

### FEATURES:

- 4 PLL architecture
- Linear frequency programming
- Independent frequency programming and SSC control
- Band-gap circuit for differential output
- High power-noise rejection ratio
- 66MHz to 533MHz CPU frequency
- VCO frequency up to 1.1G
- Support index block read/write, single cycle index block read
- Programmable REF, 3V66, PCI, 48MHz I/O drive strength
- Programmable 3V66 and PCI Skew
- Available in SSOP package

### DESCRIPTION:

IDTCV105E is a 48 pin clock generation device for desktop PC platforms. This chip incorporates four PLLs to allow independent generation of CPU, AGP/PCI, SRC, and 48MHz clocks. The dedicated PLL for Serial ATA clock provides high accuracy frequency. This device also implements Band-gap referenced IREF to reduce the impact of VDD variation on differential outputs, which can provide more robust system performance.

Static PLL frequency divide error can be as low as 36 ppm, providing high accuracy output clock. Each CPU, AGP/PCI, SRC clock has its own Spread Spectrum selection.

### KEY SPECIFICATION:

- CPU/SRC CLK cycle to cycle jitter < 125ps
- SATA CLK cycle to cycle jitter < 125ps
- PCI CLK cycle to cycle jitter < 250ps
- Static PLL frequency divide error as low as 36 ppm

### NOTE:

- Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

## SW FREQUENCY SELECTION

BS[2:0] and WBS[2:0] are band selects. Whenever there is a band switch, the user has to issue a WD soft alarm (see Byte 32 and Byte 33).

In CPU N/M programming, CPU frequency = N \* resolution.

#### NOTE:

1. Bit [21:27] = byte count.  
Bit 20 = 1, bit [21:27] will be stored into SMBus table, Byte 8. SMBus Byte 8 is read byte count register, power on default is 0FH.  
Bit 20 = 0, normal SM bus operation.

### BYTE WRITE METHODS:

- Setting bit[11:18] = starting address, bit [20:27] = 01H.

### BYTE READ METHODS (CHOOSE ONE):

- Use IDT OneCycle Index Block Read, bit[20:27] = 10000001.  
Notice that byte count register (byte 8) will be changed to 01H.
- Use Index Block Write protocol to change byte count (byte 8) to 1. After that, use Index Block Read.

### TO CHANGE BYTE 8 VALUE:

- Use IDT OneCycle Index Block Read, as above
- Use Index Block Write protocol to change byte 8 value.

## CPU AND AGP CLOCK FREQUENCY SELECTION

Band switch will take effect only when WD Soft Alarm time out is issued, which means there is a RESET issued. Even if the user changed BS[2:0], if there is no WD Soft Alarm, CPU PLL still uses the old band.

CPN[9:0] and APN[9:0] will be loaded into PLL only when CPN0 and APN0 are written respectively.

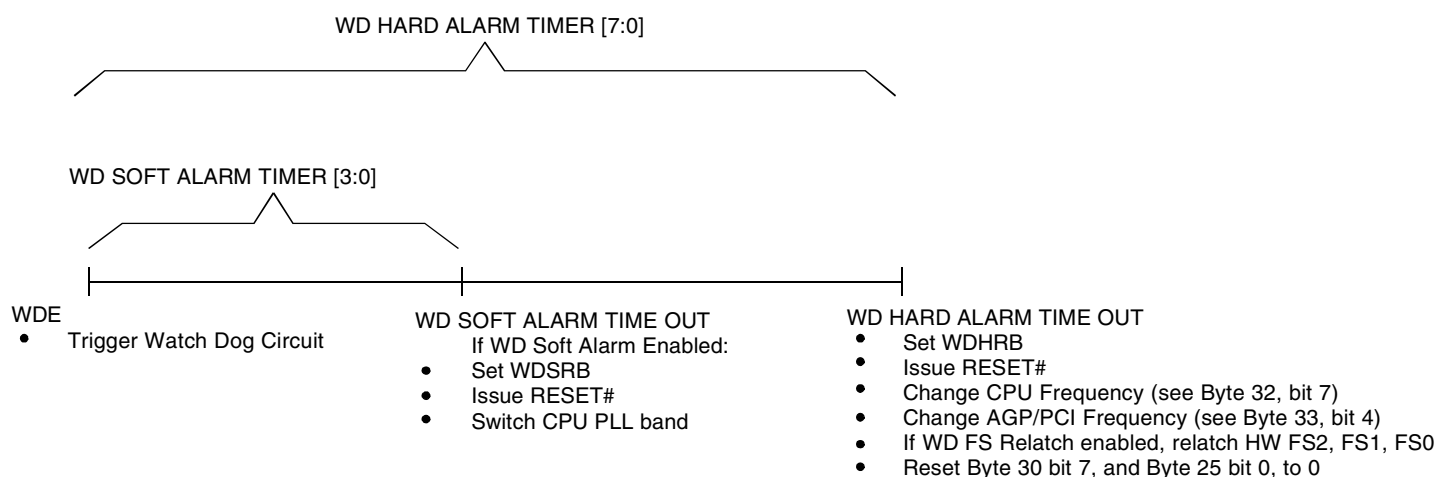

### CPU FREQUENCY

## WD SOFT AND HARD ALARM/TIME OUT OPERATION

User only uses WD Soft Alarm when there is a band switch. It can be from HW to SW select, or in the SW select with band change. Soft Alarm Timer has to be shorter than Hard Alarm Timer.

