034	Address of TGRD0
DMA transfer count register	H'0000_0000	(Setting for the maximum number of transfer operations) *
DMA transfer count register B	H'XXXX_XXXX	The number of DMA transfer requests is set in the higher- and lower-order 16 bits. (for Figure 66.16, H'0009_0009)
DMA channel control register	H'E6E8_80*C	Reload mode: Use source address registers (SARs) as the source for reloading. Fixed destination address. Incrementation of source addresses. The DMA extension resource selector is used. DMA transfer is in word (two-byte) units. The other bits are in the default settings.
DMA extension resource selector	H'17 in the bit field for the selected DMA channel	Select TPU
DMA operation register	H'0001	Permits DMA transfer on all channels. The other bits are in the default settings

Note: * Transfer is stopped when the value of the DMA transfer counter reaches 0, so change the value of the DMA transfer counter back to 1 after TPU-related operations are finished.

- Interrupt-driven transfer

Setting the TMDRFE bit in TIER0 to 1 allows the use of interrupt-driven transfer to change the step interval.

TMASR−1 + 1 (to transfer the step interval in the normal state) + TMRSR gives the number of times TGRD0 must be written to by interrupt-driven transfer.

This method is unlike DMA transfer in that an interrupt is not generated when the initial transfer is required. The initial value should thus be written to TGRD0 before counter operation starts.

Once interrupt generation starts, the interrupt handler writes the step intervals to TGRD0 and writes 0 to the TMDRFS bit after reading it as 1.

Figure 66.18 shows an example of timing in operation with interrupt-driven transfer used to set the step intervals. “( )” in Figure 66.18 means Stop Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the stop state set by TMSPR0 and TMSPR1. “[ ]” in Figure 66.18 means Operation Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the acceleration, normal, and deceleration states set by TMMPR0 and TMMPR1.

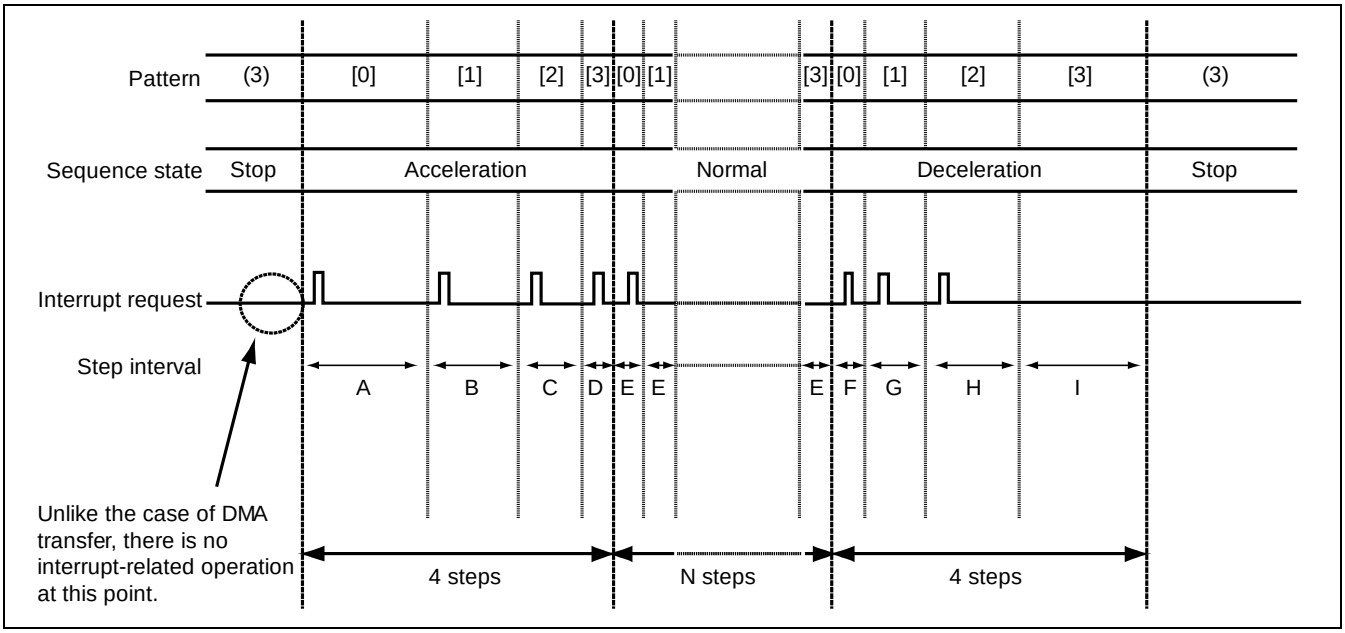

Figure 66.18 Interrupt-Driven Adjustment of the Step Interval

The step-intervals in the example of operation shown in Figure 66.18 are defined in the following stages.

Write step interval A to TGRD0 before starting the counter. Write step interval B to TGRD0 in response to the first interrupt. Write step interval C to TGRD0 in response to the second interrupt. Write step interval D to TGRD0 in response to the third interrupt.	Defining the step intervals for the number of steps in motor acceleration
Write step interval E to TGRD0 in response to the forth interrupt.	Defining the step interval for normal operation
Write step interval F to TGRD0 in response to the fifth interrupt. Write step interval G to TGRD0 in response to the sixth interrupt. Write step interval H to TGRD0 in response to the seventh interrupt. Write step interval I to TGRD0 in response to the eighth interrupt.	Defining the step intervals for the number of steps in motor deceleration

(d) Pattern Setting

In stepping-motor control mode, each four-bit value for output on pins TPU0TO0 to TPU0TO3 is regarded as a single pattern. The patterns are in a sequence, and a compare match with the timer counter triggers each transition to the next pattern.

The following rules apply to pattern transfer.

- Either a four- or an eight-pattern cycle may be used. The number is determined by the MTRPATKIND bit in TMIR0.
- Each pattern is indicated by a pattern number. The current pattern number is either incremented or decremented on each compare match with the timer counter. Incrementation or decrementation of the pattern numbers is determined by the MTRPATDOWN bit in TMIR0.
- The pattern-number counter returns to 0 when it overflows. When it underflows, the pattern number becomes three (for a four-pattern cycle) or seven (for an eight-pattern cycle).
- Operating patterns are defined as the output patterns in the acceleration, normal, and deceleration states, and stop patterns are defined as the output patterns in the stop state. In transitions from an operating pattern to a stop pattern, the pattern number remains the same. In transitions from a stop pattern to an operating pattern, the current pattern number changes to that of the next pattern.

The operating patterns are set in TMMPR0 and TMMPR1, and the stop patterns are set in TMSPR0 and TMSPR1.

Table 66.12 lists the order of patterns for different settings of the MTRPATDOWN and MTRPATKIND bits in TMIR.

Table 66.12 Settings of the MTRPATDOWN and MTRPATKIND Bits in TMIR and Orders of Patterns

TMIR		Example of Pattern Order (Operating Pattern [ ], Stop Pattern ( ))
MTRPATDOWN Bit	MTRPATKIND Bits	
0	B'00	[0] → [1] → [2] → [3] → [0] → [1] → [2] → [3] → (3) → [0]
1		[0] → [3] → [2] → [1] → [0] → [3] → [2] → [1] → (1) → [0]
0	B'01	[0] → [1] → [2] → [3] → [4] → [5] → [6] → [7] → (7) → [0]
1		[0] → [7] → [6] → [5] → [4] → [3] → [2] → [1] → (1) → [0]

(e) Specifying the Output Pattern in the Stop State

Specifying a pattern number in the NOWPAT [2:0] bits of TMOPR while output is in the stop state leads to output of the corresponding pattern on pins TPU0TO3 to TPU0TO0. The initial value is 0.

(f) Selecting the Stepping-Motor Control Mode

Stepping-motor control by the TPU circuit is selected by setting the MTRON bit in TMIR to 1. The output on pins TPU0TO3 to TPU0TO0 is switched to the output corresponding to stepping-motor control.

Switching should proceed while the motor is stopped.

The stop pattern specified as pattern 0 in TMOPR is output after switching. Therefore, verify the value in TMOPR or write the desired pattern to TMOPR.

(g) Starting Stepping-Motor Control

Stepping-motor control is started by setting the TMST bit in TSTR to 1. This bit is automatically cleared (to 0) in the stop state after motor-control operations are over.

(h) Example of the Procedure for Setting up Stepping-Motor Control

Figure 66.19 is a flowchart of stepping-motor control.

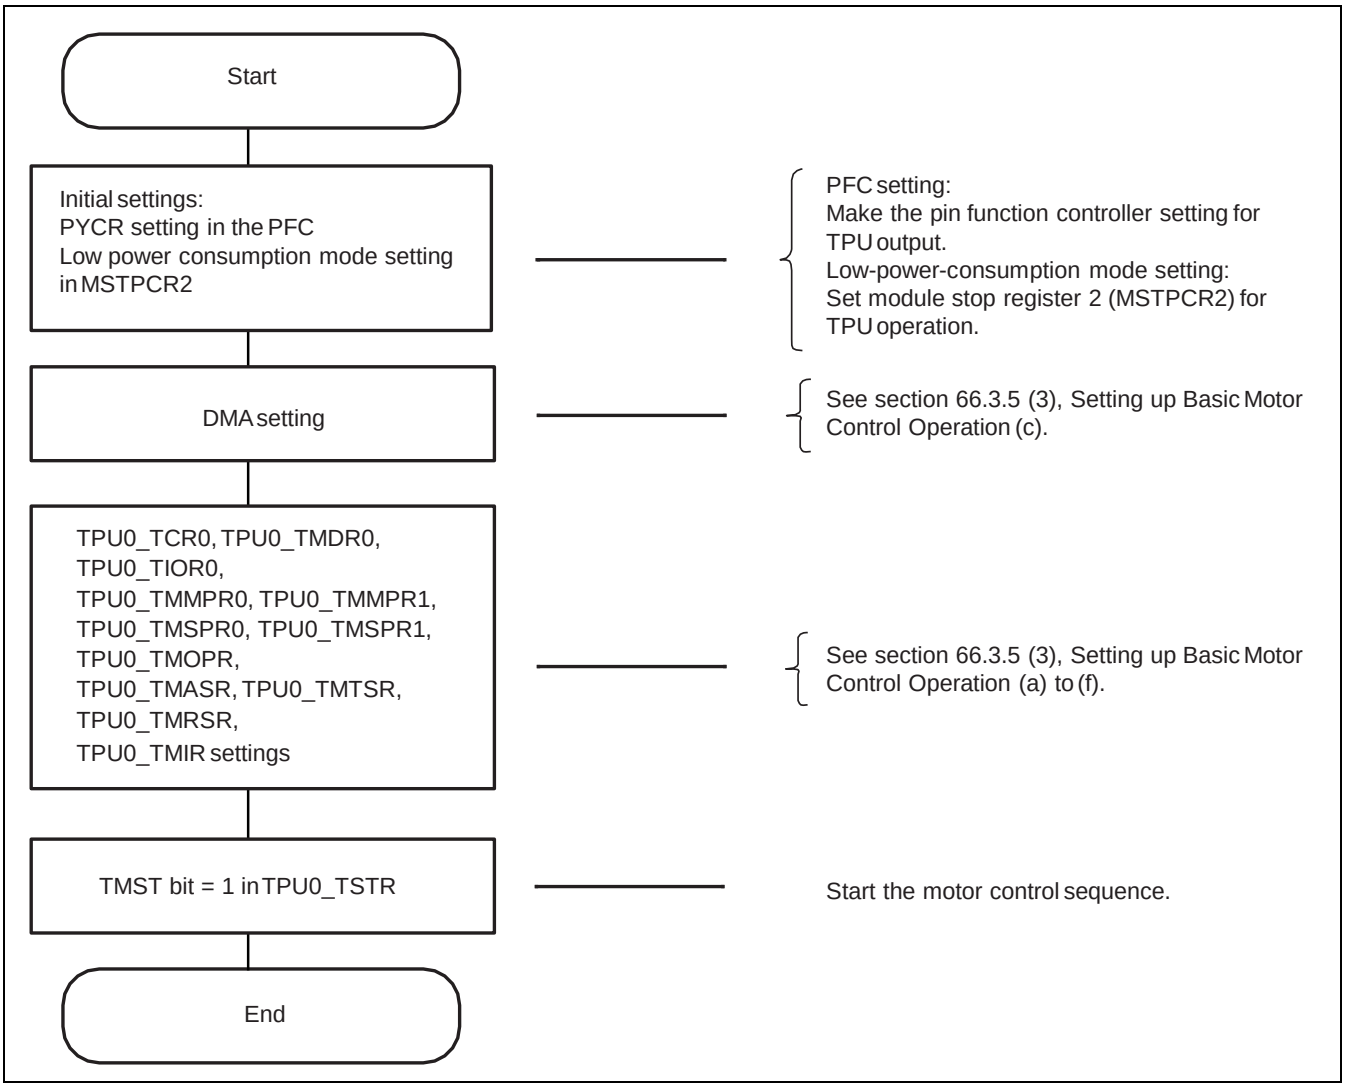

Figure 66.19 Flowchart

(4) Changing the Number of Steps in the Normal State.

The number of steps in the normal state is set in TMTSR. The operations for changing the number of steps are described under (a) and (b) below.

In manual mode (TMTSR = H'0000), the operation under (a) is the only way of switching from the normal state.

(a) Changes by TMRR

Writing 1 to the REDUON0 bit or the REDUON bit in TMRR initiates the transition to the deceleration state (or, if TMRSR = H'0000, to the stop state).

Table 66.13 describes how operation in response to the writing of 1 to the REDUON0 bit varies with the operating state. Table 66.14 describes how operation in response to the writing of 1 to the REDUON bit varies with the operating state.

Table 66.13 Timing of Writing 1 to the REDUON0 Bit and Operation

Timing of Writing 1 to the REDUON0 Bit	Operation
Acceleration	Operation continues normally until the end of acceleration. Control then enters the normal state.
Normal	Control remains in the normal state until the pattern number becomes [0]. The transition to the deceleration state (or the stop state if TMRSR is H'0000) follows the end of this step in the normal state.
Deceleration	Writing 1 to the bit has no effect on deceleration.
Stop	TMRR is cleared to H'0000 after control has made the transition from the normal or deceleration state to the stop state. When 1 is written to the REDUON0 bit after control is in the stop state, the sequence in the next round of motor control continues until the pattern number in the normal state becomes [0]. The transition to the deceleration state (or the stop state if TMRSR is H'0000) is made at the end of this step in the normal state.

Table 66.14 Timing of Writing 1 to the REDUON Bit and Operation

Timing to Write 1 in REDUON Bit	Operation
Acceleration	Operation continues normally until the end of acceleration.
Normal	The transition to the deceleration state (or the stop state if TMRSR is H'0000) is made after a single step in the normal state.
Deceleration	Writing 1 to the bit has no effect on deceleration.
Stop	TMRR is cleared to H'0000 after control has made the transition from the normal or deceleration state to the stop state. When 1 is written to the REDUON0 bit after control is in the stop state, the sequence in the next round of motor control continues until it enters the normal state. The transition to the deceleration state (or the stop state if TMRSR is H'0000) is made at the end of a single step in the normal state.

(b) Changing the Number of Steps by Changing the Value in TMSCR

In auto mode (i.e. when TMTSR ≠ H'0000), TMSCR indicates the remaining number of steps in the current state.

When the control sequence is in the normal state, the number of steps can be changed by writing the desired number of steps. Writing is ineffective in states other than the normal state.

Do not write to this register when control is in manual mode (TMTSR = H'0000).

(5) Acquiring the Number of Steps in the Normal State

In the stop state, TMTCR can be read to acquire the number of steps in the normal state of the immediately preceding sequence.

(6) Pulse Mode

Writing H'0000 to TMASR and TMRSR selects operation in the normal state alone, with a constant step interval. That is, operation starts with the step interval defined for the normal mode and the interval does not subsequently change. This is referred to as pulse mode operation.

Examples of pulse-mode operation are described below.

(a) Single-Pulse Shifts in Pulse Mode and Auto Mode

Table 66.15 gives an example of register settings for single-pulse steps in auto mode.

Figure 66.20 is a timing chart for single-pulse shifts in auto mode. “( )” in Figure 66.20 means Stop Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the stop state set by TMSPR0 and TMSPR1. “[ ]” in Figure 66.20 means Operation Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the normal states set by TMMPR0 and TMMPR1.

Table 66.15 Register Settings to Select One Pulse as the Number of Steps in Auto Mode

Register Setting Value	Contents
TMASR: H'0000	No acceleration state
TMTSR: H'0001	Only one step in the normal state
TMRSR: H'0000	No deceleration state

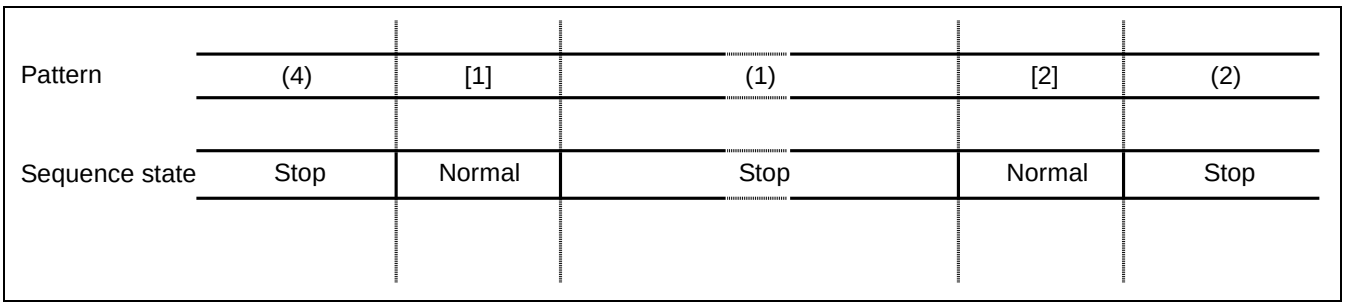

Figure 66.20 Timing of Single-Pulse Shifts in Auto Mode

(b) Single-Pulse Shifts in Pulse Mode and Manual Mode

In manual mode, setting the REDUON0 or REDUON bit in TMRR to 1 while the sequence is in the normal state enables a single pulse shift.

Table 66.16 gives an example of register settings for single-pulse steps in manual mode.

Figure 66.21 is a timing chart for single-pulse shifts in manual mode. “( )” in Figure 66.21 means Stop Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the stop state set by TMSPR0 and TMSPR1. “[ ]” in Figure 66.21 means Operation Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the normal states set by TMMPR0 and TMMPR1.

Table 66.16 Register Settings to Select One Pulse as the Number of Steps in Manual Mode

Register Setting Value	Contents
TMASR: H'0000	No acceleration state
TMTSR: H'0000	Looping in the normal state
TMRSR: H'0000	No deceleration state

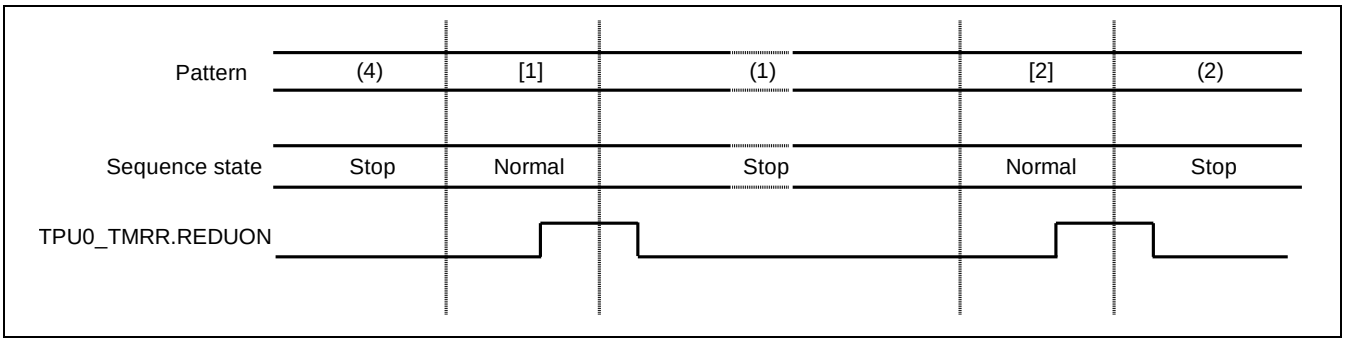

Figure 66.21 Timing of Single-Pulse Shifts in Manual Mode

(7) Interrupts

Timer 0 has six added interrupt conditions for use with stepping-motor control mode.

The interrupt conditions are described below.

(a) Detection of Overflows of Data Transferred for Motor Control

Setting the TMDOFE bit in TIER0 to 1 selects the detection of overflows of data transferred for motor control (motor control data transfer overflows). Here, overflow refers to the condition where buffer-related operation, i.e. the transfer of the data from TGRD0, is delayed; that is, when the operation TGRD0→ TGRB0 is delayed. To cancel this interrupt, write 0 to the TMDOFS bit of TSR0 after having read it as 1.

Figure 66.22 shows an example of DMA transfer where an overflow in data transfer for motor control occurs and detection of overflows has been enabled. “( )” in Figure 66.22 means Stop Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the stop state set by TMSPR0 and TMSPR1. “[ ]” in Figure 66.22 means Operation Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the acceleration, normal, and deceleration states set by TMMPR0 and TMMPR1.

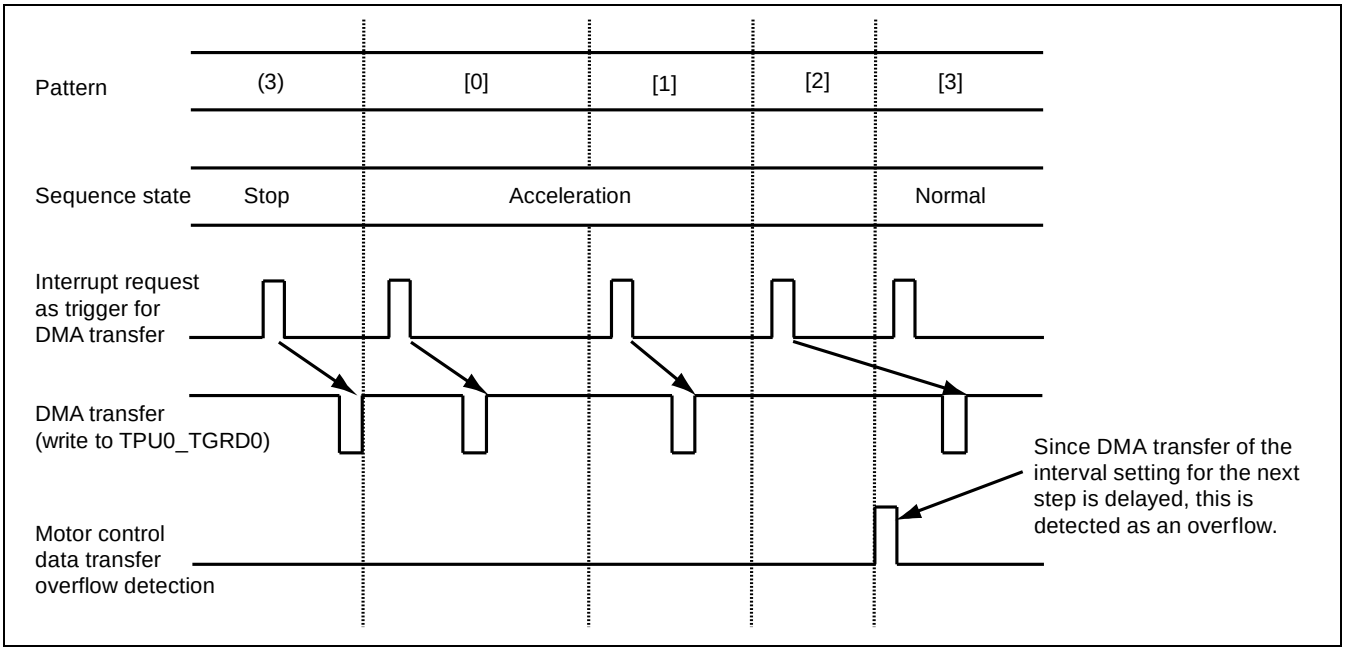

Figure 66.22 DMA Transfer with Detection of Motor Control Data Transfer Overflows Enabled

Since this interrupt is for use in the debugging of defective operation, normal operation will not be restored even if it is detected.

(b) Detection of Requirement for Transfer of Motor control Data

Detection of requirements for the transfer of motor control data (detect motor control data transfer request) is enabled by setting the TMDRFE bit of TIER0. This interrupt is generated when the next pattern interval is to be changed from the current interval. On detection of this interrupt, the handler should write the setting for the next interval to TGRD0 and then write 0 to the TMDRFS bit of TSR0 after having read it as 1.

This interrupt is not available if DMA transfer has been selected (the TDMAE bit in TMIR = 1).

See Figure 66.18 for an example of usage of this interrupt.

(c) Detecting the Transition to Deceleration

Setting the TMS1ER bit in TIER0 to 1 enables detection of the transition to deceleration. The handler should clear the TMCFR flag of TSR0 by writing 0 to the bit after having read it as 1.

(d) Detecting the Transition to the Normal State

Setting the TMS1ET bit in TIER0 to 1 enables detection of the transition to the normal state. The handler should clear the TMCFT flag of TSR0 by writing 0 to the bit after having read it as 1.

(e) Detecting the Transition to Acceleration

Setting the TMS1EA bit in TIER0 to 1 enables detection of the transition to acceleration. The handler should clear the TMCFA flag of TSR0 by writing 0 to the bit after having read it as 1.

(f) Detecting the Transition to the Stop State

Setting the TMS1ES bit in TIER0 to 1 enables detection of the transition to the stop state. The handler should clear the TMCFS flag of TSR0 by writing 0 to the bit after having read it as 1.

(8) Checking the State of Operation

Read TMSR and TMSCR to check the current state of operations. TMSCR indicates the value resulting from decrementation (on every compare match with the timer counter) from the values in the number of steps register (TMASR, TMTSR, or TMRSR) during sequence transitions.

Figure 66.23 shows how the values in TMSR and TMSCR vary through the four states. “( )” in Figure 66.23 means Stop Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the stop state set by TMSPR0 and TMSPR1. “[ ]” in Figure 66.23 means Operation Pattern outputted from TPU0TO0, TPU0TO1, TPU0TO2, and TPU0TO3 in the acceleration, normal, and deceleration states set by TMMPR0 and TMMPR1. As is shown in the figure, the current step within the overall sequence of state transitions can be estimated by, for example, reading TMSR = H'0008 and TMSCR = H'0003 in the interval indicated in the figure below.

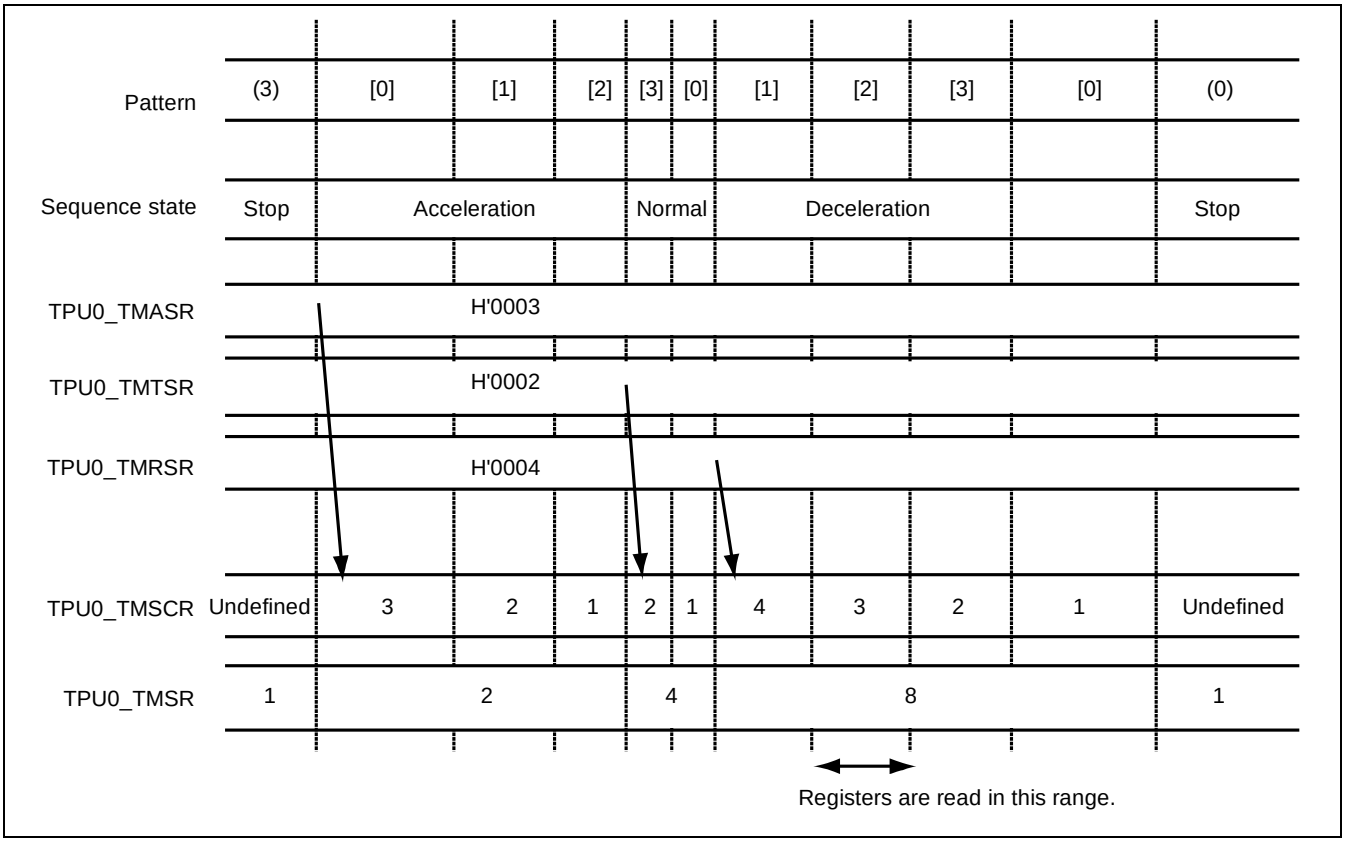

Figure 66.23 Values of TMSR and TMSCR

RZ/G2N RZ/G2E

67.1 Overview

Compare Match Timer Type0 (CMT0) is a 32-bit compare match timer of two channel.

67.1.1 Features

- Two channels
- 16 bits/32 bits can be selected as counter size (bit-width).
- Provided with 32-bit constant registers and 32-bit up counters that can be written or read at any time.
- Following four clocks can be selected as counter clocks:
  — RCLK: 1/1, 1/8, 1/32, and 1/128
- One-shot operation or free-running operation is selectable.
- Compare match or overflow can be selected as interrupt source.
- Counter operation can be enabled or disabled at the time of debugging of CPU core using the debugging mode operation selector.

67.1.2 Block Diagram

Figure 67.1 shows a block diagram of the CMT0.

