

# ISL94216A

## 16-Cell Battery Front End

The [ISL94216A](#) is a 16-cell Battery Front End (BFE) IC, an essential component of any Battery Management System (BMS), which periodically scans battery status and the operating environment to optimize battery life and prevent catastrophic failures.

A differential multiplexer and 16-bit ADC allows for accurate monitoring of cell voltage, temperature, and load current for management of the overall state of the battery pack.

The ISL94216A supports I<sup>2</sup>C, SPI, and the Single Wire Protocol (SWP) allowing customers to connect an MCU in a proprietary battery management solution.

Low current consumption with an average IDLE mode current of 200μA and a SHIP mode current of less than 18μA maximizes the storage and discharge life of a battery pack.

The ISL94216A features internal cell balancing circuitry that provides 8mA of balance current per cell. External cell balancing for higher currents is also supported.

This 16-cell high voltage BFE IC is offered in an efficient 64 Ld QFN package with a thermal pad.

## Features

- High hot plug rating: 62V
- V<sub>CELL</sub> accuracy: ±5mV
- I<sub>PACK</sub> accuracy: ±0.2%
- 16-bit V<sub>CELL</sub> and I<sub>PACK</sub> measurements
- Charge/Load wakeup detection circuitry
- 4-pin GPIO port
- Integrated 3.3V regulator
- Supports I<sup>2</sup>C, SPI, and SWP communications

## Applications

- Light electric vehicles such as e-bikes, e-scooters, and e-motorcycles
- Cordless power and gardening tools
- Home appliances
- 24V, 36V, 42V, and 48V portable battery packs
- Telecom and server farms
- Solar farms
- Energy storage systems

# 1. Overview

## 1.1 Typical Application

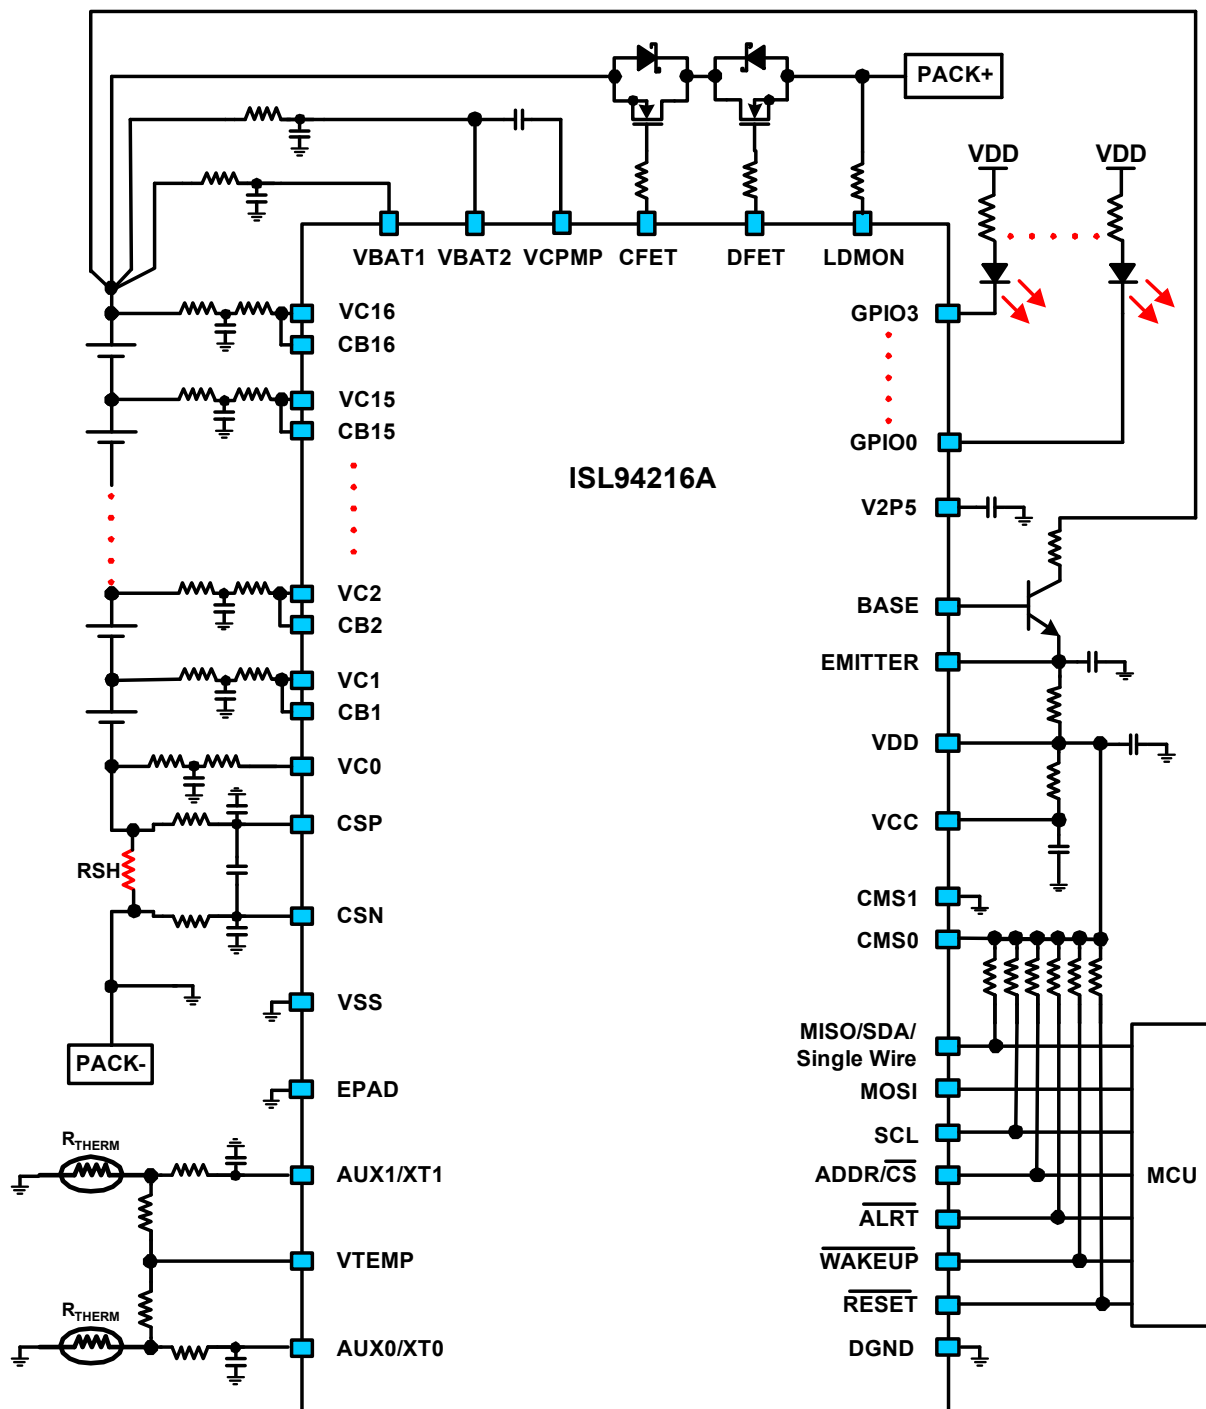

Figure 1. Typical Application

## 1.2 Block Diagram

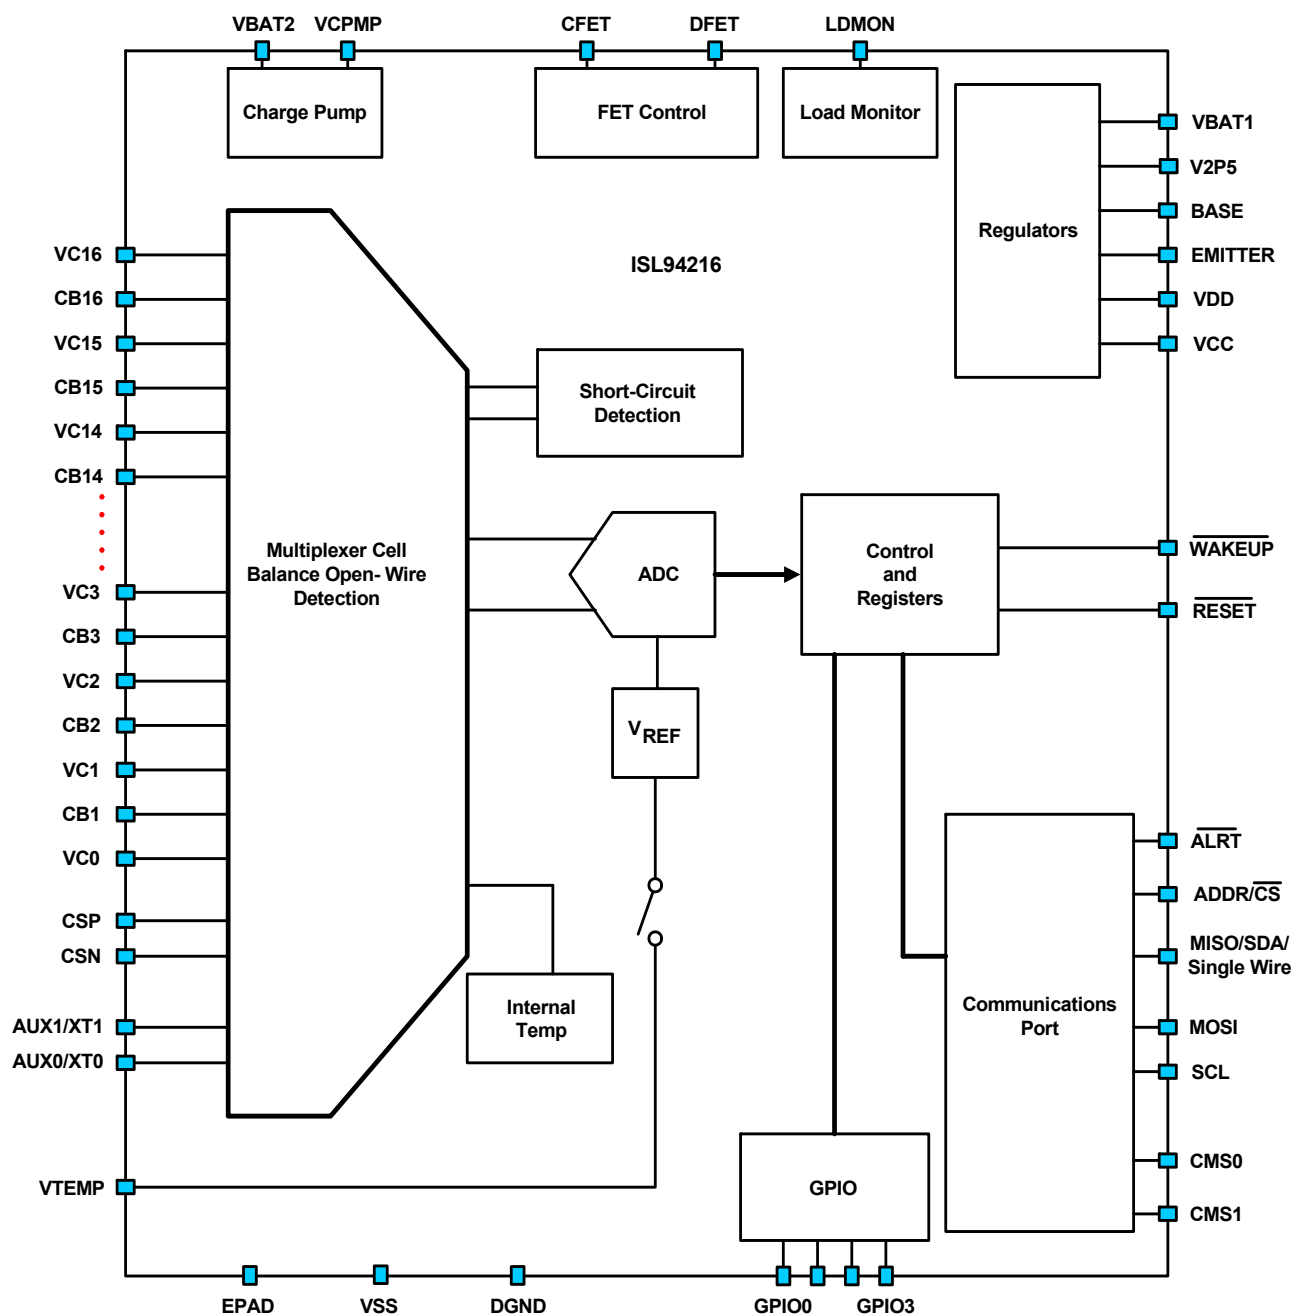

Figure 2. Block Diagram

## 2. Pin Information

### 2.1 Pin Assignments

### 2.2 Pin Descriptions

Table 1. Pin Descriptions

Pin Number	Pin Name	Description
1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 55, 57, 59, 61, 63	VCn (n = 0 to 16)	Battery cell voltage inputs. In an application with a 16-cell battery string, in which cell number 1 connects to the lowest voltage and cell number 16 connects to the highest voltage, VCn connects to the positive terminal of cell n and to the negative terminal of cell n+1 through external resistors (VC16 connects only to the positive terminal of Cell 16, VC0 only connects to the negative terminal of Cell 1). For applications with fewer than 16 cells, see <a href="#">Figure 130</a> .
2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 56, 58, 60, 62, 64	CBn (n = 1 to 16)	Cell balancing pins. When external cell balancing FETs are used, each of these pins controls an external FET. When internal cell balancing FETs are used, these pins connect to the drains of the on-chip cell balancing transistors. See <a href="#">Cell Balancing Registers on page 76</a> .

Table 1. Pin Descriptions (Cont.)

Pin Number	Pin Name	Description
24	CSP	Current sense positive input.
25	CSN	Current sense negative input.
26	VSS	Analog ground. Connect to the EPAD (electrical/thermal pad under the package).
27	AUX0/xT0	External temperature monitor or general purpose inputs. These inputs are intended for use with external resistor networks using NTC type thermistor sense elements, but can also be used as general purpose analog inputs at the user's discretion.
29	AUX1/xT1	
28	VTEMP	Reference voltage for off-chip temperature monitoring circuit. This is a switched output that supplies a reference voltage to external circuits that include thermistors. It is enabled before starting a measurement of pins AUX0/xT0, AUX1/xT1, or VTEMP itself. It is disconnected from the pin after the measurement completes.
30	VCC	3.3V analog supply voltage input. Connect to VDD using a 10Ω resistor and connect a 1μF capacitor between this pin and VSS.
31	VDD	3.3V digital supply voltage input. Connect directly or through a current sense resistor to the emitter of the external NPN transistor, connect through a 10Ω resistor to VCC. Connect a 1μF capacitor between this pin and DGND.
32	EMITTER	Regulator source current is calculated from the measured voltage between VDD and EMITTER pins. Connect this pin to the Emitter of the external NPN. Connect a regulator current sense resistor between the EMITTER and VDD pins. Connect a 1μF capacitor between this pin and DGND.
33	BASE	Regulator control pin. Connect to the external NPN transistor's base. Do not float.
34	CMS0	Communication protocol selection. Static input pins; do not change after power-up. See <a href="#">Table 76 on page 124</a> .
35	CMS1	
36	DGND	Digital ground.
37	V2P5	Internal 2.5V digital supply decoupling pin. Connect a 1μF capacitor between V2P5 and DGND.
38	$\overline{\text{RESET}}$	Active low reset digital input. Connect to a logic HIGH to enable the device. Connect to a logic LOW to reset the device to its Power-On Reset (POR) default state.
39	$\overline{\text{WAKEUP}}$	Active low wakeup digital input. Connect to a logic LOW voltage level to wake up the device and transition from SHIP or LOW POWER mode to IDLE mode.
40	$\overline{\text{ALRT}}$	Open-drain, active low alert output. It is asserted under a variety of conditions to interrupt a microcontroller. See <a href="#">System Faults and Status on page 82</a> .
41	ADDR/ $\overline{\text{CS}}$	Chip Select input for SPI communication interface or address selection pin for I <sup>2</sup> C communications interface.
42	SCL	Serial clock input pin for both SPI and I <sup>2</sup> C communications interfaces.
43	MOSI	Master Output Slave Input for SPI communication interface.
44	MISO/SDA/ SINGLE-WIRE	Master Input Slave Output for SPI communication interface, or open-drain serial data I/O for I <sup>2</sup> C and Single Wire communication interfaces.
45	GPIO0	General purpose digital I/Os. Open drain when used as outputs. They can be used as general purpose inputs or outputs, as status LED drivers, or as part of FET driving circuits. See <a href="#">0x12 ALRT and GPIO on page 60</a> .
46	GPIO1	
47	GPIO2	
48	GPIO3	

Table 1. Pin Descriptions (Cont.)