At the event of WD Hard Alarm time out, CPU Safe return frequency is decided by two bits: Byte 32 bit 7 and Byte 25 bit 7. AGP/PCI Safe Return Frequency is decided by Byte 33 bit 4 and Byte 30 bit 6. Byte 30 bit 7, and Byte 25 bit 0, will be reset to 0.

Byte 32 bit 7, Byte 25 bit 7	CPU WD Hard Alarm Time Out Frequency Select:

## PD#, POWER DOWN

PD# is an asynchronous active low input used to shut off all clocks cleanly prior to clock power. When PD# is asserted low all clocks will be driven low before turning off the VCO. In PD# de-assertion all clocks will start without glitches.

PWRDWN#	CPU	CPU#	SRC	SRC#	PCIF/PCI	USB	3V66	REF
1	Normal	Normal	Normal	Normal	33MHz	48MHz	66MHz	14.318MHz
0	I <sub>REF</sub> * 2 or float	Float	I <sub>REF</sub> * 2 or float	Float	Low	Low	Low	Low

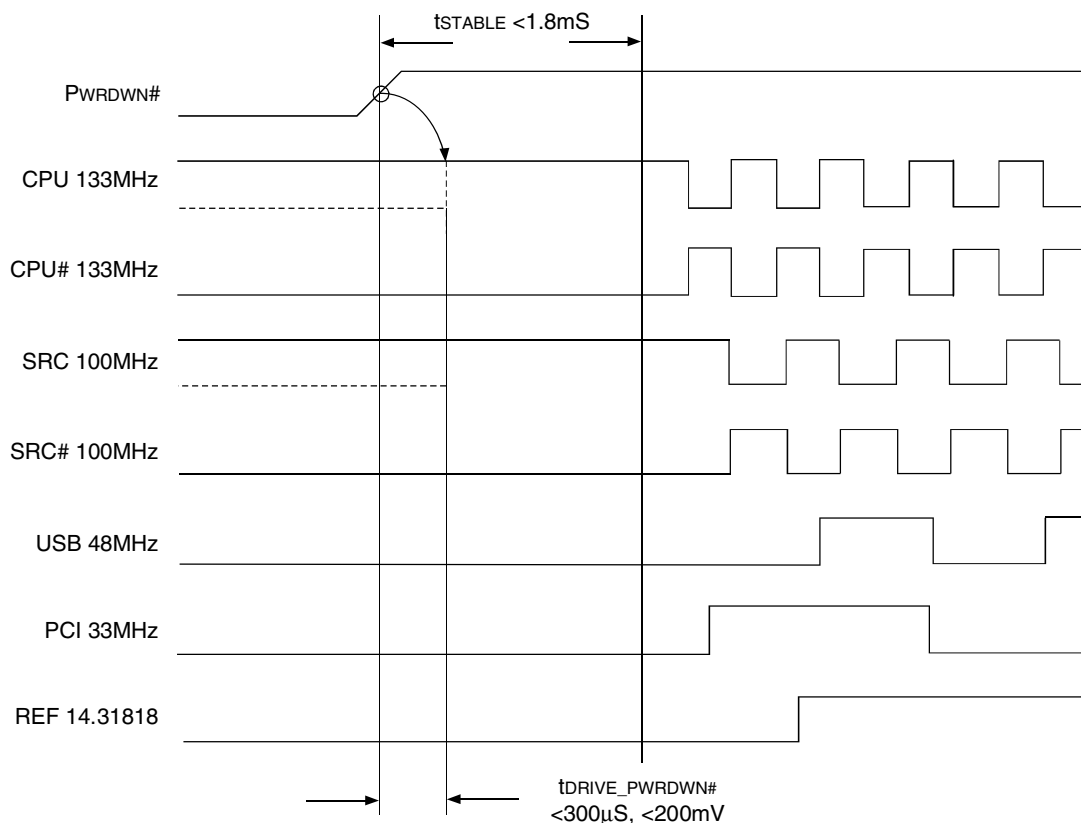

## PD# ASSERTION

PD# should be sampled low by two consecutive CPU# rising edges before stopping clocks. All single-ended clocks will be held low on their next high to low transition. All differential clocks will be held high on the next high to low transition of the complimentary clock. If the control register determining to drive mode is set to 'tri-state', the differential pair will be stopped in tri-state mode, undriven. When the drive mode but corresponding to the CPU or SRC clock of interest is set to '0' the true clock will be driven high at 2 x I<sub>REF</sub> and the complementary clock will be tristated. If the control register is programmed to '1' both clocks will be tristated.

## PD# DE-ASSERTION

The time from the de-assertion of PD# or until power supply ramps to get stable clocks will be less than 1.8ms. If the drive mode control bit for PD# tristate is programmed to '1' the stopped differential pair must first be driven high to a minimum of 200mV in less than 300µs of PD# deassertion.

## N PROGRAMMING JITTER MEASUREMENT

Tested on IDT test board, 10" trace, 10pF loading.

Measured at CPU0, differential active probe.

Data showed may vary due to CMOS process.