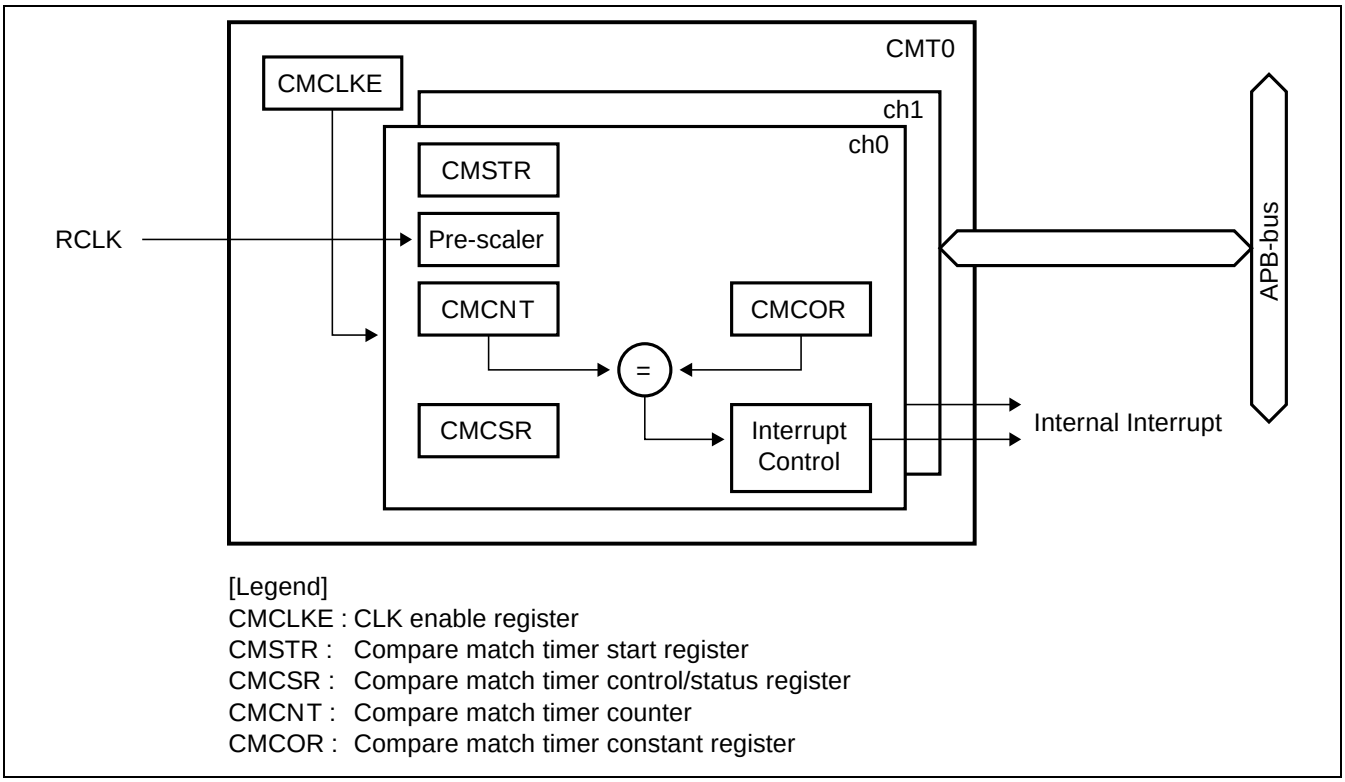

Figure 67.1 Block Diagram of CMT0

67.1.3 Register Configuration

Table 67.1 shows the CMT0 register configuration. Table 67.2 shows the register states in each operating mode. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined. Access the register as a longword (32 bits). Operation cannot be guaranteed if the register is not accessed as a longword.

67.2 Register Description

[Legend for Register Description]

Initial value: Register value after a reset.

—: Undefined value

R/W: Bit or field is readable and writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R: Read-only. The write value should always be initial value.

All access to register is made in longword units.

67.2.1 CLK Enable Register (CMCLKE)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMCLKE is a 32-bit register, which specifies clock supply to each channel. When there are unused channels, set 0 to this register, for stop supplying clock to the channel. It is prohibited to stop clock supply, while counter is working.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	STR0	B'1	R/W	Count Start These bits specify start/halt of compare match timer counter (CMCNTn). 0: CMCNTn halts 1: CMCNTn starts counting

67.2.3 Compare Match Timer Control/Status Registers 0 and 1 (CMCSR0, CMCSR1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMCSRn (n = 0 and 1) is a 32-bit register that indicates the occurrence of compare matches, enables interrupts, and sets the counter input clocks.

Do not change bits other than the CMF and OVF bits, while compare match timer counter (CMCNTn) is under counting.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	CMF	OVF	WRFLG	—	—	—	CMS	CMM	—	—	CMR[1:0]		DBGIVD	CKS[2:0]		
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	1	1	1	1
R/W:	R/WC0	R/WC0	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	CMF	B'0	R/WC0	Compare Match Flag This flag indicates whether values of the compare match timer counter (CMCNTn) and compare match timer constant register (CMCORn) have matched or not. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CMCNTn and CMCORn values have not matched. [Clearing condition] Write 0 to CMF 1: CMCNTn and CMCORn values have matched. Note: Only 0 can be written to clear the flag.
14	OVF	B'0	R/WC0	Overflow Flag This flag indicates whether the compare match timer counter (McCants) has overflowed or not. Software cannot write 1 to this bit. 0: CMCNTn has not overflowed. [Clearing condition] Write 0 to OVF 1: CMCNTn has overflowed. Note: Only 0 can be written to clear the flag.
13	WRFLG	B'0	R	Write State Flag Write access to CMCNTn is prohibited, while this this bit is 1. Further behavior is not guaranteed, if data is written while this bit is 1. This bit indicates CMCNTn is in synchronization period for setting previously written data. Confirm that this flag is 0, before writing to CMCNTn.

Bit	Bit Name	Initial Value	R/W	Description
12 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	CMS	B'0	R/W	Compare Match Timer Counter Size Specify whether the compare match timer counter (CMCNTn) is used as a 16-bit counter or a 32-bit counter. This bit specifies the valid size of compare match timer constant register (CMCORn). 0: Operates as a 32-bit counter. 1: Operates as a 16-bit counter. Note: Refer to section 67.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.
8	CMM	B'1	R/W	Compare Match Mode Specify counter operation mode. 0: One-shot operation 1: Free-running operation Note: Refer to section 67.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.
7, 6	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
5, 4	CMR[1:0]	B'00	R/W	Compare Match Request These bits enable or disable an internal interrupt request in a compare match. B'00: Disables an internal interrupt request. B'01: Setting prohibited B'10: Enables an internal interrupt request. B'11: Setting prohibited Note: Refer to section 67.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.
3	DBGIVD	B'1	R/W	Debug Mode Operation Select Sets the counter operation in debug mode. 0: Stops the counter operation in debug mode. 1: Enables the counter operation even in debug mode. Note: Refer to section 67.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.
2 to 0	CKS[2:0]	B'111	R/W	Clock Select These bits select the input clock to CMCNTn. When the count start bit (STR0) in CMSTRn is set to 1, CMCNTn begins incrementing with the clock selected by these bits. B'000: Setting prohibited B'001: Setting prohibited B'010: Setting prohibited B'011: Setting prohibited B'100: RCLK/8 B'101: RCLK/32 B'110: RCLK/128 B'111: RCLK/1 Note: Refer to section 67.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.

67.2.4 Compare Match Timer Counters 0 and 1 (CMCNT0, CMCNT1)

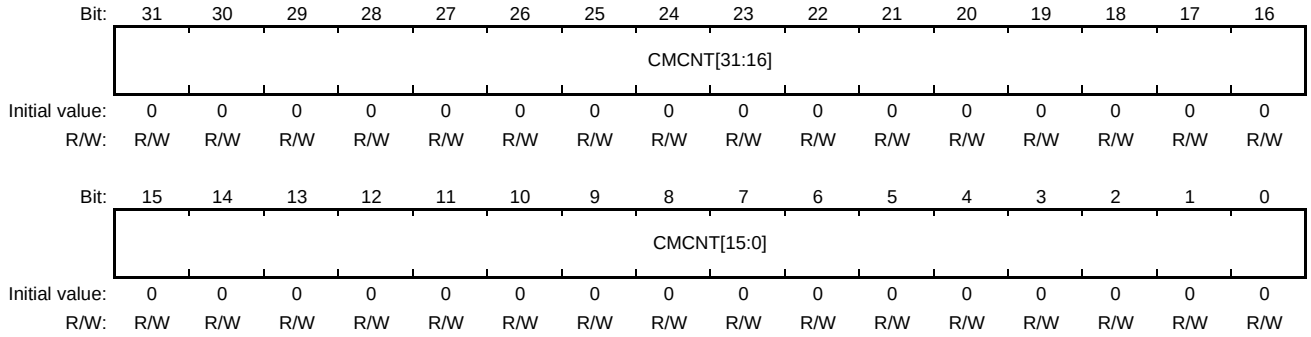
RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMCNTn (n = 0 and 1) is a 32-bit register that is used as an up-counter.

To specify counter operation, set compare match timer control/status register n (CMCSRn), before starting operation of corresponding channel.

When the 16-bit counter operation is selected by the CMS bit, bits 31 to 16 of this register become invalid. When data is written to this register in 16-bit mode, write H'0000 to the upper 16 bits.

When CMCNTn is read during the counter operation, the read value may be wrong because different clock is used between counter and bus-interface. For exact value, read this register continuously, until same values are read from this register.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMCNT [31:0]	H'0000_0000	R/W	Compare match timer counter bit31 to 0 Note: Refer to section 67.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.

67.2.5 Compare Match Timer Constant Registers 0 and 1 (CMCOR0, CMCOR1)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMCORn (n = 0 and 1) is a 32-bit register that sets the compare match period with CMCNTn.

When the 16-bit counter operation is selected by the CMS bit in CMCSRn, bits 15 to 0 of this register become valid. Write H'0000 to upper 16bits in 16-bit counter operation.

An overflow is detected when CMCNTn is cleared to 0 and this register is H'FFFF_FFFF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CMCOR[31:16]															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMCOR[15:0]															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMCOR [31:0]	H'FFFF_FFFF	R/W	Compare match timer constant register bit31 to 0 Note: Refer to section 67.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.

67.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

67.3.1 Counter Operation

The CMT0 starts the operation of the counter by writing 1 to the STR0 bit in CMSTRn after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than clearing flag bits, during the compare match timer n (CMCNTn) is under operation.

The counter operates in one of two ways.

- One-Shot Operation

  One-shot operation is selected by setting the CMM bit in CMCSRn to 0. When the value in CMCNTn matches the value in CMCORn, the value in CMCNTn is cleared to H'0000_0000 and the CMF bit in CMCSRn is set to 1. Counting by CMCNTn stops after it has been cleared.

  To detect an overflow interrupt, set the value in CMCORn to H'FFFF_FFFF. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'0000_0000 and the CMF and OVF bits in CMCSRn are set to 1.

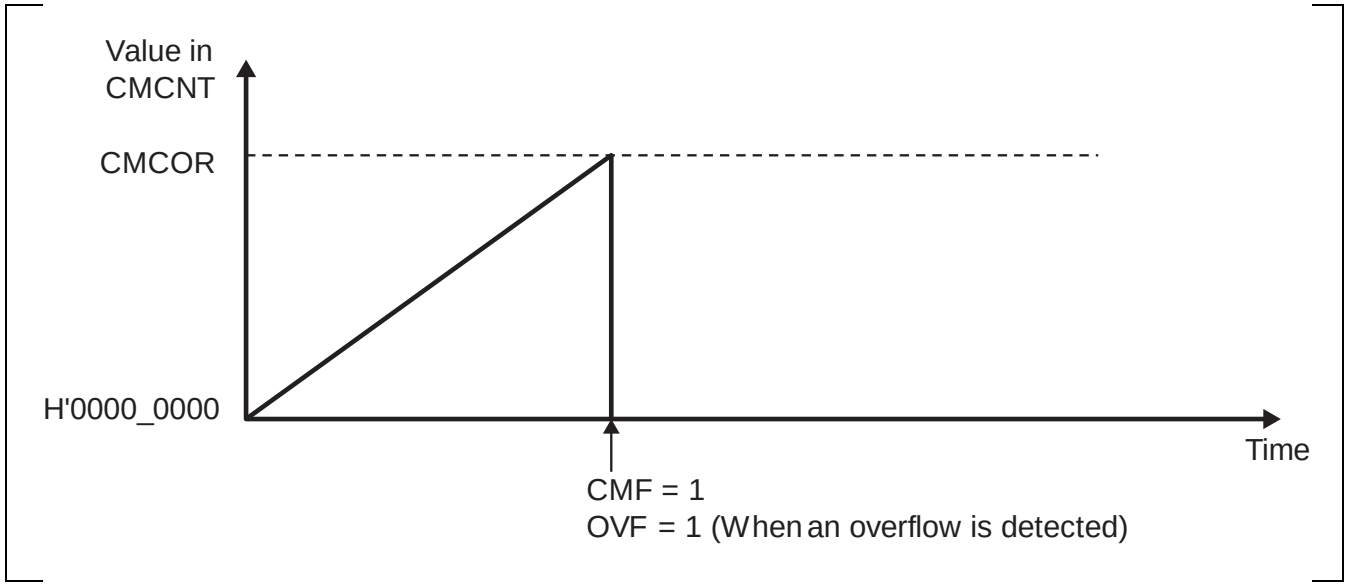


Figure 67.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

  Free-running operation is selected by setting the CMM bit in CMCSRn to 1. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'0000_0000 and the CMF bit in CMCSRn is set to 1. CMCNTn resumes counting-up after it has been cleared.

  To detect an overflow interrupt, set CMCORn to H'FFFF_FFFF. When the values in CMCNTn and CMCORn match, CMCNTn is cleared to H'0000_0000 and the CMF and OVF bits in CMCSRn are set to 1.

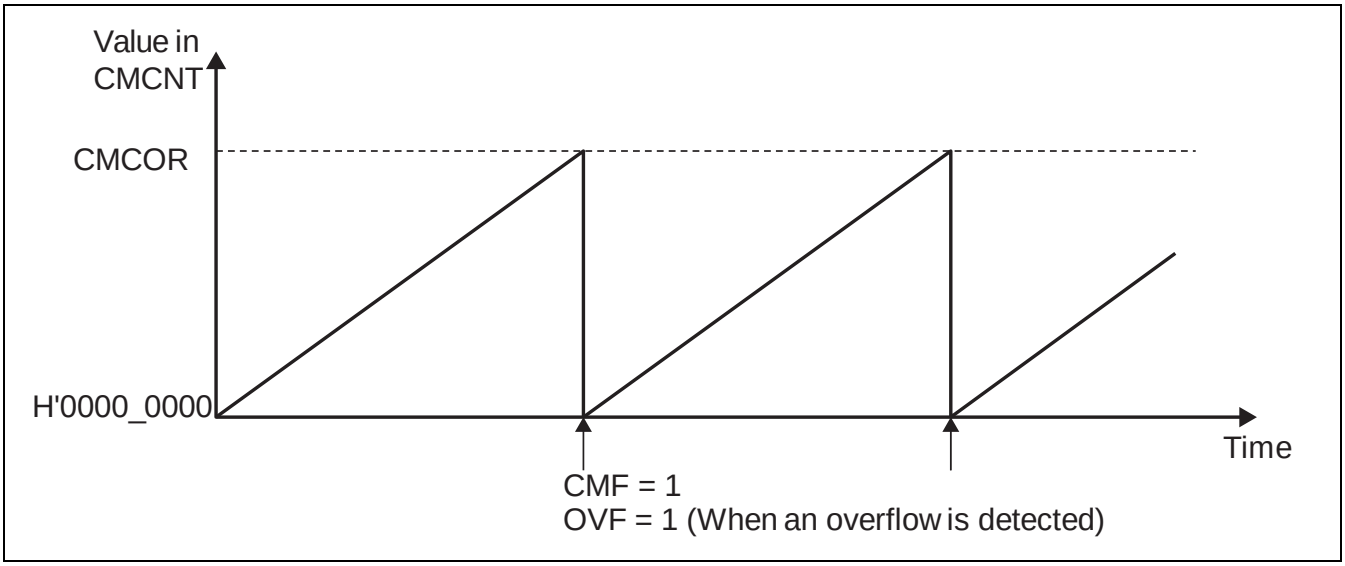

Figure 67.3 Counter Operation (Free-Running Operation)

67.3.2 Counter Size

In this module, the size of the counter can be selected from 16, or 32 bits. This is selected by the CMS bit in CMCSRn.

When the 16-bit size is selected, H'0000 should be used as upper 16 bits of write data to CMCORn. To detect an overflow interrupt, CMCORn must be set to H'0000_FFFF.

67.3.3 Timing for Counting by CMCNTn

In this module, the clock for the counter can be selected from among the following:

- RCLK: 1/1, 1/8, 1/32, and 1/128

The clock for the counter is selected by the CKS bits in CMCSRn. CMCNTn is incremented at the rising edge of the selected clock.

67.3.4 Internal Interrupt Request to CPU

By CMR bits in CMCSRn, internal interrupt request to the CPU at a compare match can be asserted.

To clear an internal interrupt request to the CPU in Free-Running Operation, the CMF bit should be set to 0. Set the CMF bit to 0 in the handling routine for the CMT0 interrupt.

To clear an internal interrupt request to the CPU with resuming count-up in One-Shot Operation, the CMF bit should be set to 0 while keeping 1 in STR0 bit in CMSTRn. Set the CMF bit to 0 while keeping 1 in STR0 bit in the handling routine for the CMT0 interrupt.

To clear an internal interrupt request to the CPU without resuming count-up in One-Shot Operation, the CMF bit should be set to 0 after setting STR0 bit in CMSTRn to 0. Set the CMF bit to 0 after setting STR0 bit to 0 in the handling routine for the CMT0 interrupt.

67.3.5 CMT0 Register Access

After writing to following registers, written data can be read 2 cycles in counter input clock (RCLK) after writing has finished. And it takes 2 cycles in counter input clock (RCLK), for reflecting written data to counter behavior.

CMCSRn: Bits CKS, CMM, CMS, CMR, DBGIVD

CMCORn: Bits 31 to 0

CMSTRn: Bit STR0

After writing to following registers, written data can be read 2 cycles in counter input clock (RCLK) after writing has finished. And it takes 2 cycles in counter input clock (RCLK), for reflecting written data to counter behavior.

And for following registers, write access is prohibited, while previously written data is under writing. Do not perform next write access, while CMCSRn.WRFLG is 1.

CMCNT*: Bits 31 to 0

67.3.6 Compare Match Flag Set/Clear Timing

The CMF bit in CMCSRn is set to 1 by the compare match signal generated when CMCORn and CMCNTn match. The compare match signal is generated upon the final state of the match (timing at which the CMCNTn value is updated to 0). Consequently, after CMCORn and CMCNTn match, a compare match signal will not be generated until a CMCNTn counter clock is input. Figure 67.4 shows the set timing of the CMF bit.

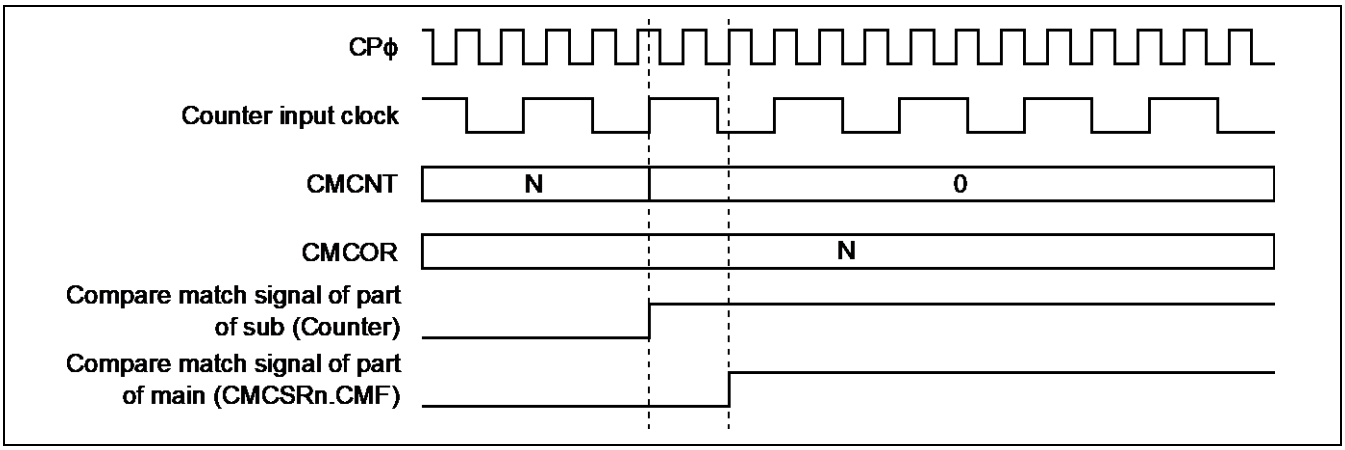

Figure 67.4 CMF Set Timing

Set the CMF bit as 0. The CMF flag is cleared immediately.

67.3.7 CMT0 Usage

Take the following steps to use the CMT0.

1. Clear the STR0 bit in CMSTRn to 0 to temporarily stop counting.
   (Confirm that RCLK was input more than 2 cycles.)
2. Write H'0000_0000 on CMCNTn.
3. Set counter size, compare match mode, type of counter clock and interrupt request and clear the bit of OVF and CMF in CMCSRn.
4. Set the value on CMCORn.
5. Confirm that CMCSRn.WRFLG is 0.
   If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the STR0 bit in CMSTRn to 1.
   (Refer to section 67.3.5, CMT0 Register Access)

67.3.8 Module Stop/ CMCLKE Setting

When counter is not used, clock of this module can be stopped by CMCLKE register. Confirm that, following conditions are satisfied, before stopping counter’s clock.

- CMSTRn.STR0 bit is 0
- CMCSRn.WRFLG is 0
- 3 or more cycles have passed in RCLK, since the last Register access

68. Compare Match Timer Type1 (CMT1)

RZ/G2H

RZ/G2N RZ/G2E

68.1 Overview

This section is written to introduce about CMT1/2/3, total include 24 channels, CMT2/3 are exactly same as CMT1, CMT1's usage are introduced here in, refer to 68.3 for CMT2/3 register address.

68.1.1 Features

- Eight channels
- 16 bits/32 bits/48 bits can be selected as counter size (bit-width).
- 48-bit constant registers and 48-bit up counters that can be written or read at any time.
- For channel 0 to 4, following twelve clocks can be selected as counter clock.
  - CPEXϕ: 1/8, 1/32, 1/128, and 1/1
  - RCLK: 1/1, 1/8, 1/32, and 1/128
  - Pseudo 32 kHz: 1/1, 1/8, 1/32, and 1/128
- For channel 5 to 7, following four clocks can be selected as counter clock.
  - RCLK: 1/1,1/8, 1/32, and 1/128
- One-shot operation or free-running operations are selectable.
- Compare match can be used as interrupt source.
- Support Module standby mode.
- RCLK-synchronous counter start/stop mode for channel 0
- Counter operation can be enabled or disabled at the time of debugging of CPU core using the debugging mode operation selector.

68.2 Register Description

[Legend for Register Description]

Initial value: Register value after a reset.

—: Undefined value

R/W: Bit or field is readable and writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R: Read-only. The write value should always be initial value.

All access to register is made in longword units.

68.2.1 CLK Enable Register (CMCLKE)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMCLKE is a 32bits register, which specify clock supply to each channel. When there are unused channels, set ‘0’ as this register, to stop supplying clock to the channel. It is prohibited to stop clock supply, while counter is working.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
7	Ch7clke	B’1	R/W	0: Clock isn’t supplied to ch7 1: Clock is supplied to ch7
6	Ch6clke	B’1	R/W	0: Clock isn’t supplied to ch6 1: Clock is supplied to ch6
5	Ch5clke	B’1	R/W	0: Clock isn’t supplied to ch5 1: Clock is supplied to ch5
4	Ch4clke	B’1	R/W	0: Clock isn’t supplied to ch4 1: Clock is supplied to ch4
3	Ch3clke	B’1	R/W	0: Clock isn’t supplied to ch3 1: Clock is supplied to ch3
2	Ch2clke	B’1	R/W	0: Clock isn’t supplied to ch2 1: Clock is supplied to ch2

Bit	Bit Name	Initial Value	R/W	Description
1	Ch1clke	B'1	R/W	0: Clock isn't supplied to ch1 1: Clock is supplied to ch1
0	Ch0clke	B'1	R/W	0: Clock isn't supplied to ch0 1: Clock is supplied to ch0

68.2.2 Compare Match Timer Start Registers 0 to 7 (CMSTRn)

CMSTRn (n = 0 to 7) is a 32-bit register which specify the operation of compare match timer counter (CMCNTn). Refer to section 68.3.5, Register Access, for register value update timing.

(1) CMSTR0

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	STR0	B'1	R/W	Count Start 0 These bits specify start/halt of compare match timer counter (CMCNTn). 0: CMCNTn halts 1: CMCNTn starts counting

68.2.3 Compare Match Timer Control/Status Registers 0 to 7 (CMCSRn)

CMCSRn (n = 0 to 7) is a 32-bit register that indicates the occurrence of compare match, enable interrupt and set the counter input clock.

Do not change bits other than the CMF and OVF bits, while compare match timer counter (CMCNTn) is under counting.

Note: * Refer to section 68.3.5, Register Access, for the note regarding writing to or reading form the following bits.

- CMCSR0.CH0SSIE
- CMCSRn.CMS
- CMCSRn.CMM
- CMCSRn.CMR [1:0]
- CMCSRn.DBGIVD
- CMCSRn.CKS [2:0]

Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	1	1	1	1
R/W:	R/WC0	R/WC0	R	R/WC0	R/WC0	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	CMF	B'0	R/WC0	Compare Match Flag This flag indicates whether values of the compare match timer counter (CMCNT0) and compare match timer constant register (CMCOR0) have matched or not. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CMCNT0 and CMCOR0 values have not matched [Clearing conditions] • Write 0 to this bit 1: CMCNT0 and CMCOR0 values have matched Note: Only 0 can be written to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
14	OVF	B'0	R/WC0	Overflow Flag This flag indicates whether the compare match timer counter (CMCNT0) has overflowed or not. Software cannot write 1 to this bit. 0: CMCNT0 has not overflowed [Clearing conditions] • Write 0 to this bit 1: CMCNT0 has overflowed Note: Only 0 can be written to clear the flag.
13	WRFLG	B'0	R	Write State Flag Write access to CMCNT0 is prohibited, while this bit is 1. Further behavior is not guaranteed, if data is written while this bit is 1. This bit indicates CMCNT0 is in synchronization period for setting previously written data. Confirm that this flag is 0, before writing to CMCNT0.
12	CH0STTF	B'0	R/WC0	Channel 0 Start Flag When RCLK-synchronous channel 0 counter start/stop mode is selected, this flag indicates whether the counter in channel 0 started on detecting an RCLK rising edge after 1 was written to the STR0 bit in CMSR. 0: Channel 0 counter has not started. [Clearing condition] • Write 0 to CH0STTF. 1: Channel 0 counter has started. Note: Only 0 can be written to clear the flag.
11	CH0STPF	B'0	R/WC0	Channel 0 Stop Flag When RCLK-synchronous channel 0 counter start/stop mode is selected, this flag indicates whether the counter in channel 0 stopped on detecting an RCLK rising edge after 1 was written to the STR0 bit in CMSR. 0: Channel 0 counter has not stopped. [Clearing condition] • Write 0 to CH0STPF. 1: Channel 0 counter has stopped. Note: Only 0 can be written to clear the flag.
10	CH0SSIE	B'0	R/W	Channel 0 Start/Stop Interrupt Enable When RCLK-synchronous channel 0 counter start/stop mode is selected, this bit enables or disables an interrupt due to the start or stop of the counter in channel 0. 0: Disables an interrupt due to start or stop of channel 0 counter. 1: Enables an interrupt due to start or stop of channel 0 counter.

Bit	Bit Name	Initial Value	R/W	Description
9	CMS	B’0	R/W	Compare Match Timer Counter Size This bit and CMCSRH0.CMSH select whether the compare match timer counter 0 (CMCNTH0 [15:0], and CMCNT0 [31:0]) is used as a 16-bit counter, a 32-bit counter, or a 48-bit counter. This bit also specifies valid size of the compare match timer constant register 0 (CMCORH0 [15:0], and CMCOR0 [31:0]). CMCSRH0[9].CMSH, and CMCSR0[9].CMS: B’1x: Operates as a 48-bit counter B’00: Operates as a 32-bit counter B’01: Operates as a 16-bit counter
8	CMM	B’1	R/W	Compare Match Mode Specify operation mode of the counter. 0: One-shot operation 1: Free-running operation
7	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
5, 4	CMR[1:0]	B’00	R/W	Compare Match Request These bits enable or disable internal interrupt request in a compare match. B’00: Disables internal interrupt request B’01: Setting prohibited B’10: Enables an internal interrupt request B’11: Setting prohibited
3	DBGIVD	B’1	R/W	Debug Mode Operation Select Sets the counter operation in debugging mode. 0: Stops the counter operation in debugging mode. 1: Continues the counter operation even in debugging mode.
2 to 0	CKS[2:0]	B’111	R/W	Clock Select These bits and CMCSRH0.CKSH select the clock input to CMCNT0. 68.2.5 Compare Match Timer Counters 0 to 7 (CMCNTn)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

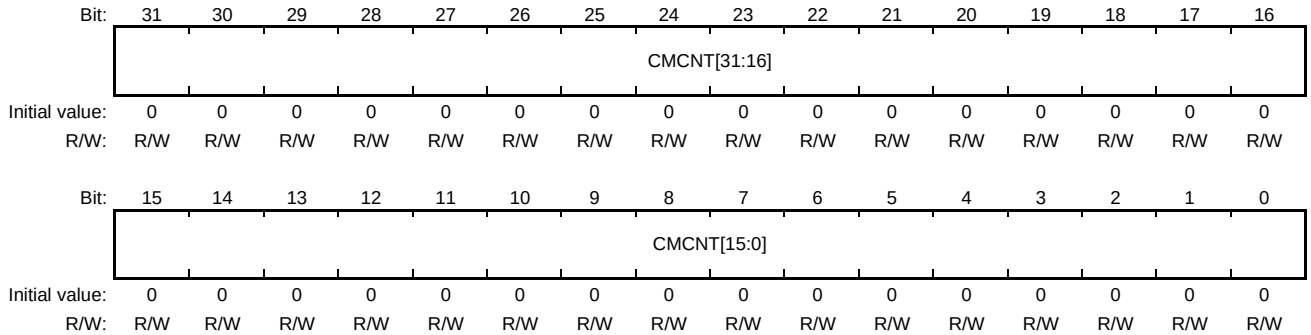
CMCNTn (n = 0 to 7) is a 32-bit register which is used as an up-counter of each channel.

To specify counter operation, set compare match timer control/status register n (CMCSRn), before starting operation of corresponding channel. When the 16-bit counter operation is selected by the CMCSRH.CMSH and CMCSR.CMS bits, bits 31 to 16 of this register is invalid. When data is written to this register in 16-bit mode, write H'0000 to the upper 16 bit.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMCNT [31:0]	H’0000_0000	R/W	Compare match timer counter bit31 to 0 Note: For access to this register, refer to section 68.3.5, Register Access.

68.2.6 Compare Match Timer Counters H 0 to 4 (CMCNTHn)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMCNTHn (n = 0 to 4) is a 32-bit register which is used as an up-counter for channel0 to 4.

To specify counter operation, set compare match timer control/status register n (CMCSRn/CMCSRHn), before starting operation of corresponding channel. When the 48-bit counter operation is selected by the CMCSRHn.CMSH and CMCSRn.CMS bits, bits 15 to 0 of this register become valid as the upper 16-bit of 48-bit counter. The value written to this register is reflected to counter behavior, when lower data is written to CMCNTn. Write the upper data to this register first. The value is not reflected to counter's behavior, if data is not written to CMCNTn later.

When reading the value of 48-bit counter, upper 16-bit can be read out by reading bits 15 to 0 of this register. At the same time of the reading, the value of 48-bit counter is stored to the read-buffer. After reading CMCNTHn, lower 32-bit can be read out by reading CMCNTn.

Note: If CMCNTn is read out before reading CMCNTHn, the read out value of 48-bit counter may not be correct.

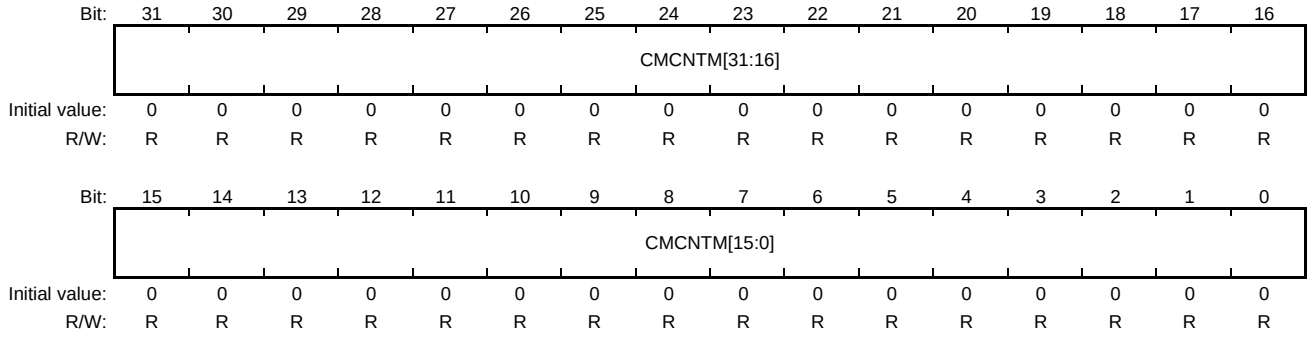
1	CMPCLR	B'0	R/W	Counter Clear [When writing] 0: No operation 1: Clears counter When CMPCLR and CMPSTART are written 1 at the same time, the counter starts after clearing the counter. [When reading] This bit is always read as 0.
0	CMPSTART	B'0	R/W	Count Start This bit specifies start/halt of the compare match timer match counter (CMCNTMn) of each channel. 0: CMCNTMn Halts 1: CMCNTMn Starts counting

68.2.12 Compare Match Timer Match Counters 0 and 3 (CMCNTMn)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMCNTMn is a 32-bit register which is used as an up-counter. This register is only present in channels 0 and 3.