Pin Number	Pin Name	Description
49	LDMON	Load monitor input. This analog voltage monitor determines whether a normal load, short, or no load is connected to the battery pack. This pin is internally connected to the DFET pin when the DFET is off.
50	DFET	Drives the gate of an external NMOS that controls the current path between the battery pack and the load. This pin is internally connected to the LDMON pin when the DFET is off.
51	CFET	Drives the gate of an external NMOS that controls the current path between the battery pack and the charger. This pin is internally connected to the VBAT2 pin when the CFET is off.
52	VCPMP	Charge pump output voltage. Place a capacitor between VCPMP and VBAT2. The charge pump provides power to FET drivers and part of the cell balancing circuits.
53	VBAT2	Power supply pin. Connect to the most positive terminal of the battery pack through dedicated filter. This pin is internally connected to the CFET pin when the CFET is off.
54	VBAT1	Power supply pin. Connect to the most positive terminal of the battery pack through dedicated filter.
Bottom	EPAD	Analog ground. Metal pad under the package. Connect to the VSS pin and ground plane for thermal dissipation.

### 3. Specifications

#### 3.1 Absolute Maximum Ratings

**CAUTION:** Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions can adversely impact product reliability and result in failures not covered by warranty.

Parameter <sup>[1]</sup>	Minimum	Maximum	Unit
DGND	-0.5	+0.5	V
CSP, CSN, VC0	-1.0	+1.0	V
VBAT1, VBAT2, VCPMP	-0.5	+70	V
VCn (n = 13 to 16)	-0.5	+70	V
VCn (n = 9 to 12)	-0.5	+63	V
VCn (n = 6 to 8)	-0.5	+54	V
VCn (n = 2 to 5)	-0.5	+45	V
VC1	-0.5	+9	V
CBn (n = 13 to 16)	-0.5	+70	V
CBn (n = 9 to 12)	-0.5	+63	V
CBn (n = 6 to 8)	-0.5	+54	V
CBn (n = 2 to 5)	-0.5	+45	V
CB1	-1	+9	V
CBn [Internal Cell Balancing Current when active] <sup>[2]</sup>		±20	mA
CFET, DFET, V <sub>CPMP</sub> , LDMON <sup>[2]</sup>	-0.5	+70	V
CFET	V <sub>BAT2</sub> - 0.5	V <sub>BAT2</sub> + 12	V
DFET	LDMON - 0.5	V <sub>BAT2</sub> + 12	V
VCPMP	V <sub>BAT2</sub> - 1.0	V <sub>BAT2</sub> + 12	V
V2P5 <sup>[2]</sup>	-0.5	+2.9	V
BASE, EMITTER, VCC, VDD, VTEMP, Aux0/xT0, Aux1/xT1 <sup>[2]</sup>	-0.5	+6	V
SCL, S-WIRE/MISO/SDA, MOSI, ADDR/ $\overline{\text{CS}}$ , GPIOx, CMS0, CMS1, $\overline{\text{ALRT}}$ , $\overline{\text{RESET}}$ , WAKEUP <sup>[3]</sup>	DGND - 0.5	DGND + 6	V
SDA/Single Wire, $\overline{\text{ALRT}}$ , GPIOx Pull-Down Current <sup>[3]</sup>		10	mA
ESD Rating	Value		Unit
Human Body Model (Tested per JS-001-2014)	1.5		kV
Charged Device Model (Tested per JS-002-2014)	750		V
Latch-Up (Tested per JESD78E; Class 2, Level A)	100		mA

1. All voltages are specified with respect to VSS, unless otherwise noted.
2. V<sub>CPMP</sub>, CFET, DFET, CB[1:16], V2P5, VTEMP, and BASE pins are analog outputs and should not be driven from an external source. VCC and VDD can be driven only by the external NPN connected to the BASE and EMITTER pins.
3.  $\overline{\text{ALRT}}$ , GPIO0, GPIO2, GPIO3 (configure as an output) and MISO/SDA/SINGLE-WIRE (operating as an output) pins are digital outputs. These pins should not be driven from an external source.

### 3.2 Thermal Information

Thermal Resistance (Typical)	$\theta_{JA}$ (°C/W) <sup>[1]</sup>	$\theta_{JC}$ (°C/W) <sup>[2]</sup>
64 Ld QFN	24	1.1

1.  $\theta_{JA}$  is measured in free air with the component mounted on a high-effective thermal conductivity test board with direct attach features. See [TB379](#).
2. For  $\theta_{JC}$ , the case temperature location is the center of the exposed metal pad on the package underside.

Parameter	Minimum	Maximum	Unit
Maximum Continuous Power Dissipation		400	mW
Maximum Storage Temperature Range	-55	+125	°C
Maximum Junction Temperature ( $T_{JMAX}$ )		+125	°C
Pb-Free Reflow Profile	see <a href="#">TB493</a>		

### 3.3 Recommended Operation Conditions

Parameter	Minimum	Maximum	Unit
Ambient Temperature Range ( $T_A$ )	-40	+85	°C
Junction Temperature ( $T_J$ )	-40	+125	°C
$V_{BAT1}$ , $V_{BAT2}$	12	55	V
DFET, CFET, VCPMP	$V_{BAT2}$	66	V
CFET, DFET	$V_{BAT2}$	$V_{BAT2} + 11$	V
VCPMP	$V_{BAT2}$	$V_{BAT2} + 11$	V
LDMON	0	$V_{BAT2}$	V
$VC(n+1) - VC(n)$ ( $n = 0$ to 15)	2.2	4.7	V
$CB(n+1) - VC(n)$ ( $n = 0$ to 15)	0	6	V
VC0	-600	300	mV
$CB(n)$ ( $n = 1$ to 16) <sup>[2]</sup>	$VC_{(n-1)}$	$VC_{(n-1)} + 5$	V
CSN, DGND	-10	+10	mV
(CSP - CSN) [Current Measurement]	-600	+300	mV
VTEMP, AUX0/xT0, AUX1/xT1	0	1.22	V
EMITTER - $V_{DD}$	0	275	mV
SDA/Single Wire, $\overline{ALRT}$ , GPIOx Pull Down Current <sup>[3]</sup>		2.5	mA
GPIOx, $\overline{ALRT}$ , MOSI, MISO/SDA/SINGLE-WIRE, SCL, ADDR/ $\overline{CS}$ , CMS0, CMS1, $\overline{WAKEUP}$ , $\overline{RESET}$ <sup>[3]</sup>	0	$V_{DD}$	V

### 3.4 Electrical Specifications

Unless otherwise specified:  $T_A = +25^{\circ}\text{C}$ ,  $V_{\text{BAT1}} = V_{\text{BAT2}} = 48\text{V}$ ,  $(V_{\text{Cn}} - V_{\text{Cn-1}}) = 3\text{V}$ ,  $V_{\text{CC}} = V_{\text{DD}} = 3.3\text{V}$ , control registers at default,  $V_{\text{SS}} = \text{DGND} = 0\text{V}$ , cell balancing is off. Voltages are with respect to  $V_{\text{SS}}$ . External components are per [Pin Functionality on page 92](#).

Parameter	Symbol	Test Conditions	Min <sup>[1]</sup>	Typ	Max <sup>[1]</sup>	Unit
Power Supply (System Operation on page 103)						
V <sub>BAT</sub> Voltage Range	V <sub>BAT1</sub> , V <sub>BAT2</sub>	For V <sub>BAT1</sub> , V <sub>BAT2</sub>	12		55	V
Total Average Current Consumed at VBAT1, VBAT2, VDD, and VCC Pins	I <sub>total</sub>	IDLE Mode; Charge Pump On	250	330	380	μA
		IDLE Mode; Charge Pump Off	200	290	340	μA
		SCAN Mode; Charge Pump and FETs on, Current during VCell Scan	600	820	1000	μA
		SCAN Mode; Charge Pump and FETs off, Current during VCell Scan	540	760	940	μA
		LOW POWER Mode; Strong Reg on; LP REG = 1		39	200	μA
		LOW POWER Mode; Weak Reg on; LP REG = 0		10	50	μA
		SHIP Mode		5	18	μA
Cell Measurement (0x30 - 0x4F V <sub>CELL</sub> Voltage (R) on page 46)						
V <sub>CELL</sub> Measurement Error	V <sub>CELLME</sub>	0°C to +60°C; 3V to 4.5V, Register 0x02 = 0x9C, 14 cell configuration at 4.5V.	-10	±5	10	mV
V <sub>CELL</sub> Input Leakage Current		Not Scanning	-0.3		0.3	μA
I <sub>PACK</sub> Functional Block (0x52 - 0x53 I <sub>PACK</sub> Voltage (R) on page 47) <sup>[2]</sup>

1. Compliance to datasheet limits is assured by one or more of the following methods: production test, characterization, and design.  
Recommended external components are listed in [Pin Functionality on page 92](#).
2. Also see [CSP and CSN Pins \(24, 25\) on page 94](#) for typical circuit.
3. Drivers are open drain.  $V_{DD}$  is the power supply of the chip's digital IOs.
4. Pulse widths measured from the  $0.3 \times V_{CC}$  crossing during the falling edge to the  $0.7 \times V_{CC}$  crossing during the rising edge.
5. Timing selected to work with clock tolerances up to  $\pm 20\%$  at both the master and the slave.

## 4. Typical Performance Curves

## 5. System Registers

Each system register contains eight bits and is accessed using a 7-bit address plus an 8th bit that indicates a read or a write. For details about reading and writing registers, see [Communication Interface on page 124](#) and the register descriptions.

All system registers are listed in [Table 2](#). Each register listing includes the address, register name, and a page number for more details, as well as a depiction of the contents with bit names, value at power up or after the chip is reset (POR value), and the type of register follow (Read or Read/Write). The ISL94216A is configured for specific applications by a microcontroller accessing these registers.

The ISL94216A has a 16-bit ADC for voltage measurements. The outputs of many parameter readings use two 8-bit values to represent the digitized result. Register addresses of some readings are shown as two register values delimited with a comma. For example, 0x52, 53 are register addresses for the  $I_{PACK}$  voltage. Register 0x52 contains the MSB and register 0x53 contains the LSB. The 8-bit threshold registers are compared to the upper 8-bits of the 16-bit measurements.

The ranges and step-sizes listed for threshold and measurement registers are the ideal values to be used for calculation purposes. Threshold settings that would require operation outside of the recommended operating conditions are not supported. The usable measurement range is also limited by the recommended operating conditions and by non-idealities of the measurement channel. Measurement results registers may or may not reach the maximum or minimum for input voltages within the ideal voltage range listed.

Within some control registers are bits called Trigger bits that execute automatic sequences when set to 1. Triggered sequences are initiated by a 0 to 1 transition of a Trigger bit. See [Trigger Bits on page 123](#) for a detailed description of the use and limitations of Trigger bits.

Registers at addresses 0x83 through 0x89 contain Mask bits. Set Mask bits to 1 (default) to prevent the fault related to that bit from asserting the  $\overline{ALRT}$  pin low. A Mask bit must be set to 0 to allow the assertion of the  $\overline{ALRT}$  pin LOW when the fault related to that bit occurs.

Reserved bits (RSV) should be ignored when reading registers and set to 0 when writing to them.

## 5.1 IC Device Details

### 5.1.1 0x00 Product ID Register (R)

The 1-byte Product Identification register contains information about the die and is read only.

Table 3. 0x00 Product ID Register

Bits	D[7:4]	D[3:1]	D[0]
Bit Name	Part ID	Revision	RSV
Default	1111	XXX	X

#### 5.1.1.1 0x00.7:4 Part ID

The bit value of the Part ID represents the last two digits of the part ID minus one.

#### 5.1.1.2 0x00.3:1 Product Revision

The product revision is indicated by the value of this register.

## 5.2 Global IC Controls

### 5.2.1 0x01 Global Operation

The 1-byte Global Operation register includes controls and status of the overall state of the ISL94216A.

Table 4. 0x01 Operation Register

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	SFT RST	RST2IDLE	RCAL V <sub>OS</sub> Trigger	RCAL LPM	RCAL Scan	BUSY	Scan Sel	System Trigger
Default	0	0	0	0	0	0	0	0

#### 5.2.1.1 0x01.7 Soft Reset

Setting the Soft Reset bit of the Operation register to 1 resets all register values back to factory defaults, including data registers. All counters are set to 0, all timers and faults are cleared, and the System mode is set to IDLE. A low voltage offset calibration is performed, the power and cell balancing FETs are turned off, and the state machines are reset. This bit is cleared on completion.

#### 5.2.1.2 0x01.6 Reset to IDLE

When set to 1, the Reset to IDLE bit of the Operation register stops all state machines and moves the chip state to IDLE mode upon receiving a stop bit. This command sets all counters to 0 and clears all timers and faults. The power and cell balancing FETs are turned off. The state machines are reset. All other register settings are not affected by this command and remain unchanged. This bit is cleared on completion.

#### 5.2.1.3 0x01.5 Recalibrate V<sub>OS</sub> Trigger

A 0 to 1 transition of this bit in IDLE mode initiates a low voltage offset recalibration. Low voltage offset affects the V<sub>BAT1</sub>, V<sub>VCC</sub>, V<sub>TEMP</sub>, IT, xT0, and xT1 measurements. This bit is cleared on completion.

This trigger bit is ignored in SHIP and LOW POWER Modes and can only trigger sequences in IDLE or SCAN mode.

#### 5.2.1.4 0x01.4 Recalibrate in LOW POWER Mode

Setting the Recalibrate in LOW POWER mode bit of the Operation register to 1 starts a low voltage offset recalibration for every measurement pass while in LOW POWER mode.

#### 5.2.1.5 0x01.3 Recalibrate Scan

Setting the Recalibrate Scan bit of the Operation register to 1 initiates a low voltage offset recalibration before performing another System Scan. This bit has significance only in SCAN mode and must be set before starting continuous Scan.

#### 5.2.1.6 0x01.2 Busy

A value of 1 for the Busy bit indicates that ISL94216A is busy either performing measurements or internal housekeeping. The Busy bit is read only and has a masking bit that connects the Busy bit status (inverted) to the  $\overline{\text{ALRT}}$  pin. A Busy bit of 1 sets  $\overline{\text{ALRT}}$  low. See [0x85 Other Fault Mask on page 87](#) for more information about the masking bit. **Note:** Do not read measurement result registers when the ISL94216A is busy making measurements to avoid obtaining stale or mixed results. The ISL94216A saves each measurement result as it is obtained, reading data registers while Busy can produce a mix of previous and present scan results.

### 5.2.1.7 0x01.1 Scan Select

The Scan Select bit chooses the type of System Scan that is performed when a System Trigger is initiated and the device is in SCAN mode.

If continuous System Scan (Default of 0) is chosen, the device periodically measures system parameters as described in [System Scan Sequence on page 108](#). This selection reports a fault when the failure has exceeded the parameters fault delay setting. All fault counters are cleared at the beginning of a continuous scan, and no trace is left from previous System Scans. If a fault is detected, the power FETs turn off only if the fault output is connected to the FET driver (see [0x24 Power FET Operation on page 72](#)). A fault forces continuous scan to abort regardless of the connect bit settings and the MCU is expected to react.

If one instance of the System Scan is chosen (setting of 1), the device measures system parameters as described in [System Scan Sequence on page 108](#). This System Scan also performs an open-wire check if [0x24.6 OW EN on page 73](#) is set to 1. One cycle of cell balancing is executed if appropriate per settings. Measurements are made if the function(s) are enabled. Any faults are reported after the single System Scan completes.

If changes to continuous scan are necessary, set Scan Select bit to 1 and wait for the Busy bit to clear indicating the Scan has completed. Make the necessary changes and set Scan Select bit to 0 and the System Trigger bit (0x01.0) to 1 to restart continuous Scan.

### 5.2.1.8 0x01.0 System Trigger

A 0 to 1 transition of this bit in SCAN mode initiates a System Scan ([Figure 106 on page 109](#)). The type of System Scan is determined by the Scan Select bit setting. When the System Trigger bit has been received, the Busy bit (see [page 41](#)) transitions from a 0 to a 1, and the System Trigger bit returns to 0. The Busy bit remains high until the Scan Delay timer has started ([0x2E.2:0 Scan Delay on page 105](#)), and returns to 0. If the System Trigger bit is set during an active scan, it is ignored and remains set until manually cleared.

If the Scan Select bit is set for continuous scan and there is an active fault, a System Scan is not initiated. The System Trigger bit does not automatically transition to a low. The fault must be cleared and the trigger bit set to a low before System Trigger is operational again. See [Trigger Bits on page 123](#) for detailed information.

The System Trigger bit is ignored when the System mode bits are SHIP, LOW POWER, or IDLE. It is executed only when the System mode bits are set to SCAN mode.

## 5.3 V<sub>CELL</sub> and I<sub>PACK</sub> Measurement

A level shifter/multiplexer and 16-bit ADC within the ISL94216A enable measurement of BMS parameters ([Figure 80](#)). The results of these measurements are compared to user-selected detection thresholds.

Figure 80. Voltage Measurement Block Diagram

An analog comparator checks for short-circuit conditions. Digital comparators are used for overcurrent and undercurrent, and overvoltage and undervoltage detection. For cell voltages, the detection thresholds are set by the user to prevent overcharge or discharge of individual cells based on chemistry and/or other considerations.

The ISL94216A measures the pack current sense resistor (RSH) voltage before cell voltage measurements. A delta timer tracks elapsed time between current sense measurements.

### 5.3.1 0x02 V<sub>CELL</sub> Operation

The V<sub>CELL</sub> Operation register controls data acquisition and part of the OV/UV fault behavior for V<sub>CELL</sub> measurements. This register also contains the bit that clears latched fault and status bits.

**Table 5. 0x02 V<sub>CELL</sub> Operation Register**

Bits	D[7]	D[6]	D[5]	D[4:2]	D[1]	D[0]
Bit Name	V <sub>CELL</sub> EN	DCHRWOV	CHRWUV	V <sub>CELL</sub> Averages	Clear Faults/Status	V <sub>CELL</sub> Trigger
Default	1	0	0	0 00	0	0

#### 5.3.1.1 0x02.7 V<sub>CELL</sub> EN

Set the V<sub>CELL</sub> Enable bit to 1 (default) to enable V<sub>CELL</sub> measurements within System Scans. The cells to be included in a System Scan are determined by the setting of registers [0x04 - 0x05 Cell Select on page 46](#). Set this bit to 0 to disable V<sub>CELL</sub> measurement during System Scans.

This bit does not prevent cell voltage measurements during Open Wire test or when started with the VCell Trigger bit 0x02.0.

#### 5.3.1.2 0x02.6 DCHRWOV

Set the Discharge While Overvoltage bit to 1 to disable V<sub>CELL</sub> overvoltage detection during continuous System Scans while discharging. This setting allows the power FETs to remain on and discharging to occur if one or more cells are above the OV threshold set in register [0x06 - 0x07 V<sub>CELL</sub> OV/UV Threshold on page 48](#). Set this bit to 0 (default) to allow an OV to disable DFET and/or CFET (also dependent on [0x0E.3 CPWR on page 55](#) and [0x24.4 CELLCON on page 73](#)) and/or stop System Scan.

#### 5.3.1.3 0x02.5 CHRWUV

Set the Charge While Undervoltage bit to 1 to disable V<sub>CELL</sub> undervoltage detection while charging. This setting allows CFET to remain on and charging to occur if one or more cells are below the UV threshold set in register [0x06 - 0x07 V<sub>CELL</sub> OV/UV Threshold on page 48](#). Set this bit to 0 (default) to allow a UV to disable CFET and/or DFET (also dependent on CPWR and CELLCON) and/or stop System Scan.

#### 5.3.1.4 0x02.4:2 V<sub>CELL</sub> Averages

The V<sub>CELL</sub> Averages bits set the number of samples averaged (per cell) before writing the measurement results to their respective registers. [Table 6 on page 44](#) lists the options for these bits.

The conversion time for each V<sub>CELL</sub> measurement can be estimated as [Equation 1](#):

$$(EQ. 1) \quad V_{CELL\_CT} = (3 + (\text{SamplesToAverage})) \cdot ADC_{CT2}$$

ADC<sub>CT2</sub> is the base conversion time of the ADC (see [Electrical Specifications on page 13](#)).

Table 6.  $V_{CELL}$  Average Bits

$V_{CELL}$ Averages: D[4:2]			Samples to Average
0	0	0	1
0	0	1	2
0	1	0	4
0	1	1	8
1	0	0	16
1	0	1	32
1	1	0	64
1	1	1	128

#### 5.3.1.5 0x02.1 Clear Faults and Status

Write a 1 to the Clear Faults and Status bit to clear the faults and status. All bits in registers 0x63-0x69, except for [0x67.5 CH PRESI on page 90](#), along with all counters are cleared (set to 0). Other register settings are maintained with this command. On completion the bit is set to 0, this command takes ~100 $\mu$ s to complete.

The Fault and Status bits cannot be cleared while the condition that sets them is present.

The CH PRESI (charger present) bit is a straight connection to the  $\overline{WAKEUP}$  pin inverted and can only be set or cleared by the status of this pin.

#### 5.3.1.6 0x02.0 $V_{CELL}$ Trigger

A 0 to 1 transition of this bit initiates cell voltage measurements if the Busy bit is 0 and no other trigger is active, regardless of the setting of bit [0x02.7  \$V\_{CELL}\$  EN on page 43](#). The measured cells are determined by registers [0x04 - 0x05 Cell Select on page 46](#). When the command bit has been received, the Busy bit ([page 41](#)) transitions from a 0 to a 1 and the trigger bit clears. The Busy bit remains set until the measurement scan is completed, and returns to a 0.

This trigger bit is ignored in SHIP and LOW POWER Modes and can trigger sequences in IDLE or SCAN mode only. This trigger should be used in IDLE mode because Renesas recommends reserving SCAN mode for System Scans only.

### 5.3.2 0x03 $I_{PACK}$ Operation

$I_{PACK}$  Operation is a 1-byte register that controls the system behavior related to  $I_{PACK}$  measurements and how often the open-wire test is executed.

Table 7. 0x03  $I_{PACK}$  Operation Register

Bits	D[7]	D[6:5]	D[4:2]	D[1]	D[0]
Bit Name	$I_{PACK}EN$	OW Update	$I_{PACK}AVE$	$I_{DIR}Delay$	$I_{PACK}Trigger$
Default	1	00	0 00	0	0

#### 5.3.2.1 0x03.7 $I_{PACK}$ EN

Set this bit to 1 (default) to enable  $I_{PACK}$  measurement during System Scans. Set to 0 to disable  $I_{PACK}$  measurement during System Scans. This bit does not prevent  $I_{PACK}$  measurement during open-wire detection or when started by the  $I_{PACK}$  Trigger bit.

### 5.3.2.2 0x03.6:5 OW Update

The Open-Wire Update bits of the I<sub>PACK</sub> Operation register control how often the open-wire test is executed as part of continuous System Scans. The frequency of the open-wire test is defined in terms of System Scans in [Table 8](#).

Open-Wire operation is detailed in [Open-Wire Function on page 116](#) and [Aux Pins Open-Wire Test on page 96](#). The Aux Pins open-wire test is not controlled by the 0x03.6:5 OW Update bits or [0x24.6 OW EN on page 73](#) and is not triggered by [0x24.5 OW Trigger on page 73](#).

**Table 8. OW Update Bits**

D[6:5]		How Often the Open-Wire Test is Executed?
0	0	256 (Update on scan 1, 257, 513, 769...)
0	1	512 (Update on scan 1, 513, 1025, 1567...)
1	0	1024 (Update on scan 1, 1025, 2049, 3071...)
1	1	2048 (Update on scan 1, 2049, 4097, 6145...)

### 5.3.2.3 0x03.4:2 I<sub>PACK</sub> Averages

The I<sub>PACK</sub> Averages bits determine the number of samples averaged before writing the measurement result to its register. [Table 9](#) lists the options for these bits.

**Table 9. I<sub>PACK</sub> Averages Bits**

I <sub>PACK</sub> Averages: D[4:2]			Samples to Average
0	0	0	1
0	0	1	2
0	1	0	4
0	1	1	8
1	0	0	16
1	0	1	32
1	1	0	64
1	1	1	128

The conversion time for an I<sub>PACK</sub> measurement can be estimated as [Equation 2](#):

$$(EQ. 2) \quad I_{PACK\_CT} = (3 + SamplesToAverage) \cdot ADC_{CT2}$$

ADC<sub>CT2</sub> is the base conversion time of the ADC (see the [Electrical Specifications on page 13](#)).

### 5.3.2.4 0x03.1 I<sub>DIR</sub> Delay

The Current Direction delay bit of the I<sub>PACK</sub> Operation register sets the number of consecutive current measurement readings in one direction required before setting the CHRGI or DCHRG (0x67 Status on page 90) bits in SCAN mode. The default setting of 0 requires only one reading. Set this bit to 1 to require three consecutive readings in SCAN mode during continuous scans. This bit has no effect on single scans or in other operating modes.

The [0x67.6 CHRGI on page 90](#) and [0x67.7 DCHRG on page 90](#) bits are evaluated at the end of each I<sub>PACK</sub> measurement.

For an  $I_{DIR}$  Delay of 0, CHRG1 is set to 1 immediately if the  $I_{PACK}$  measurement result is  $>208\mu V$  or it is reset to 0 if the result is  $<208\mu V$ . DCHRG1 is set to 1 immediately if the  $I_{PACK}$  measurement result is  $<-219\mu V$  or it is reset to 0 if the result  $>-219\mu V$  (typical voltage thresholds).

With  $I_{DIR}$  Delay set to 1, CHRG1 is set to 1 after three consecutive  $I_{PACK}$  measurement results  $>208\mu V$  or it is reset to 0 immediately if a result  $<208\mu V$ . DCHRG1 is set to 1 after three consecutive  $I_{PACK}$  measurement results  $<-219\mu V$  or it is reset to 0 immediately if a result  $>-219\mu V$  (typical voltage thresholds).

### 5.3.2.5 0x03.0 $I_{PACK}$ Trigger

A 0 to 1 transition of this bit instructs the device to start an  $I_{PACK}$  and Delta Timer measurement. When received, the Busy bit transitions from a 0 to a 1 and the trigger bit clears. The Busy bit remains set until the action is completed and next returns to a 0.

The  $I_{PACK}$  Trigger bit initiates an  $I_{PACK}$  measurement regardless of the setting of the  $I_{PACK}$  Enable bit.

This trigger bit is ignored in SHIP and LOW POWER Modes and can trigger sequences in IDLE or SCAN mode only. It should be used in IDLE mode only as Renesas recommends reserving SCAN mode for System Scans.

### 5.3.3 0x04 - 0x05 Cell Select

The Cell Select registers indicate to the ISL94216A state machine which cells exist in the BMS. This setting determines the cells to include during  $V_{CELL}$  scans, Open-Wire test, Cell Balancing, and System Scans. A 1 includes the cell and a 0 bypasses the cell in all functions. Unused cell locations MUST be disabled (set to 0) before starting System Scans or triggering measurements, Open-Wire, or Cell Balancing functions.

Table 10. 0x04 - 0x05 Cell Select Registers

Address - Bits	Bit Name	Default
0x04 - D[7:0]	Cell Number 16 (MSB) to 9 (LSB)	1111 1111
0x05 - D[7:0]	Cell Number 8 (MSB) to 1 (LSB)	1111 1111

### 5.3.4 0x30 - 0x4F $V_{CELL}$ Voltage (R)

Registers 0x30 through 0x4F report  $V_{CELL}$  measurements. The  $V_{CELL}$  output voltage is stored across two adjacent bytes as listed in Table 11.

Table 11.  $V_{CELL}$  Measurement Registers

Address - Bits	Bit Name	Default	$V_{CELL\_Step}$
0x30, 32, 34...4E - D[7:0]	15 (MSB) to 8 (LSB)	0000 0000	73.55 $\mu V$
0x31, 33, 35...4F - D[7:0]	7 (MSB) to 0 (LSB)	0000 0000	

Addresses 0x30 and 0x31 contain the voltage reading for Cell 1. Locations 0x4E and 0x4F correspond to Cell 16's voltage reading.

**(EQ. 3)**  $V_{Cell} = (RegVal) \cdot V_{CELL\_Step} + 0.5 \cdot V_{CELL\_Step}$

Use Equation 3 to calculate the cell voltage by multiplying the 16-bit register value by the step size  $V_{CELL\_Step}$  and add the 1/2 LSB offset. The register records results from 36.77 $\mu V$  to 4.82V.

### 5.3.5 0x50 - 0x51 V<sub>CELL</sub> Max Delta Voltage (R)

The V<sub>CELL</sub> Maximum Delta registers store the difference between the maximum V<sub>CELL</sub> voltage and the minimum V<sub>CELL</sub> voltage (registers 0x30-0x4F). It is evaluated immediately after a V<sub>CELL</sub> scan completes. [Table 12](#) shows the format of these registers.

Table 12. 0x50-51 V<sub>CELL</sub> Delta Register

Address - Bits	Bit Name	Default	V <sub>CELL</sub> <sub>Step</sub>
0x50 - D[7:0]	15 (MSB) to 8 (LSB)	0000 0000	73.55μV
0x51 - D[7:0]	7 (MSB) to 0 (LSB)	0000 0000	

Calculate the Maximum Delta Voltage by multiplying the 16-bit register value by the step size V<sub>CELL</sub><sub>Step</sub> as shown in [Equation 4](#). The register records results from 0V to 4.82V.

$$(EQ. 4) \quad V_{CellMaxDelta} = (RegVal) \cdot V_{CELL\_Step}$$

### 5.3.6 0x52 - 0x53 I<sub>PACK</sub> Voltage (R)

The I<sub>PACK</sub> registers hold the 16-bit 2's complement measurement result representing the I<sub>PACK</sub> sense resistor (R<sub>SHUNT</sub>) voltage. Calculate the voltage as outlined below; next, divide the result by the shunt resistance R<sub>SHUNT</sub> (see [CSP and CSN Pins \(24, 25\) on page 94](#)) to calculate the current.

The MSB of the 16-bit register reading (0x52.7) is the sign bit. If it is 0 then:

$$V(I_{PACK}) = (Code_{16}) \times LSB + \frac{1}{2}LSB. \text{ Otherwise,}$$

$$V(I_{PACK}) = (Code_{16} - 65536) \times LSB + \frac{1}{2}LSB$$

The LSB value is 10.51μV. Examples:

$$Code_{16} \ 0x0000 = \frac{1}{2}LSB = 5.25\mu V$$

$$Code_{16} \ 0x7FFF = (2^{15} - 1) \times LSB + \frac{1}{2}LSB = +344.28mV$$

$$Code_{16} \ 0x8000 = (2^{15} - 65536) \times LSB + \frac{1}{2}LSB = -344.28mV$$

**NOTE:** Every time current is measured, the Delta Timer value is written to [0x54 - 0x57 I<sub>PACK</sub> Timer \(R\)](#).