A counter operation is set by the compare match timer match control/status register (CMCSRMn). After the counter CMCNTn starts, this counter increases whenever at a compare match.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMCNTM [31:0]	H'0000_0000	R	Compare match timer match counter bit31 to 0

68.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

68.3.1 Counter Operation

The CMT1 starts the operation of the counter by writing H'1 to the STR0 bit in CMSTRn after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than clearing flag bits, while the compare match timer (CMCNTn) is under operation.

The counter operates in one of two ways.

- One-Shot Operation

  One-shot operation is selected by setting the CMM bit in CMCSRn to H'0. When the value in CMCNTn matches the value in CMCORn, the value in CMCNTn is cleared to H'0000_0000 and the CMF bit in CMCSRn is set to H'1. Counting by CMCNTn stops after it has been cleared.

  To detect an overflow interrupt, set the value in CMCORn to H'FFFF_FFFF. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'0000_0000 and the CMF and OVF bits in CMCSRn are set to H'1.

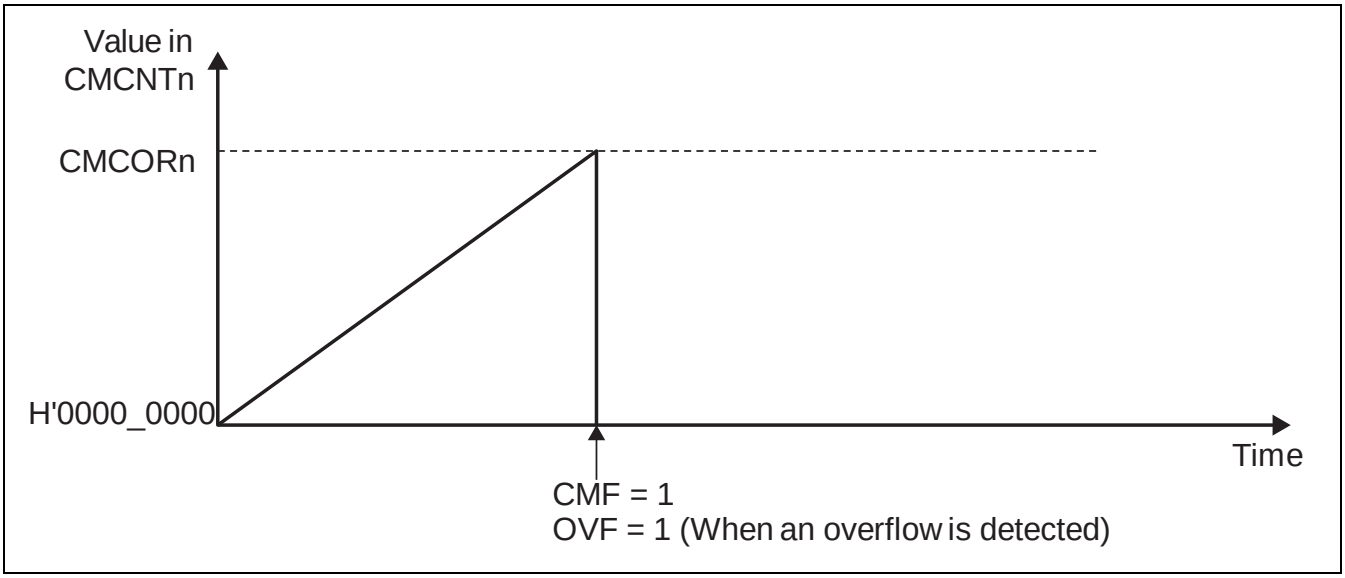


Figure 68.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

  Free-running operation is selected by setting the CMM bit in CMCSRn to H'1. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'0000_0000 and the CMF bit in CMCSRn is set to H'1. CMCNTn resumes counting-up after it has been cleared.

  To detect an overflow interrupt, set CMCORn to H'FFFF_FFFF. When the values in CMCNTn and CMCORn match, CMCNTn is cleared to H'0000_0000 and the CMF and OVF bits in CMCSRn are set to H'1.

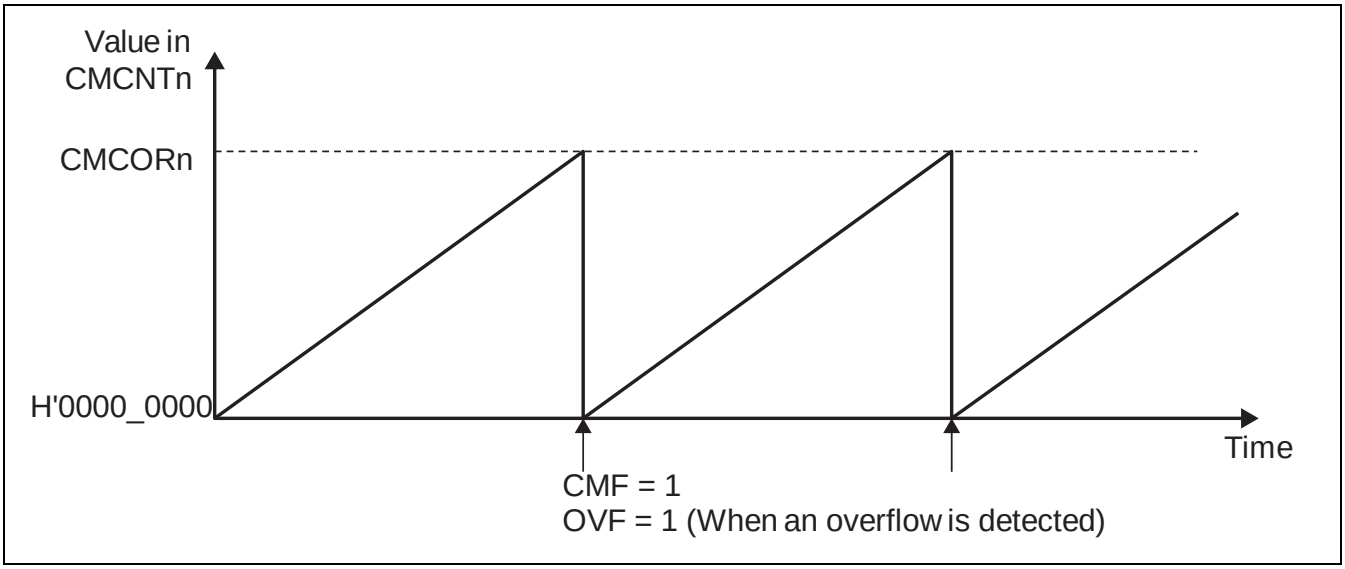

Figure 68.3 Counter Operation (Free-Running Operation)

68.3.2 Counter Size

In this module, the size of the counter can be selected from 16, 32, or 48 bits. This is selected by the CMS bit in CMCSRn and CMSH bit in CMCSRHn.

When the 16-bit/32-bit size is selected, upper 32 bits/16 bits of CMCORn is ignored. To detect an overflow interrupt, the value 1 must be set to valid bits of CMCORn.

(for example, H'0000_0000_FFFF, H'0000_FFFF_FFFF)

68.3.3 Timing for Counting by CMCNTn

In this module, the clock for the counter can be selected from among the following:

Channels 0 to 4:	CPEXϕ clock:	1/1, 1/8, 1/32, and 1/128
	RCLK:	1/1, 1/8, 1/32, and 1/128
	Pseudo 32-kHz:	1/1, 1/8, 1/32 and 1/128
Channel 5 to 7:	RCLK:	1/1, 1/8, 1/32, and 1/128

For details of CPEXϕ and RCLK, refer to section 11, Clock Pulse Generator (CPG).

Pseudo 32-kHz is a clock, which is generated inside this module. Refer to section 68.3.8, Pseudo 32-kHz Counter.

The clock for the counter is selected by the CKS bits in CMCSRn and CKSH bit in CMCSRHn. CMCNTn is incremented at the rising edge of the selected clock.

68.3.4 Internal Interrupt Request to CPU

By CMR bits in CMCSRn, internal interrupt request to the CPU at a compare match can be asserted.

To clear an internal interrupt request to the CPU in Free-Running Operation, the CMF bit should be set to H'0. Set the CMF bit to H'0 in the handling routine for the CMT1 interrupt.

To clear an internal interrupt request to the CPU with resuming count-up in One-Shot Operation, the CMF bit should be set to H'0 while keeping H'1 in STR0 bit in CMSTRn. Set the CMF bit to H'0 while keeping H'1 in STR0 bit in the handling routine for the CMT1 interrupt.

To clear an internal interrupt request to the CPU without resuming count-up in One-Shot Operation, the CMF bit should be set to H'0 after setting STR0 bit in CMSTRn to H'0. Set the CMF bit to H'0 after setting STR0 bit to H'0 in the handling routine for the CMT1 interrupt.

68.3.5 Register Access

After writing to following registers, written data can be read 2 cycles in counter input clock (RCLK) after writing has finished. And it takes 2 cycles in counter input clock (RCLK), for reflecting written data to counter behavior.

- CMCSRn: Bits CH0SSIE(ch0), CMS, CMM, CMR[1:0], DBGIVD, CKS[2:0]
- CMCORn, CMCORHn
- CMSTRn: Bit STR0RS, STR0
- CMCSRMn: Bit CMPCLR, CMPSTART

After writing to following registers, written data can be read 2 cycles in counter input clock (RCLK or CPEXϕ) after writing has finished. And it takes 2 cycles in counter input clock (RCLK or CPEXϕ), for reflecting written data to counter behavior. After writing data to this register, next write access is prohibited, until CMCSRn.WRFLG become 0.

- CMCNTn, CMCNTHn

68.3.6 Compare Match Flag Set/Clear Timing

The CMF bit in CMCSRn is set to 1 by the compare match signal generated when CMCORn and CMCNTn match. The compare match signal is generated upon the final state of the match (timing at which the CMCNTn value is updated to H'0000). Consequently, after CMCORn and CMCNTn match, a compare match signal will not be generated until a CMCNTn counter clock is input. Figure 68.4 shows the set timing of the CMF bit.

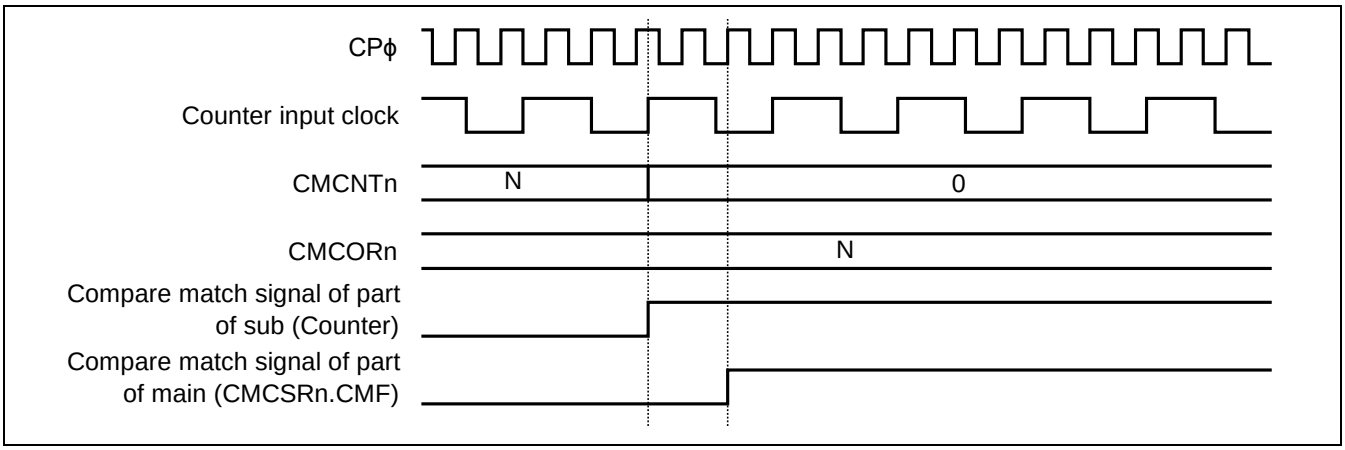

Figure 68.4 CMF Set Timing

Set the CMF bit to 0. The CMF flag is cleared immediately.

68.3.7 RCLK-Synchronous Counter Start/Stop Mode in Channel 0

The CMT1 provides the RCLK-synchronous counter start/stop mode in channel 0, in which channels 0 and 3 can be used together for time measurement.

Figure 68.5 shows a flow chart for preparation.

Figure 68.6 shows a flow chart for starting measurement.

Figure 68.7 shows a flow chart for stopping measurement.

Figure 68.8 shows a timing chart when measurement starts.

Figure 68.9 shows a timing chart when measurement stops.

Figure 68.10 shows how to calculate the time measured by the counters.

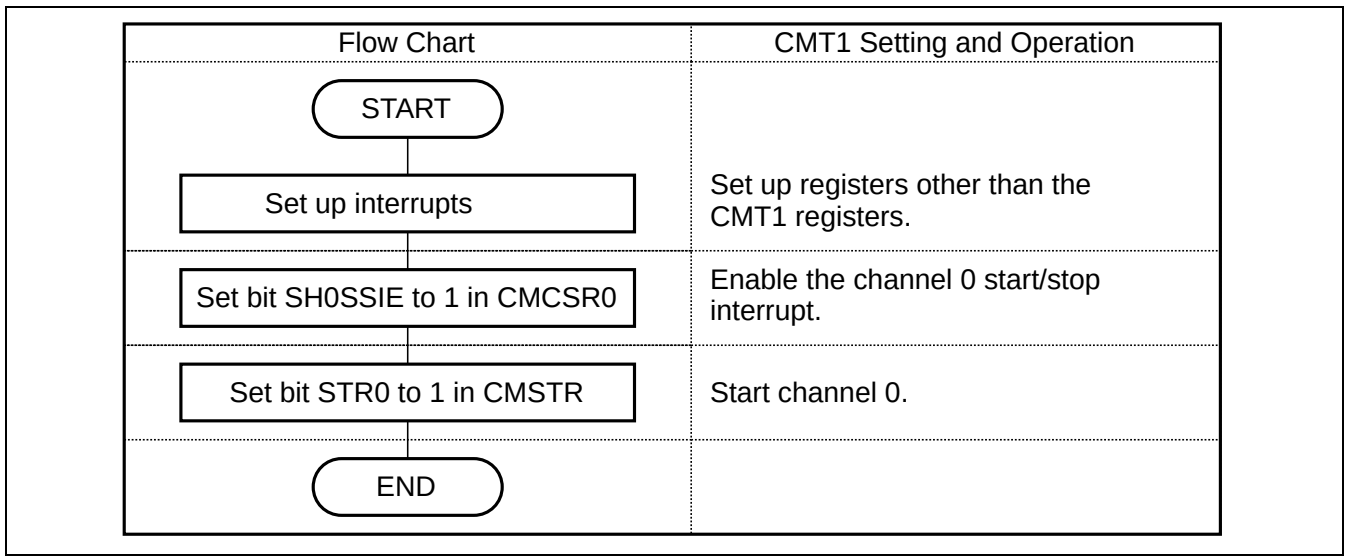

Figure 68.5 Flow Chart for Preparation

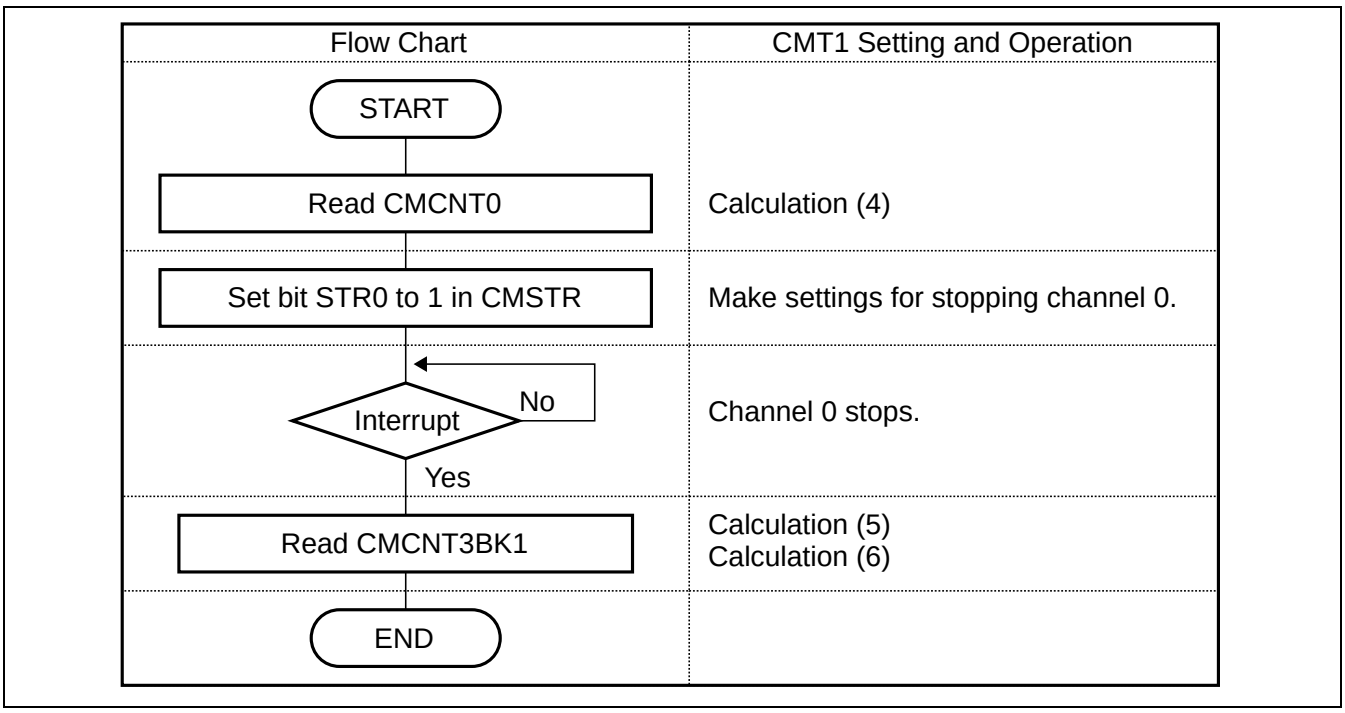

Figure 68.7 Flow Chart for Stopping Measurement

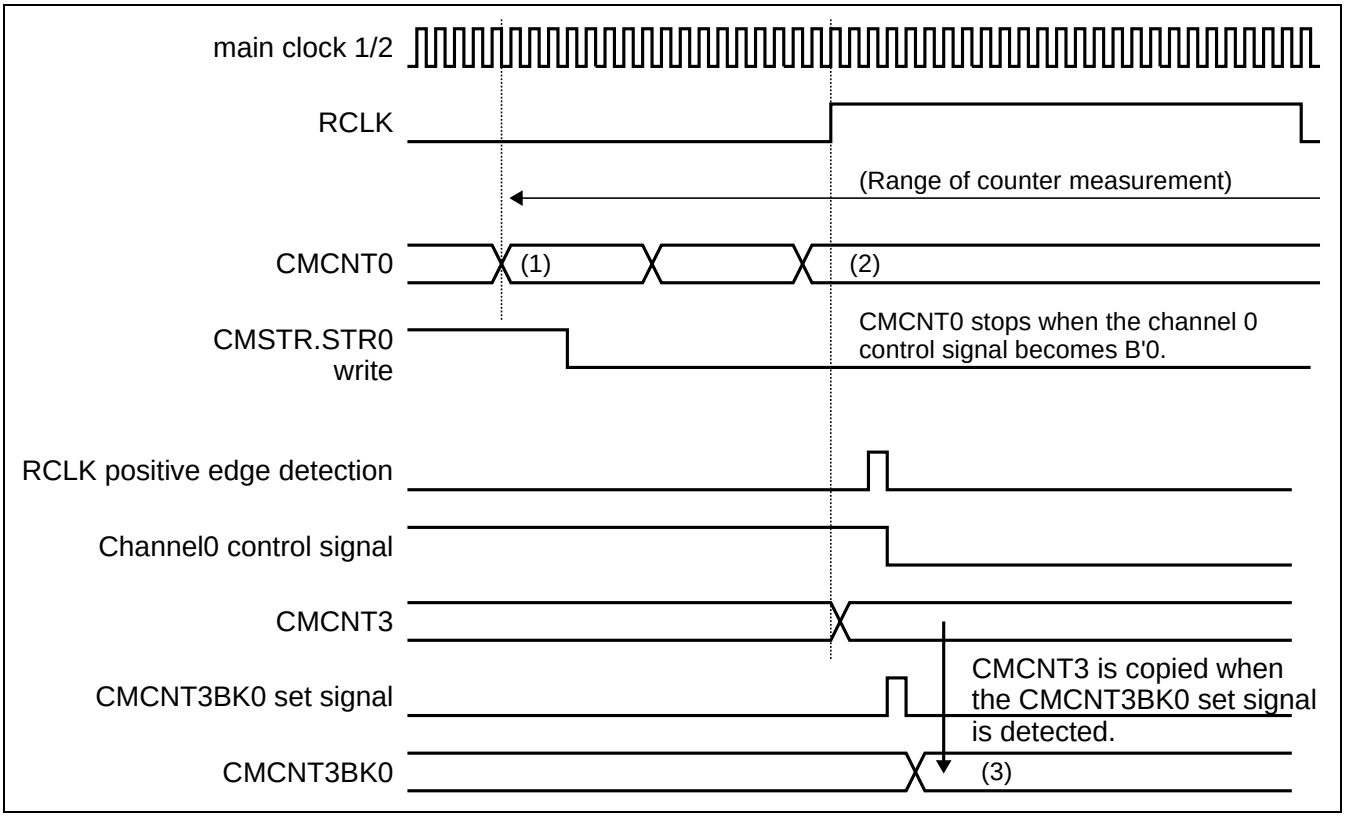

Figure 68.8 Timing Chart When Measurement Starts

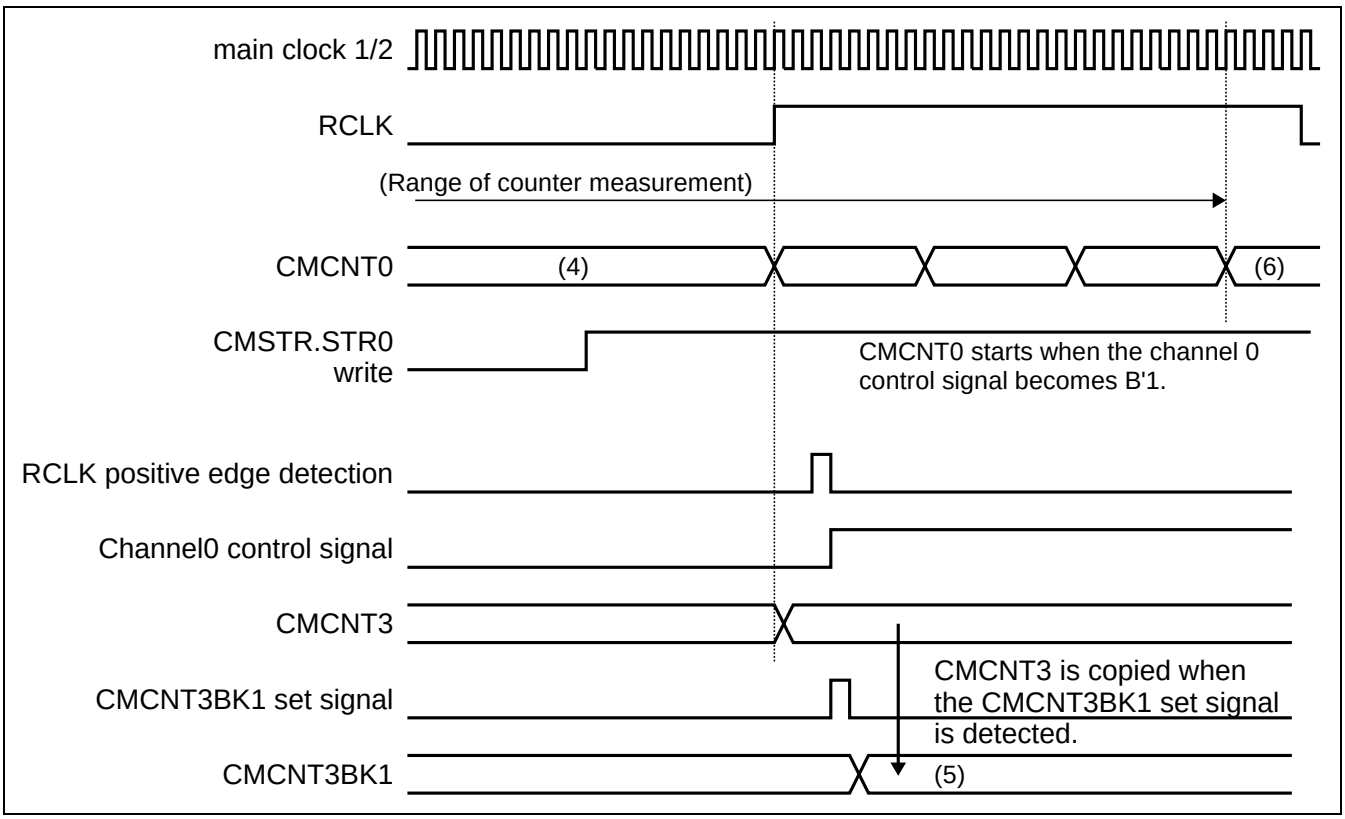

Figure 68.9 Timing Chart When Measurement Stops

$$(((2) - (1)) + ((6) - (4) - 1)) \times Tapc + ((5) - (3)) \times Tr$$

Tapc : Cycle of main clock 1/2

Tr : Cycle of RCLK

Figure 68.10 Calculation of Time Measured by Counters

68.3.8 Pseudo 32-kHz Counter

Pseudo 32-kHz clock is created inside this module, based on RCLK by Pseudo 32-kHz Counter. By removing 3 edge of RCLK every 128 cycle, Pseudo 32-kHz clock is generated. By this edge removing, frequency of this clock becomes 128/131 of RCLK.

68.3.9 CMT1 Usage

Take the following steps to use the CMT1.

1. Clear the STR0 bit in CMSTRn to 0 to temporarily stop counting.
   (Confirm that Counter input clock was input more than 2 cycles.)
2. Write H'0000_0000 on CMCNTn.
3. Set counter size, compare match mode, kind of count clock and interrupt request and clear the bit of OVF and CMF in CMCSRn.
4. Set the value on CMCORn.
5. Confirm that CMCSRn.WRFLG is 0.
   If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the STR0 bit in CMSTRn to 1 (refer to section 68.3.5, Register Access).

68.3.10 Module Stop/ CMCLKE Setting

When counter is not used, clock of this module can be stopped by CMCLKE register. Confirm that, following conditions are satisfied, before stopping counter’s clock.

- CMSTRn.STR0 bit is 0
- CMCSRn.WRFLG is 0
- 3 or more cycles have passed in Counter input clock since the last Register access

69. Timer Unit (TMU)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

69.1 Overview

[RZ/G2H]

This LSI includes a 32-bit timer unit (TMU) with 15 channels (channels 0 to 14).
Channels 0 to 2, 3 to 5, 6 to 8, 9 to 11 and 12 to 14 are grouped into timers 0, 1, 2, 3, 4 respectively.
For channels 0 to 2, CPϕ is provided as a base clock. For channels 3 to 11, S3D2ϕ is provided. For channels 12 to 14, S0D6ϕ is provided.

[RZ/G2M V1.3, RZ/G2M V3.0]

This LSI includes a 32-bit timer unit (TMU) with 15 channels (channels 0 to 14).
Channels 0 to 2, 3 to 5, 6 to 8, 9 to 11 and 12 to 14 are grouped into timers 0, 1, 2, 3, 4 respectively.
For channels 0 to 2, CPϕ is provided as a base clock. For channels 3 to 11, S3D2ϕ is provided. For channels 12 to 14, S0D6ϕ is provided.

[RZ/G2N]

This LSI includes a 32-bit timer unit (TMU) with 15 channels (channels 0 to 14).
Channels 0 to 2, 3 to 5, 6 to 8, 9 to 11 and 12 to 14 are grouped into timers 0, 1, 2, 3, 4 respectively.
For channels 0 to 2, CPϕ is provided as a base clock. For channels 3 to 11, S3D2ϕ is provided. For channels 12 to 14, S0D6ϕ is provided.

[RZ/G2E]

This LSI includes a 32-bit timer unit (TMU) with 15 channels (channels 0 to 14).

Channels 0 to 2, 3 to 5, 6 to 8, 9 to 11 and 12 to 14 are grouped into timers 0, 1, 2, 3, 4 respectively.

For channels 0 to 2, CPϕ is provided as a base clock. For channels 3 to 11, S3D2Cϕ is provided. For channels 12 to 14, S0D6Cϕ is provided.

69.1.1 Features

TMU has the following features:

[RZ/G2H]

- Auto-reload type 32-bit down counter is provided for each channel.
- Input capture function provided: Channels 5 and 8.
- Selection of rising edge or falling edge as external clock input edge when external clock is selected or input capture function is used: Channels 3 to 8.
- 32-bit timer constant register for auto-reload use, readable/writable at any time, and 32-bit down-counter are provided for each channel.
- Selection of five counter input clocks: Channels 0 to 2.
  Five peripheral clocks (CPϕ/4, CPϕ/16, CPϕ/64, CPϕ/256, and CPϕ/1024).
- Selection of six counter input clocks: Channels 3 to 8.
  External clock (TCLK1/2), and five peripheral clocks (S3D2ϕ/4, S3D2ϕ/16, S3D2ϕ/64, S3D2ϕ/256, and S3D2ϕ/1024).
- Selection of five counter input clocks: Channels 9 to 11.
  Five peripheral clocks (S3D2ϕ/4, S3D2ϕ/16, S3D2ϕ/64, S3D2ϕ/256, and S3D2ϕ/1024).
- Selection of five counter input clocks: Channels 12 to 14.
  Five peripheral clocks (S0D6ϕ/4, S0D6ϕ/16, S0D6ϕ/64, S0D6ϕ/256, and S0D6ϕ/1024).
- Two interrupt sources.
  One underflow source (each channel) and one input capture source (channels 5 and 8).

[RZ/G2M V1.3, RZ/G2M V3.0]

- Auto-reload type 32-bit down counter is provided for each channel.
- Input capture function provided: Channels 5 and 8.
- Selection of rising edge or falling edge as external clock input edge when external clock is selected or input capture function is used: Channels 3 to 8.
- 32-bit timer constant register for auto-reload use, readable/writable at any time, and 32-bit down-counter are provided for each channel.
- Selection of five counter input clocks: Channels 0 to 2.
  Five peripheral clocks (CPϕ/4, CPϕ/16, CPϕ/64, CPϕ/256, and CPϕ/1024).
- Selection of six counter input clocks: Channels 3 to 8.
  External clock (TCLK1/2), and five peripheral clocks (S3D2ϕ/4, S3D2ϕ/16, S3D2ϕ/64, S3D2ϕ/256, and S3D2ϕ/1024).
- Selection of five counter input clocks: Channels 9 to 11.
  Five peripheral clocks (S3D2ϕ/4, S3D2ϕ/16, S3D2ϕ/64, S3D2ϕ/256, and S3D2ϕ/1024).
- Selection of five counter input clocks: Channels 12 to 14.
  Five peripheral clocks (S0D6ϕ/4, S0D6ϕ/16, S0D6ϕ/64, S0D6ϕ/256, and S0D6ϕ/1024).
- Two interrupt sources.
  One underflow source (each channel) and one input capture source (channels 5 and 8).

[RZ/G2N]

- Auto-reload type 32-bit down counter is provided for each channel.
- Input capture function provided: Channels 5 and 8.
- Selection of rising edge or falling edge as external clock input edge when external clock is selected or input capture function is used: Channels 3 to 8.
- 32-bit timer constant register for auto-reload use, readable/writable at any time, and 32-bit down-counter are provided for each channel.
- Selection of five counter input clocks: Channels 0 to 2.
  Five peripheral clocks (CPϕ/4, CPϕ/16, CPϕ/64, CPϕ/256, and CPϕ/1024).
- Selection of six counter input clocks: Channels 3 to 8.
  External clock (TCLK1/2), and five peripheral clocks (S3D2ϕ/4, S3D2ϕ/16, S3D2ϕ/64, S3D2ϕ/256, and S3D2ϕ/1024).
- Selection of five counter input clocks: Channels 9 to 11.
  Five peripheral clocks (S3D2ϕ/4, S3D2ϕ/16, S3D2ϕ/64, S3D2ϕ/256, and S3D2ϕ/1024).
- Selection of five counter input clocks: Channels 12 to 14.
  Five peripheral clocks (S0D6ϕ/4, S0D6ϕ/16, S0D6ϕ/64, S0D6ϕ/256, and S0D6ϕ/1024).
- Two interrupt sources.
  One underflow source (each channel) and one input capture source (channels 5 and 8).