### 5.3.7 0x54 - 0x57 I<sub>PACK</sub> Timer (R)

The I<sub>PACK</sub> Timer is 32 bits with a nominal step size of 15ms. It Functions as a time stamp for I<sub>PACK</sub> current measurements. When a pack current measurement is made, the value of the I<sub>PACK</sub> Timer is pushed to these registers. The timer runs in LOW POWER, IDLE, and SCAN Modes and is designed to count to two years without rolling over.

Multiply the step size ΔTimer<sub>Step</sub> by the 32-bit register value to calculate the elapsed time. The register records results from 0ms to 2.043 years. Multiplying the elapsed time between two measured currents by the current results in an electric charge value in Coulombs.

The timer is reset and begins counting immediately on POR, see [RESET Pin \(38\) on page 97](#), [0x01.7 Soft Reset on page 41](#), and [0x01.6 Reset to IDLE on page 41](#).

## 5.4 V<sub>CELL</sub> Fault Detectors

The V<sub>CELL</sub> Fault Detectors consist of digital OV/UV comparators and fault delay timers. The digital comparators and delay timers are responsible for detecting OV/UV events while charging and discharging in SCAN mode to

provide an automatic fault response. Fault response is up to the MCU in IDLE mode. Figure 81 is a block diagram of the  $V_{CELL}$  Fault Detection function.

#### 5.4.1 0x06 - 0x07 $V_{CELL}$ OV/UV Threshold

Each  $V_{CELL}$  measurement is compared to overvoltage and undervoltage limits. During discharge, undervoltage threshold detectors alert the system to prevent discharging to a nonchargeable state. During charge, the overvoltage threshold detectors alert the system to discontinue charging at the selected voltage. These threshold detectors only operate under charge (0x67.6 [CHRG1](#) on page 90) or discharge (0x67.7 [DCHRG1](#) on page 90) conditions. The  $V_{CELL}$  Fault Delay counters are bypassed if the part is not running in continuous scan.

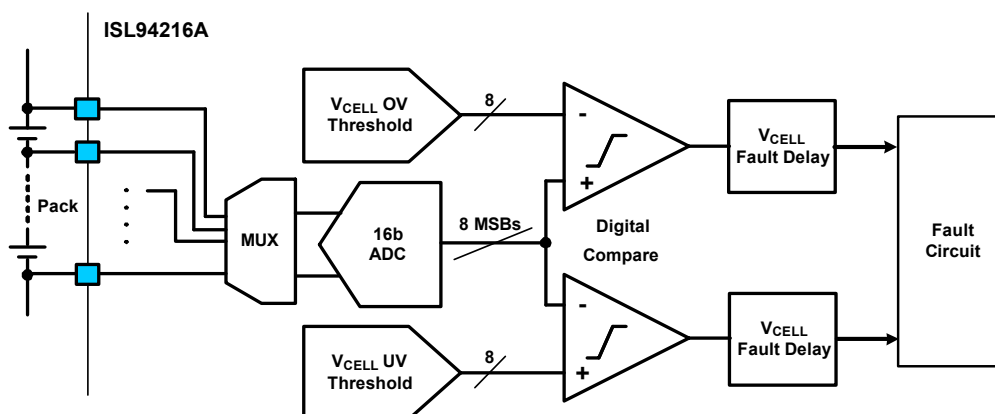

Figure 81.  $V_{CELL}$  OV/UV Detectors

The threshold detectors are digital comparators that require an ADC  $V_{CELL}$  conversion to compare. These two comparators (OV/UV) are fault detectors. If the FET control bit 0x24.4 [CELLCON](#) on page 73 is set, a OV or UV event can shut off the power FET(s) depending on the bit settings of 0x0E.3 [CPWR](#) on page 55, 0x02.6 [DCHRWOV](#) on page 43, and 0x02.5 [CHRWUV](#) on page 43. The overvoltage and undervoltage registers are shown in Table 13.

Table 13. 0x06 OV and 0x07 UV  $V_{CELL}$  Threshold Registers

Address - Bits	Name	Default	$V_{thStep}$	Offset
0x06 - D[7:0]	OV Threshold	1111 1111	18.83mV	18.79mV
0x07 - D[7:0]	UV Threshold	0000 0000		36.77μV

$OV_{thStep}$  and  $UV_{thStep}$  are the same value for both thresholds, the Offsets are different. Multiply the register value by the step size, and add the fixed offset to calculate the threshold using Equation 5. The OV threshold register supports settings from 18.79mV to 4.82V while the UV threshold register supports settings from 36.77μV to 4.801V.

(EQ. 5) 
$$V_{Threshold} = (RegVal) \cdot V_{thStep} + Offset$$

A  $V_{CELL}$  OV threshold violation sets the fault 0x63.0 [OVF](#) when any cell is greater than the threshold and the device is charging. A UV threshold violation sets the fault 0x63.1 [UVF](#) if any cell is less than or equal to the threshold and the device is discharging. These faults are gated by fault counters, see 0x09.3:0 [V\\_CELL Fault Delay](#).

### 5.4.2 0x08 V<sub>CELL</sub> Max Delta Threshold

The V<sub>CELL</sub> Max Delta register sets the threshold for a digital compare with the V<sub>CELL</sub> Max Delta Voltage (0x50 - 0x51). The detection is used to maintain cell voltage readings within a predetermined voltage range. [Table 14](#) shows the format of this register.

**Table 14. 0x08 V<sub>CELL</sub> Maximum Delta Threshold Register**

Bits	Bit Name	Default	DVCELL <sub>Step</sub>	Offset
D[7:0]	DVCMAX - V <sub>CELL</sub> Max Delta Threshold	1111 1111	18.83mV	18.79mV

Multiply the register value by the step size DVCELL<sub>Step</sub>, and add the fixed offset to calculate the threshold using [Equation 6](#). The register supports settings from 18.79mV to 4.82V.

**(EQ. 6)**  $V_{Threshold} = (RegVal) \cdot DVCELL_{Step} + Offset$

A V<sub>CELL</sub> Max Delta threshold violation sets the fault [0x66.3 DVCF](#) when any cell voltage delta is greater than the threshold. This fault is gated by a fault counter, see [0x09.6 Delta V<sub>CELL</sub> Fault Delay](#).

### 5.4.3 0x09 Fault Delay

When a fault is detected, the ISL94216A reacts following a set delay. The delay to report a fault is a function of the ADC conversion time, the functions included in scans, the type of scan, and the Fault Delay register settings (if in continuous scan). The fault delays are user-programmable scan counters that are active only during continuous scans. [Table 15](#) shows the format of this register.

**Table 15. 0x09 Fault Delay Register**

Bits	D[7]	D[6]	D[5]	D[4]	D[3:0]
Bit Name	AUX Pull-up	DV <sub>CELL</sub> Fault Delay	Other Fault Delay	ETAUX Fault Delay	V <sub>CELL</sub> Fault Delay
Default	0	0	0	0	0000

#### 5.4.3.1 0x09.7 AUX/xTn Pull-Up

When the Auxiliary input Pull-Up bit is 1, an internal test resistor (R<sub>ETAUX</sub>, [page 14](#)) is connected between AUX0/xT0 and VCC and another between AUX1/xT1 and VCC.

The resistors should only be connected to conduct an open-wire test of the AUX0/xT0 and AUX1/xT1 pins and disconnected during normal operation by setting it back to 0 (default). See [Aux Pins Open-Wire Test on page 96](#) for details about the operation of this bit.

#### 5.4.3.2 0x09.6 Delta V<sub>CELL</sub> Fault Delay

The DV<sub>CELL</sub> fault detector has a scan delay counter gating the output of the DV<sub>CELL</sub> Voltage threshold comparator when the device is in continuous SCAN mode. These counters are bypassed during single triggered scans. The DV<sub>CELL</sub> Fault Delay is set to either a single failure (default of 0) or three consecutive scan failures (if set to 1) required. The selected count must be met during continuous scan before a fault is reported.

### 5.4.3.3 0x09.5 Other Fault Delay

When the ISL94216A is in continuous SCAN mode, the Other Fault Delay bit controls individual scan delay counters that gate the output of the following fault comparators; [0x63.7 VCCF on page 82](#), [0x67.0 VTMPF on page 91](#), [0x67.2 IREG1 on page 91](#), [0x67.1 IREG2 on page 91](#), [0x65.7 VBOVF on page 86](#), [0x65.6 VBUVF on page 86](#), [0x63.5 IOTF on page 82](#), and [0x66.6 IOTW on page 88](#). The scan delay count can be set to either a single failure (default setting of 0) or three consecutive scan failures (if set to 1) before setting the fault bit. The selected count of consecutive errors must be met during continuous scan before a fault is reported. These counters are bypassed during single triggered scans.

### 5.4.3.4 0x09.4 ETAUX Fault Delay

The ETAUX fault detector has a scan delay counter gating the output of the ETAUX Voltage threshold comparators when the device is in continuous SCAN mode, these counters are bypassed during single triggered scans. The ETAUX Fault Delay is set to either a single (default of 0) or three consecutive scan failures (if set to 1) required. The selected count must be met during continuous scan before a fault is reported.

### 5.4.3.5 0x09.3:0 V<sub>CELL</sub> Fault Delay

The V<sub>CELL</sub> Fault Delay bits set the required count of consecutive V<sub>CELL</sub> scans with a Cell OV or UV failure before a fault is reported (see [0x06 - 0x07 V<sub>CELL</sub> OV/UV Threshold on page 48](#)). This delay counter is only functional when the device is running continuous System Scans and a charge ([0x67.6 CHRGI on page 90](#)) or discharge current ([0x67.7 DCHRGI on page 90](#)) is detected. These counters are bypassed during single triggered scans. If the device is in continuous SCAN mode and a cell voltage is outside the limits during consecutive measurements that exceeds the V<sub>CELL</sub> Fault Delay setting, a fault is reported. The V<sub>CELL</sub> Fault Delay count threshold is the decimal value of these bits plus 1. The range is between 1 scan (default setting of 0000) and 16 scans (setting of 1111).

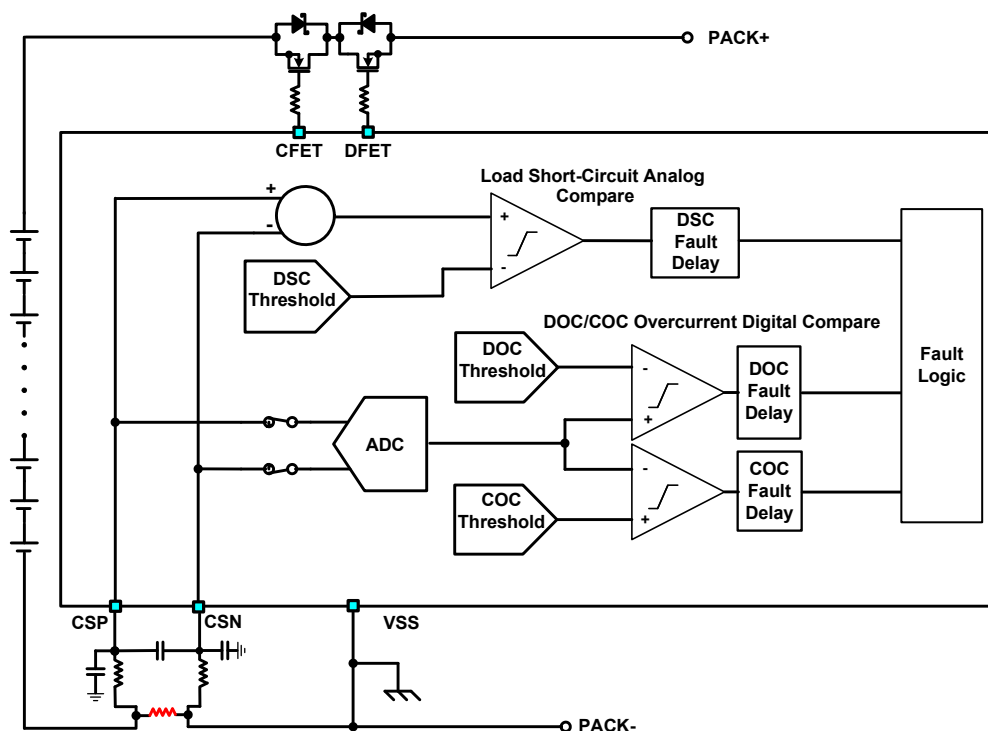

Figure 82. Current Sense Block Diagram

## 5.5 I<sub>PACK</sub> Fault Detectors

The I<sub>PACK</sub> Fault Detectors consist of a short-circuit analog comparator and two digital overcurrent comparators. The analog comparator disconnects the battery pack from the load when a short-circuit is detected. The comparator is operational in all modes except in SHIP. The digital comparators are responsible for detecting overcurrent events while charging and discharging. [Figure 82](#) is a block diagram of the I<sub>PACK</sub> Fault Detection function.

### 5.5.1 0x0A DSC Threshold

The Discharge Short-Circuit Threshold register sets the short-circuit threshold of the analog comparator. [Table 16](#) shows the format of the Discharge Short-Circuit Threshold register. Short-circuit detection is disabled by setting the register to 0x00. **Note:** This is for test purposes and is not recommended for normal operation.

**Table 16. 0x0A DSC Threshold Register**

Bits	Bit Name	Default	VDSC <sub>Step</sub>	Offset	Min Threshold (0x0A.[3:0] = 0001)
D[7:4]	RSV	0000	-	-	-
D[3:0]	DSC Discharge Short-Circuit Threshold	1111	-20.083mV	-20.083mV	-40.167mV

Multiply the register value by the step size VDSC<sub>Step</sub> and subtract the fixed offset to calculate the threshold for non-zero settings using [Equation 7](#). The register supports settings from -40.167mV to -321.33mV (typical). This register represents a negative value without a sign bit. If the voltage across the current sense resistor (see [CSP and CSN Pins \(24, 25\)](#)) is more negative than this threshold for more than [0x0C DSC Delay](#), then fault bit [0x63.2 DSCF](#) is set. See [Short-Circuit Detection and Recovery](#) for a detailed description of the relationship between the DSC Threshold, DSC Delay and [0x0E.4 ELR](#).

**(EQ. 7)**  $V_{Threshold} = ((RegVal) \cdot VDSC_{Step}) + Offset$

### 5.5.2 0x0B DOC Threshold

The Discharge Overcurrent Threshold register sets the overcurrent threshold of a digital comparator. [Table 17](#) shows the format of this register.

**Table 17. 0x0B DOC Threshold Register**

Bits	Bit Name	Default	VDOC <sub>Step</sub>	Offset
D[7:0]	DOC - Discharge Overcurrent Threshold	1111 1111	-1.345mV	-5.25μV

The comparator for overcurrent detection relies on ADC conversions in addition to a number of System Scans. If the measurement is continuously above the threshold after the selected number of scans occurs (see [0x0D OC Delay on page 53](#)), then a fault is asserted.

**(EQ. 8)**  $V_{Threshold} = ((RegVal) \cdot VDOC_{Step}) + Offset$

Multiply the register value by the step size VDOC<sub>Step</sub> and subtract the fixed offset to calculate the threshold [Equation 8](#). The register supports settings from -5.25μV to -342.95mV. This register represents a negative value without a sign bit.