[RZ/G2E]

- Auto-reload type 32-bit down counter is provided for each channel.
- Input capture function provided: Channels 5 and 8.
- Selection of rising edge or falling edge as external clock input edge when external clock is selected or input capture function is used: Channels 3 to 8.
- 32-bit timer constant register for auto-reload use, readable/writable at any time, and 32-bit down-counter are provided for each channel.
- Selection of five counter input clocks: Channels 0 to 2.
  Five peripheral clocks (CPϕ/4, CPϕ/16, CPϕ/64, CPϕ/256, and CPϕ/1024).
- Selection of six counter input clocks: Channels 3 to 8.
  External clock (TCLK1/2), and five peripheral clocks (S3D2Cϕ/4, S3D2Cϕ/16, S3D2Cϕ/64, S3D2Cϕ/256, and S3D2Cϕ/1024).
- Selection of five counter input clocks: Channels 9 to 11.
  Five peripheral clocks (S3D2Cϕ/4, S3D2Cϕ/16, S3D2Cϕ/64, S3D2Cϕ/256, and S3D2Cϕ/1024).
- Selection of five counter input clocks: Channels 12 to 14.
  Five peripheral clocks (S0D6Cϕ/4, S0D6Cϕ/16, S0D6Cϕ/64, S0D6Cϕ/256, and S0D6Cϕ/1024).
- Two interrupt sources.
  One underflow source (each channel) and one input capture source (channels 5 and 8).

69.2 Register Description

Registers in the TMU are allocated to and arranged in the address space of the internal bus.

Legend for Register Description

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R: Read-only. When the bit is reserved, the write value should always be 0. Writing 1 to these bits can cause a malfunction of TMU.

—/W: Write-only. The read value is undefined.

69.2.1 Timer Start Registers (TSTRn) (n = 0 to 4)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TSTR are 8-bit readable/writable registers that select whether to run or halt the TCNT.

69.2.4 Timer Control Registers (TCRn) (n = 0 to 14)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TCR are 16-bit readable/writable registers that select a count clock and edge when an external clock is selected, and control an interrupt generation when the flag that indicates the generation of a TCNT is set to 1.

TCR of channels 5 and 8 control the input capture function and generation of an interrupt during the input capture.

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	ICPF*1	B'0	R/W	Input Capture Interrupt Flag Status flag, provided in channels 5 and 8 which indicates the occurrence of input capture. 0: No input capture has occurred [Clearing condition] When 0 is written to ICPF 1: Input capture has occurred [Setting condition] When an input capture occurs*2
8	UNF	B'0	R/W	Underflow Flag Status flag which indicates the occurrence of a TCNT underflow. 0: TCNT has not underflowed [Clearing condition] When 0 is written to UNF 1: TCNT has underflowed [Setting condition] When TCNT underflows*2

Bit	Bit Name	Initial Value	R/W	Description
7, 6	ICPE*1	B'00	R/W	Input Capture Control A function of channels 5, 8: determines whether the input capture function can be used, and when used, whether or not to enable interrupts. Use the CKEG bits to designate use of either the rising or falling edge of the TCLK pin to set the values of TCNT5, TCNT8 to TCPR5, TCPR8 respectively. Only when the ICPF bits in TCR5, TCR8 are 0, the values of TCNT5, TCNT8 are set to TCPR5, TCPR8. When the ICPF bit is set to 1, neither TCPR5, TCPR8 is set even when input capture is generated. B'00: Input capture function is not used. B'01: Reserved (setting prohibited). B'10: Input capture function is used. Interrupt due to input capture (TICPI5, TICPI8) is not enabled. B'11: Input capture function is used. Interrupt due to input capture (TICPI5, TICPI8) is enabled.
5	UNIE	B'0	R/W	Underflow Interrupt Control Controls enabling of interrupt generation when the status flag (UNF) indicating TCNT underflow has been set to 1. 0: Interrupt due to underflow (TUNI) is not enabled 1: Interrupt due to underflow (TUNI) is enabled
4, 3	CKEG	B'00	R/W	Clock Edge Select an input edge of the external clock when the external clock is selected, or when the input capture function is used. B'00: Count/capture register set on rising edge B'01: Count/capture register set on falling edge Other: Count/capture register set on both rising and falling edge
2 to 0	TPSC	B'000	R/W	Timer Pre-scaler 2 to 0 Select the TCNT count clock. B'000: Count on (input-clock)/4 B'001: Count on (input-clock)/16 B'010: Count on (input-clock)/64 B'011: Count on (input-clock)/256 B'100: Count on (input-clock)/1024 B'101: Setting prohibited B'110: Setting prohibited B'111: Count on external clock Channels 3 to 5 TCLK1, channels 6 to 8 TCLK2. Not usable in channels 0, 1, 2, 9, 10, 11, 12, 13, 14. Note: Input-clock is CPϕ for channel 0/1/2, S3D2ϕ for channel 3/4/5/6/7/8/9/10/11, S0D6ϕ for channel 12/13/14 in the RZ/G2H. Input-clock is CPϕ for channel 0/1/2, S3D2ϕ for channel 3/4/5/6/7/8/9/10/11, S0D6ϕ for channel 12/13/14 in the RZ/G2M V1.3, RZ/G2M V3.0. Input-clock is CPϕ for channel 0/1/2, S3D2ϕ for channel 3/4/5/6/7/8/9/10/11, S0D6ϕ for channel 12/13/14 in the RZ/G2N. Input-clock is CPϕ for channel 0/1/2, S3D2Cϕ for channel 3/4/5/6/7/8/9/10/11, S0D6Cϕ for channel 12/13/14 in the RZ/G2E.

Notes: 1. Reserved in channels 0, 1, 2, 3, 4, 6, 7, 9, 10, 11, 12, 13 and 14 (initial value is 0 and read-only).

2. Writing 1 does not change the value.

69.2.5 Input Capture Registers n (TCPRn)

Note: n = 5 and 8

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

TCPR5, TCPR8 are read-only 32-bit registers used for the input capture function provided only in channels 5, 8. The ICPE and CKEG bits in TCR5, TCR8 control the input capture function. When an input capture occurs, the value of TCNT5 is copied to TCPR5, the value of TCNT8 is copied to TCPR8. The values of TCNT5, TCNT8 are set in TCPR5, TCPR8, respectively, only when the ICPF bits in TCR5, TCR8 are 0.

69.3 Operation

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

Each channel has a 32-bit timer counter (TCNT) and 32-bit timer constant register (TCOR). TCNT counts down. The auto-reload function enables synchronized counting and external-event counting. Channels 5, 8 have the input capture function.

69.3.1 Counter Operation

When the bits STR0 to STR14 in TSTR0 to TSTR4 are set to 1, TCNT of corresponding channel starts counting. When TCNT underflows, the UNF flag of corresponding TCR is set. In this case, if the UNIE bit in TCR is set to 1, an interrupt request is sent to the CPU. Also, the value is copied from TCOR to TCNT and the down-count operation is continued (Auto reload function).

(1) Procedure for setting count operation

Figure 69.3 shows an example of the procedure for setting the count operation.

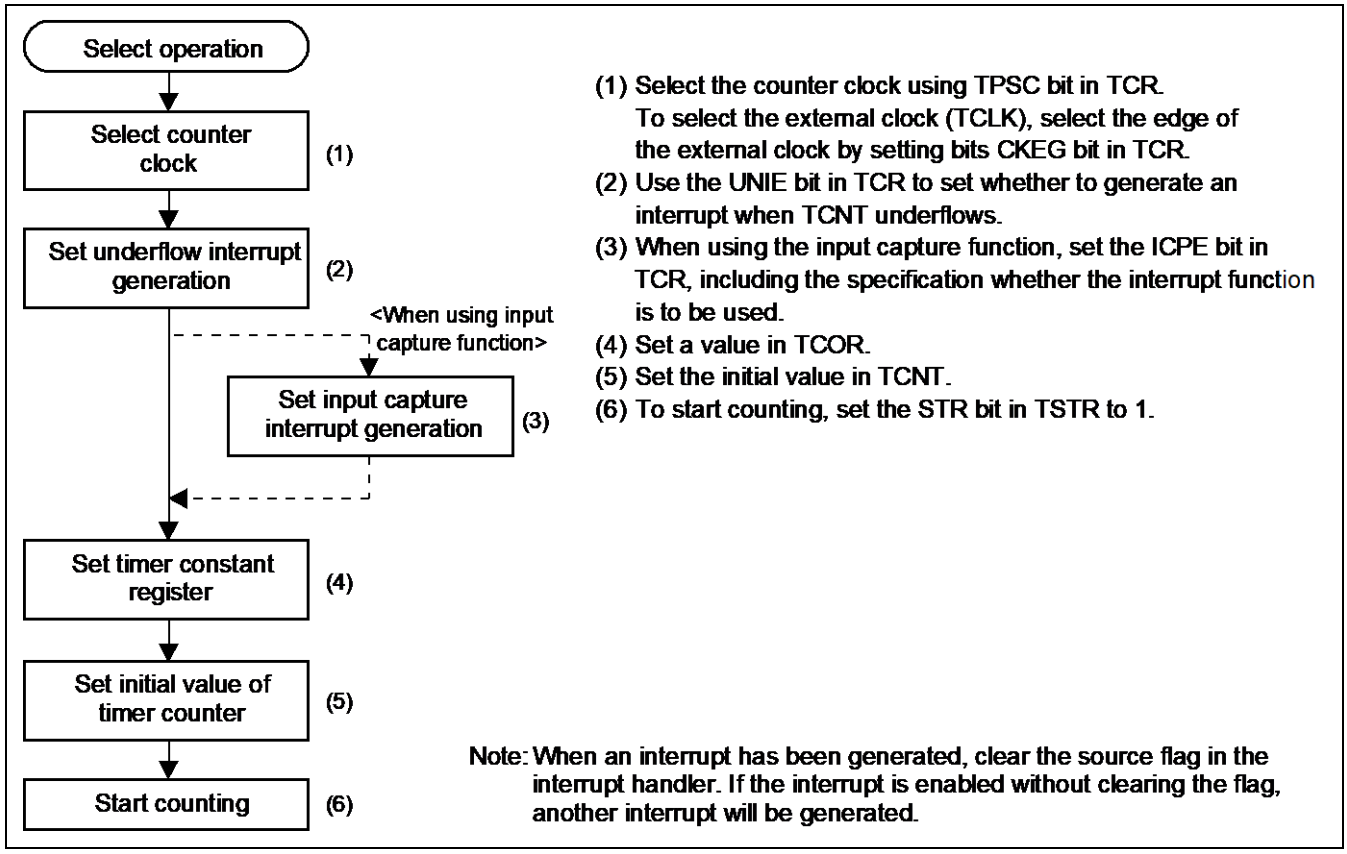

Figure 69.3 Procedure for Setting Count Operation

(2) Auto-reload count operation

Figure 69.4 shows the TCNT auto-reload operation.

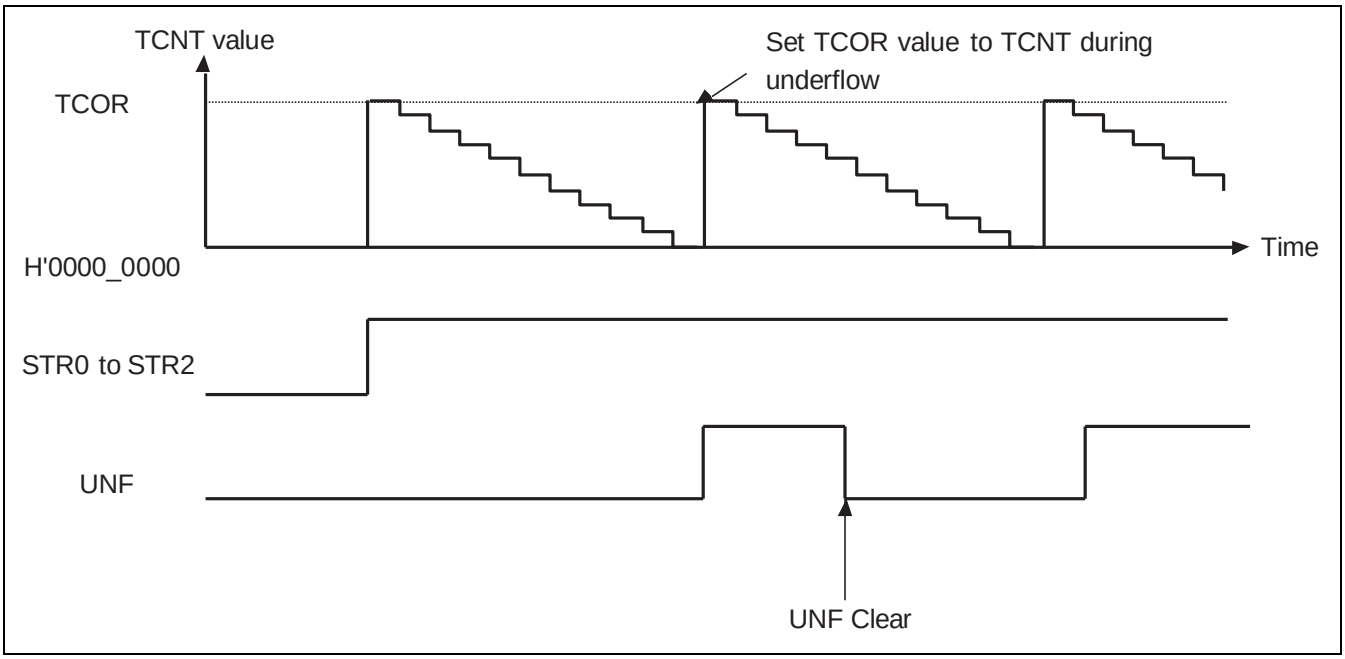

Figure 69.4 TCNT Auto-Reload Operation

- Internal clock operation

  [RZ/G2H]:

  Five clocks (S3D2ϕ/4, S3D2ϕ/16, S3D2ϕ/64, S3D2ϕ/256, S3D2ϕ/1024) and five clocks (CPϕ/4, CPϕ/16, CPϕ/64, CPϕ/256, CPϕ/1024) and five clocks (S0D6ϕ/4, S0D6ϕ/16, S0D6ϕ/64, S0D6ϕ/256, S0D6ϕ/1024) that are created by dividing peripheral clocks are selected as count clocks by setting bits TPSC2 to TPSC0 in TCR.

  [RZ/G2M V1.3, RZ/G2M V3.0]:

  Five clocks (S3D2ϕ/4, S3D2ϕ/16, S3D2ϕ/64, S3D2ϕ/256, S3D2ϕ/1024) and five clocks (CPϕ/4, CPϕ/16, CPϕ/64, CPϕ/256, CPϕ/1024) and five clocks (S0D6ϕ/4, S0D6ϕ/16, S0D6ϕ/64, S0D6ϕ/256, S0D6ϕ/1024) that are created by dividing peripheral clocks are selected as count clocks by setting bits TPSC2 to TPSC0 in TCR.

  [RZ/G2N]:

  Five clocks (S3D2ϕ/4, S3D2ϕ/16, S3D2ϕ/64, S3D2ϕ/256, S3D2ϕ/1024) and five clocks (CPϕ/4, CPϕ/16, CPϕ/64, CPϕ/256, CPϕ/1024) and five clocks (S0D6ϕ/4, S0D6ϕ/16, S0D6ϕ/64, S0D6ϕ/256, S0D6ϕ/1024) that are created by dividing peripheral clocks are selected as count clocks by setting bits TPSC2 to TPSC0 in TCR.

  [RZ/G2E]:

  Five clocks (S3D2Cϕ/4, S3D2Cϕ/16, S3D2Cϕ/64, S3D2Cϕ/256, S3D2Cϕ/1024) and five clocks (CPϕ/4, CPϕ/16, CPϕ/64, CPϕ/256, CPϕ/1024) and five clocks (S0D6Cϕ/4, S0D6Cϕ/16, S0D6Cϕ/64, S0D6Cϕ/256, S0D6Cϕ/1024) that are created by dividing peripheral clocks are selected as count clocks by setting bits TPSC2 to TPSC0 in TCR.

  Figure 69.6, 69.7, 69.8 and 69.9 show the timing.

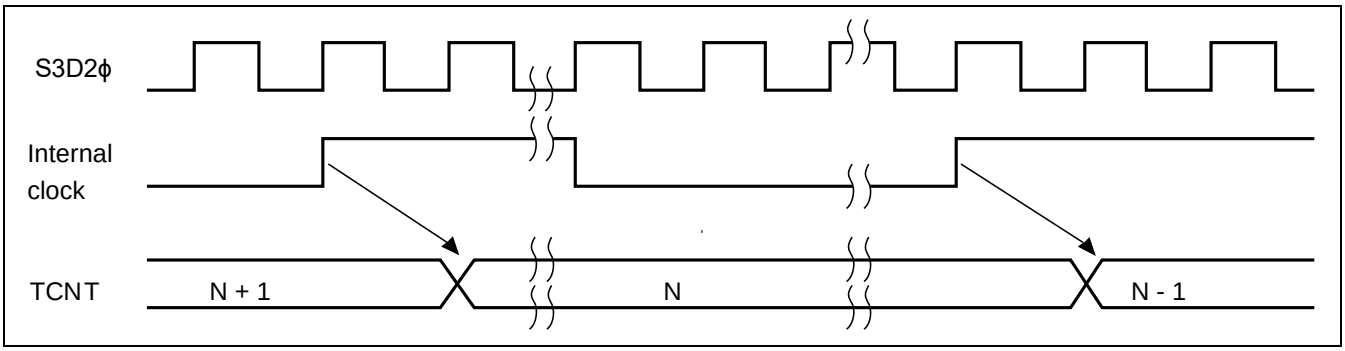

Figure 69.6 Count Timing when Internal Clock is Operating for , RZ/G2H

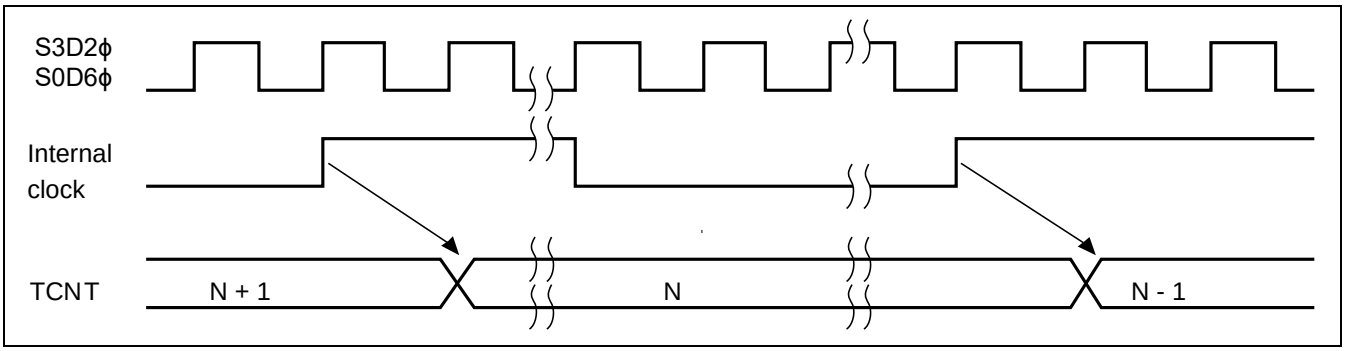

Figure 69.7 Count Timing when Internal Clock is Operating for RZ/G2M V1.3, RZ/G2M V3.0

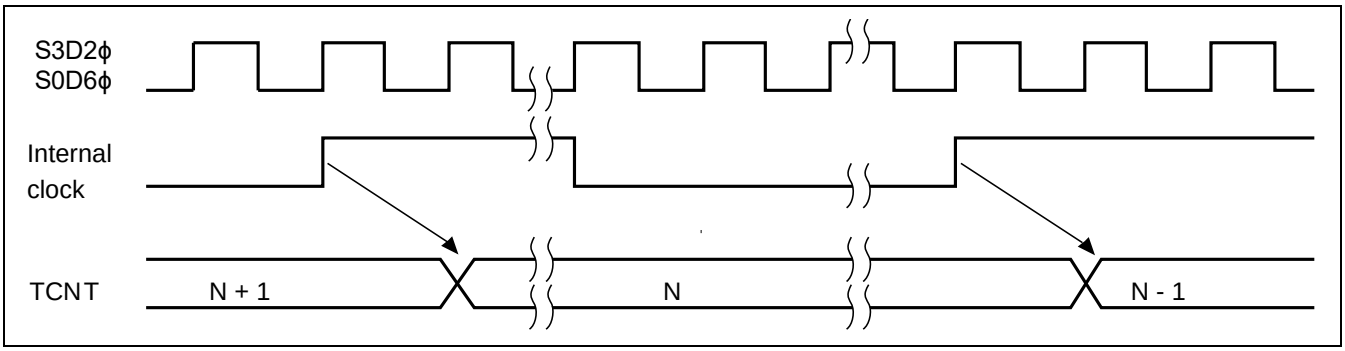

Figure 69.8 Count Timing when Internal Clock is Operating for RZ/G2N

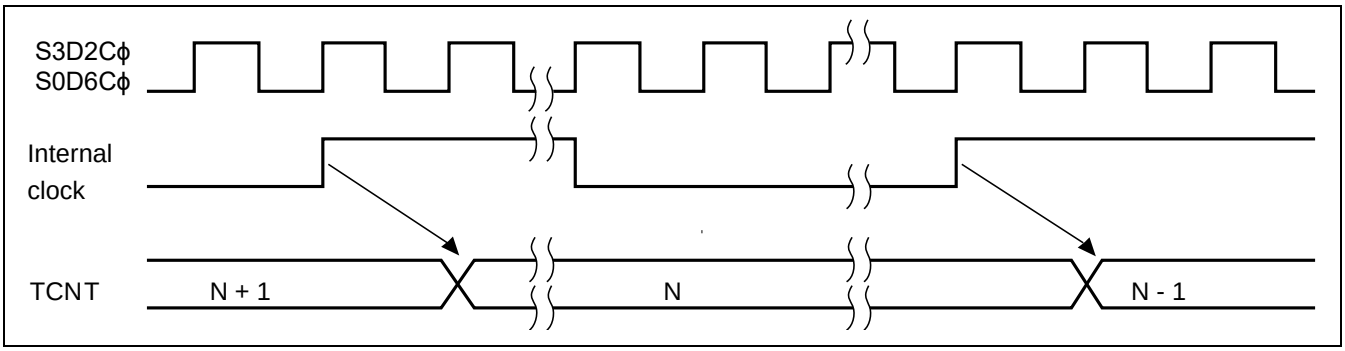

Figure 69.9 Count Timing when Internal Clock is Operating for RZ/G2E

- External clock operation

  Set the bits TPSC2 to TPSC0 in TCR to select the external clock pin (TCLK) as the timer clock. Use the bits CKEG1 and CKEG0 in TCR to select the detection edge. Rise, fall, or both can be selected.

  Figure 69.10, 69.11, 69.12 and 69.13 show the timing for both-edge detection.

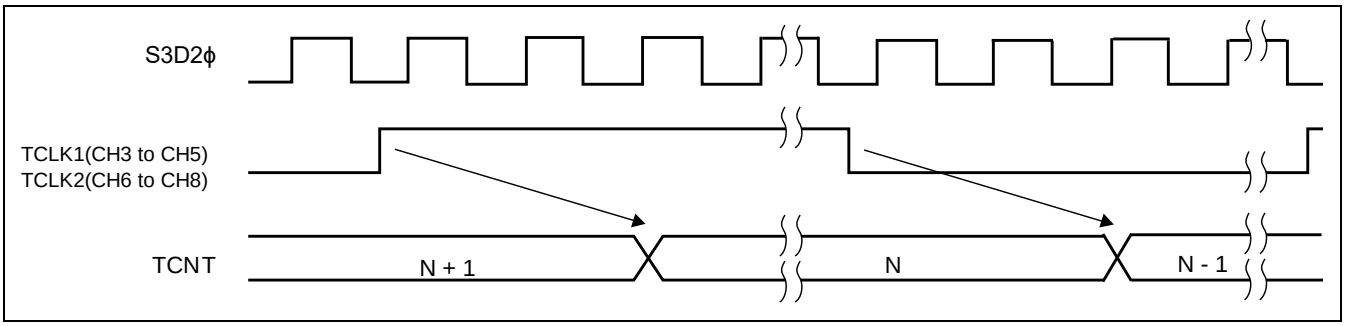

Figure 69.10 Count Timing when External Clock is Operating for , RZ/G2H

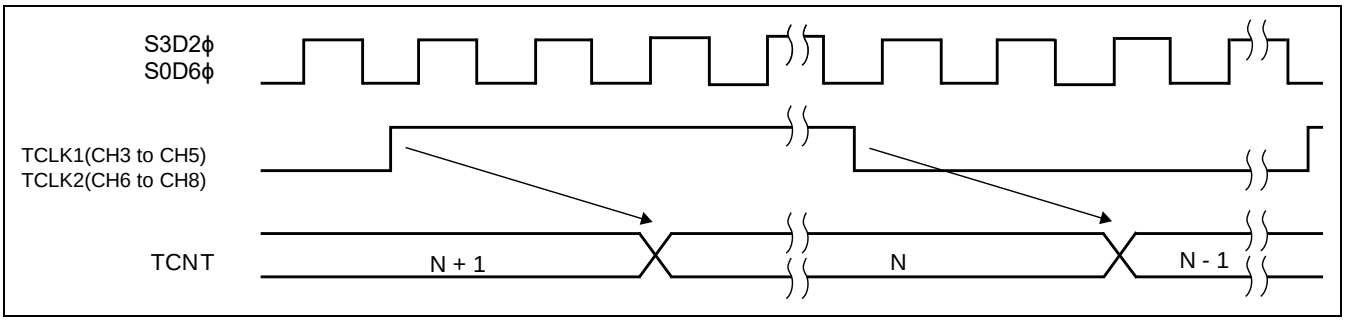

Figure 69.11 Count Timing when External Clock is Operating for RZ/G2M V1.3, RZ/G2M V3.0

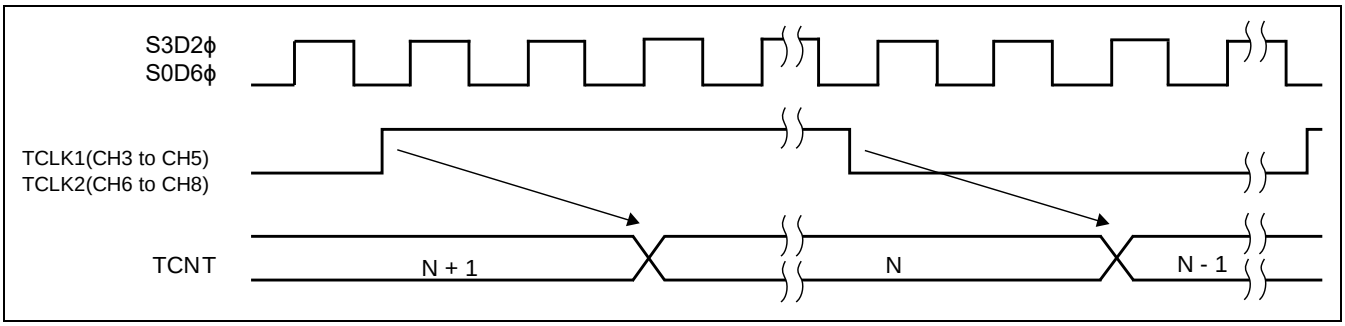

Figure 69.12 Count Timing when External Clock is Operating for RZ/G2N

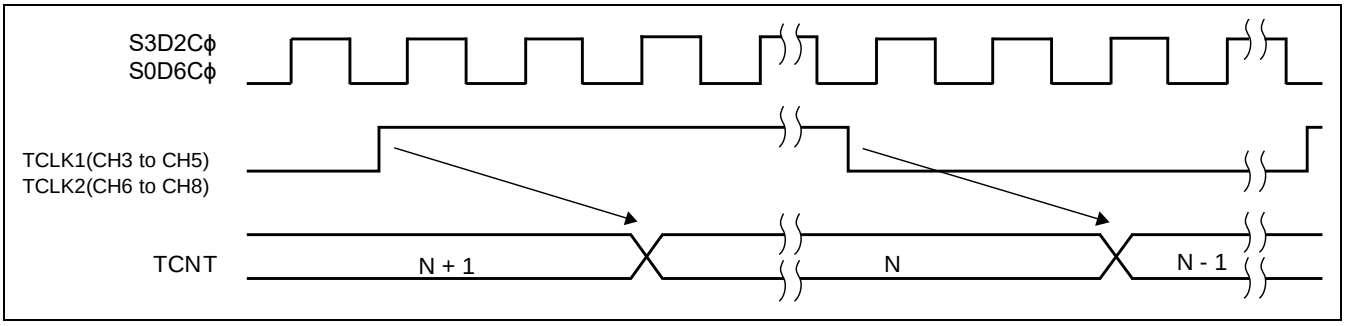

Figure 69.13 Count Timing when External Clock is Operating for RZ/G2E

69.3.2 Input Capture Function

Channels 5 and 8 have the input capture function.

1. Set the timer operating clock as an internal clock with bits TPSC2 to TPSC0 in TCR.
2. Set use of the input capture function and whether to generate an interrupt on using it with bits ICPE1 and ICPE0 in TCR.
3. Specify either rising edge or falling edge of the TCLK1 (channel 5), TCLK2 (channel 8) pin to be used to set the value of TCNT to TCPR5, TCPR8 with bits CKEG1 and CKEG0 in TCR.

Only when an input capture is occurred and the ICPF bits in TCR5, TCR8 are 0, the values of TCNT5, TCNT8 are set in TCPR5, TCPR8 respectively.

Figure 69.14 shows the operating timing when the input capture function is used (the rising edge of TCLK1/2 is used).

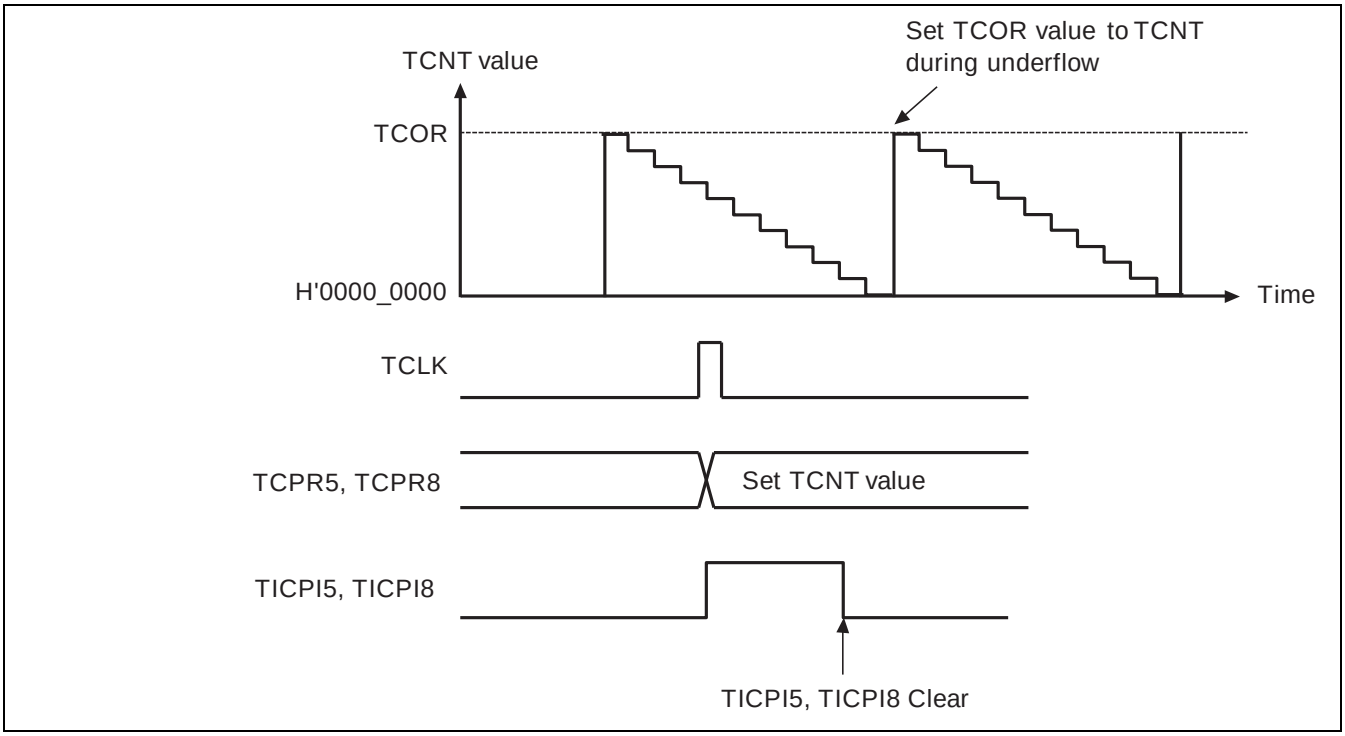

Figure 69.14 Operating Timing when Using Input Capture Function

69.3.3 Interrupt

The TMU interrupt sources are underflow interrupt or input capture interrupt when the input capture function is used. The underflow interrupt is generated at each channel. The input capture interrupt is generated at channels 5, 8 only.

An underflow interrupt request is generated (for each channel) when both the UNF bit and the interrupt enable bit for that channel are set to 1.

When the input capture function is used and the input capture request is generated, an interrupt request is generated if the ICPF bit in TCR5 or TCR8 is 1 and the input capture control bits ICPE1 and ICPE0 in TCR5 or TCR8 are 11.

Table 69.4 shows the TMU interrupt sources.

Table 69.4 TMU Interrupt Sources

69.4 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

69.4.1 Writing to Registers

When writing to the TMU registers, clear the start bits (STR14 to STR0) of the corresponding TSTR channel to stop the timer counting.

Writing to TSTR and clearing bits UNF and ICPF in TCR can be executed during counting. To clear flags UNF and ICPF during counting, do not change the values of bits other than those to be cleared.

69.4.2 Reading TCNT Register

Reading from TCNT is performed synchronously with the timer count operation. When timer counting and register read processing are performed simultaneously, the value before TCNT counting down is read.

69.4.3 External Clock Frequency

The frequency of external clock (TCLK1/2) for each channel should be S3D2ϕ/4 or less in the RZ/G2H.

The frequency of external clock (TCLK1/2) for each channel should be S3D2ϕ/4 or less in the RZ/G2M V1.3, RZ/G2M V3.0.

The frequency of external clock (TCLK1/2) for each channel should be S3D2ϕ/4 or less in the RZ/G2N.

The frequency of external clock (TCLK1/2) for each channel should be S3D2Cϕ/4 or less in the RZ/G2E.

70. System Timer (SCMT)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

70.1 Overview

System Timer is a 32-bit compare match timer of one channel.

70.1.1 Features

- One channel is implemented.
- 16 bits/32 bits can be selected.
- Provided with 32-bit constant registers and 32-bit up-counters that can be written or read at any time.
- Allows selection among four counter input clocks
  — OSCCLK: 1/1, 1/8, 1/32, and 1/128
- One-shot operation or free-running operation is selectable.
- Compare match or overflow can be selected as interrupt source.
- Counter operation can be enabled or disabled at the time of debugging of CPU core using the debugging mode operation selector.

70.1.2 Block Diagram

Figure 70.1 shows a block diagram of the System Timer.

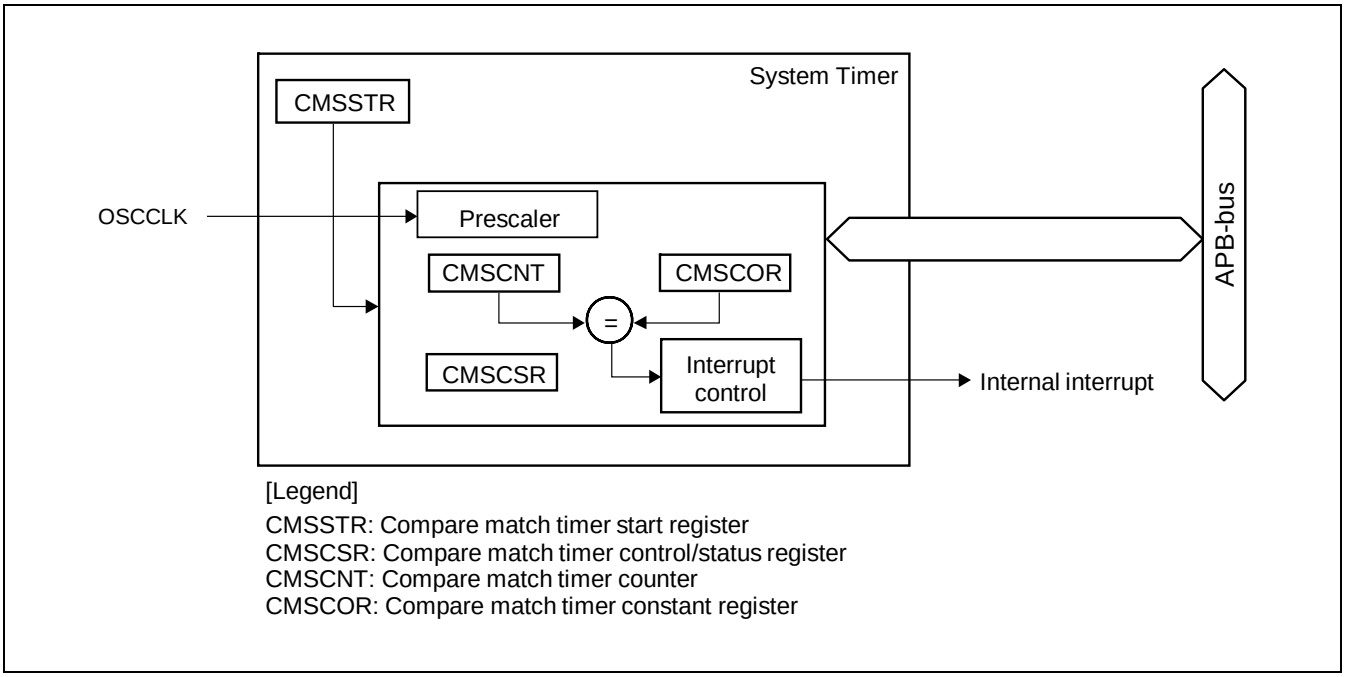

Figure 70.1 Block Diagram of System Timer

70.1.3 Register Configuration

Table 70.1 shows the System Timer register configuration. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined. Access CMSSTR and CMSCSR as a word (16 bits). Operation cannot be guaranteed if CMSSTR and CMSCSR are not accessed as a word. Access CMSCNT and CMSCOR as a longword (32 bits). Operation cannot be guaranteed if CMSCNT and CMSCOR are not accessed as a longword.

70.2 Register Description

[Legend for Register Description]

Initial value: Register value after a reset.

—: Undefined value

R/W: Bit or field is readable and writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R: Read-only. The write value should always be initial value.

70.2.1 Compare Match Timer Start Register (CMSSTR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMSSTR is a 16-bit register which specify whether the compare match timer counter (CMSCNT) is operated or halted.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	STR5	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	STR5	B’0	R/W	Count Start Specify halt/counting of compare match timer counter (CMSCNT). 0: CMSCNT Halts. 1: CMSCNT starts counting.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

70.2.2 Compare Match Timer Control/Status Register (CMSCSR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMSCSR is a 16-bit register that indicates the occurrence of compare matches, enables interrupts, and sets the counter input clocks.

Do not change bits other than the CMF and OVF bits, while the compare match timer counter (CMSCNT) is under operating.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMF	OVF	WRFLG	—	—	—	CMS	CMM	—	—	CMR[1:0]		DBGIVD	CKS[2:0]		
Initial value:	0	0	0	0	0	0	0	1	0	0	1	0	1	1	1	1
R/W:	R/WC0	R/WC0	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	CMF	B’0	R/WC0	Compare Match Flag This flag indicates whether the values of the compare match timer counter (CMSCNT) and the compare match timer constant register (CMSCOR) have matched or not. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CMSCNT and CMSCOR values have not matched. [Clearing condition] • Write 0 to CMF 1: CMSCNT and CMSCOR values have matched. * Only 0 can be written, for flag clearing.
14	OVF	B’0	R/WC0	Overflow Flag This flag indicates whether the compare match timer counter (CMSCNT) has overflowed or not. Software cannot write 1 to this bit. 0: CMSCNT has not overflowed. [Clearing condition] • Write 0 to OVF 1: CMSCNT has overflowed. * Only 0 can be written, for flag clearing.
13	WRFLG	B’0	R	Write State Flag When this bit is 1, write access to CMSCNT is prohibited. If it isn't maintained, operation isn't secured. This bit indicates the period that the writing to CMSCNT is masked for synchronization after the writing to CMSCNT. Confirm that this flag is 0 when CMSCNT is written to continuously.
12 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	CMS	B’0	R/W	Compare Match Timer Counter Size This bit selects whether the compare match timer counter (CMSCNT) is used as a 16-bit counter or 32-bit counter. This register setting becomes the valid bit-size for the compare match timer constant register (CMSCOR). 0: Operates as a 32-bit counter. 1: Operates as a 16-bit counter. Note: When Write or Read in this bit, refer to 70.3.5 Register Access.
8	CMM	B’1	R/W	Compare Match Mode Specify operation mode of the counter. 0: One-shot operation 1: Free-running operation Note: When Write or Read in this bit, refer to 70.3.5 Register Access.
7,6	—	B’00	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	CMR[1:0]	B’10	R/W	Compare Match Request These bits enable or disable an internal interrupt request at a compare match. B’00: Disables an internal interrupt request. B’01: Setting prohibited B’10: Enables an internal interrupt request. B’11: Setting prohibited
3	DBGIVD	B’1	R/W	Debug Mode Operation Select This bit sets counter operation when in debug mode. 0: Stops counter operation when in debug mode. 1: Enables counter operation even when in debug mode. Note: When Write or Read in this bit, refer to 70.3.5 Register Access.
2 to 0	CKS[2:0]	B’111	R/W	Clock Select These bits select the clock input to CMSCNT. When the count start bit (STR5) in CMSSTR is set to 1, CMSCNT begins incrementing with the clock selected by these bits. B’000: Setting prohibited B’001: Setting prohibited B’010: Setting prohibited B’011: Setting prohibited B’100: clock/8 B’101: clock/32 B’110: clock/128 B’111: clock/1 Note: When Write or Read in this bit, refer to 70.3.5 Register Access.

70.2.3 Compare Match Timer Counter (CMSCNT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMSCNT is a 32-bit register which is used as an up-counter.

To specify counter operation, set compare match timer control/status register (CMSCSR), before starting operation.

When the 16-bit counter operation is selected by the CMS bit, bits 31 to 16 of this register is invalid. When data is written in 16-bit mode, write H'0000 as upper 16-bits data.

When CMSCNT is read during the counter operation, the read value may be wrong because of an asynchronous clock between counter and bus-interface. For exact value, read this register continuously, until same values are read from this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CMSCNT[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMSCNT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMSCNT [31:0]	H'0000_0000	R/W	Compare match timer counter bit 31 to 0 Note: When Write or Read in this bit, refer to 70.3.5 Register Access.

70.2.4 Compare Match Timer Constant Register (CMSCOR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMSCOR is a 32-bit register which specify the compare match period with the compare match timer counter (CMSCNT).

The initial value of this register is H'0144_3FCF.

When the 16-bit counter operation is selected by the CMS bit in the compare match timer control/status register (CMSCSR), bits 15 to 0 of this register become valid. When data is written to this register in 16-bit mode, write H'0000 as upper 16-bits data.

An overflow is detected when CMSCNT is cleared to 0 and this register is set to H'FFFF_FFFF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CMSCOR[31:16]															
Initial value:	0	0	0	0	0	0	0	1	0	1	0	0	0	1	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMSCOR[15:0]															
Initial value:	0	0	1	1	1	1	1	1	1	1	0	0	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMSCOR [31:0]	H'0144_3FCF	R/W	Compare match timer constant register bit31 to 0 Note: When Write or Read in this bit, refer to 70.3.5 Register Access.

70.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

70.3.1 Counter Operation

System Timer starts the operation of the counter by writing 1 to the STR5 bit in CMSSTR after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than by clearing flag bits during the compare match timer (CMSCNT) operation.

The counter operates in one of two ways.

- One-Shot Operation

  One-shot operation is selected by setting the CMM bit in CMSCSR to 0. When the value in CMSCNT matches the value in CMSCOR, the value in CMSCNT is cleared to H'0000_0000, and the CMF bit in CMSCSR is set to 1. Counting by CMSCNT stops after it has been cleared.

  To detect an overflow interrupt, set the value in CMSCOR to H'FFFF_FFFF. When the value in CMSCNT matches the value in CMSCOR, CMSCNT is cleared to H'0000_0000 and the CMF and OVF bits in CMSCSR are set to 1

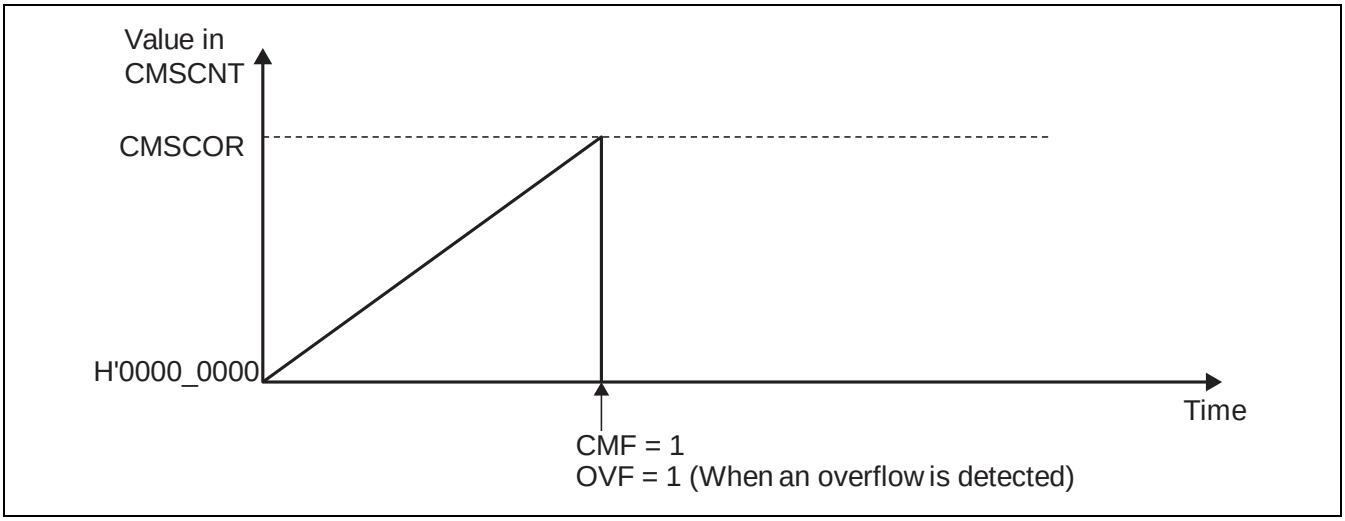

Figure 70.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

  Free-running operation is selected by setting the CMM bit in CMSCSR to 1. When the value in CMSCNT matches the value in CMSCOR, CMSCNT is cleared to H'0000_0000 and the CMF bit in CMSCSR is set to 1. CMSCNT resumes counting-up after it has been cleared.

  To detect an overflow interrupt, set CMSCOR to H'FFFF_FFFF. When the values in CMSCNT and CMSCOR match, CMSCNT is cleared to H'0000_0000 and the CMF and OVF bits in CMSCSR are set to 1.

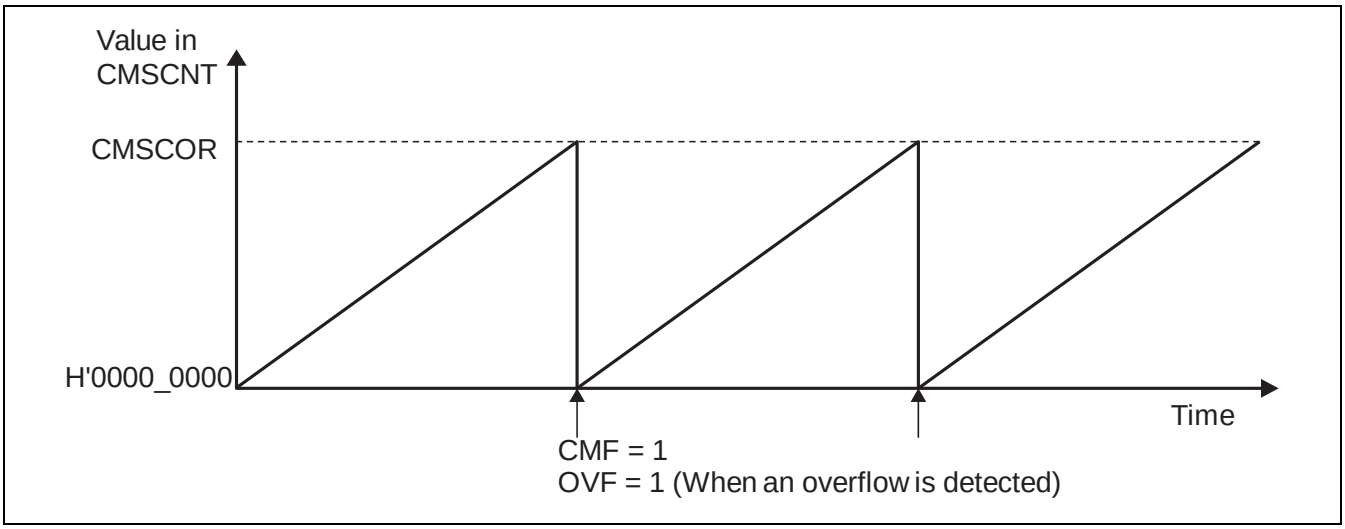

Figure 70.3 Counter Operation (Free-Running Operation)

70.3.2 Counter Size

In this module, the size of the counter can be selected from 16 or 32 bits. This is selected by the CMS bit in CMSCSR.

When the 16-bit size is selected, use H'0000 for upper 16-bit of write data for CMSCOR. To detect an overflow interrupt, CMSCOR must be set to H'0000_FFFF.

70.3.3 Timing for Counting by CMSCNT

In this module, the clock for the CMSCNT counter can be selected from following clocks:

- OSCCLK: 1/1, 1/8, 1/32, and 1/128

The clock for the counter is selected by the CKS bits in CMSCSR. CMSCNT is incremented at the rising edge of the selected clock.

70.3.4 Internal Interrupt Request to CPU

The setting of the CMR bits in CMSCSR selects the sending of an internal interrupt request to the CPU at a compare match.

To clear an internal interrupt request to the CPU in Free-Running Operation, the CMF bit should be set to b'0. Set the CMF bit to b'0 in the handling routine for the System Timer interrupt.

To clear an internal interrupt request to the CPU with resuming count-up in One-Shot Operation, the CMF bit should be set to b'0 while keeping b'1 in STR5 bit in CMSSTR. Set the CMF bit to b'0 while keeping b'1 in STR5 bit in the handling routine for the System Timer interrupt.

To clear an internal interrupt request to the CPU without resuming count-up in One-Shot Operation, the CMF bit should be set to b'0 after setting STR5 bit in CMSSTR to b'0. Set the CMF bit to b'0 after setting STR5 bit to b'0 in the handling routine for the System Timer interrupt.

70.3.5 Register Access

After writing to following registers, written data can be read 2 cycles in counter input clock (OSCCLK) after writing has finished. And it takes 2 cycles in counter input clock (OSCCLK), for reflecting written data to counter behavior.

CMSCSR: Bits CKS, CMM, CMS, CMR, DBGIVD

CMSCOR: Bits 31 to 0

CMSSTR: Bit STR5

After writing to following registers, written data can be read 2 cycles in counter input clock (OSCCLK) after writing has finished. And it takes 2 cycles in counter input clock (OSCCLK), for reflecting written data to counter behavior.

And for following registers, write access is prohibited, while previously written data is under writing. Do not perform next write access, while CMSCSR.WRFLG is 1.

CMSCNT: Bits 31 to 0

70.3.6 Compare Match Flag Set/Clear Timing

The CMF bit in CMSCSR is set to 1 by the compare match signal generated when CMSCOR and CMSCNT match. The compare match signal is generated upon the final state of the match (timing at which the CMSCNT value is updated to H'0000_0000). Consequently, after CMSCOR and CMSCNT match, a compare match signal will not be generated until a CMSCNT counter clock is input. Figure 70.4 shows the set timing of the CMF bit.

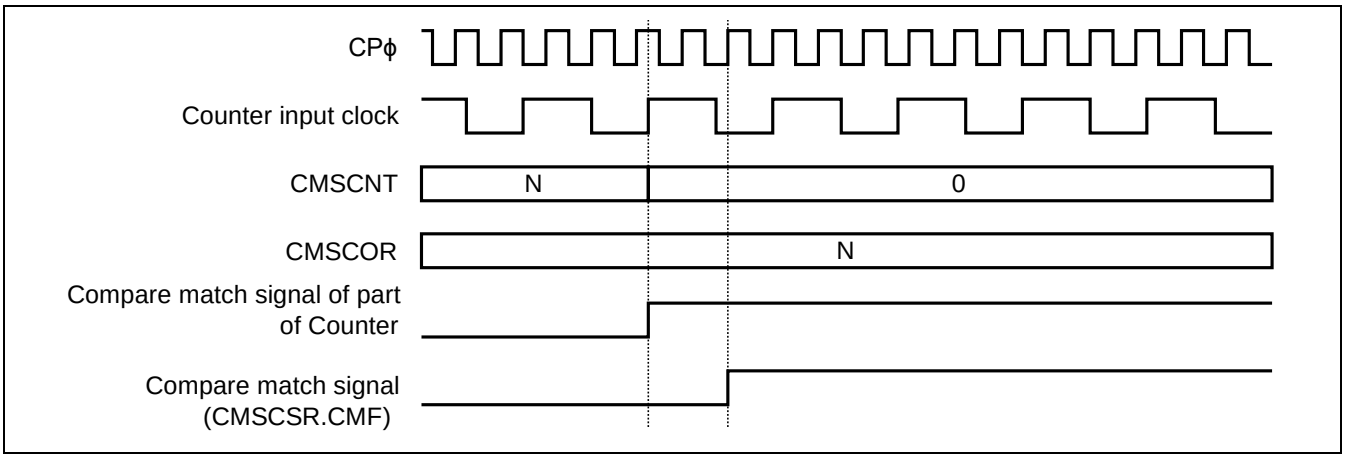

Figure 70.4 CMF Set Timing

Set the CMF bit as 0. The CMF flag is cleared immediately.

70.3.7 System Timer Usage

Take the following steps to use the System Timer.

1. Clear the STR5 bit in CMSSTR to 0 to temporarily stop counting.
   (Confirm that OSCCLK was input more than 2 cycles.)
2. Write H'0000_0000 on CMSCNT.
3. Set counter size, compare match mode, kind of count clock and interrupt request and clear the bit of OVF and CMF in CMSCSR.
4. Set the value on CMSCOR.
5. Confirm that CMSCSR.WRFLG becomes 0.
   If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the STR5 bit in CMSSTR to 1.
   (Refer to 70.3.5 Register Access)

71. System Up-Time Clock (SUCMT)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

71.1 Overview

System Up-Time Clock is an internal 32-bit compare match timer of one channel.

71.1.1 Features

- One channel is installed.
- 16 bits/32 bits can be selected as counter size (bit-width).
- Provided with 32-bit constant registers and 32-bit up-counters that can be written or read at any time.
- Following four clocks can be selected as counter clocks.
  — RCLK: 1/1, 1/8, 1/32, and 1/128
- One-shot operation or free-running operation is selectable.
- Compare match or overflow can be selected as interrupt source.
- Module standby mode can be set.
- Counter operation can be enabled or disabled at the time of debugging of CPU core using the debugging mode operation selector.

71.1.2 Block Diagram

Figure 71.1 shows a block diagram of the System Up-Time Clock.

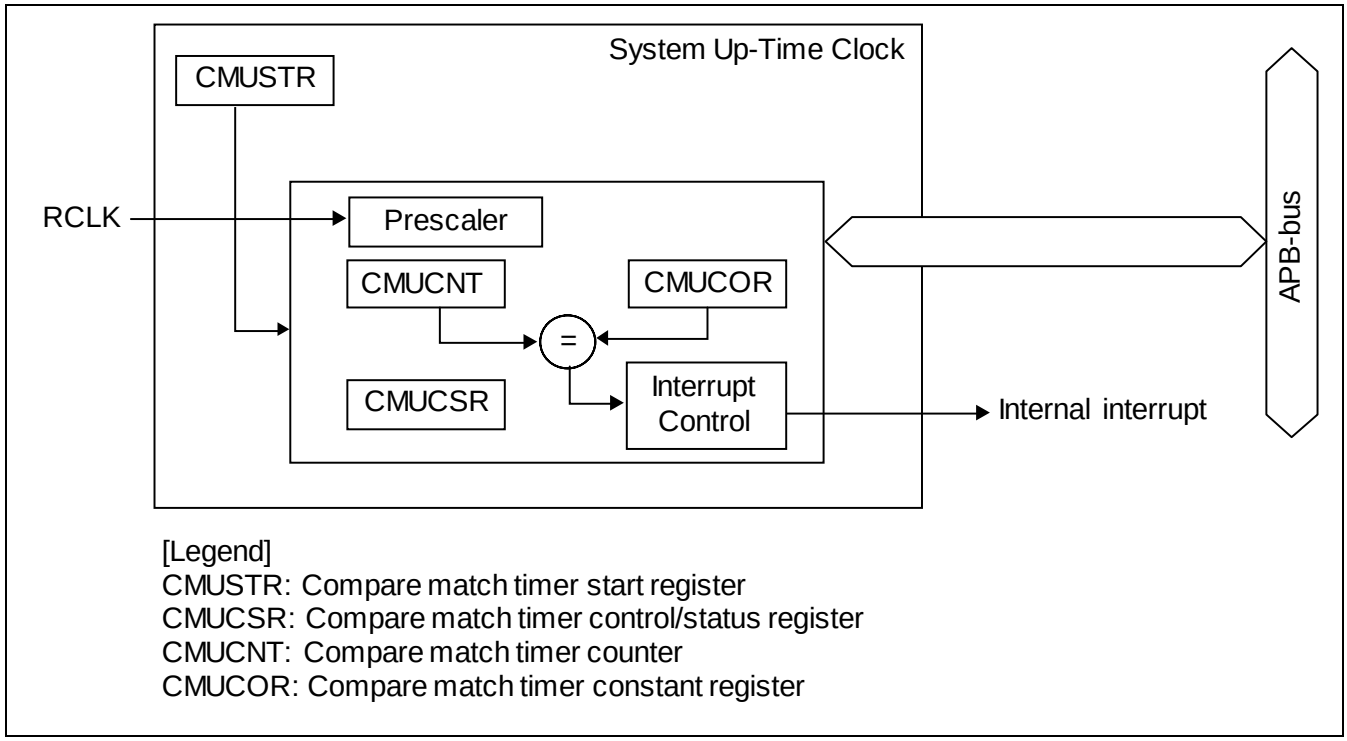

Figure 71.1 Block Diagram of System Up-Time Clock

71.1.3 Register Configuration

Table 71.1 shows the System Up-Time Clock register configuration. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined. Access CMUSTR and CMUCSR as a word (16 bits). Operation cannot be guaranteed if CMUSTR and CMUCSR are not accessed as a word. Access CMUCNT and CMUCOR as a longword (32 bits). Operation cannot be guaranteed if CMUCNT and CMUCOR are not accessed as a longword.

Bit	Bit Name	Initial Value	R/W	Description
15	CMF	B’0	R/WC0	Compare Match Flag This flag indicates whether the values of the compare match timer counter (CMUCNT) and the compare match timer constant register (CMUCOR) have matched or not. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CMUCNT and CMUCOR values have not matched. [Clearing condition] • Write 0 to CMF 1: CMUCNT and CMUCOR values have matched.
14	OVF	B’0	R/WC0	Overflow Flag This flag indicates whether the compare match timer counter (CMUCNT) has overflowed or not. Software cannot write 1 to this bit. 0: CMUCNT has not overflowed. [Clearing condition] • Write 0 to OVF 1: CMUCNT has overflowed.
13	WRFLG	B’0	R	Write State Flag When this bit is 1, write access to CMUCNT is prohibited. If it isn't maintained, operation isn't secured. This bit indicates the period that the writing to CMUCNT is masked for synchronization after the writing to CMUCNT. Confirm that this flag is 0 when CMUCNT is written to continuously.
12	WERR	B’0	R	Write Access Error Flag This flag indicates whether or not the write access from the public domain. Software cannot write 1 to this bit. 0: Public domain has not Write access [Clearing condition] • Read register 1: Public domain has Write access
11 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	CMS	B’0	R/W	Compare Match Timer Counter Size This bit selects whether the compare match timer counter (CMUCNT) is used as a 16-bit counter or 32-bit counter. This register setting becomes the valid bit-size for the compare match timer constant register (CMUCOR). 0: Operates as a 32-bit counter. 1: Operates as a 16-bit counter. Note: When Write or Read in this bit, refer to 71.3.5 Register Access.
8	CMM	B’1	R/W	Compare Match Mode This bit selects one-shot operation or free-running operation of the counter. 0: One-shot operation 1: Free-running operation Note: When Write or Read in this bit, refer to 71.3.5 Register Access.
7	—	B’0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	WER	B’0	R/W	Write Access Error Request This bit Write Access Error interrupt request at the public domain. 0: Disables an internal interrupt request. 1: Enables an internal interrupt request. Note: When Write or Read in this bit, refer to 71.3.5 Register Access.
5, 4	CMR[1:0]	B’00	R/W	Compare Match Request These bits enable or disable an internal interrupt request at a compare match. B’00: Disables an internal interrupt request. B’01: Setting prohibited B’10: Enables an internal interrupt request. B’11: Setting prohibited Note1: When various standby modes are canceled by the System Up-Time Clock, these bits should be set to B'10. Note2: When Write or Read in this bit, refer to 71.3.5 Register Access.
3	DBGIVD	B’1	R/W	Debug Mode Operation Select This bit sets counter operation when in debug mode. 0: Stops counter operation when in debug mode. 1: Enables counter operation even when in debug mode. Note: When Write or Read in this bit, refer to 71.3.5 Register Access.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	CKS[2:0]	B’111	R/W	Clock Select These bits select the clock input to CMUCNT. When the count start bit (STR5) in CMUSTR is set to 1, CMUCNT begins incrementing with the clock selected by these bits. B’000: Setting prohibited B’001: Setting prohibited B’010: Setting prohibited B’011: Setting prohibited B’100: RCLK/8 B’101: RCLK/32 B’110: RCLK/128 B’111: RCLK/1 Note: When Write or Read in this bit, refer to 71.3.5 Register Access.

Note: * Only 0 can be written, for flag clearing.

71.2.3 Compare Match Timer Counter (CMUCNT)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMUCNT is a 32-bit register which is used as an up-counter.

To specify counter operation, set compare match timer control/status register n (CMUCSR), before starting operation of corresponding channel.

When the 16-bit counter operation is selected by the CMS bit, bits 31 to 16 of this register become invalid. When data is written to this register in 16-bit mode, write H'0000 as upper 16bits

When CMUCNT is read during counter operation, the read value may be wrong because different clock is used between counter and bus-interface. For exact value, read this register continuously, until same values are read from this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CMUCNT[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMUCNT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMUCNT [31:0]	H'0000_0000	R/W	Compare match timer counter bit31 to 0 Note: When Write or Read in this bit, refer to 71.3.5 Register Access.

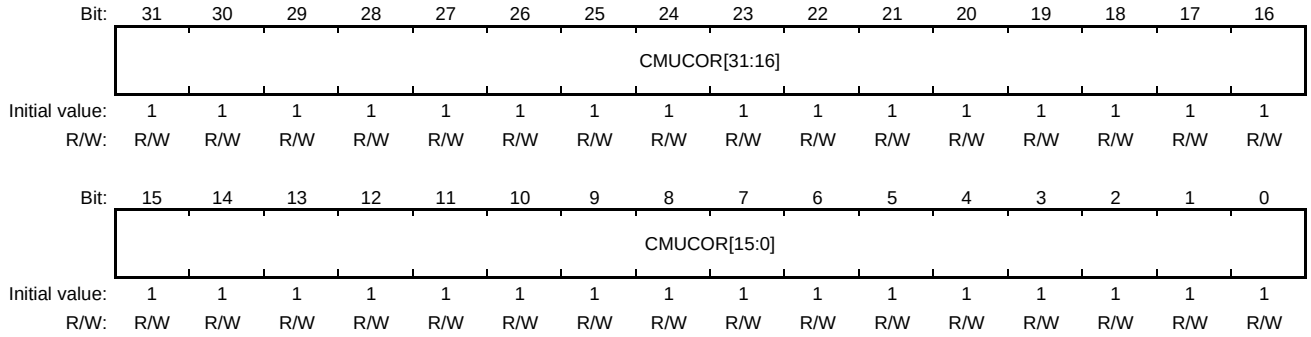
71.2.4 Compare Match Timer Constant Register (CMUCOR)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

CMUCOR is a 32-bit register which specify the compare match period with the compare match timer counter (CMUCNT).