If the voltage across the current sense resistor (see [CSP and CSN Pins \(24, 25\) on page 94](#)) is less than or equal to this threshold for more than [0x0D.7:4 DOCD](#) Scans during discharge, then the fault bit [0x63.3 DOCF on page 83](#) is set and continuous scan is halted. If bit [0x0E.7 CFD on page 54](#) is set, then DFET is also shut off.

### 5.5.3 0x0C DSC Delay

The Discharge Short-Circuit Delay register sets the delay time for short-circuit current detection. If the short-circuit remains (as determined by the 0x0A DSC threshold) after the delay has timed out, it shuts off the DFET and sets the fault bit [0x63.2 DSCF on page 83](#). [Table 18](#) outlines the Discharge Short-Circuit Delay register.

**Table 18. 0x0C Discharge Short-Circuit Delay Register**

Bits	D[7]	D[6:0]
Bit Name	RSV	DSC - Discharge Short-Circuit Delay
Default	0	000 0000
DSC <sub>Step</sub>		31.25μs

There is a fixed delay of 100-125μs between DSC comparator detection and  $\overline{\text{ALRT}}$  assertion if the DSCF Mask bit is clear ([0x83 Priority Fault Mask on page 84](#)), otherwise  $\overline{\text{ALRT}}$  is not asserted. With DSC Delay set to 0x00, the comparator detection is decoupled from the delay circuitry and acts within a few μs to shut off the power FETs. This setting is recommended for applications capable of producing component damaging short-circuit currents.

For non-zero delay settings, the comparator output detection and  $\overline{\text{ALRT}}$  assertion is delayed by this fixed delay plus the selected delay. The device acts to shut off the power FETs ~125μs after  $\overline{\text{ALRT}}$  asserts. The total delay is composed of these two fixed delays of ~250μs plus the selected delay.

Multiply the 7-bit register value by the step size DSC<sub>Step</sub> (31.25μs) then add the fixed delay to calculate the total delay. The register supports additional delay values from 0μs to 3968.75μs. Set this register to 0x00 for no DSC Delay.

#### 5.5.3.1 Short-Circuit Detection and Recovery

When a discharge current exceeds the DSC Threshold for longer than the DSC Delay setting, the bit [0x63.2 DSCF on page 83](#) is set to 1 and the DFET is shut off. The DSCF bit is cleared by either the load detection circuitry or by writing a 0 to the bit. **Note:** Do not clear the DSCF bit until the load is removed and a pack current measurement confirms the current was shut off.

If the load detection ([0x0E.6:5 ELD on page 54](#)) and recovery functions ([0x0E.4 ELR on page 55](#)) are enabled, the load recovery circuitry checks if the load (or short) has been removed ([Figure 83](#)). This happens after a nominal delay of  $t_{\text{LDEN}}$  (~256ms, [page 14](#)) following the shutoff of the DFET. An on-chip pull-up resistor determined by the ELD setting ([0x0E.6:5 ELD on page 54](#)) is connected between the LDMON and V<sub>BAT2</sub> pins. After LD Delay ([0x1B.3:2 LD Delay on page 66](#)) the LDMON voltage is compared to the V<sub>LDThr</sub> threshold (1.2V nominal, [page 14](#)). If the LDMON voltage is less than the threshold, the load is considered present and bit [0x67.4 LD PRESI on page 90](#) is set. The load recovery circuitry is looking for a no load present before clearing the DSCF bit. When the voltage at the LDMON pin is above V<sub>LDThr</sub>, and the DSC comparator no longer indicates the current is above the [0x0A DSC Threshold on page 51](#) setting, both the DSCF and LDPRESI bits are cleared and DFET is allowed to turn on. **Note:** The unsigned DSC Threshold represents a negative voltage because the discharge current generates a negative voltage across the current sense resistor.

The DFET output is not automatically turned back on when DSCF clears; it should be turned on by the microcontroller only following confirmation that the short-circuit is no longer present. The DSCF bit cannot be cleared by the user while the Short-Circuit Recovery Sequence is in progress.

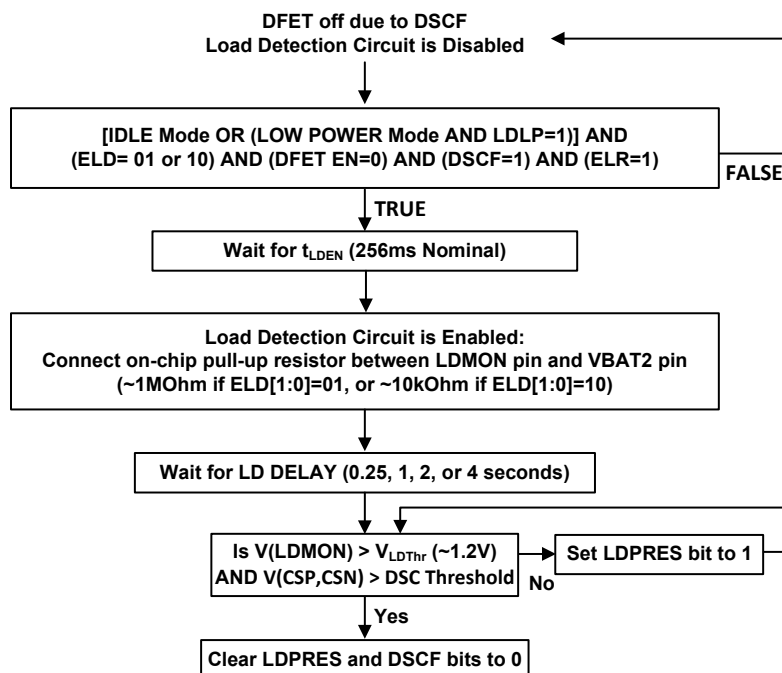

Figure 83. Simplified Short-Circuit Recovery Sequence

### 5.5.4 0x0D OC Delay

The Overcurrent Delay register defines the delay in terms of System Scans for charge and discharge overcurrent detection. The delay function only operates when the device is in SCAN mode during a continuous scan, the delay is ignored in single triggered scans. Table 19 details the Overcurrent Delay register.

Table 19. 0x0D Overcurrent Delay Register

Bits	Bit Name	Default
D[7:4]	DOCD - Discharge Overcurrent Delay	0000
D[3:0]	COCD - Charge Overcurrent Delay	0000

#### 5.5.4.1 0x0D.7:4 DOCD

The Discharge Overcurrent Delay bits select the number of consecutive System Scans with a DOC threshold violation (0x0B DOC Threshold on page 51) that is required before it is reported to the DFET control circuitry and fault bit 0x63.3 DOCF on page 83 is set. The number of System Scans can be programmed to between 1 and 15 scans. If this register is set to 0000, the fault is declared as soon as detected, a setting of 0001 or higher delays the fault declaration until the end of the selected number of scans.

#### 5.5.4.2 0x0D.3:0 COCD

The Charge Overcurrent Delay bits select the number of consecutive System Scans with a COC threshold violation (0x0F COC Threshold on page 56) that is required before it is reported to the CFET control circuitry and fault bit 0x63.4 COCF on page 82 is set. The number of System Scans can be programmed to between 1 and 15 scans. If this register is set to 0000, the fault is declared as soon as detected, a setting of 0001 or higher delays the fault declaration until the end of the selected number of scans.

### 5.5.5 0x0E Load/Charge Operations

This register is responsible for controlling various operations relevant to load and fault detection during charging and discharging and their relationship to the power FET drivers. Allocation of the Load/Charge Operations register is detailed in [Table 20](#).

**Table 20. 0x0E Load/Charge Operations Register**

Bits	D[7]	D[6:5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	CFD	ELD	ELR	CPWR	FCDC	LDLP	RSV
Default	1	01	1	0	1	0	0

#### 5.5.5.1 0x0E.7 CFD

The Connect for Discharge fault bit of the Load/Charge Operations register connects a discharge overcurrent detection ([0x0B DOC Threshold on page 51](#)) to the FET Driver when set to 1 (default). This allows the FET Driver to automatically turn off the power FET(s) if a DOC fault occurs during discharge ([0x67.7 DCHRG1 on page 90](#) is 1).

Setting bit CFD to 0 prevents a DOCF ([0x63.3 DOCF on page 83](#)) from shutting off the power FET(s), transferring responsibility to the MCU.

A DOCF stops the continuous scan regardless of the setting of CFD.

Bit [0x0E.3 CPWR on page 55](#) determines if DFET or both DFET and CFET are turned off and System Scan is stopped.

#### 5.5.5.2 0x0E.6:5 ELD

The Enable Load Detection bits configure the load detection circuitry. [Table 21](#) shows the configuration options of the ELD bits. ELR is ignored and automatic load recovery is not performed if the ELD bits are set to 00.

Load detection is described further in [LDMON Pin \(49\) on page 99](#) and [Load Detection on page 56](#).

**Table 21. ELD Bits**

D[6:5]		ELD
0	0	Do Not Enable Load Detection
0	1	Load Detection Enabled with 1MΩ Pull Up to V <sub>BAT2</sub>
1	0	Load Detection Enabled with 10kΩ Pull Up to V <sub>BAT2</sub>
1	1	RSV

Leakage current when a load is not connected to a battery pack is often dependent on the protection circuitry on the load side of DFET. The amount of leakage usually increases with pack voltage and current rating. Too much leakage can cause a false load detection. The maximum pull-down leakage current that does not trigger a false load detection is defined by [Equation 9](#). The maximum leakage current before load detect is dependent on pack voltage, V<sub>LDT<sub>thr</sub></sub> ([page 14](#)) and R<sub>LDP<sub>U</sub></sub> ([page 14](#)) resistance.

**(EQ. 9)**  $(\text{LeakageCurrent}(\text{Max})) < (V_{\text{BAT}} - V_{\text{LDT}_{\text{thr}}}(\text{Max})) / (R_{\text{LDP}_{\text{U}}}(\text{Max}))$

**Note:** About Off-Chip Protection Resistor at the LDMON pin and DFET:

When the DFET is off and the load pull-up resistor is 10kΩ, it is possible to turn on DFET if the value of R<sub>LDISO</sub> is too high. [Figure 93 on page 72](#) illustrates DFET interacts with the load monitor pin. When the DFET is off, a switch connects R<sub>DFOFF</sub> ([page 16](#)) between the two pins. The LDMON pull-up resistor, R<sub>LDP<sub>U</sub></sub> ([page 14](#)), is also connected. If the value of R<sub>LDISO</sub> ([page 14](#)) is high enough, a large enough voltage between the gate and source

of the DFET when Pack+ is close to ground can cause the DFET to turn on. To prevent this from happening, size  $R_{LDISO}$  to keep the VGS of the FET low enough to remain off but as high as possible for maximum protection.

#### 5.5.5.3 0x0E.4 ELR

The Enable Load Recovery bit enables the load recovery function. If a short-circuit is detected, the load recovery circuitry tests for load removal after a fixed delay of  $t_{LDEN}$  (page 14) plus a selectable delay of  $t_{LDDELAY}$  (0x1B.3:2 LD Delay on page 66) following the shut off of DFET (default setting of 1). If set to 0, no load recovery test is executed and the DFET remains off until the MCU resolves the issue.

If ELR is enabled when a DSCF occurs, and the load recovery function determines if the load was removed, then the DSCF bit is automatically cleared. This function does not re-enable the DFET. See [Short-Circuit Detection and Recovery on page 52](#) for a detailed description of the relationship between the DSC Threshold, DSC Delay and ELR.

**Note:** If the ELD bits are set to 00 (Table 21 on page 54), ELR is ignored and a load recovery is not performed.

#### 5.5.5.4 0x0E.3 CPWR

The Configure Power FET bit configures the ISL94216A for either a series (default setting of 0) or parallel (if set to 1) CFET and DFET configuration (Figure 84). This setting determines whether one or both CFET and DFET are shut off and if System Scan stops when certain indicators and/or Faults are set to 1. The CPWR bit has no effect on short-circuit events, or events not directly related to charge or discharge.

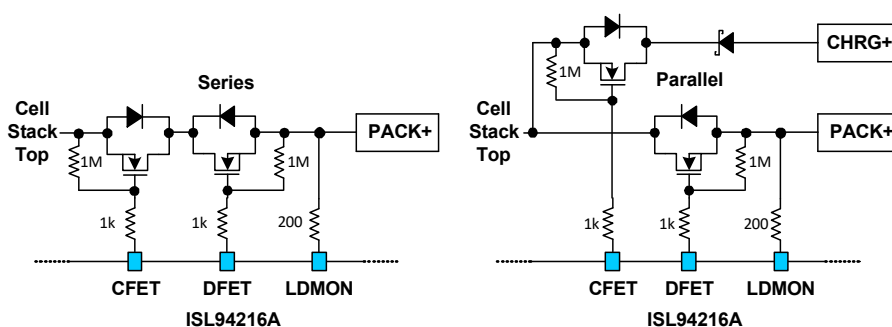

Figure 84. Power FET Configurations

See [CFET and DFET Pins \(50, 51\) on page 100](#) for complete details about the CPWR, fault, and control bits as they relate to FET control. See [Scan Will Not Start on page 115](#) for information about how the CPWR setting effects System Scan.

#### 5.5.5.5 0x0E.2 FCDC

The FET Charge Driver Connect bit of the Load/Charge Operations register connects the charge overcurrent (0x0F COC Threshold on page 56) fault to the FET Driver when set to 1 (default). This allows the FET Driver to automatically turn off CFET when a COC fault (0x63.4 COCF on page 82) occurs. When FCDC = 1, CPWR = 1 and COCF = 1, the CFET is turned off. When FCDC = 1, CPWR = 0, and COCF = 1, both CFET and DFET are turned off and System Scan stops.

Setting this bit to 0 prevents a COCF from shutting off CFET (and DFET if CPWR = 0), transferring responsibility to the MCU. A COCF causes continuous scan to halt regardless of the setting of FCDC.

#### 5.5.5.6 0x0E.1 LDLP

The Load Detect while in LOW POWER mode bit keeps the load detection circuit off when the ISL94216A is in LOW POWER mode with the default setting of 0. Setting the bit to 1 allows turning on load detection with bits 0x0E.6:5 ELD on page 54 while in LOW POWER mode. When LDLP is enabled a detection causes the ISL94216A to transition to IDLE mode.

This bit has no effect on other modes. See [Load Detection](#) for more details.

### 5.5.5.7 0x0E.0 RSV

The Reserve bit should be ignored during a read command and should be set to 0 during a write command.

### 5.5.5.8 Load Detection

The Load Connection Detection state machine only operates when DFET is off. The LDMON circuit is disabled when DFET is turned on. The load detection circuit includes an analog comparator and a pull-up resistor to  $V_{BAT2}$ .

When the DFET transitions to the off state, the LD PRESI bit is cleared (see [0x67.4 LD PRESI on page 90](#)). After a nominal delay of  $t_{LDEN}$  (~256ms, [page 14](#)) following DFET turn off an on-chip pull-up resistor determined by the ELD setting (0x0E.6:5) is connected between the LDMON and  $V_{BAT2}$  pins. After LD Delay (0x1B.3:2 LD Delay on [page 66](#)) the LD PRESI bit continuously follows the LDMON voltage. It is 1 when the voltage is below  $V_{LDThr}$  (1.2V nominal, [page 14](#)) or 0 otherwise.

The load detection circuit operates in SCAN and IDLE modes if enabled by the ELD bits 0x0E.6:5, and in LOW POWER mode if also enabled by LDLP bit 0x0E.1.