When the 16-bit counter operation is selected by the CMS bit in the compare match timer control/status register (CMUCSR), bits 15 to 0 of this register become valid. Write H'0000 to upper 16bits in 16-bit counter operation.

An overflow is detected when CMUCNT is cleared to 0 and this register is set to H'FFFF_FFFF.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMUCOR [31:0]	H'FFFF_FFFF	R/W	Compare match timer counter bit31 to 0 Note: When Write or Read in this bit, refer to 71.3.5 Register Access.

71.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

71.3.1 Counter Operation

System Up-Time Clock starts the operation of the counter by writing 1 to the STR5 bit in CMUSTR after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than by clearing flag bits during the compare match timer (CMUCNT) operation.

The counter operates in one of two ways.

- One-Shot Operation

  One-shot operation is selected by setting the CMM bit in CMUCSR to H'0. When the value in CMUCNT matches the value in CMUCOR, the value in CMUCNT is cleared to H'0000_0000, and the CMF bit in CMUCSR is set to 1. Counting by CMUCNT stops after it has been cleared.

  To detect an overflow interrupt, set the value in CMUCOR to H'FFFF_FFFF. When the value in CMUCNT matches the value in CMUCOR, CMUCNT is cleared to H'0000_0000 and the CMF and OVF bits in CMUCSR are set to 1

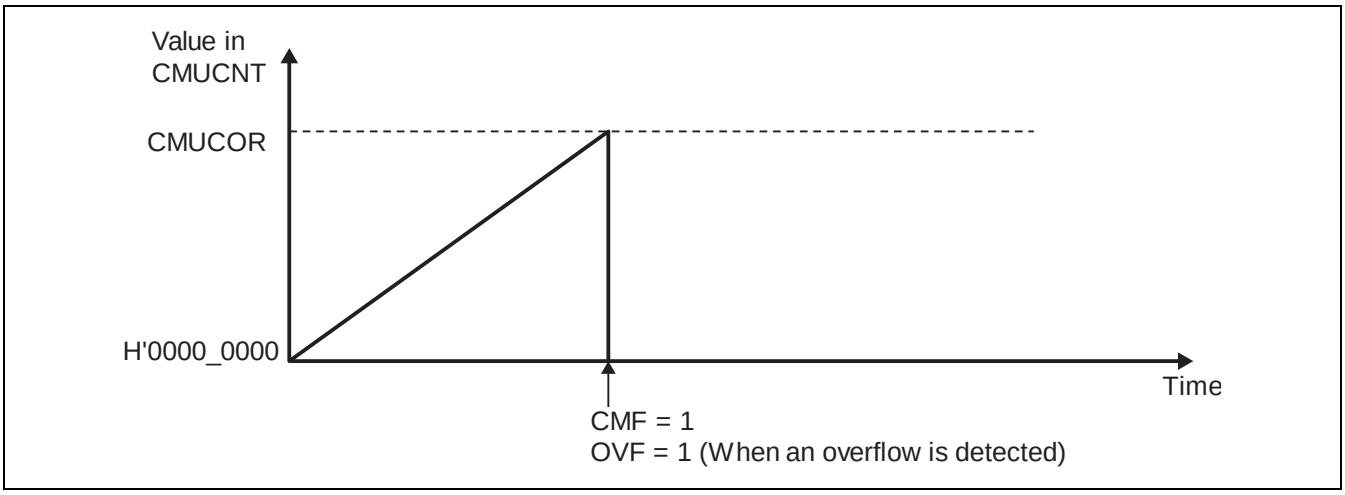


Figure 71.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

  Free-running operation is selected by setting the CMM bit in CMUCSR to 1. When the value in CMUCNT matches the value in CMUCOR, CMUCNT is cleared to H'0000_0000 and the CMF bit in CMUCSR is set to 1. CMUCNT resumes counting-up after it has been cleared.

  To detect an overflow interrupt, set CMUCOR to H'FFFF_FFFF. When the values in CMUCNT and CMUCOR match, CMUCNT is cleared to H'0000_0000 and the CMF and OVF bits in CMUCSR are set to 1.

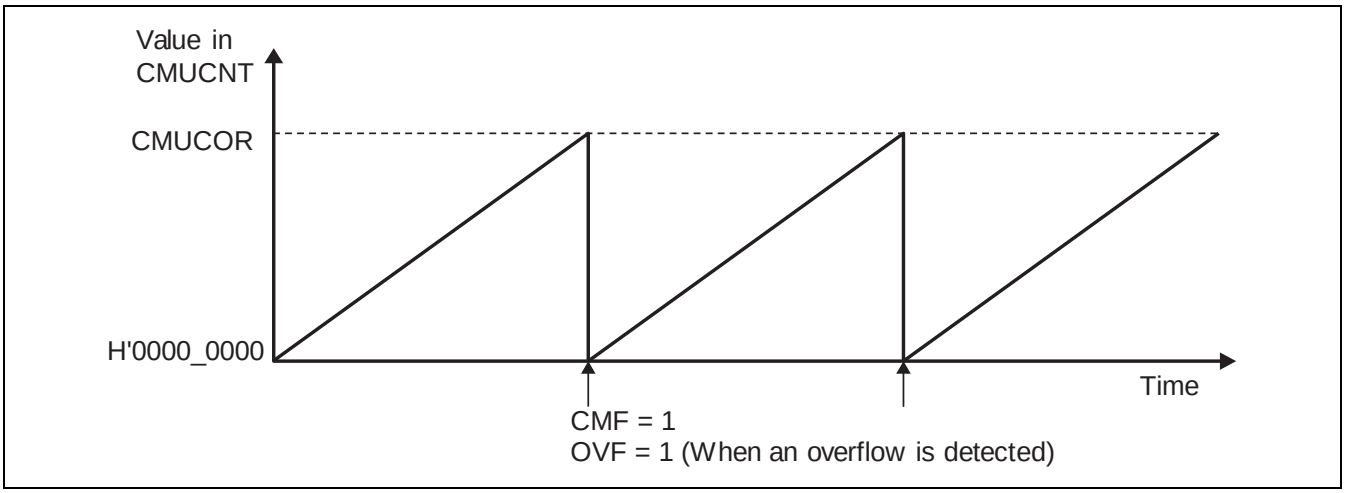

Figure 71.3 Counter Operation (Free-Running Operation)

71.3.2 Counter Size

In this module, the size of the counter can be selected from either 16, or 32 bits. This is selected by the CMS bit in CMUCSR.

When the 16-bit size is selected, H'0000 should be used as upper 16bit of write data to CMUCOR. To detect an overflow interrupt, CMUCOR must be set to H'0000_FFFF.

71.3.3 Timing for Counting by CMUCNT

In this module, the clock for the CMUCNT counter can be selected from following clocks:

- RCLK: 1/1, 1/8, 1/32, and 1/128

The clock for the counter is selected by the CKS bits in CMUCSR. CMUCNT is incremented at the rising edge of the selected clock.

71.3.4 Internal Interrupt Request to CPU

By CMR bits in CMUCSR, interrupt request to CPU can be asserted, at a compare match.

To clear an internal interrupt request to the CPU in Free-Running Operation, the CMF bit should be set to 0. Set the CMF bit to 0 in the handling routine for the System Up-Time Clock interrupt.

To clear an internal interrupt request to the CPU with resuming count-up in One-Shot Operation, the CMF bit should be set to 0 while keeping 1 in STR5 bit in CMUSTR. Set the CMF bit to 0 while keeping 1 in STR5 bit in the handling routine for the System Up-Time Clock interrupt.

To clear an internal interrupt request to the CPU without resuming count-up in One-Shot Operation, the CMF bit should be set to 0 after setting STR5 bit in CMUSTR to 0. Set the CMF bit to 0 after setting STR5 bit to 0 in the handling routine for the System Up-Time Clock interrupt.

71.3.5 Register Access

After writing to following registers, written data can be read 2 cycles in counter input clock (RCLK) after writing has finished. And it takes 2 cycles in counter input clock (RCLK), for reflecting written data to counter behavior.

CMUCSR: Bits CKS, CMM, CMS, WER, CMR, DBGIVD
CMUCOR: Bits 31 to 0
CMUSTR: Bit STR5

After writing to following registers, written data can be read 2 cycles in counter input clock (RCLK) after writing has finished. And it takes 2 cycles in counter input clock (RCLK), for reflecting written data to counter behavior.

And for following registers, write access is prohibited, while previously written data is under writing. Do not perform next write access, while CMUCSR.WRFLG is 1.

CMUCNT: Bits 31 to 0

71.3.6 Compare Match Flag Set/Clear Timing

The CMF bit in CMUCSR is set to 1 by the compare match signal generated when CMUCOR and CMUCNT match. The compare match signal is generated upon the final state of the match (timing at which the CMUCNT value is updated to H'0). Consequently, after CMUCOR and CMUCNT match, a compare match signal will not be generated until a CMUCNT counter clock is input. Figure 71.4 shows the set timing of the CMF bit.

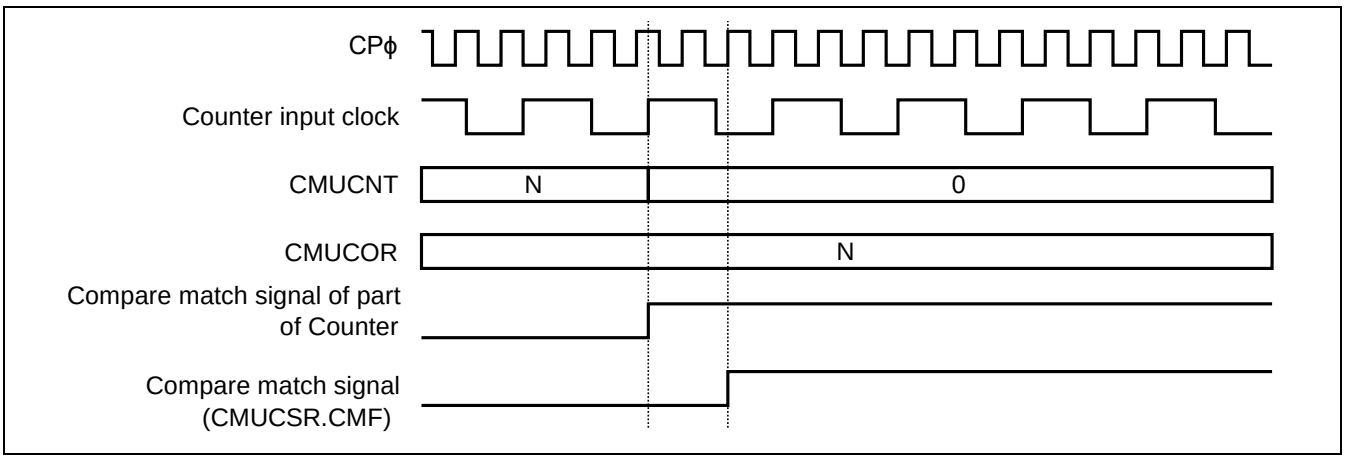

Figure 71.4 CMF Set Timing

Set the CMF bit to 0. The CMF flag is cleared immediately.

71.3.7 System Up-Tim Clock Usage

Take the following steps to use the System Up-Time Clock.

1. Clear the STR5 bit in CMUSTR to 0 to temporarily stop counting.
   (Confirm that RCLK was input more than 2 cycles.)
2. Write H'0000_0000 on CMUCNT.
3. Set counter size, compare match mode, kind of count clock and interrupt request and clear the bit of OVF and CMF in CMUCSR.
4. Set the value on CMUCOR.
5. Confirm that CMUCSR.WRFLG becomes 0.
   If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the STR5 bit in CMUSTR to 1.
   (Refer to 71.3.5 Register Access)

72. Debug and Trace

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

72.1 Overview

This module controls debug function of Cortex-A57 and Cortex-A53 via JTAG ports.

72.1.1 Features

72.1.1.1 RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0 features

- JTAG interface
  - Supports dedicated 5-pin JTAG and SWD
- The cross trigger function between following IPs.
  - Cortex-A57 CPUn
  - Cortex-A53 CPUn.
  - CoreSight
- Tracing function
  - A maximum of 16 bits × 266 Mbps (133MHz DDR) trace*1 data pin
  output— A maximum of 4 bits × 266 Mbps (133MHz DDR) trace*1 data pin
  output— 16-Kbyte embedded trace FIFO each Cortex-A57 and Cortex-A53
  cluster— 4-Kbyte embedded trace FIFO for CoreSight

Notes: 1. Trace bandwidth of internal logic. This is limited by I/O buffer performance.

72.1.1.2 RZ/G2N features

- JTAG interface
  - Supports dedicated 5-pin JTAG and SWD
- The cross trigger function between following IPs.
  - Cortex-A57 CPUn
  - CoreSight
- Tracing function
  - A maximum of 16 bits × 266 Mbps (133MHz DDR) trace*1 data pin
  output— A maximum of 4 bits × 266 Mbps (133MHz DDR) trace*1 data pin
  output— 16-Kbyte embedded trace FIFO for Cortex-A57
  - 4-Kbyte embedded trace FIFO for CoreSight

Notes: 1. Trace bandwidth of internal logic. This is limited by I/O buffer performance.

72.1.1.3 RZ/G2E features

- JTAG interface
  - — Supports dedicated 5-pin JTAG and SWD
- The cross trigger function between following IPs.
  - — Cortex-A53 CPUn
  - — CoreSight
- Tracing function
  - — A maximum of 16 bits × 266 Mbps (133MHz DDR) trace*1 data pin
  - output— A maximum of 4 bits × 266 Mbps (133MHz DDR) trace*1 data pin
  - output— 16-Kbyte embedded trace FIFO for Cortex-A57
  - — 4-Kbyte embedded trace FIFO for CoreSight

Notes: 1 Trace bandwidth of internal logic. This is limited by I/O buffer performance.

72.1.3 External Pins

72.1.3.1 JTAG Pins

5-pin JTAG and SWD are supported as dedicated JTAG port. JTAG ports support 1.8V only. Each JTAG port can be connected to different TAP controller through MD pins. Refer to JTAG selection tables in Table 72.12 and Table 72.13.

Table 72.1 JTAG pin for RZ/G2H

IF	Pin name	I/O	Function *	
			JTAG IF	Serial Wire Debug IF for CoreSight
JTAG	TRST#	Input	TRST#	—
	TCK	Input	TCK	SWCLK
	TMS	I/O	TMS	SWDIO
	TDI	Input	TDI	—
	TDO	Output	TDO	SWO

Note: * The pin operates as JTAG IF from startup period. It can be switched to Serial Wire Debug IF by control from the debugger side. (It cannot be switched by pin setting)

Table 72.2 JTAG pin for RZ/G2M V1.3, RZ/G2M V3.0

72.1.4 Register Configuration

Do not write to addresses other than those listed below, otherwise normal operation cannot be guaranteed. Values read from other addresses are undefined.

[Legend]

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R: Read-only. The write value should always be the initial value.

—/W: Write-only. The read value is undefined.

72.1.4.3 TDBG registers configurations

TDBG is the collection of trace pin control registers and debugging status registers for chip-specific debug features. Only after write operation to the KEY bit in DBGREG9 is done, it is possible to write to DBGREG1. Note that asserting KEY bit in DBGREG9 register requires two phases of writing as describing in section 72.2.3.3.

Table 72.9 TDBG register configurations

						Second Generation RZ/G Series Products			
Name of Register	Abbreviation	R/W	Address (CPU/ Debugger View)	Initial Value	Access Size	RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
Debug Register 1	DBGREG1	R/W	H'E610_0020	H'x00x_0000 *	32	√	√	√	√
Debug Register 4	DBGREG4	R	H'E610_002C	H'0000_0xxx *	32	√	√	√	√
Debug Register 9	DBGREG9	R/W	H'E610_0040	H'0000_0000	32	√	√	√	√

Note: * The initial value is determined by input of LSI pin.

72.1.5 Connected module

Table 72.10 Connected module

			Second Generation RZ/G Series Products			
Module name	Connected module name	Function of connected module	RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
CoreSight	AP-System Core	Processor	√	√	√	√
	CPG	Clock Pulse Generator	√	√	√	√
	PFC	Pin function	√	√	√	√

72.1.6 Part number and TARGETID

Part number is a product identification. This number is stored in Peripheral Identification Registers of ROM Table and TARGETID Register. Debugger reads those registers to identify the product. Each product has unique value of part number as shown in Table 72.11:

Note: Refer to Arm CoreSight Architecture Specification v2.0 for more detail information.

Table 72.11 Part number and TARGETID

Second Generation of RZ/G Series Products	Part number	TARGETID
RZ/G2H	H'008	H'0008_0447
RZ/G2M V1.3, RZ/G2M V3.0	H'00D	H'000D_0447
RZ/G2N	H'021	H'0021_0447
RZ/G2E	H'026	H'0026_0447

72.2 Register Description

72.2.1 CoreSight and Debug registers

Refer to following manuals for generic CoreSight components.

- Arm Architecture Reference Manual Armv8-A
- Arm Architecture Reference Manual Armv7-A and Armv7-R edition
- Arm Cortex-A53 MPCore Processor Technical Reference Manual
- Arm Cortex-A57 MPCore Processor Technical Reference Manual
- Arm CoreSight SoC-400 Technical Reference Manual
- Arm CoreSight Trace Memory Controller Technical Reference Manual
- Arm CoreSight STM-500 System Trace Macrocell Technical Reference Manual

72.2.2 CSreg registers

CSreg is the collection of control registers for chip-specific debug features. These registers can be accessed from both Debugger and CPU via Debug-APB.

72.2.2.1 ATCLKCR_CA57 Register

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E

72.2.3.2 Debug register 4 (DBGREG4)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This is a status register showing debug features are enable or disable. It is possible to perform read operations only from the CPU.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CS_DEVEN	CS_SPNIDEN	CS_SPIDEN	CS_NIDEN	CS_DBGEN	—	—	CA_SPNIDEN	CA_SPIDEN	CA_NIDEN	CA_DBGEN
Initial value:	0	0	0	0	*	*	*	*	*	*	*	*	*	*	*	*
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0.
11	Reserved	*	R	Reserved
10	CS_DEVEN	*	R	Indicates disable or enable of the DAP_DEVICEEN of CoreSight. 0: Disable 1: Enable
9	CS_SPNIDEN	*	R	Indicates disable or enable of the SPNIDEN of CoreSight. 0: Disable 1: Enable
8	CS_SPIDEN	*	R	Indicates disable or enable of the SPIDEN of CoreSight. 0: Disable 1: Enable
7	CS_NIDEN	*	R	Indicates disable or enable of the NIDEN of CoreSight. 0: Disable 1: Enable
6	CS_DBGEN	*	R	Indicates disable or enable of the DBGEN of CoreSight. 0: Disable 1: Enable
5	CR_NIDEN	*	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
4	CR_DBGEN	*	R	Reserved
3	CA_SPNIDEN	*	R	Indicates disable or enable of the SPNIDEN of Cortex-A57/ Cortex-A53. 0: Disable 1: Enable (RZ/G2E: only support Cortex-A53) (RZ/G2N: only support Cortex-A57)
2	CA_SPIDEN	*	R	Indicates disable or enable of the SPIDEN of Cortex-A57/ Cortex-A53. 0: Disable 1: Enable (RZ/G2E: only support Cortex-A53) (RZ/G2N: only support Cortex-A57)
1	CA_NIDEN	*	R	Indicates disable or enable of the NIDEN of Cortex-A57/ Cortex-A53. 0: Disable 1: Enable (RZ/G2E: only support Cortex-A53) (RZ/G2N: only support Cortex-A57)
0	CA_DBGEN	*	R	Indicates disable or enable of the DBGEN of Cortex-A57/ Cortex-A53. 0: Disable 1: Enable (RZ/G2E: only support Cortex-A53) (RZ/G2N: only support Cortex-A57)

Note: * Depends on the setting of the MD21, MD20, MD11, MD10, MDT[1:0] pins.

72.2.3.3 Debug register 9 (DBGREG9)

RZ/G2H	RZ/G2M V1.3, RZ/G2M V3.0	RZ/G2N	RZ/G2E
√	√	√	√

This register has a key role in preventing invalid access. It is possible to perform read/write operations only from the CPU. DBGREG1 can only be written when the KEY bit in DBGREG9 is updated as below procedure.

First, write H'A500 to DBGREG9[15:0]. This enables to write to DBGREG9[0]. Then, write H'A501 to DBGREG9[15:0]. After this writing is done, DBGREG1 can be written.

It is recommended to clear the KEY bit in DBGREG9 after finishing writing to DBGREG1. To clear KEY bit in DBGREG9, write H’0000_0000 to DBGREG9.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AID[7:0]								—	—	—	—	—	—	—	KEY
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	AID[7:0]	H’00	R/W	KEY Bit Write Aid Use this bit to write a bit pattern (H'A5) to be written to the KEY bit.
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	KEY	B’0	R/W	DBGREG1 access control Provides access control to the DBGREG1. 0: It is not possible to perform write operations to the DBGREG1. 1: It is possible to perform write operations to the DBGREG1. When writing 1 to this bit, be sure to write H'A5 to the AID bits at the same time.

72.3 Operation

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

72.3.1 JTAG selection

JTAG function can be selected through MD pins setting below.

If CoreSight is selected through MD pins, internal debug enable signals for Cortex-A57/Cortex-A53 are asserted automatically.

Table 72.12 JTAG selection table for RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0 and RZ/G2N

MD pin				
MD10	**MD21,20**	**MD11**	**MDT[1:0]**	**JTAG**
B'0	B'00	*	*	—
	B'10	B'0	*	CoreSight

*: don't care, —: No connection with TAP controller
Note : Other than above, setting prohibited.

Table 72.13 JTAG selection table for RZ/G2E

MD pin				
MD10	**MD21,20**	**MD11**	**MDT[1:0]**	**JTAG**
B’0	B’00	*	*	—
	B’10	B'0	*	CoreSight

*: don’t care, —: No connection with TAP controller
Note : Other than above, setting prohibited.

72.3.2 Trace output selection

Trace Data source can be selected by DBGREG1.TRC[2:0] setting. Cortex-A57, CoreSight, and Cortex-A53 can be selected.

DBGREG1.DMON1EN[1:0] can selects pin function of trace data bit width. The trace clock is ZTRϕ.

72.3.3 STM output selection

DBGREG1.STMSEL bits can select STM Port output. System Trace clock is ZTRϕ.

72.3.4 STM Master ID mapping

STM-500 is used for system trace to output some information from CPU and monitor the contents stored in memories such as DDR memories and internal SRAMs (e.g. System RAM by utilizing DMA transfer. Following table lists of Master ID value (output of STM) to identify the master module sending the transaction to STM-500 in each product.

Table 72.14 STM Master ID mapping

—: no use

Master name	STM number	Secure Access	Master_ID	Second Generation RZ/G Series Products			
				RZ/G2H	RZ/G2M V1.3 RZ/G2M V3.0	RZ/G2N	RZ/G2E
Cortex-A57 Core#0	STM0	Secure	H'20	√	√	√	—
Cortex-A57 Core#1	STM0	Secure	H'21	√	√	√	—
Cortex-A57 Core#2	STM0	Secure	H'22	√	—	—	—
Cortex-A57 Core#3	STM0	Secure	H'23	√	—	—	—
Cortex-A53 Core#0	STM0	Secure	H'24	√	√	—	√
Cortex-A53 Core#1	STM0	Secure	H'25	√	√	—	√
Cortex-A53 Core#2	STM0	Secure	H'26	√	√	—	—
Cortex-A53 Core#3	STM0	Secure	H'27	√	√	—	—
SYS-DMAC *	STM0	Secure	H'30 – H'3F	√	√	√	√
Cortex-A57 Core#0	STM0	Non-secure	H'60	√	√	√	—
Cortex-A57 Core#1	STM0	Non-secure	H'61	√	√	√	—
Cortex-A57 Core#2	STM0	Non-secure	H'62	√	—	—	—
Cortex-A57 Core#3	STM0	Non-secure	H'63	√	—	—	—
Cortex-A53 Core#0	STM0	Non-secure	H'64	√	√	—	√
Cortex-A53 Core#1	STM0	Non-secure	H'65	√	√	—	√
Cortex-A53 Core#2	STM0	Non-secure	H'66	√	√	—	—
Cortex-A53 Core#3	STM0	Non-secure	H'67	√	√	—	—
SYS-DMAC *	STM0	Non-secure	H'70 – H'7F	√	√	√	√

Note: * SYS-DMAC are not distinguishable. Either one DMA Controller is expected to use at the same time.

72.3.5 STM AXI Slave Interface

Each address in stimulus port of STM is corresponding to the types of trace packet to be generated; therefore, for choosing the type of trace packet, issue AXI transactions with the corresponding addresses to STM.

STM has a 64-bit (8-byte) AXI write slave interface which can accept a single 8-byte write. Sending more than 8-byte in a burst access to STM is prohibited. Otherwise, the AXI addresses are incremental and unintended types of trace packets are generated.

72.3.5.1 STM FIXED AWBURST [RZ/G2E]

By setting 1 to "FIXED AWBURST enable" bit in CSREG_E00 register, RZ/G2E can send more than 8-byte to STM in a burst access. In that case, the AXI addresses become the same for every transfer in the burst access by overriding the AXI burst type to the "FIXED" type.

72.3.6 Cross Trigger Connection

Cross trigger connections shows below.

72.4 Usage Notes

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

72.4.1 EDPRSR.PU polling

For Cortex-A53 and Cortex-A57, all register settings in Core Power Domain need to be done after EDPRSR.PU in Debug Power Domain becomes one.

Figure 72.5 is an example for Cortex-A53 with 2 CPUs. The number of CPU is dependent on product.

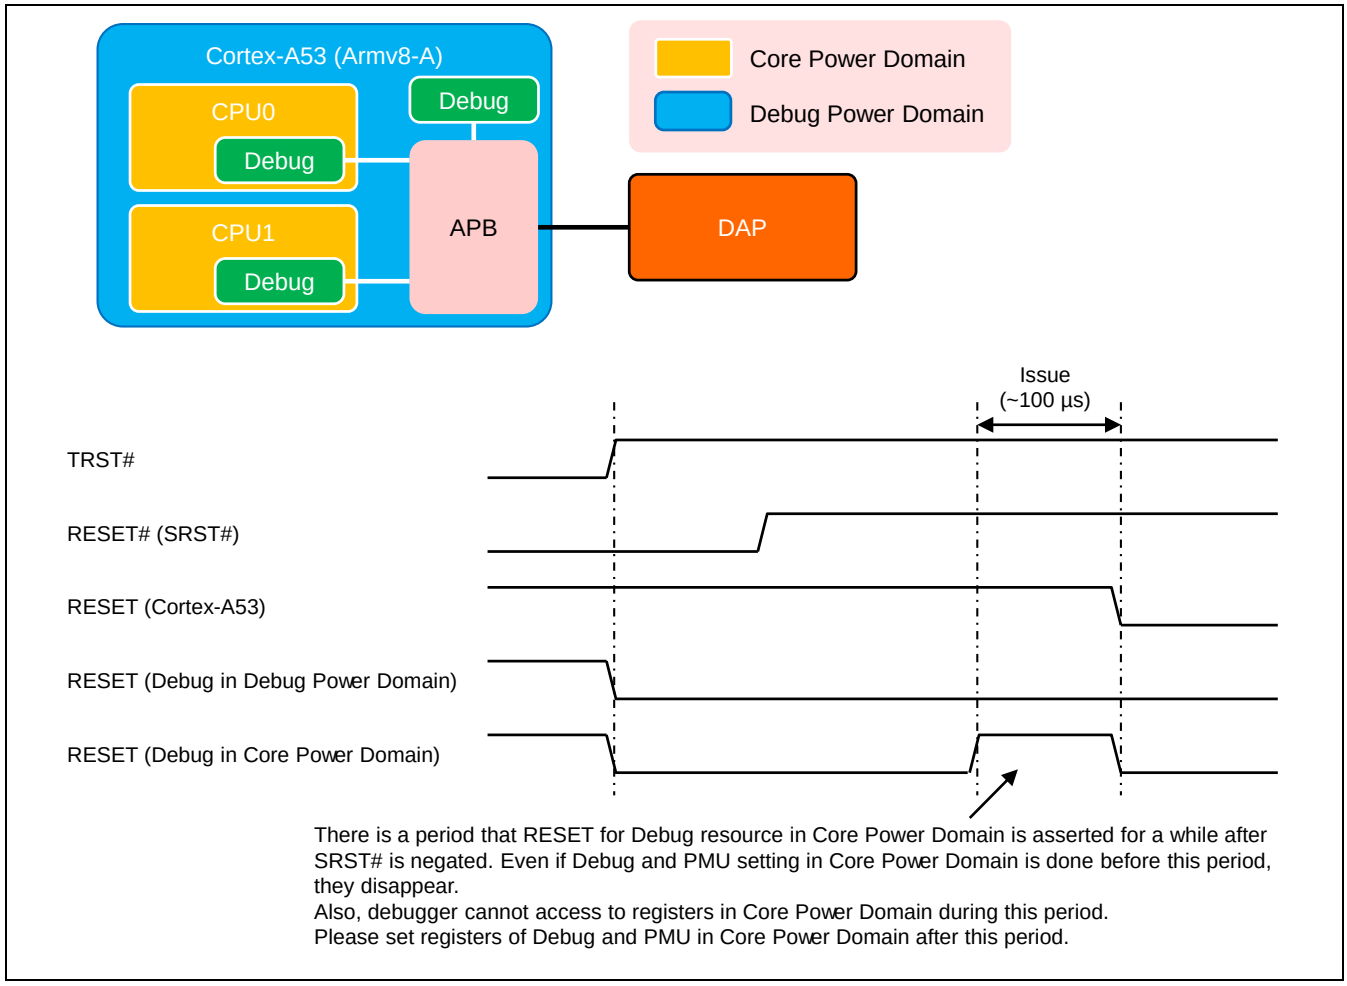

Figure 72.5 Reset timing in Core Power domain

72.4.2 TRST control in no JTAG selection

If the JTAG Ports are not selected by debug related MD pins (MD[11:10], MD[21:20], MDT[1:0] pins are all low level), TRST# pin of JTAG should be set to low level or driven with the same level of PRESET# pin.

72.4.3 Pseudo Power down

Pseudo Power down is not supported at debugging.

72.4.4 Important notice for soft power-on reset

In debug mode*[1], soft power-on reset (WDT reset or SRESCR.SPRES = 1) cannot be issued. Do not change the following register settings.

- RWDT_RSTMSK bit (bit 0 in the WDTRSTCR register): Initial value 1.
- SWDT_RSTMSK bit (bit 1 in the WDTRSTCR register): Initial value 1.
- SPRES bit (bit 15 in the SRESCR register): Initial value 0.

Note: 1. LSI is in debug mode when read value of MD21 bit (bit 29 in the DBGREG1 register) is 1.

Input voltage (0.9-V I/O [VDD09_USB3n])	-0.3 to VDD09_USB3n + 0.3	V	*5
Input voltage (0.9-V I/O [VDD09_USB3HSn])	-0.3 to VDD09_USB3HSn + 0.3	V	*5
Input voltage (0.9-V I/O [VDD09_USB2n])	-0.3 to VDD09_USB2n + 0.3	V	*5
Input voltage (0.9-V I/O [VDDQ09_HDMIn])	-0.3 to VDDQ09_HDMIn + 0.3	V	*5
Input voltage (0.9-V I/O [VDDQ09_LVDS])	-0.3 to VDDQ09_LVDS + 0.3	V	*5
Input voltage (0.9-V I/O [VDD09_CSIn])	-0.3 to VDD09_CSIn + 0.3	V	*5
Output voltage (3.3-V I/O)	-0.3 to VDDQ33 + 0.3	V	*1
Output voltage (3.3-V I/O [SDHI])	-0.3 to VDDQVA_SDn + 0.3	V	*1
Output voltage (3.3-V I/O [SATA])	-0.3 to VDD33_SATA + 0.3	V	*1
Output voltage (3.3-V I/O [PCIE])	-0.3 to VDD33_PCIEn + 0.3	V	*1
Output voltage (3.3-V I/O [USB3])	-0.3 to VDD33_USB3n + 0.3	V	*1
Output voltage (3.3-V I/O [USB3HSH])	-0.3 to VDD33_USB3HSHn + 0.3	V	*1
Output voltage (3.3-V I/O [USB3HS])	-0.3 to VDD33_USB3HSn + 0.3	V	*1
Output voltage (3.3-V I/O [USB2H])	-0.3 to VDDQ33_USB2Hn + 0.3	V	*1
Output voltage (3.3-V I/O [USB2])	-0.3 to VDDQ33_USB2 + 0.3	V	*1
Output voltage (3.3-V I/O [GE])	-0.3 to VDDQ25_GE + 0.3	V	*1
Output voltage (3.3-V I/O [AVB])	-0.3 to VDDQ25_AVB + 0.3	V	*1
Output voltage (3.3-V I/O [VDDQ_DU])	-0.3 to VDDQ_DU + 0.3	V	*1
Output voltage (3.3-V I/O [VDDQ_VIN01])	-0.3 to VDDQ_VIN01 + 0.3	V	*1
Output voltage (2.5-V I/O [ETH])	-0.3 to VDDQ25_ETH + 0.3	V	*2
Output voltage (2.5-V I/O [GE])	-0.3 to VDDQ25_GE + 0.3	V	*2
Output voltage (2.5-V I/O [AVB])	-0.3 to VDDQ25_AVB + 0.3	V	*2
Output voltage (1.8-V I/O)	-0.3 to VDDQ18 + 0.3	V	*3
Output voltage (1.8-V I/O [HDMI])	-0.3 to VDDQ18_HDMIn + 0.3	V	*3
Output voltage (1.8-V I/O [VDDQ18_LVDS])	-0.3 to VDDQ18_LVDS + 0.3	V	*3
Output voltage (1.8-V I/O [VDDQ18_CSIn])	-0.3 to VDDQ18_CSIn + 0.3	V	*3
Output voltage (1.8-V I/O [VDDQVA_SDn])	-0.3 to VDDQVA_SDn + 0.3	V	*3, SDR50, SDR104
Output voltage (1.8-V I/O [VDDQ18_DIGRF])	-0.3 to VDDQ18_DIGRF + 0.3	V	*3
Output voltage (1.8-V I/O [VDDQ18_DU])	-0.3 to VDDQ_DU + 0.3	V	*3
Output voltage (1.8-V I/O [VDDQ_VIN01])	-0.3 to VDDQ_VIN01 + 0.3	V	*3
Output voltage (1.1-V I/O [VDDQVA_DDRn])	-0.3 to VDDQVA_DDRn + 0.3	V	*4, LPDDR4
Output voltage (0.9-V I/O [VDD09_SATA])	-0.3 to VDD09_SATA + 0.3	V	*5

Item	Value	Unit	Remarks
Output voltage (0.9-V I/O [VDD09_PCIEn])	-0.3 to VDD09_PCIEn + 0.3	V	*5
Output voltage (0.9-V I/O [VDD09_USB3n])	-0.3 to VDD09_USB3n + 0.3	V	*5
Output voltage (0.9-V I/O [VDD09_USB3HSn])	-0.3 to VDD09_USB3HSn + 0.3	V	*5
Output voltage (0.9-V I/O [VDD09_USB2n])	-0.3 to VDD09_USB2n + 0.3	V	*5
Output voltage (0.9-V I/O [VDDQ09_HDMIn])	-0.3 to VDDQ09_HDMIn + 0.3	V	*5
Output voltage (0.9-V I/O [VDDQ09_LVDS])	-0.3 to VDDQ09_LVDS + 0.3	V	*5
Output voltage (0.9-V I/O [VDD09_CSIn])	-0.3 to VDD09_CSIn + 0.3	V	*5
Operating temperature	-40 to +85	°C	Ta (ambient)
	-40 to +115	°C	Tj (junction)
Maximum rating temperature	-40 to +125	°C	Tj (junction)
Storage temperature	-55 to +125	°C	Ta (ambient)

Notes: Permanent damage to the LSI may result if absolute maximum ratings are exceeded. In normal operation, this LSI should be used within the specifications described in the following descriptions. If this LSI is not used within the specifications, the reliability of this LSI may lower.

Voltages are referenced at GND = VSS = AVSS = 0 V.

Abbreviations in the tables have the following meanings.

SDHI: SDHI does not operate through SDR50 and SDR104.

SDHI (SDR50, SDR104): SDHI operates through SDR50 and SDR104.

For details of the number of channels or available modules, refer to each manual; SDHI, DU/LVDS, SATA/PCIEC/USB3.0, DBSC4 (DDR), USB2.0, HDMI and CSI and Pin Information of Individual RZ/G Series Product.

1. Do not exceed 3.84 V.
2. Do not exceed 2.90 V.
3. Do not exceed 2.34 V.
4. Do not exceed 1.50 V.
5. Do not exceed 1.12 V.

Table 73.1.2 Absolute Maximum Ratings for [RZ/G2E]

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N **RZ/G2E**

Item	Value	Unit	Remarks
Power supply voltage (3.3 V) (VDDQ33, VDDQ25_AVB0, VDDQ_SDn (n = 0, 1, 3), VDDQ_QSPI, VDDQ33_USB2)	-0.3 to +4.6	V	*1
Power supply voltage (2.5 V) (VDDQ25_AVB0)	-0.3 to +3.3	V	*2
Power supply voltage (1.8 V) (VDDQ18, VDD18_CPGPLLn (n = 0, 1, 3) VDDQ18_LVDS, VDD18_LVDSnPLL (n = 0, 1), VDDQ18_CSI0, VDDQ18_USB20, VDDQ18_USB30, VDDQ18_PCIE0, VDDQ_MAPLL, VDDQ_SD0, VDDQ_SD1, VDDQ_SD3, VDDQ_QSPI)	-0.3 to +2.5	V	*3
Power supply voltage (1.5 V) (VDDQ_CK, VDDQ_DDR)	-0.3 to + 1.875	V	*4
Power supply voltage (1.35 V) (VDDQ_CK, VDDQ_DDR)	-0.3 to + 1.75	V	*5
Power supply voltage (1.0 V) (VDD, VDDD_USB30, VDDD_PCIE0)	-0.3 to + 1.26	V	
Input voltage (3.3-V I/O)	-0.3 to VDDQ33 + 0.3	V	*1
Input voltage (3.3-V I/O [AVB0])	-0.3 to VDDQ25_AVB0 + 0.3	V	*1
Input voltage (3.3-V I/O [VDDQ_SD])	-0.3 to VDDQ_SDn + 0.3 (n = 0, 1, 3)	V	*1
Input voltage (3.3-V I/O [VDDQ_QSPI])	-0.3 to VDDQ_QSPI + 0.3	V	*1
Input voltage (2.5-V I/O [AVB0])	-0.3 to VDDQ25_AVB0 + 0.3	V	*2
Input voltage (1.8-V I/O)	-0.3 to VDDQ18 + 0.3	V	*3
Input voltage (1.8-V I/O [VDDQ_SD])	-0.3 to VDDQ_SDn + 0.3 (n = 0, 1, 3)	V	*1
Input voltage (1.8-V I/O [VDDQ_QSPI])	-0.3 to VDDQ_QSPI + 0.3	V	*1
Input voltage (1.35-V I/O [VDDQ_DDR])	-0.3 to VDDQ_DDR + 0.3	V	*5
Output voltage (3.3-V I/O)	-0.3 to VDDQ33 + 0.3	V	*1
Output voltage (3.3-V I/O [AVB0])	-0.3 to VDDQ25_AVB0 + 0.3	V	*1
Output voltage (2.5-V I/O [AVB0])	-0.3 to VDDQ25_AVB0 + 0.3	V	*2
Output voltage (1.8-V I/O)	-0.3 to VDDQ18 + 0.3	V	*3
Output voltage (1.8-V I/O [VDDQ18_LVDS])	-0.3 to VDDQ18_LVDS + 0.3	V	*3
Output voltage (1.8-V I/O [VDDQ_SD])	-0.3 to VDDQ_SDn + 0.3 (n = 0, 1, 3)	V	*1
Output voltage (1.8-V I/O [VDDQ_QSPI])	-0.3 to VDDQ_QSPI + 0.3	V	*1
Output voltage (1.35-V I/O [VDDQ_DDR])	-0.3 to VDDQ_DDR + 0.3	V	*5
Operating temperature	-40 to +115	°C	Tj (junction)
Maximum rating temperature	-40 to +125	°C	Tj (junction)
Storage temperature	-55 to +125	°C	Ta (ambient)

Notes: Permanent damage to the LSI may result if absolute maximum ratings are exceeded. In normal operation, this LSI should be used within the specifications described in the following descriptions. If this LSI is not used within the specifications, the reliability of this LSI may lower.

Voltages are referenced at GND = VSS = AVSS = 0 V.

1. Do not exceed 4.6 V
2. Do not exceed 3.3 V
3. Do not exceed 2.5 V
4. Do not exceed 1.875 V
5. Do not exceed 1.75 V

Power supply (3.3-V I/O[SD]	VDDQ_SDn (n = 0, 1, 3)	3.0	3.3	3.6	V	VDDQ_SDn (n = 0, 1, 3) for power supply and VSS for ground respectively
Power supply (3.3-V I/O[QSPI])	VDDQ_QSPI	3.0	3.3	3.6	V	VDDQ_QSPI for power supply and VSS for ground respectively
Power supply (PLL)	VDDQ_ MAPLL	1.7	1.8	1.9	V	VDDQ_MAPLL for power supply and VSS for ground respectively
Power supply (PLL)	VDDQ_MDPLLn (n = 0, 1)	1.7	1.8	1.9	V	VDDQ_MDPLLn (n = 0, 1) for power supply and VSS for ground respectively

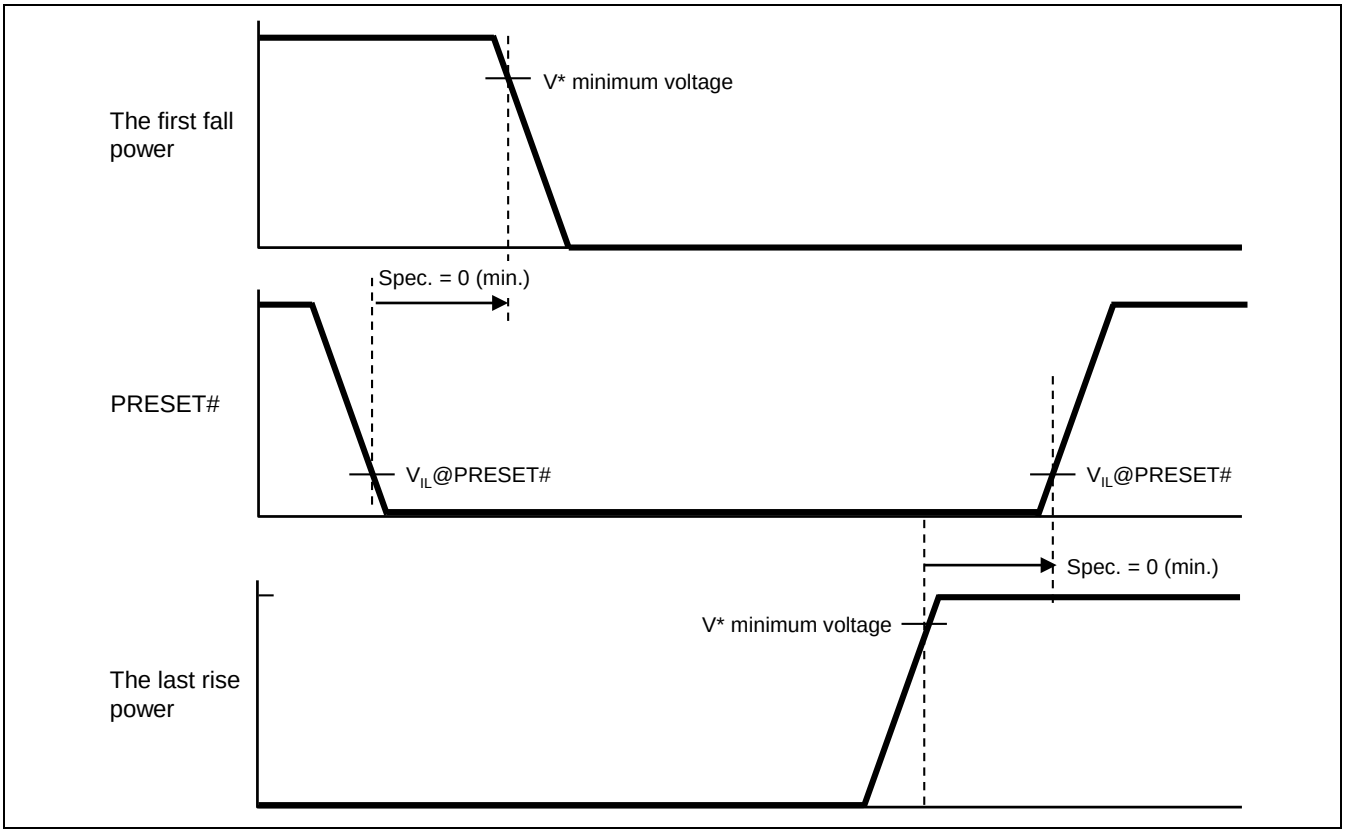
Item	Symbol	Voltage			Unit	Remarks
		Min.	Typ.	Max.		
Power supply (USB)	AVDD_USB	1.7	1.8	1.9	V	AVDD_USB for power supply and AVSS for ground respectively
	VDDQ33_USB2	3.0	3.3	3.6	V	VDDQ33_USB2 for power supply and VSS for ground respectively
	VDDQ18_USB20	1.7	1.8	1.9	V	VDDQ18_USB20 for power supply and VSS for ground respectively
Power supply (USB3.0)	VDDD_USB30	0.98	1.03	1.08	V	VDDD_USB30 for power supply and VSS for ground
	VDDQ18_USB30	1.7	1.8	1.9	V	VDDQ18_USB30 for power supply and VSS for ground
Power supply (PCIe)	VDDD_PCIE0	0.98	1.03	1.08	V	VDDD_PCIE0 for power supply and VSS for ground
	VDDQ18_PCIE0	1.7	1.8	1.9	V	VDDQ18_PCIE0 for power supply and VSS for ground

73.3 Sequence of Turning On/Off Power Supplies

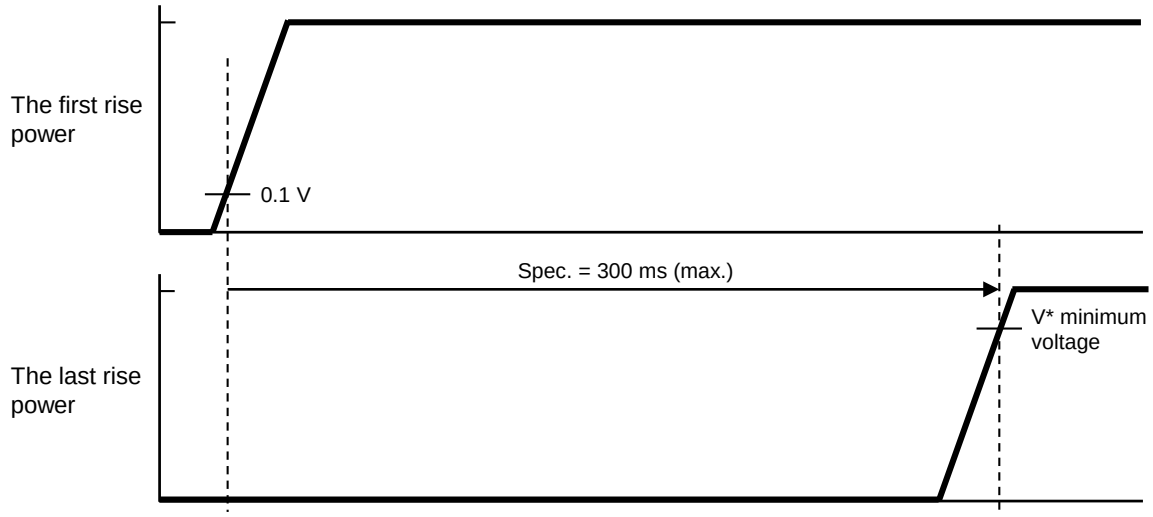
73.3.1 Sequence of Turning On/Off Power Supplies for [RZ/G2H] [RZ/G2M V1.3] [RZ/G2M V3.0] [RZ/G2N]

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

(1) PRESET# VS. Power

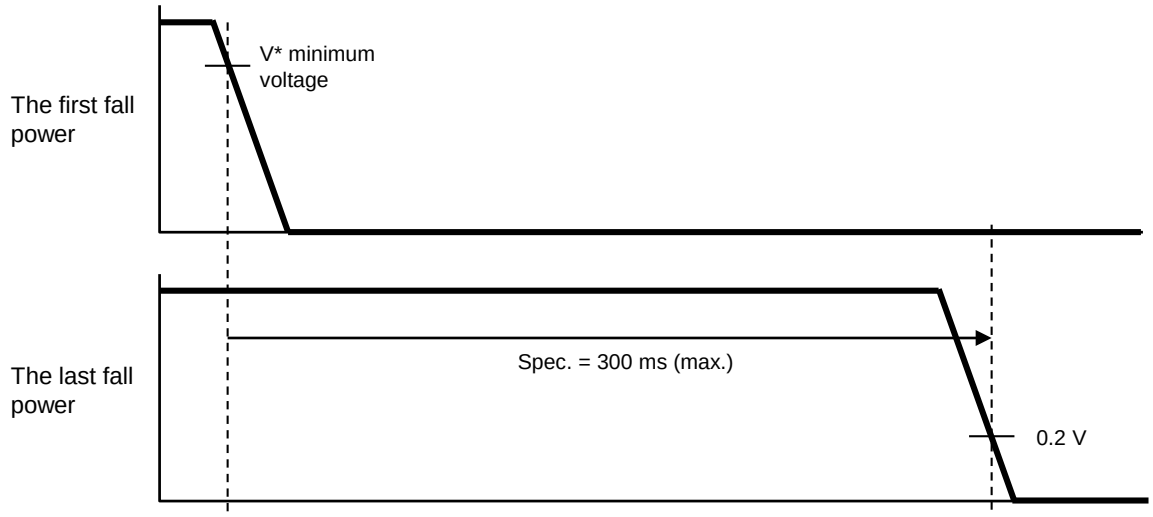


(2) Period for Power Rise for RZ/G2H, RZ/G2M V1.3, RZ/G2N



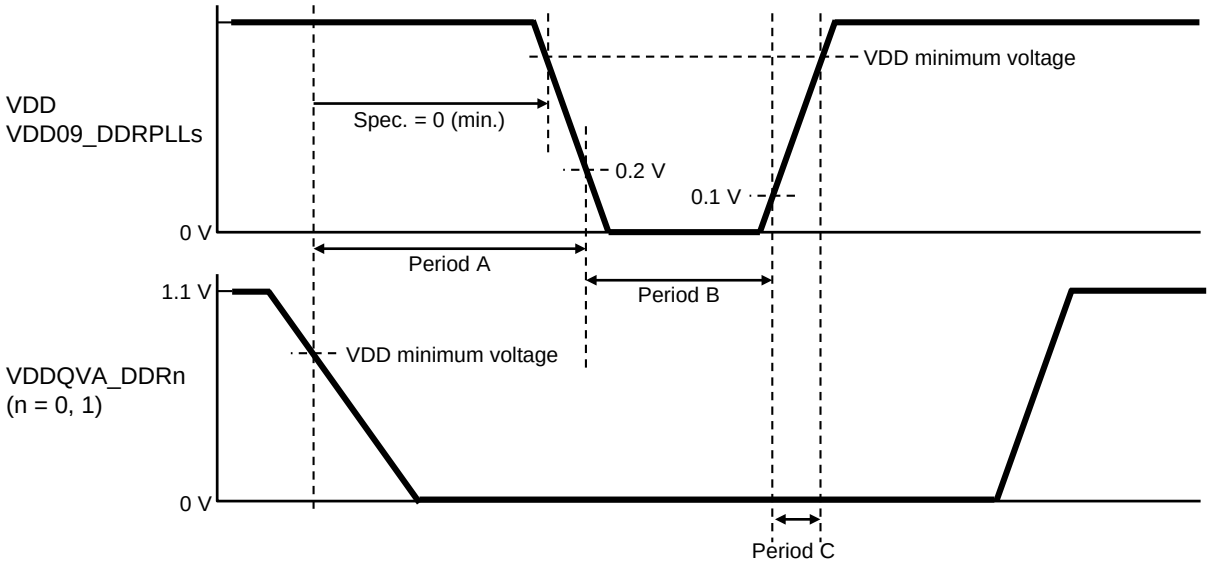
For all V*, power off state must be 0 V (GND), power rising must be started from 0 V, and end to 0 V respectively. (excluding DDR-SDRAM power-supply backup state)
Period from 0 V to 0.1V at power-on and from 0.2 V to 0 V at power-off should be shorten as much as possible.

(3) Period for Power Fall for RZ/G2H, RZ/G2M V1.3, RZ/G2N



For all V*, power off state must be 0 V (GND), power rising must be started from 0 V, and end to 0 V respectively. (excluding DDR-SDRAM power-supply backup state)
Period from 0 V to 0.1V at power-on and from 0.2 V to 0 V at power-off should be shorten as much as possible.

(4) VDD and VDD09_DDRPLLs vs VDDQVA_DDRn (n = 0, 1)

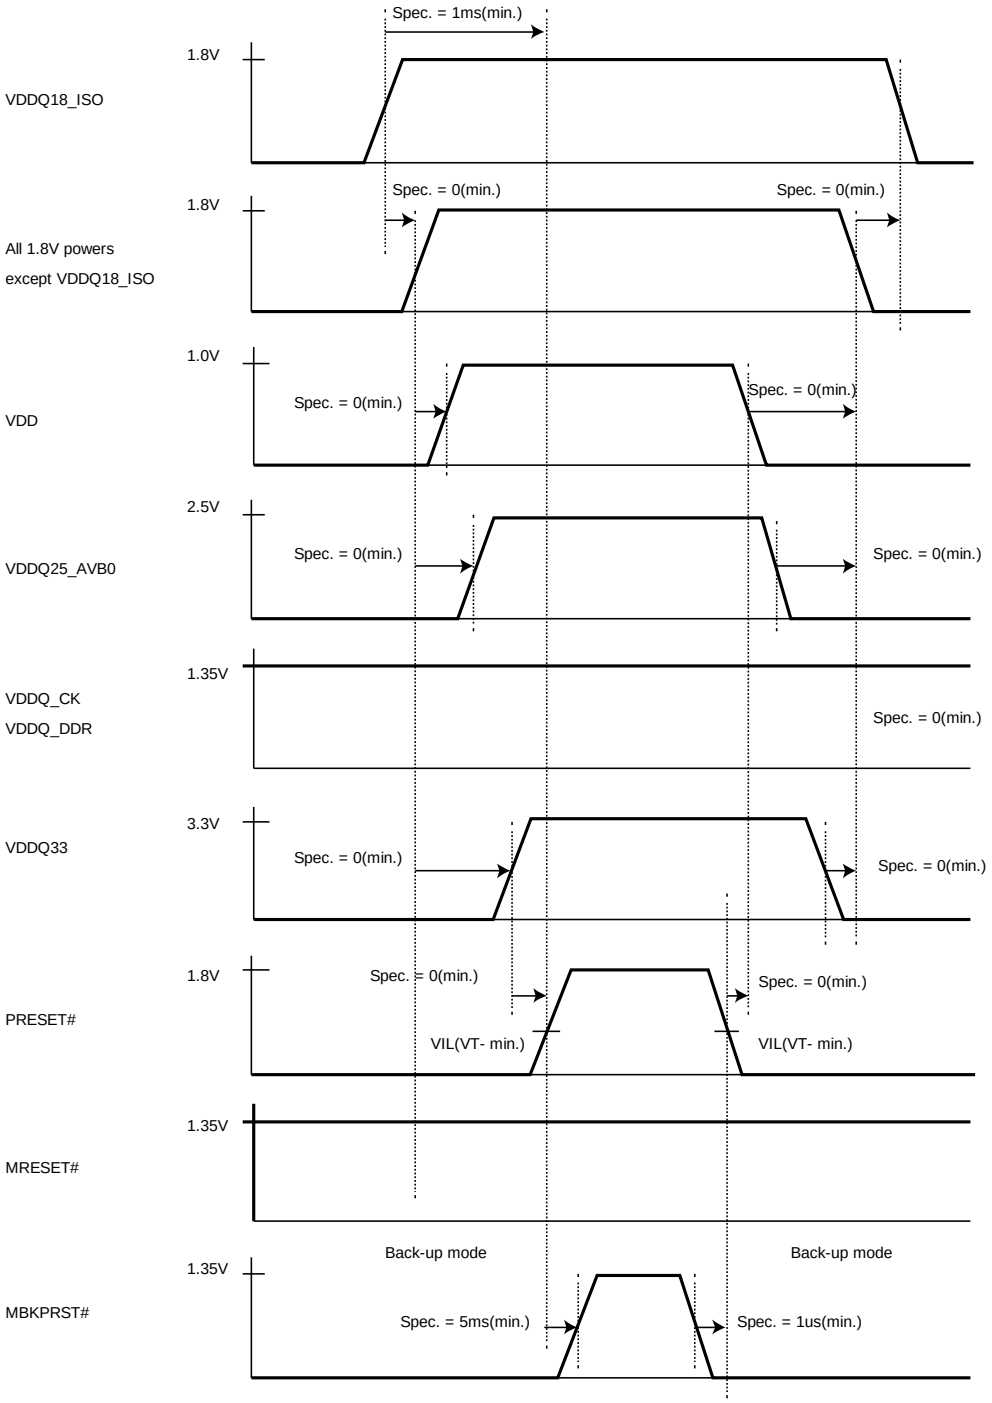


VDD and VDD09_DDRPLLs must be greater than VDDQVA_DDRn (n = 0, 1) for Period A.
VDDQVA_DDRn (n = 0, 1) must be off for Period B.
VDD and VDD09_DDRPLLs must be greater than VDDQVA_DDRn (n = 0, 1) for Period C.
VDD09_DDRPLLs are VDD09_DDRPLLnm (n = 0-3, m = CA, DQ01, DQ23)

73.3.2 Sequence of Turning On/Off Power Supplies for [RZ/G2E]

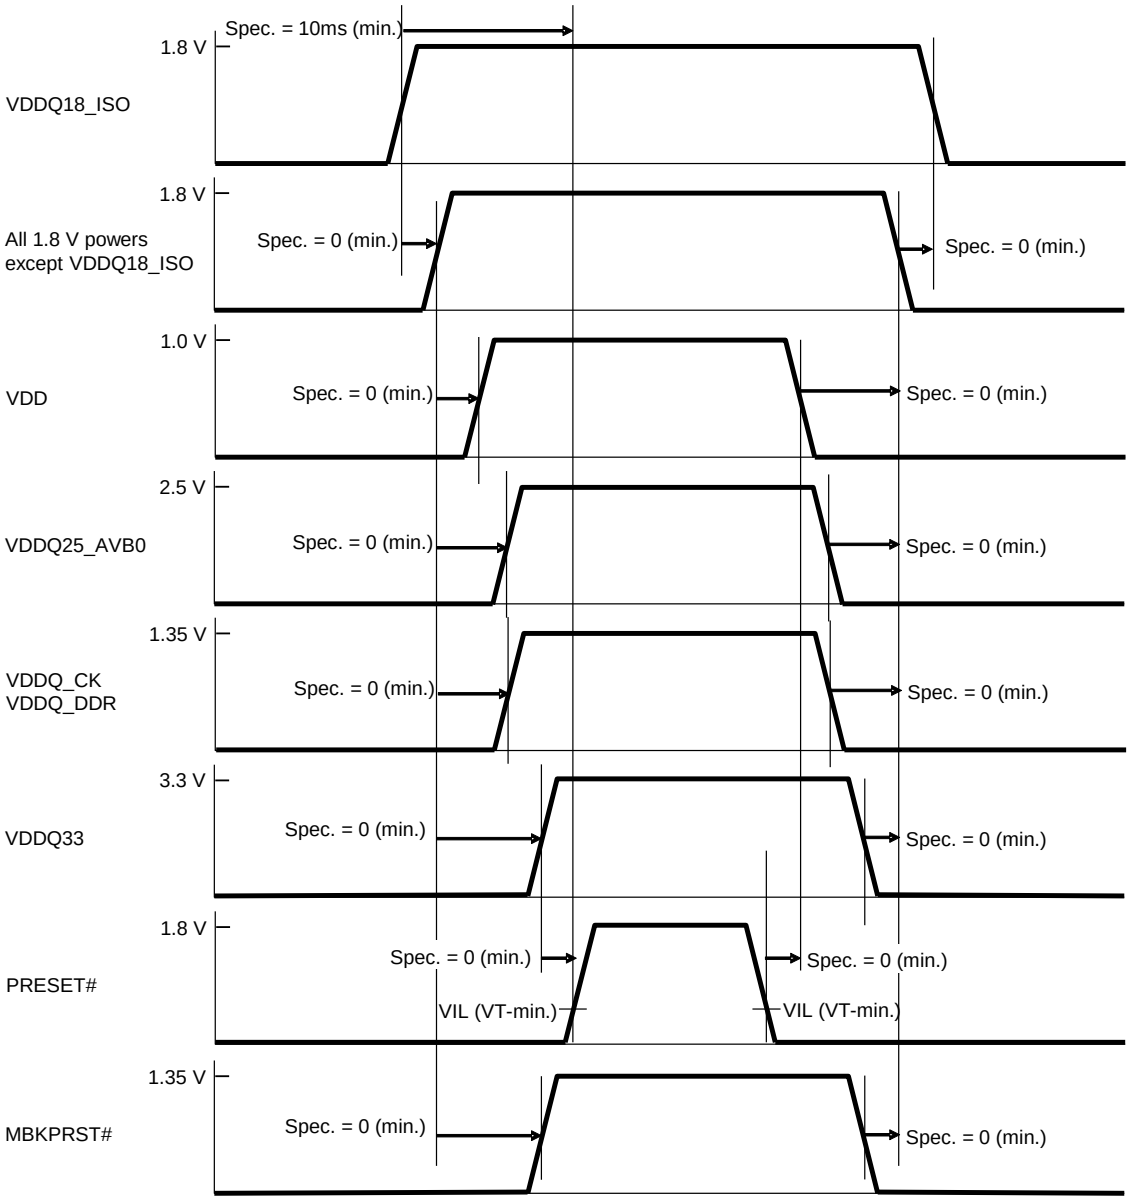
RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N **RZ/G2E**

(1) RZ/G2E power-up/down sequence with DDR backup



Note: Maximum time from first power rising to last power rising is 300ms.
Maximum time from first power failing to last power failing is 300ms.
Notes that the PRESET# must be asserted for 5 ms or more for the PRESET# tOSC specification at a power-on reset.
Even when DDR backup mode is used, the first power up sequence must keep the sequence “RZ/G2E power-up/down sequence without DDR backup”.

(2) RZ/G2E power-up/down sequence without DDR backup



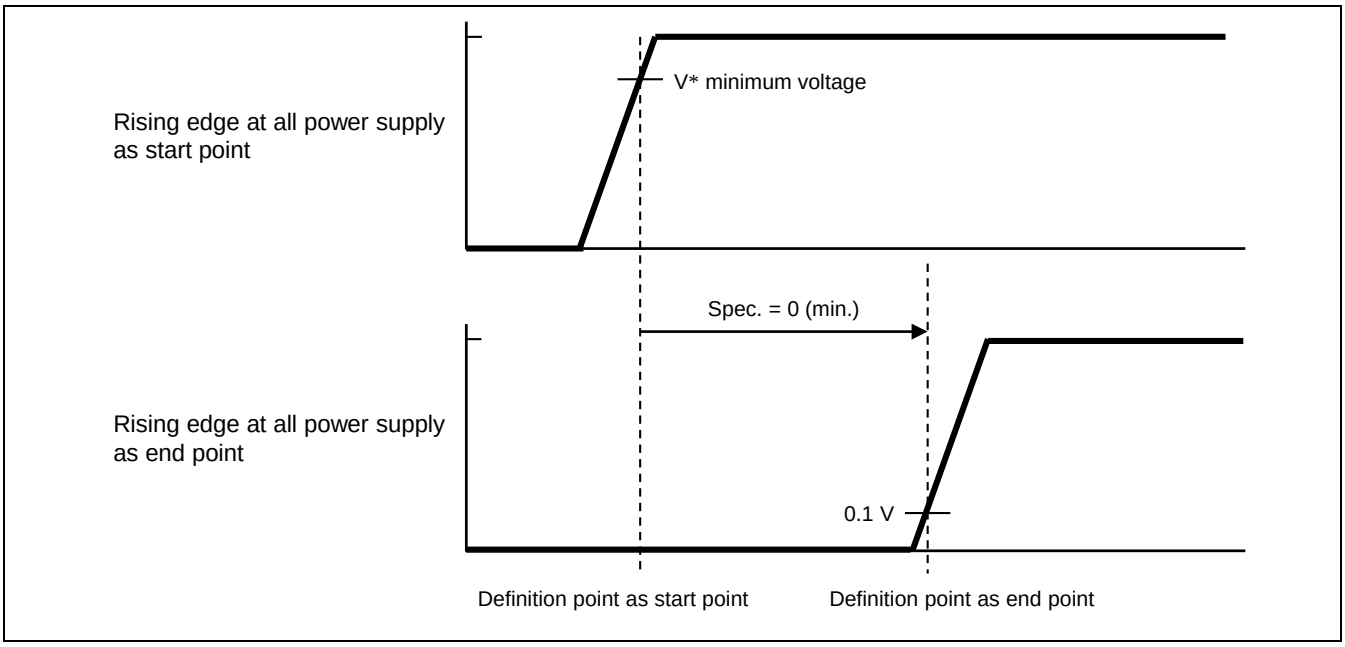
Notes: 1. Maximum time from first power rising to last power rising is 300ms.
Maximum time from first power failing to last power failing is 300ms.
Notes that the PRESET# must be asserted for 5 ms or more for the PRESET# tOSC specification at a power-on reset.