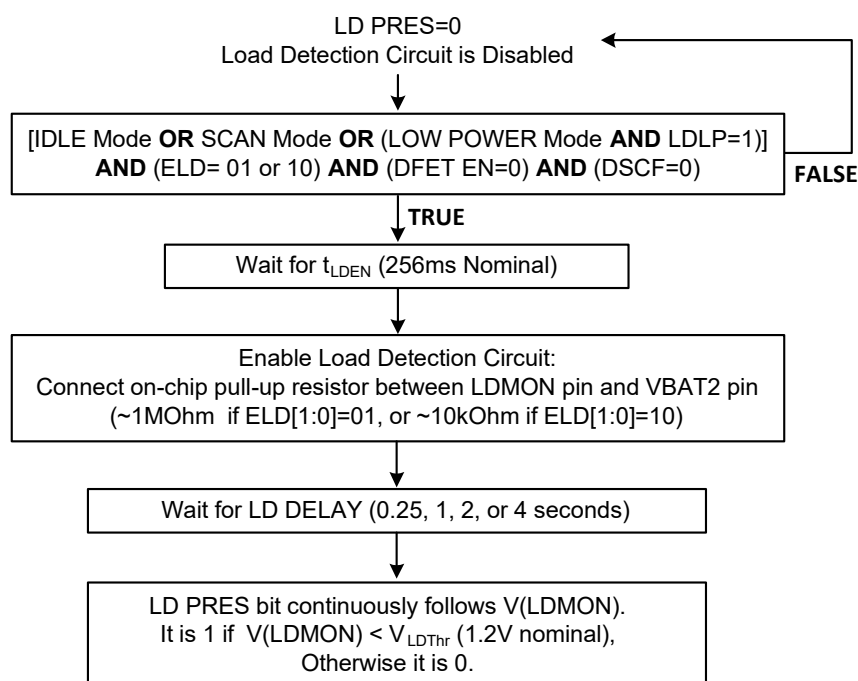

Figure 85. Simplified Load Connection Detection Sequence

### 5.5.6 0x0F COC Threshold

The Charge Overcurrent Threshold register sets the overcurrent threshold of a digital comparator. [Table 22](#) shows the format of this register. If the measurement is continuously above the threshold after the selected number of scans expires (see [0x0D OC Delay on page 53](#)), then a fault is asserted.

Table 22. 0x0F Charge Overcurrent Threshold Register

Bits	Bit Name	Default	VCOC <sub>Step</sub>	Offset
D[7:0]	COC - Charge Overcurrent Threshold	1111 1111	1.345mV	5.25μV

The comparator for overcurrent detection relies on ADC conversions in addition to a number of System Scans set by [0x0D.3:0 COCD on page 53](#). If the  $I_{Pack}$  voltage continuously measures greater than or equal to this threshold after the selected number of scans occurs, then fault bit [0x63.4 COCF on page 82](#) is asserted and continuous

scan is halted. If bit [0x0E.2 FCDC on page 55](#) is set, the CFET is automatically shut off. See [Charge Overcurrent Detection on page 57](#) and [Table 19 on page 53](#).

(EQ. 10)  $V_{Threshold} = (RegVal) \cdot VCOC_{Step} + Offset$

Multiply the register value by the step size  $VCOC_{Step}$  add the fixed offset to calculate the threshold ([Equation 10](#)). The register supports settings from 5.25μV to 342.95mV.

### 5.5.6.1 Charge Overcurrent Detection

When the ISL94216A detects an overcurrent condition while charging for the number of consecutive System Scans set by COCD ([0x0D.3:0 COCD on page 53](#)), fault bit [0x63.4 COCF on page 82](#) is set. If the COCF Mask bit is clear, then the  $\overline{ALRT}$  pin goes low. If the FET Charge Driver Connect bit ([0x0E.2 FCDC on page 55](#)) is set, then CFET is automatically turned off. If CPWR = 0 ([0x0E.3 CPWR on page 55](#)), then DFET also turns off and the chip transitions to IDLE mode.

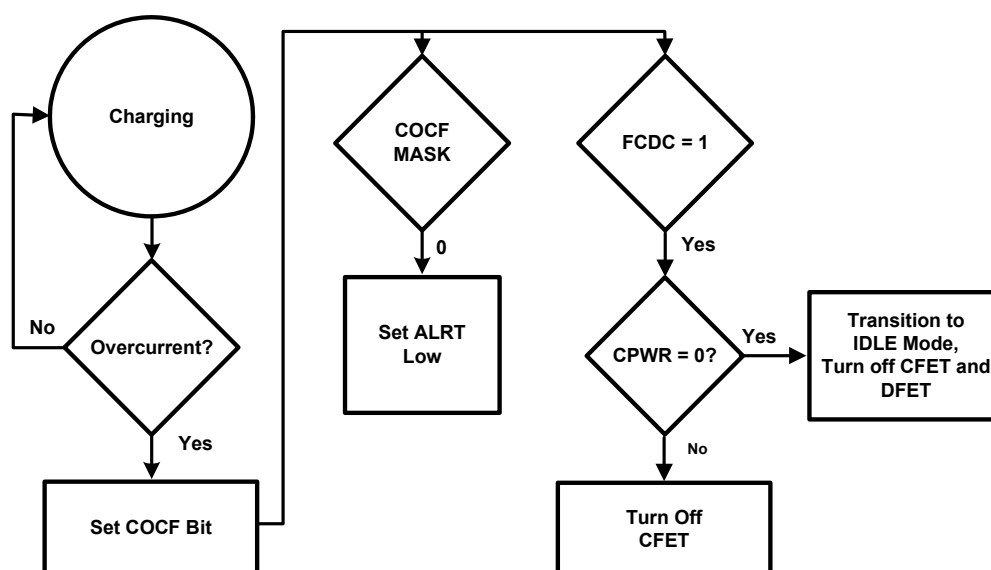

Figure 86. COC Detect Flow Diagram

The FET off state is the responsibility of the MCU when  $FCDC = 0$ . A COCF causes continuous scan to halt regardless of the setting of FCDC. [Figure 86](#) is the flow diagram for charge overcurrent detection and response.

## 5.6 ETAUX Port

Figure 87 shows the typical configuration of the External Temperature/Auxiliary (ETAUX) port with two external thermistors.

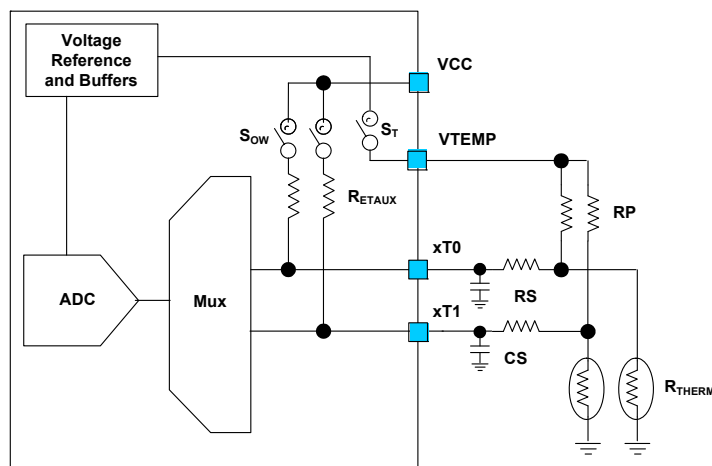

Figure 87. ETAUX Port Configured to Measure External Temperature

The ISL94216A ETAUX port consists of two analog input pins (xT0, xT1) that support two external thermistors, plus the VTEMP reference pin. Negative Temperature Coefficient thermistors (NTCs) are typically used to measure temperature within the battery pack.

Battery cell temperature is monitored for safety purposes because of battery type and chemistry limits on when to allow charge or discharge. Other potential thermal monitoring locations are the DFET, CFET, or the current sense resistor.

### 5.6.1 0x11 ETAUX Operation

The ETAUX Operation register controls the data acquisition behavior of the ETAUX inputs within the ISL94216A.

Table 23. 0x11 ETAUX Operation Register

Bits	D[7:6]	D[5]	D[4:2]	D[1]	D[0]
Bit Name	ETAUX EN	RSV	ETAUX Averages	RSV	ETAUX Trigger
Default	11	0	0 00	0	0

#### 5.6.1.1 0x11.7:6 ETAUX Enable

If set to 1 (default), the ETAUX Enable bits include voltage measurement of the ETAUX pins xT0 and xT1 in SCAN mode. Set one or both bits to 0 to bypass measurement of the related pin during System Scans. See Table 24 for more information.

An 0x11.0 ETAUX Trigger executes measurement of the enabled pins in IDLE or SCAN Mode.

Table 24. ETAUX Enable

D[7:6]		ETAUX Enable
0	0	ETAUX is Not Part of the System Scan
0	1	xT0 is Part of the System Scan
1	0	xT1 is Part of the System Scan
1	1	xT0 and xT1 is Part of the System Scan

### 5.6.1.2 0x11.5,1 RSV

Reserve Bits 5 and 1 should be ignored during a read command and should be set to 0 during a write command.

### 5.6.1.3 0x11.4:2 ETAUX Averages

The ETAUX Averages bits determine the number of samples averaged per measurement before reporting the results to the respective registers. The ETAUX averages bits control averaging for xT0 and xT1 measurements only. [Table 25](#) lists the options for these bits.

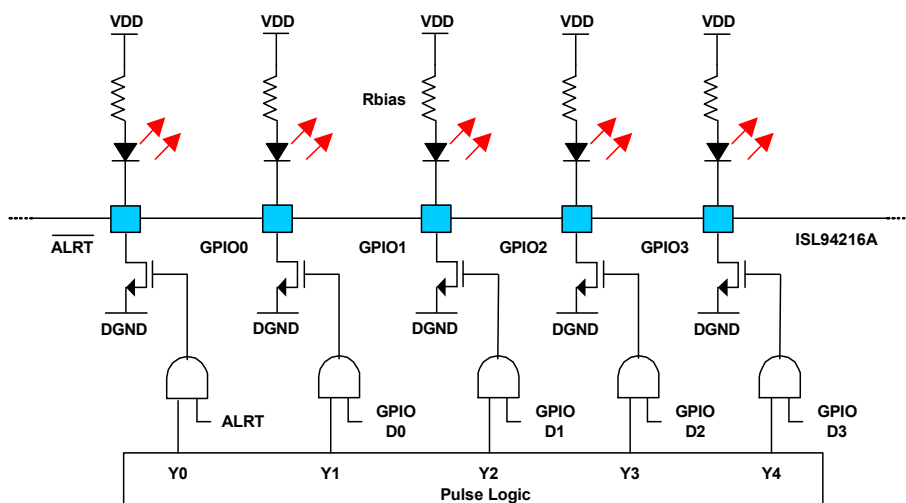

### Table 25. ETAUX Averages

ETAUX Averages: D[4:2]			Samples to Average
0	0	0	1
0	0	1	2
0	1	0	4
0	1	1	8
1	0	0	16
1	0	1	32
1	1	0	64
1	1	1	128

#### 5.6.1.4 0x11.0 ETAUX Trigger

A 0 to 1 transition of this bit in IDLE mode starts an ETAUX measurement. When received, the Busy bit transitions from 0 to 1 and the trigger bit clears. The Busy bit remains set until the action is completed and then returns to 0.

This trigger bit is ignored in SHIP and LOW POWER Modes and can trigger sequences in IDLE or SCAN mode only. This trigger should be used in IDLE mode because Renesas recommends reserving SCAN mode for System Scans only.

**Figure 88. ALRT Pulse EN and GPIOx Drive LEDs**

## 5.7 0x12 $\overline{\text{ALRT}}$ and GPIO

This register displays the status of the GPIO pins and configures the GPIO port and the  $\overline{\text{ALRT}}$  pin.

**Table 26. 0x12 GPIO and  $\overline{\text{ALRT}}$  Operation Register**

Bits	D[7]	D[6]	D[5:4]	D[3:0]
Bit Name	$\overline{\text{ALRT}}$ Assert	$\overline{\text{ALRT}}$ PULSE EN	GPIO Config	GPIO Status
Default	0	0	01	1111

### 5.7.1 0x12.7 $\overline{\text{ALRT}}$ Assert

The  $\overline{\text{ALRT}}$  Assert bit forces the  $\overline{\text{ALRT}}$  pin state to a low when the bit is set to 1. Clear the bit (default 0) to return the  $\overline{\text{ALRT}}$  pin to normal operation. This bit enables testing of the connection between the  $\overline{\text{ALRT}}$  pin and microcontroller.

### 5.7.2 0x12.6 $\overline{\text{ALRT}}$ Pulse EN

The  $\overline{\text{ALRT}}$  Pulse Enable bit can be used to drive the  $\overline{\text{ALRT}}$  pin in a more power efficient manner. When the bit is 1 and an alert is active, the ISL94216A turns on the  $\overline{\text{ALRT}}$  pin output pull-down device for GPIOpulse\_on (~2ms, [page 17](#)) within a GPIOpulse\_per (~10ms, [page 17](#)) period. When this bit is 0 (Default) and an alert is active, the ISL94216A drives the  $\overline{\text{ALRT}}$  pin LOW constantly. [Figure 88](#) illustrates the circuit.

### 5.7.3 0x12.5:4 GPIO CONFIG

GPIO Configuration bits allow the GPIO pins to be used as digital inputs, digital outputs, LED drivers, or as outputs to drive external power FET circuits. [Table 27](#) shows the possible configurations of the GPIO port.

**Table 27. GPIO Configuration Bits**

D[5:4]	GPIO Configuration
00	Digital Inputs
01	Digital Outputs
10	Drive LED
11	Power FETs Gate Drive Out

See [0x12.3:0 GPIO STATUS](#) for Digital Input and Output configurations.

**Drive LED:** This option pulses the GPIO pins in a sequential manner to save power. Each GPIO pin is set LOW for GPIOpulse\_on (~2ms, [page 17](#)) within a GPIOpulse\_per (~10ms, [page 17](#)) period. A simplified schematic is shown in [Figure 88](#). See [0x12.3:0 GPIO STATUS](#) to set the state of GPIO output. Set the GPIO Status bit to 1 to light an LED or to 0 to shut it off.

**Power FETs Gate Drive Out:** This selection enables the ISL94216A to be designed with a low side FET configuration. It connects GPIO2 to the DFET state and GPIO3 to the CFET state. These states are dependent on bits [0x24.1 DFET EN](#) and [0x24.0 CFET EN](#) on [page 75](#) along with other settings and faults as described in [CFET and DFET Pins \(50, 51\) on page 100](#). The DFET and CFET states follow the same expected behavior of the DFET and CFET pins except that the state does not depend on the charge pump. That means the state can be On (LOW) even when the [0x24.7 CPMP EN](#) on [page 72](#) bit is 0 and/or the [0x65.5 CPMP NRDY](#) on [page 86](#) bit is 1 even though the high-side DFET and CFET pins are off. [Table 28](#) defines the logic state of the GPIO output pins (3, 2, 0) as a function of the GPIO1 input, the device Mode, and the internal DFET and CFET enable bits.

GPIO1 is configured as a FETs Off digital input pin. If the logic input is high, both DFET and CFET GPIO pins, along with the high-side DFET and CFET pins (if enabled), turn off. If the logic input is low, the DFET and CFET states pass to GPIO2 and GPIO3. Prior to choosing this configuration, disable both CFET and DFET by setting their enable bits to 0; next, write 0x3E to register 0x12.

GPIO0 is configured as a FETs ON digital output pin. The output of the pin is LOW when CFET and DFET are both off. It is high impedance when one or both of the CFET and DFET GPIO outputs are On.

Table 28. GPIO Pins Logic States in FETs Out Mode

Internal State Variable			Input Pin	Output Pins		
Mode	DFET	CFET	FETs Off (GPIO1)	FETs On (GPIO0)	DFET (GPIO2)	CFET (GPIO3)
SCAN or IDLE	OFF	OFF	LOW	LOW	HI-Z	HI-Z
	OFF	ON	LOW	HI-Z	HI-Z	LOW
	ON	OFF	LOW	HI-Z	LOW	HI-Z
	ON	ON	LOW	HI-Z	LOW	LOW
	X	X	HIGH	LOW	HI-Z	HI-Z
LOW POWER or SHIP	X	X	X	HI-Z	HI-Z	HI-Z

### 5.7.4 0x12.3:0 GPIO STATUS

The GPIO Status bits report the status of each GPIO pin. The GPIO Status bits are read only when configured as inputs. Reading these bits returns the input status of the GPIO pins.

If the GPIO pins are set up as Digital outputs, then writing to these bits sets the GPIO pins state. Set a GPIO Status bit to 0 to pull the output pin low or to 1 to release it.

In Drive LED mode, set a GPIO Status bit to 1 to light an LED or to 0 to shut it off. The GPIO pins are connected to open-drain NMOS transistors designed to drive 2mA nominal LEDs. **Note:** Drive LED and Digital Output modes force the outputs to the opposite level given the same bit setting.

## 5.8 ETAUX Detectors

The ETAUX Detectors are threshold comparators that detect over-temperature and under-temperature conditions based on readings from the xT0 and xT1 pins. The ETAUX Fault Delay counters are bypassed if the part is not running in continuous SCAN mode. [Figure 89](#) is the block diagram of the ETAUX fault detection function.

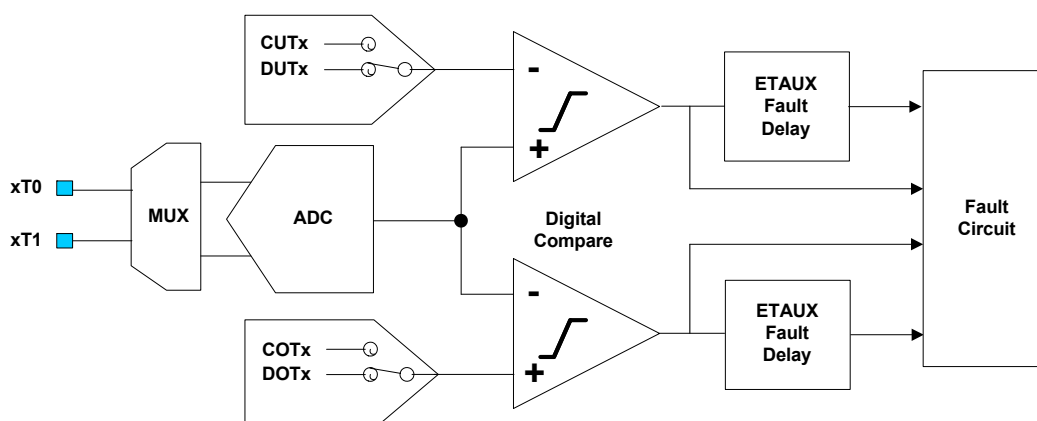

Figure 89. ETAUX Fault Detector Block Diagram

### 5.8.1 0x13-1A ETAUX Thresholds

The Under-Temperature and Over-Temperature ETAUX fault detectors consist of two digital comparators with four digital thresholds for each ETAUX (xT0 or xT1) input. The device has two sets of limits to which the ETAUX readings are compared based on whether the pack is charging or discharging.

The thresholds for overvoltage (UT) and undervoltage (OT) are set by programming the CUTn, DUTn, COTn, and DOTn (n = 0 for AUX0/xT0 and n = 1 for AUX1/xT1) registers. Table 29 and Table 30 show the format of these registers.

Table 29. 0x13, 15, 17, 19 (D,C) UT Threshold Registers

Bits	Name	Default	ETAUX <sub>thstep</sub>	Offset
D[7:0]	UT (OV) Threshold [7 to 0]	1111 1111	6.276mV	6.263mV

Table 30. 0x14, 16, 18, 1A (D,C) OT Threshold Registers

Bits	Name	Default	ETAUX <sub>thstep</sub>	Offset
D[7:0]	OT (UV) Threshold [7 to 0]	0000 0000	6.276mV	6.263mV

To calculate the threshold voltage for all COT, DOT, CUT, and DUT registers, multiply the register value by the step size ETAUX<sub>thstep</sub>, and add the offset (Equation 11). The registers support settings from 6.263mV to 1606.67mV.

**(EQ. 11)**  $V_{Threshold} = (RegVal) \cdot ETAUX_{thStep} + Offset$

Eight associated Fault/Indicator bits are located at Register Address 0x64 [ETAUX Fault on page 84](#). Each of the bits is linked to a UT or OT threshold register. Each time the ISL94216A measures AUX1/xT1 and AUX0/xT0 voltages (0x58-59 xT0, 0x5A-5B xT1 (R)), the results are compared to the relevant thresholds. If the external voltage is greater than the relevant UT threshold or less than or equal to the relevant OT threshold, the appropriate Fault/Indicator bit is set.

Each Fault/Indicator bit has a masking bit (see 0x84 [ETAUX Fault Mask on page 85](#)) that connects the Fault/Indicator bit to the ALRT pin if cleared (set to 0/ The default is 1).

The bit 0x24.2 [ETA Connect on page 74](#) determines if the ETAUX OT/UT faults control the power FETs automatically. These faults halt continuous scan regardless of ETA Connect.

UT thresholds detect under-temperature conditions when a pin connects to a negative temperature coefficient (NTC) circuit, or they detect overvoltage conditions when the pins are used for auxiliary input voltages.

OT thresholds detect over-temperature conditions when a pin connects to a negative temperature coefficient (NTC) circuit, or they detect undervoltage conditions when the pins are used for auxiliary input voltages.

The charge and discharge temperature comparisons are a function of bits 0x67.6 [CHRG1 on page 90](#) and 0x67.7 [DCHRG1 on page 90](#). When the CHRG1 bit is set, the AUXn readings are compared to the COT and CUT thresholds. When the DCHRG1 bit is set, the AUXn readings are compared to the DUT and DOT threshold.

- When  $I_{PACK} < -20$  (decimal), the chip compares  $V(xTn, VSS)$  to the COT/CUT thresholds.
- When  $I_{PACK} > 19$ , the chip compares  $V(xTn, VSS)$  to the DOT/DUT thresholds.
- When  $-20 \leq I_{PACK} \leq 19$ , the chip does not compare  $V(xTn, VSS)$  to any of these thresholds.

If neither the CHRG1 or DCHRG1 bits are set, then no action is taken in SCAN mode, but in IDLE mode a violation of any of these thresholds set the related fault bit.

## 5.8.2 0x58-59 xT0, 0x5A-5B xT1 (R)

The ETAUX Voltage registers report the voltage measurement readings for the xT0 and xT1 pins. Each register is two bytes.

Table 31. 0x58-5B ETAUX Voltage

Register Name	Address - Bits	Byte Order	ETAUX <sub>Step</sub>
xT0/AUX0	0x58 - D[7:0]	MSB	24.52μV
	0x59 - D[7:0]	LSB	
xT1/AUX1	0x5A - D[7:0]	MSB	
	0x5B - D[7:0]	LSB	

$$(EQ. 12) \quad xTnVoltage = (RegVal) \cdot ETAUX_{Step} + 0.5 \cdot ETAUX_{Step}$$

Multiply the 16-bit register value by the step size  $ETAUX_{Step}$ , and add the 1/2 LSB offset to calculate the voltage. The registers support values from 12.26μV to 1606.67mV.

These voltages are compared to [0x13-1A ETAUX Thresholds](#), violations set fault bits in register [0x64 ETAUX Fault](#) and stop continuous scan. If the control bit [0x24.2 ETA Connect](#) is set, a fault in SCAN mode shuts off power FETs depending on the setting of [0x0E.3 CPWR](#) and current direction. A violation of any of these thresholds in IDLE mode sets the fault bit regardless of current direction.

## 5.9 Internal Temperature

### 5.9.1 0x22 - 0x23 IOTW and IOTF Thresholds

The Internal Over-Temperature Threshold detectors allow for two limit settings on the ISL94216A die temperature. The internal temperature sensor is monitored to prevent the die from over heating.

The Internal Over-Temperature Warning (IOTW) Threshold (0x22) is the first temperature threshold. It is intended to be a warning and sets the flag [0x66.6 IOTW](#) when the internal temperature exceeds its temperature limit.

If the internal temperature rises above the second temperature threshold, bit [0x63.5 IOTF](#) is set, the power FETs are disabled, and System Scan stops.

Both the IOTW and Internal Over-Temperature Fault (IOTF) bits require [0x09.5 Other Fault Delay](#) consecutive measurements in violation of the limit in continuous System Scan before the fault bit is set. The Other Fault Delay counters are bypassed if the part is not running in continuous SCAN mode. [Figure 90](#) is the block diagram for the IOT detection functions.

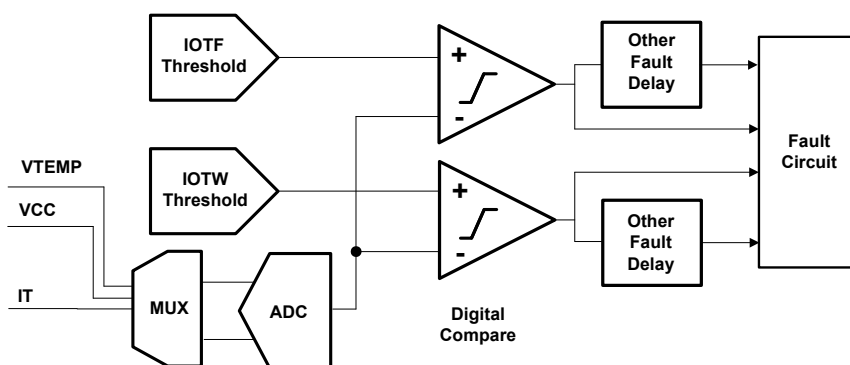

Figure 90. IOT Fault Detectors

Table 32 shows the format of these registers.

**Table 32. 0x22, 0x23 IOT Threshold Registers**

Register	Bits D[7:0]
0x22: Internal Over Temperature Warning Threshold	0x51 (~85C) Default
0x23: Internal Over Temperature Fault Threshold	0x45 (~95C) Default

Setting IOT register(s) to the minimum of 0x00 equates to an internal temperature of +151.1°C. The maximum setting of 0xFF is -63.7°C. Round the result of Equation 13 to the nearest integer (max 255, min 0) to set the Temperature Threshold register values based on the desired temperature (°C).

$$(EQ. 13) \quad \text{RegVal} = (-2.95 \times 10^{-4}) \cdot \text{Temp}^2 - 1.15975 \cdot \text{Temp} + 182.23$$

Use Equation 14 to convert these two threshold register values (or the internal temperature register value) read from the ISL94216A to temperature in °C.

$$(EQ. 14) \quad \text{TempThreshold} = (-1.82 \times 10^{-4}) \cdot \text{RegVal}^2 - 0.79605 \cdot \text{RegVal} + 151.11$$

## 5.9.2 0x5E Internal Temperature (R)

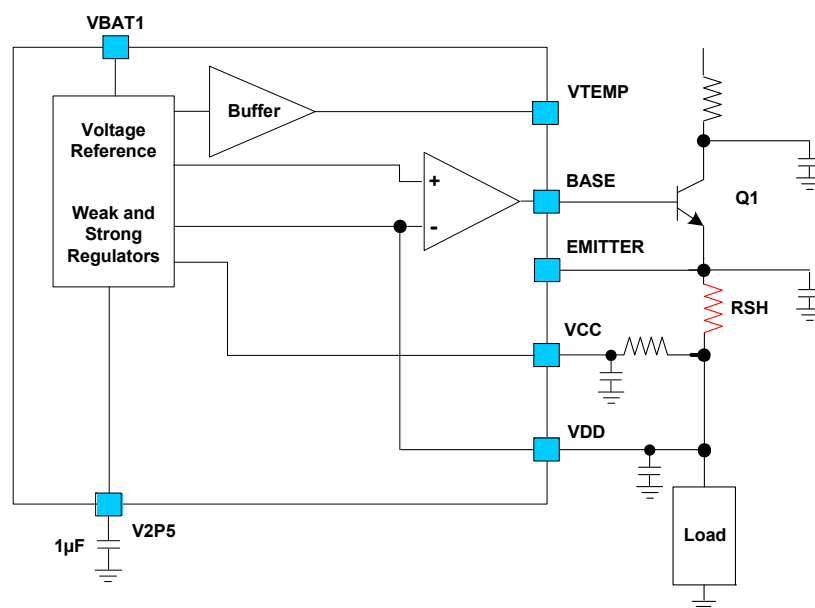

The Internal Temperature register reports the internal temperature of the ISL94216A based on an internal Negative Temperature Coefficient (NTC) temperature sensing circuit. As the internal temperature increases the voltage across the element decreases.

Use Equation 15 to calculate the internal temperature in °C directly from the register decimal value:

$$(EQ. 15) \quad \text{IT}_C = (-1.82 \times 10^{-4}) \cdot (\text{RegVal}^2) - 0.79605 \cdot (\text{RegVal}) + 151.11$$

## 5.10 Regulator Measurements and Detectors

The regulator and voltage reference blocks with a typical external component configuration is illustrated in Figure 91. The external component configuration is detailed in Figure 100 on page 96.

**Figure 91. Regulator and Reference**

The VBAT1 pin connects to internal regulators that have low current sourcing capabilities. Their purpose is to power up essential circuitry when the part starts up or is in LOW POWER or SHIP mode (with bit [0x1B.1 LP REG](#) on page 66 set to 0).

The VCC pin is the analog power input of the device while the VDD pin is the digital power input. The VCC, VDD, and V2P5 pins have window comparators that monitor the voltages. If their respective voltages are outside the  $PG_{VCC}$ ,  $PG_{VDD}$ , or  $PG_{2p5v}$  (page 15) windows for 1ms, the device transitions to SHIP mode.

ADC multiplexer inputs (not shown) are connected to the VTEMP and VCC pins of the device. Voltage measurement of these pins tests the health of the regulators and loads. The Emitter to VDD pin voltage is also measured by the ADC and is stored in register [0x61-62 I<sub>REG</sub> Voltage \(R\)](#) on page 68. This voltage can be used to calculate the NPN emitter current.

The amplifier driving the BASE pin sources a minimum of 1mA over the operating temperature range. This corresponds to a maximum regulation current of around 100mA assuming a minimum NPN  $\beta$  of 100.

### 5.10.1 0x1B V<sub>REG</sub> Operation

The V<sub>REG</sub> Operation register holds settings for Communications Timeout, Other scan and load detect delays, regulator operation in LOW POWER and SHIP Modes and the V<sub>REG</sub> measurement Trigger.

**Table 33. 0x1B V<sub>REG</sub> Operation Register**

Bits	D[7:6]	D[5:4]	D[3:2]	D[1]	D[0]
Bit Name	Communications Timeout	Update Other	LD Delay	LP REG	V <sub>REG</sub> Trig
Default	11	11	00	0	0

#### 5.10.1.1 0x1B.7:6 Communications Timeout

The Communications Timeout bits set the timeout period if bit [0x1F.1 Communication Timeout EN](#) on page 69 is set (1) to enable the timer. The Communication Timeout Enable bit enables the  $t_{COM}$  (page 16) timer that transitions the part from either SCAN or IDLE to LOW POWER Mode if no communications have been received in the selected time. The timeout setting is ignored if the Communication Timeout Enable bit is clear (0), disabling this feature and preventing the automatic mode transition.

**Table 34. Timeout Selections**

D[7:6]	Communications Timeout
00	128ms
01	512ms
10	2.048s
11	4.096s

#### 5.10.1.2 0x1B.5:4 Update Other

The Update Other bits set the number of System Scans required before ETAUX, V<sub>BAT1</sub>, V<sub>VCC</sub>, I<sub>REG</sub>, V<sub>TEMP</sub>, and Internal Temperature (IT) measurements are made in SCAN mode as part of continuous scans. Setting 00 enables an update on every System Scan while the other settings enable an update at other frequencies. This setting is ignored during single triggered scans.

Table 35. Update Other Bits

D[5:4]	Update Other Number of System Scans
00	1 (Update on every scan)
01	8 (Update on scan 1, 9, 17, 25...)
10	16 (Update on scan 1, 17, 33, 49...)
11	64 (Update on scan 1, 65, 129...)