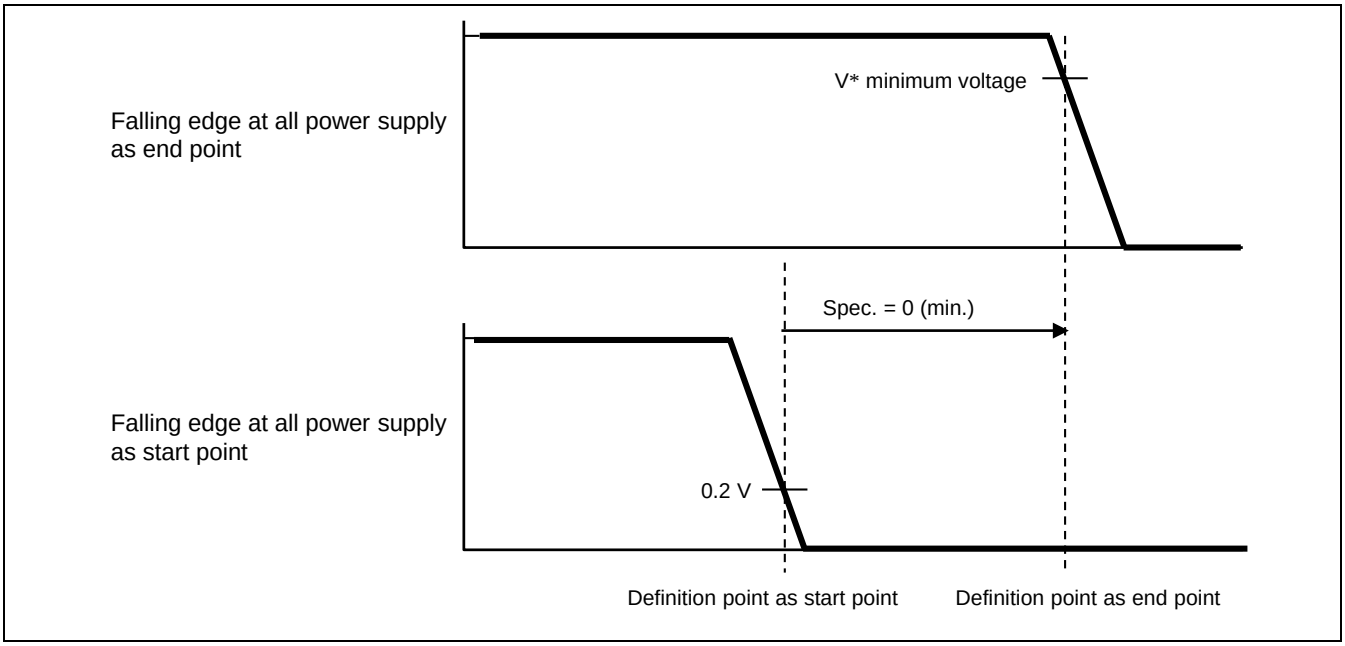
2. MBKPRST# input must track VDDQ_DDR/VDDQ_CK during VDDQ_DDR/VDDQ_CK power-up.

73.3.3 Wave form definition for power sequence

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N **RZ/G2E**

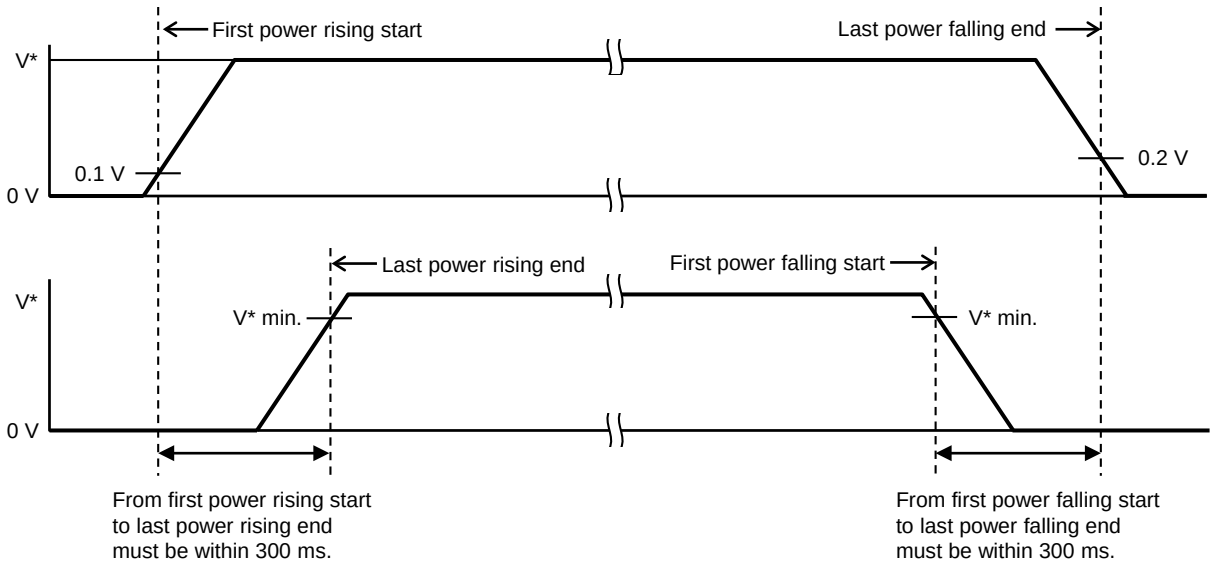
This definition is for the different voltage power supply for example between 1.8-V and 3.3-V, it is possible to turn on or off at the same time for the same voltage power supply.





73.3.4 Power On and Power Off Wave Form

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N **RZ/G2E**



Note: For all V*, power off state must be 0 V (GND), power rising must be started from 0 V and power falling must be ended to 0 V (excluding DDR-SDRAM power-supply backup state).
Periods from 0 V to 0.1 V at power-on and from 0.2 V to 0 V at power-off should be shortened as much as possible.

73.4 DC Characteristics

Table 73.4.1 Supply Current for LSI

Low Hi-Z leak current	IOZL	-10	—	—	µA		
High Hi-Z leak current	IOZH	—	—	10	µA		MZQ pin
Low Hi-Z leak current	IOZL	-10	—	—	µA		
Pin capacitance	CL	—	—	15	pF	—	All pins*

Note: * Except power supply pins.

Table 73.4.23 LPDDR4 Interface ODT Characteristics

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
ODT resistance (40 Ω)	RTT40	36	—	44	Ω	VDDQVA_DDRn = 1.06 to 1.17 V (n = 0 to 1)	—

73.4.1 Overload Condition (Injection Current)

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

The overload condition describes the behavior in case of current injection to the port pins.
Condition: Tj = -40c to Tj Max

Table 73.4.24 Overload Current [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, and RZ/G2N)

Parameter		Symbol	Condition	Ratings*1	Unit
Overload Current *2 Vin > VCC Vin < VSS	Pins supplied by VDDQ33	IINJPM	1 pin	±2	mA
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *3	|50|	mA
	Pins supplied by VDDQ18	IINJPM	1 pin	±2	mA
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *3	|50|	mA
	Pins supplied by VDDQVA_SDn (n = 0,1,2)	IINJPM	1 pin	±2	mA
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *3	|12|	mA
	Pins supplied by VDDQVA_SDn (n = 3)	IINJPM	1 pin	±2	mA
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *3	|22|	mA
	Pins supplied by VDDQ25_ETH	IINJPM	1 pin	±2	mA
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *3	|36|	mA

Notes: 1. The Total current may be limited further by the total power dissipation.
2. Be sure not to exceed the absolute maximum ratings (Max value) of each supply voltage.
3. The total overload current must be within the output current.

Table 73.4.25 Overload Current [RZ/G2E]

Parameter		Symbol	Condition	Ratings*1	Unit
Overload Current *2 Vin > VCC Vin < VSS	Pins supplied by VDDQ33	IINJPM	1 pin	±2	mA
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *3	|50|	mA
	Pins supplied by VDDQ18	IINJPM	1 pin	±2	mA
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *3	|25.2|	mA
	Pins supplied by VDDQ25_AVB0	IINJPM	1 pin	±2	mA
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *3	|24.4|	mA
	Pins supplied by VDDQ_SDn (n = 0,1)	IINJPM	1 pin	±2	mA
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *3	|5.4|	mA
	Pins supplied by VDDQ_SD3	IINJPM	1 pin	±2	mA
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *3	|22|	mA
	Pins supplied by VDDQ_QSPI	IINJPM	1 pin	±2	mA
		IINJNM	Sum of all absolute IINJPM + IINJNM of pins supplied as group *3	|21.6|	mA

Notes: 1. The Total current may be limited further by the total power dissipation.
2. Be sure not to exceed the absolute maximum ratings (Max value) of each supply voltage.
3. The total overload current must be within the output current.

73.5 Clock and Reset Timings

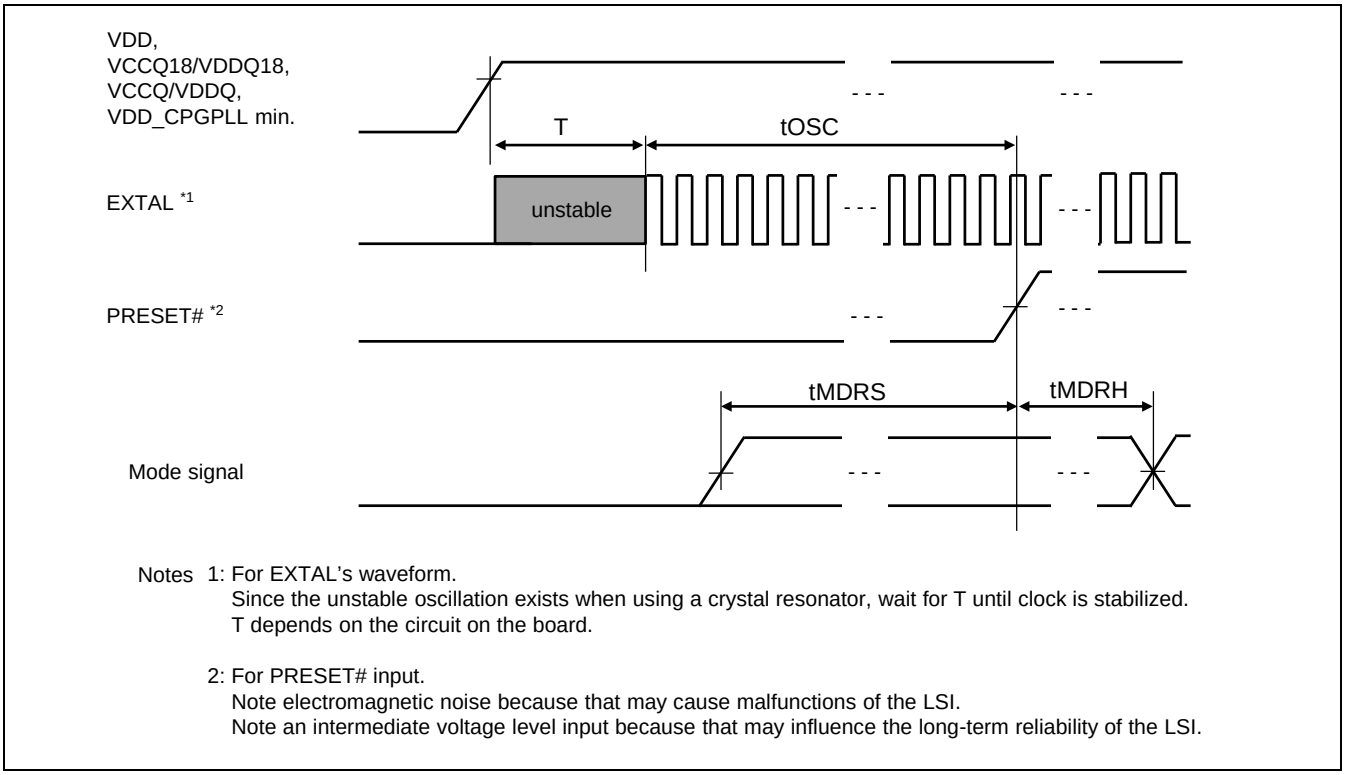
RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

Table 73.5.1 Clock and Reset Timing

Conditions: VDDQ33 = 3.3 V ± 0.2 V [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N] / ± 0.3 V [RZ/G2E],
VDDQ18 = 1.8 V ± 0.1 V, GND = VSS = 0 V,
Tc = -40 to +115 °C [RZ/G2H, RZ/G2M V1.3]
Ta = -40 to +85 °C [RZ/G2M V3.0, RZ/G2N, RZ/G2E],
Tj = -40 to +115 °C [RZ/G2M V3.0, RZ/G2N, RZ/G2E]

Pin	Item	Symbol	Min.	Max.	Unit	Figures
PRESET#, EXTAL	Power-on oscillation settling time (Period from power and EXTAL stable clock input to PRESET# rise.)	tOSC	5	—	ms	Figure 73.5.1
		T	0*2	*3	ms	
Mode signal*1	MD reset setup time	tMDRS	5	—	ms	
Mode signal*1	MD reset hold time	tMDRH	3	—	ns	

Notes: 1. MDn (n = 0, 1, 2 ...) and MDT [1:0]. For details of mode signals, refer to section 3, 4, 5 and.6, Mode Pin Settings.
2: Using 0 stabilization time requires an external clock. For mode setting refer to Table 11.3 MD9 Settings.
3: The oscillation stabilization time differs according the matching with the external resonator circuit. It is recommended to determine the oscillation stabilization time by a crystal resonator matching test. For details of the stabilization time “T”, please contact the crystal manufacture.



Notes 1: For EXTAL’s waveform.
Since the unstable oscillation exists when using a crystal resonator, wait for T until clock is stabilized.
T depends on the circuit on the board.

2: For PRESET# input.
Note electromagnetic noise because that may cause malfunctions of the LSI.
Note an intermediate voltage level input because that may influence the long-term reliability of the LSI.

Input clock rise time	tSCKr	—	—	0.8	tCYC	
Input clock fall time	tSCKf	—	—	0.8	tCYC	

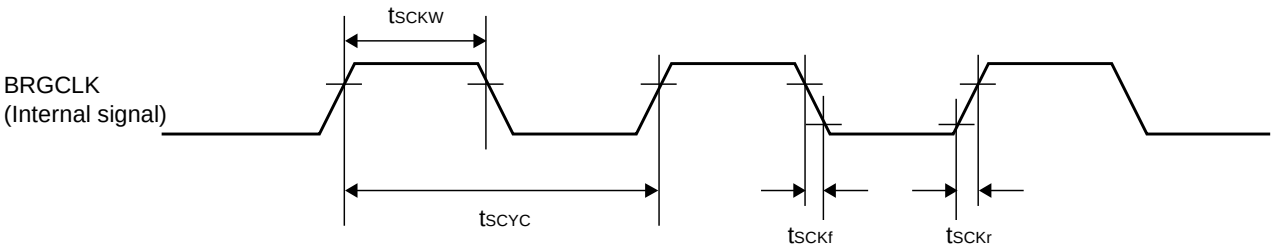
Note: RZ/G2H, RZ/G2M V1.3,RZ/G2M V3.0, RZ/G2N: tCYC is for one cycle of the S3D1ϕ clock.
RZ/G2E: tCYC is for one cycle of the S3D1Cϕ clock.



Note: The output signal (BRGCLK) of the external baud rate generator (BRG) is an HSCIF internal signal.
Set the input signal and the DL and CKS registers of the BRG so that the BRGCLK signal can satisfy the above specification.

Notes. 1. All values are referenced at VDDQ*4 × 0.3 and VDDQ*4 × 0.7 levels.

2. To satisfy the I2C-bus specification, pull-up resistors (Rp) with the appropriate resistance must be included depending on the total of bus capacitive load of each line.
   Pull-up resistor range should be following, refer Table 73.21.2.
   Rp(max) = tr /(0.8473*Cb)
   Rp(min) = (VDDQ*4-VOL(max))/IOL
3. The total capacity (Cb) should be less than or equal to 100 pF.
4. VDDQ means VDDQ33 or VDDQ18

73.27 Serial ATA (Gen3)

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

The description in this section is compliant with the following Serial ATA standard: 'Serial ATA International Organization: Serial ATA Revision 3.2, August 7, 2013'.

Table 73.27.1 Serial ATA (Gen3) Interface Characteristics [RZ/G2H, RZ/G2N]

Conditions: VDD33_SATA = VDD33_PCIE = 3.3 ± 0.3 V, VDD09_SATA = VDD09_PCIE = 0.82 -0.07 V / + 0.06 V, GND = 0 V, Tc = -40 to +115 °C [RZ/G2H], Ta = -40 to +85 °C [RZ/G2N], Tj = -40 to +115 °C [RZ/G2N]

Test Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
RX Differential Input Voltage (Gen1i)	Vdiff RX	325	—	600	mVppd	*1
RX Differential Input Voltage (Gen2i)	Vdiff RX	275	—	750	mVppd	*1
RX Differential Input Voltage (Gen3i)	Vdiff RX	200	—	900	mVppd	*1
TX Differential Output Voltage (Gen1i)	Vdiff TX	400	—	600	mVppd	*2
TX Differential Output Voltage (Gen2i)	Vdiff TX	400	—	700	mVppd	*2
TX Differential Output Voltage (Gen3i)	Vdiff TX	240	—	1000	mVppd	*2
DC Coupled Common Mode Voltage (Gen1i)	Vcm dc	200	—	450	mV	*2
Unit Interval (Gen1i)	TUI	666.4333	666.6667	670.2333	ps	*3
Unit Interval (Gen2i)	TUI	333.2167	333.3333	335.1167	ps	*3
Unit Interval (Gen3i)	TUI	166.6083	166.6667	167.5583	ps	*3
COMRESET Transmit Gap Length (Gen1i and Gen2i and Gen3i)	TScomreset	—	480	—	UIOOB	*4
COMWAKE Transmit Gap Length (Gen1i and Gen2i and Gen3i)	TScomwake	—	160	—	UIOOB	*4
TX Differential Impedance (Gen1i)	ZdiffTX	85	—	115	Ω	*2
TX Single-Ended Impedance (Gen1i)	Zs-eTX	40	—	—	Ω	*2
RX Differential Impedance (Gen1i)	ZdiffRX	85	—	115	Ω	*1
RX Single-Ended Impedance (Gen1i)	Zs-eRX	40	—	—	Ω	*1

Notes: 1. RXP, RXN: DC test
2. TXP, TXN: DC test
3. Need Reference Clock (Low Voltage Swing, Differential Clocks). The nominal single-ended swing for each clock is 0 to 0.7 V and a nominal frequency of 100 MHz ± 100 PPM.
4 TXP, TXN: UIOOB (UI During OOB Signaling) = 646.67 to 686.67 ps, Not tested.

Table 73.27.2 Serial ATA (Gen3) External Clock Accuracy

Conditions: VDD09_PCIE = 0.82 V – 0.07 V / + 0.06 V, GND = 0 V, Tc = −40 to +115 °C [RZ/G2H], Ta = -40 to +85 °C [RZ/G2N], Tj = -40 to +115 °C [RZ/G2N]

Test Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
External clock accuracy (PCIE1_CLK_P, PCIE1_CLK_M)	—	—	100.000	—	MHz	Frequency accuracy: ±100 ppm or less

73.28 USB Signal Timing

RZ/G2H RZ/G2M V1.3 RZ/G2M V3.0 RZ/G2N RZ/G2E

The descriptions in this section are compliant with the following USB 2.0 standards: "Universal Serial Bus Specification Revision 2.0" and "On-The-Go and Embedded Host Supplement to the USB Revision 2.0 Specification".

Table 73.28.1 USB High-speed Signal Timing

Conditions: VDDQ33 = VDDQ33_USB2* = 3.3 ± 0.2 V, VDDQ18 = 1.8 ± 0.1 V, VDD09_USB2* = 0.82 – 0.07 V / + 0.06 V [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N], VDDQ33 = VDDQ33_USB2* = 3.3 ± 0.3 V, VDDQ18 = VDDQ18_USB20 = 1.8 ± 0.1 V [RZ/G2E], VSS = 0 V,
Tc = −40 to +115 °C [RZ/G2H, RZ/G2M V1.3],
Ta = -40 to +85 °C [RZ/G2M V3.0, RZ/G2N, RZ/G2E],
Tj = -40 to +115 °C [RZ/G2M V3.0, RZ/G2N, RZ/G2E]

Item	Symbol	Min.	Typ.	Max.	Unit	Figure
High-speed data rate	THSDRAT	479.76	480	480.24	Mb/s	—

Table 73.28.2 USB Low-/full-speed Signal Timing

Conditions: VDDQ33 = VDDQ33_USB2* = 3.3 ± 0.2 V, VDDQ18 = 1.8 ± 0.1 V, VDD09_USB2* = 0.82 - 0.07 V / + 0.06 V [RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0, RZ/G2N],
VDDQ33 = VDDQ33_USB2* = 3.3 ± 0.3 V, VDDQ18 = VDDQ18_USB20 = 1.8 ± 0.1 V [RZ/G2E],
VSS = 0 V,
Tc = −40 to +115 °C [RZ/G2H, RZ/G2M V1.3],
Ta = -40 to +85 °C [RZ/G2M V3.0, RZ/G2N, RZ/G2E],
Tj = -40 to +115 °C [RZ/G2M V3.0, RZ/G2N, RZ/G2E], CL = 50 pF

Item		Symbol	Min.	Typ.	Max.	Unit	Figure
Low-speed*	Rise time	tR	75	—	300	ns	Figure 73.28.1
	Fall time	tF	75	—	300	ns	
	Differential Rise and Fall Time Matching (tR/tF)	tRFM1	80	—	125	%	
Full-speed	Rise time	tR	4	—	20	ns	
	Fall time	tF	4	—	20	ns	
	Differential Rise and Fall Time Matching (tR/tF)	tRFM	90	—	111.11	%	

Note: * The USB 2.0 Function module does not support Low-speed.

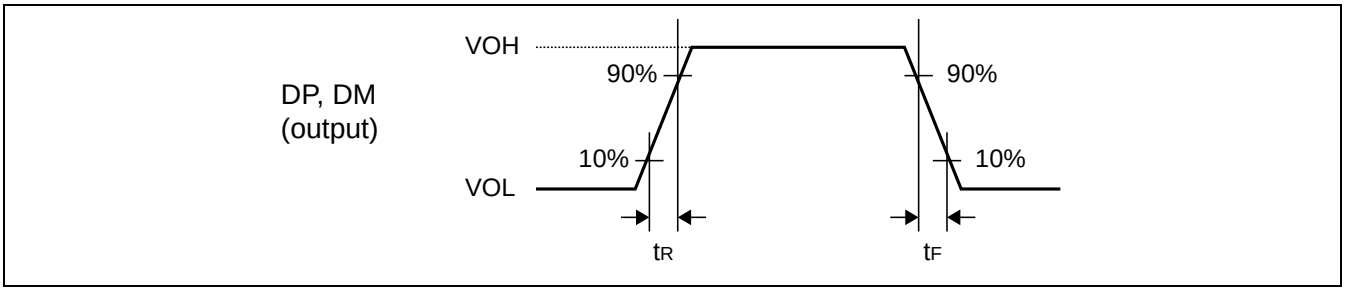

Figure 73.28.1 USB Low-/full-speed Signal Timing

Table 73.28.3 USB 2.0 External Clock Accuracy

Conditions: VDDQ18 = 1.8 V ± 0.1V,
VSS = 0 V,
Tc = −40 to +115°C [RZ/G2H, RZ/G2M V1.3], Ta = -40 to +85 °C [RZ/G2M V3.0, RZ/G2N, RZ/G2E],
Tj = -40 to +115 °C [RZ/G2M V3.0, RZ/G2N, RZ/G2E]

Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
External clock accuracy (USB_XTAL, USB_EXTAL)	—	—	50.000	—	MHz	Frequency deviation: ±100 ppm or less

Note: USB2.0 External Clock is not supported RZ/G2E.

73.29 USB 3.0 (Super-Speed)

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

The description in this section is compliant with the following USB 3.0 standard: 'Universal Serial Bus 3.0 Specification Revision 1.0, Jun 6, 2011'.

Table 73.29.1 USB 3.0 (Super-Speed 5 GT/s) Interface Characteristics

Conditions: VDDQ33_USB3* = 3.3 ± 0.3 V, VDD09_USB3* = 0.82 V – 0.07 V / + 0.06 V,
VSS = 0 V, Tc = −40 to +115 °C [RZ/G2H, RZ/G2M V1.3], Ta = -40 to +85 °C [RZ/G2M V3.0, RZ/G2N],
Tj = -40 to +115 °C [RZ/G2M V3.0, RZ/G2N]
VDDQ18_USB30 = 1.8 ± 0.1 V, VDDD_USB30 = 1.03 ± 0.05 V
Ta = −40 to +85 °C , Tj = −40 to + 115 °C [RZ/G2E]

Test Item	Symbol	Min.	Typ.	Max.	Unit	Remarks

Appendix B. Sequence of Activation for the RZ/G series, 2nd generation products

RZ/G2H
RZ/G2M V1.3 RZ/G2M V3.0
RZ/G2N RZ/G2E

The following describes the initialization sequence of a second generation RZ/G series product.

(1) Selection of Master Boot Processor and External Boot Device

Select the master boot processor by placing the required levels on the MD6 and MD7 pins and external boot device by placing the required levels on the MD1, MD2, MD3 and MD4 pins before booting up the LSI. For details, see section 24, Booting.

Note: The following steps from (2) to (6) are not included in the sequence described in section 24, Booting because these steps are not relevant to booting. Note, however, that steps (2) to (6) must be executed before restoring the power supply to modules, including CPUs other than the master boot processor, to which the power has been cut off.

(2) Stopping the RWDT and SWDT

To prevent the watchdog timer issuing an unexpected reset or interrupt while the activation sequence is in progress, be sure to disable the RCLK watchdog timer (RWDT) and System watchdog timer (SWDT). Enable their operation at an appropriate time after the activation sequence is completed. For details, see section 17, Reset (RST), section 18, Interrupt Controller (INTC), section 64, RCLK Watchdog Timer (RWDT), and section 65, SystemWatchDog Timer (SWDT).

Notes: Use the RWTCSRA register to disable the RWDT. Since the detailed specifications of the SWDT are not disclosed in this manual, contact us to inquire about the details or use the sample driver included in the board support package (BSP).

Currently, the reset and interrupt signals caused by the watchdog timer overflowing are initially masked in second generation RZ/G series products. Accordingly, this step of disabling the watchdog timers within the activation sequence is not mandatory.

(3) Selecting the Functions of Multiplexed Pins

When a pin function other than that selected by the initial setting is to be used, set the relevant registers in the pin function controller (PFC). Note that, before setting these registers, the LSI multiplexed pin setting register (PMMR) must be appropriately set to prevent incorrect writing to registers. For details, see section 6, Pin Function Controller (PFC).

Note: When a GPIO function different from that selected by the initial setting is to be used, start by setting the GPIO attributes before setting the pin function controller.

(4) Initial Settings for Operating Frequency Required by the Main Processor, Cache, MMU, and Interrupt Controller

Make initial settings for operating frequency required by the master processor, cache, MMU, and interrupt control. The operating frequencies are set by using the registers FRQCRC (for Cortex-A57 and Cortex-A53) and PLL0CR. The details of the functional specifications for the CPU required for setting the cache, MMU, and interrupt control are not included in this manual.

Notes: Cortex-A57 is supported only for RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0 and RZ/G2N.
Cortex-A53 is not supported for RZ/G2N.

(5) Initial Settings for Local Bus Control

When an external device is to be connected to the local bus (bits MD[4:1] are set to 0000), make initial settings for the registers including CSWCRn as required before starting access to the external device. For details, see section 25, External Bus Controller for EX-Bus (LBSC).

(6) Initial Settings for Memory Controllers

When a program is to be stored in and run from SDRAM, make initial settings for the required registers in the DBSC4. For activation sequence, see section 26, External Bus Controller for LPDDR4/ DDR3L SDRAM (DBSC4).

Note: Each product has different initial setting. Renesas is preparing the document of each product.

(7) Settings for Restoring Power Supply to Functional Modules to be Used Immediately after Activation (Other than Cortex-A57 and Cortex-A53)

In the initial state, power may not be supplied to some modules to be used. Accordingly, for modules to be used immediately after activation, set the control registers in the system controller (SYSC) as required and read the status registers to check that the power supply has been restored. For details on the sequence for restoring the power supply, see section 14, System Controller (SYSC).

(8) Settings for Release from the Module Reset State and the Supply of Clock Signals to Functional Modules to be Used Immediately after Activation (Other than CPUs)

Depends on module, in the initial state, clock signals may not be being supplied to all modules to be used. Accordingly, for modules to be used immediately after activation, set the xxxCKCR registers (xxx represents a module name) for the respective modules in the clock pulse generator (CPG) or set the RMSTPCRn/SMSTPCRn registers (n = 0 to 11) in the module standby and software reset control block of the CPG. For details, see section 11, Clock Pulse Generator (CPG) and section 12, Module Standby and Software Reset.

Notes: The settings for modules other than those to be used immediately after activation can be made separately before the modules are used.

All registers in CPG are protected from unexpected write operation, refer to section 11.2.1.

(9) Setting of Boot Address of the CPU (as Required)

To switch the boot address to an area in the DDR memory to which high-speed access is possible, start by downloading the required program to the specified area and set the starting address for execution in the boot address register for the relevant CPU. This setting is not required if the boot address is not to be changed. For details, see section 17, Reset (RST).

(10) Restoring the Power Supply to a CPU Other than the Master Boot Device

Before using a CPU (Cortex-A57 or Cortex-A53) other than the master boot processor, start by checking the PRR register described in Appendix A to confirm which CPU is available for use. If activation of a CPU disabled by the PRR register is attempted, the clock pulse generator may not operate properly.*[1]

To use a CPU (Cortex-A57 or Cortex-A53) other than the master boot processor, set the Cortex-A53/Cortex-A57 debug resource reset control register (CA53DBGRCR/CA57DBGRCR) in the APMU module*[2] and set the relevant control register in the same module to restore the power supply. Then, read the status registers in the APMU and SYSC modules to check whether the power supply has actually been restored. This procedure must be followed for each CPU until restoration of the power supply is confirmed. For details, see section 13, Advanced Power Management Unit for AP-System Core (APMU), and section 14, System Controller (SYSC).*[2]

Notes: 1. This step can be skipped if you already know which CPU is available for use.
2. Cortex-A57 is supported only for , RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0 and RZ/G2N.
Cortex-A53 is not supported for RZ/G2N.

(11) Releasing CPUs Other than the Master Boot Processor from the Reset State

When a CPU (Cortex-A57 or Cortex-A53) other than the master boot processor is to be used, clear the relevant bit in the Cortex-A57 or Cortex-A53 reset control register (CA57RESCNT/CA53RESCNT) to 0 to release it from the reset state. To reduce fluctuations in current, release the CPUs from the reset state one at a time.

This is the end of the required initial settings and all the CPUs to be used will have been activated.

Notes: The settings in some steps of this sequence might be re-made by the OS.
Cortex-A57 is supported only for RZ/G2H, RZ/G2M V1.3, RZ/G2M V3.0 and RZ/G2N.
Cortex-A53 is not supported for RZ/G2N.

Main Revisions and Additions in this Edition	RZ/G Series, 2nd Generation User's Manual: Hardware

Rev.	Date	Description	
		Page	Summary
1.00	Mar. 20, 2020	—	First Edition issued
1.01	Jan. 29, 2021	24-13, 24-14	Figure 24.5 eMMC using DMA boot sequence, Case of booting operation goes to NG, SCIF download mode will be started. Figure notes from 4) to 6) are removed, and note 3) is changed to be matching with the flow of revised Figure 24.5.
		29-101 ~105	Changed figure number
		33-2	Changed section number written in Notes no1