#### 5.10.1.3 0x1B.3:2 LD Delay

The Load Detect time Delay bits set a time delay in addition to  $t_{LDEN}$  (page 14) before testing for a load. Available settings for the LD Delay bits are listed in Table 36. See [Short-Circuit Detection and Recovery on page 52](#), [Load Detection on page 56](#), and [LDMON Pin \(49\) on page 99](#) for more information about load detection.

Table 36. Load Detect Time Delay

D[3:2]		LD Delay (s)
0	0	0.25
0	1	1
1	0	2
1	1	4

#### 5.10.1.4 0x1B.1 LP REG

The Low Power Regulator bit selects which regulator is on between sets of measurements during LOW POWER mode (measurements are not executed in SHIP mode). For the lowest power consumption in LOW POWER and SHIP Modes, set this bit to 0 (default, Weak regulator). This setting cannot power external circuitry in LOW POWER and SHIP Modes. A setting of 1 selects the Strong regulator that uses the external NPN transistor which can power external circuitry in both LOW POWER and SHIP Modes.

#### 5.10.1.5 0x1B.0 V<sub>REG</sub> Trigger

A 0 to 1 transition of this bit in IDLE mode starts measurement of  $V_{VCC}$ ,  $V_{VTEMP}$ , and  $I_{REG}$ . When received, the Busy bit transitions from 0 to 1, and the Trigger bit clears. The Busy bit remains set until the action is completed, and then returns to 0.

After measurement, the voltages are compared to the relevant threshold registers. See [0x60 V<sub>VCC</sub> Voltage \(R\) on page 68](#), [0x5F V<sub>VTEMP</sub> Voltage \(R\) on page 67](#), and [0x61-62 I<sub>REG</sub> Voltage \(R\) on page 68](#) for details.

This trigger bit is ignored in SHIP and LOW POWER Modes and can trigger sequences in IDLE or SCAN mode only. This trigger should be used in IDLE mode because Renesas recommends to reserve SCAN mode for System Scans only.

### 5.10.2 0x1C V<sub>VCC</sub> Min Threshold

The V<sub>VCC</sub> Minimum Threshold register sets the comparator threshold for the VCC voltage measurement. After a VCC measurement, this threshold voltage is compared to the measurement result stored at [0x60 V<sub>VCC</sub> Voltage \(R\) on page 68](#). If the VCC voltage is less than or equal to the threshold, fault bit [0x63.7 VCCF on page 82](#) is set. This fault sets  $\overline{ALRT}$  low if mask bit 0x83.7 is 0 (see [0x83 Priority Fault Mask on page 84](#)). Table 37 shows the format of this register.

Table 37. 0x1C V<sub>VCC</sub> Min Threshold Register

Bits	Bit Name	Default	V <sub>VCC</sub> Step
D[7:0]	VCCMIN	0000 0000	25.104mV

$$(EQ. 16) \quad V_{Threshold} = (RegVal) \cdot V_{VCCStep} + 0.5 \cdot V_{VCCStep}$$

Multiply the register value by the step size  $V_{VCCStep}$  and add the  $\frac{1}{2}$  LSB offset to calculate the threshold value (Equation 16). The register supports settings from 12.55μV to 6.414V.

### 5.10.3 0x1D,1E IREG<sub>OC1, 2</sub> Threshold

The Regulator Overcurrent Charge Threshold registers set the digital comparator overcurrent threshold for the EMITTER to VDD measurement. IREG<sub>OC1</sub> is the limit that the  $I_{REG}$  Voltage reading is compared to while the device is in SCAN or IDLE mode. IREG<sub>OC2</sub> is the limit that the reading is compared to while the device is in LOW POWER mode. After an  $I_{REG}$  measurement, the threshold voltage is compared to the measurement result stored at 0x61-62  $I_{REG}$  Voltage (R) on page 68. If the  $I_{REG}$  measurement is greater than the threshold, the appropriate fault bit is set based on mode.

If the IREG<sub>OC1</sub> threshold comparison fails, the IREG1 fault bit 0x67.2 IREG1 on page 91 is set to 1 (applies in SCAN or IDLE modes). This fault sets  $\overline{ALRT}$  low if mask bit 0x87.2 is set to 0 (see 0x87 Status Mask on page 91).

If the IREG<sub>OC2</sub> threshold comparison fails, the IREG2 fault bit 0x67.1 IREG2 on page 91 is set to 1 (applies in LOW POWER mode). This fault sets  $\overline{ALRT}$  low if mask bit 0x87.1 is set to 0 (see 0x87 Status Mask on page 91).

Table 38. 0x1D IREG<sub>OC1</sub> and 0x1E IREG<sub>OC2</sub> Threshold Registers

Address - Bits	Name	Default	IREGOC <sub>Step</sub>	Offset
0x1D - D[7:0]	IREG <sub>OC1</sub>	1111 1111	1.345mV	1.3396mV
0x1E - D[7:0]	IREG <sub>OC2</sub>	1111 1111		

$$(EQ. 17) \quad V_{Threshold} = (RegVal) \cdot IREGOC_{Step} + Offset$$

Multiply the register value by the step size IREGOC<sub>Step</sub> and add the fixed offset from Table 38 to calculate the threshold (Equation 17). The registers support settings from 1.34mV to 344.28mV.

### 5.10.4 0x5F V<sub>TEMP</sub> Voltage (R)

The V<sub>TEMP</sub> Voltage register stores the result from the measurement of the V<sub>TEMP</sub> pin voltage, which is included in the group of measurements done in LOW POWER mode, in any System Scan, and in the group of measurements triggered with 0x1B.0 V<sub>REG</sub> Trigger on page 66 in IDLE mode. The VTEMP reference voltage powers the external thermistors. After measurement, the voltage is compared to the threshold VTEMP<sub>Min</sub> (1.1V typical, page 15). If the voltage is less than or equal to the threshold, fault bit 0x67.0 VTMPF on page 91 is set. This fault can set  $\overline{ALRT}$  low if mask bit 0x87.0 is set to 0 (see 0x87 Status Mask on page 91).

Table 39. 0x5F V<sub>TEMP</sub> Voltage

Bits	Default	V <sub>TEMPStep</sub>	Offset
D[7:0]	0000 0000	3.138mV	804.908mV

$$(EQ. 18) \quad V_{VTEMP} = (RegVal) \cdot V_{VTEMPStep} + Offset$$

Multiply the register value by the step size  $V_{VTEMPStep}$ , and add the fixed offset (minimum value of the  $V_{VTEMP}$  range) to calculate the voltage Equation 18. The register records results from 804mV to 1.605V.

### 5.10.5 0x60 V<sub>VCC</sub> Voltage (R)

The V<sub>VCC</sub> Voltage register stores the result from the internal measurement of the VCC pin voltage. The voltage measurement is compared to the threshold register 0x1C V<sub>VCC</sub> Min Threshold on page 66. If the comparison fails, the fault bit 0x63.7 VCCF on page 82 is set. This fault sets  $\overline{\text{ALRT}}$  low if the mask bit 0x83.7 is set to 0 (see 0x83 Priority Fault Mask on page 84).

Table 40. 0x60 V<sub>VCC</sub> Voltage

Bits	Default	V <sub>VCCStep</sub>
D[7:0]	0000 0000	25.104mV

$$\text{(EQ. 19)} \quad V_{VCC} = (\text{RegVal}) \cdot V_{VCC\text{Step}} + 0.5 \cdot V_{VCC\text{Step}}$$

Multiply the register value by the step size V<sub>VCCStep</sub> (Table 40) and add the ½ LSB offset to calculate the voltage Equation 19. The register records results from 12.55mV to 6.414V.

### 5.10.6 0x61-62 I<sub>REG</sub> Voltage (R)

The read only I<sub>REG</sub> registers contain the 16-bit result of the measurement of the voltage across the sense resistor between the EMITTER and VDD pins. After measurement, the voltage is compared to the 0x1D IREG<sub>OC1</sub> threshold register in SCAN or IDLE modes or the 0x1E IREG<sub>OC2</sub> threshold register if in LOW POWER mode (see 0x1D, 1E IREG<sub>OC1, 2</sub> Threshold on page 67). If the 0x1D IREG<sub>OC1</sub> comparison fails, the fault bit 0x67.2 IREG1 on page 91 is set. If the 0x1E IREG<sub>OC2</sub> comparison fails, the fault bit 0x67.1 IREG2 on page 91 is set. These faults set  $\overline{\text{ALRT}}$  low if mask bits IREG1 and IREG2 are 0 (see 0x87 Status Mask on page 91).

Table 41. 0x61-62 I<sub>REG</sub> Voltage

Address - Bits	Byte Order	IREG <sub>Step</sub>
0x61 - D[7:0]	MSB	10.507μV
0x62 - D[7:0]	LSB	

$$\text{(EQ. 20)} \quad V_{IREG} = (\text{RegVal}) \cdot \text{IREG}_{\text{Step}} + 0.5 \cdot \text{IREG}_{\text{Step}}$$

Multiply the 16-bit register value by the step size IREG<sub>Step</sub> and add the ½ LSB offset to calculate the voltage (Equation 20); next, divide by the sense resistor value to calculate the current. The register records results from 5.25μV to 344.28V.

## 5.11 V<sub>BAT1</sub>

### 5.11.1 0x1F V<sub>BAT1</sub> Operation

The V<sub>BAT1</sub> Operation register is used to enable and/or trigger measurement of V<sub>BAT1</sub> and I<sub>TEMP</sub>. It also controls averaging for these and regulator measurements.

Table 42. 0x1F V<sub>BAT1</sub> Operation Register

Bits	D[7]	D[6]	D[5]	D[4:2]	D[1]	D[0]
Bit Name	V <sub>BAT1</sub> EN	I <sub>TEMP</sub> EN	I <sub>TEMP</sub> Trigger	OTHER Averages	COMM TO EN	V <sub>BAT1</sub> Trigger
Default	1	1	0	0 00	1	0

**5.11.1.1 0x1F.7 V<sub>BAT1</sub> EN**

The V<sub>BAT1</sub> Enable bit set to 1 (default) includes V<sub>BAT1</sub> measurement during System Scans. The measurement is excluded if this bit is set to 0. This bit has no effect on V<sub>BAT1</sub> Trigger. The result of a V<sub>BAT1</sub> voltage measurement is stored in register [0x5C - 0x5D V<sub>BAT1</sub> Voltage \(R\) on page 71](#).

**5.11.1.2 0x1F.6 I<sub>TEMP</sub> EN**

The Internal Temperature Enable bit set to 1 (default) includes an internal temperature measurement during System Scans. The measurement is excluded if this bit is set to 0. This bit has no effect on I<sub>TEMP</sub> Trigger. The result of a I<sub>TEMP</sub> voltage measurement is stored in register [0x5E Internal Temperature \(R\) on page 64](#).

**5.11.1.3 0x1F.5 I<sub>TEMP</sub> Trigger**

A 0 to 1 transition of this bit instructs the device to start an I<sub>TEMP</sub> measurement. When received, the Busy bit transitions from 0 to 1 and the trigger bit is cleared. The Busy bit remains set until the action is completed and then returns to a 0.

This trigger bit is ignored in SHIP and LOW POWER Modes and can only trigger sequences in IDLE or SCAN mode. This trigger should be used in IDLE mode because Renesas recommends to reserve SCAN mode for System Scans only.

**5.11.1.4 0x1F.4:2 Other Averages**

The Other Averages bits set the number of samples averaged before passing the measurement results to the respective registers. The Other Averaging bits control averaging for [0x5C - 0x5D V<sub>BAT1</sub> Voltage \(R\)](#), [0x5F V<sub>VTEMP</sub> Voltage \(R\)](#), [0x60 V<sub>VCC</sub> Voltage \(R\)](#), and [0x61-62 I<sub>REG</sub> Voltage \(R\)](#). [Table 43](#) lists the options for this bit.

**Table 43. Other Averages**

Other Averages: D[4:2]			Samples to Average
0	0	0	1
0	0	1	2
0	1	0	4
0	1	1	8
1	0	0	16
1	0	1	32
1	1	0	64
1	1	1	128

The conversion time for these measurements can be estimated as [Equation 21](#):

$$(EQ. 21) \quad OTHER_{CT} = (3 + SamplesToAverage) \cdot ADC_{CT2}$$

ADC<sub>CT2</sub> is the base conversion time of the ADC and can be found in the specification table on [page 16](#).

**5.11.1.5 0x1F.1 Communication Timeout EN**

The Communication Timeout Enable bit enables the t<sub>COM</sub> ([page 16](#)) timer that transitions the part from SCAN or IDLE to LOW POWER mode if no communications have been received in the selected time. Set the bit to 1 (default) to enable the timer. Set to 0 to disable this feature and prevent the automatic mode transition. See [0x1B.7:6 Communications Timeout on page 65](#) for the timer settings available.

### 5.11.1.6 0x1F.0 V<sub>BAT1</sub> Trigger

A 0 to 1 transition of this bit instructs the device to start a V<sub>BAT1</sub> measurement. When received, the Busy bit transitions from 0 to 1 and the trigger bit is cleared. The Busy bit remains set until the action is completed and returns to 0.

This trigger bit is ignored in SHIP and LOW POWER Modes and can trigger sequences in IDLE or SCAN mode only. This trigger should be used in IDLE mode because Renesas recommends to reserve SCAN mode for System Scans only.

### 5.11.2 0x20 - 0x21 V<sub>BAT1</sub> Thresholds

The V<sub>BAT1</sub> Threshold registers set the upper and lower voltage thresholds that are compared to V<sub>BAT1</sub> measurements. A violation of these thresholds may result in a disconnection of the power FETs. See [0x24.3 VBAT1CON on page 73](#). The simplified block diagram of the V<sub>BAT1</sub> fault detection functions is illustrated in [Figure 92](#).

The [0x09.5 Other Fault Delay on page 50](#) counters are bypassed if the part is not running in continuous SCAN mode.

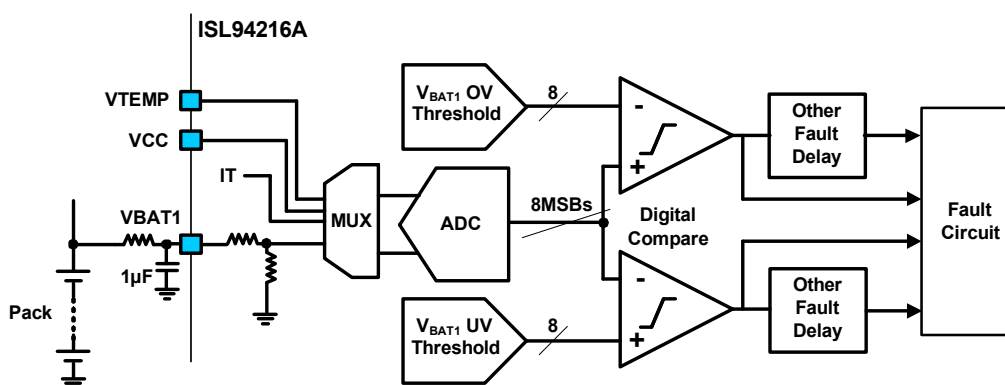

Figure 92. V<sub>BAT</sub> OV/UV Detectors

#### 5.11.2.1 0x20 V<sub>BAT1</sub> OV Threshold

The V<sub>BAT1</sub> OV Threshold register sets the threshold voltage for the digital comparator that monitors for V<sub>BAT1</sub> overvoltage. The V<sub>BAT1</sub> overvoltage threshold register format is shown in [Table 44](#).

Table 44. 0x20 OV<sub>BAT1</sub> Threshold Register

Bits	Bit Name	Default	VBAT1 <sub>thStep</sub>	Offset
D[7:0]	V <sub>BAT1</sub> OV Threshold	1111 1111	301.25mV	300.66mV

Multiply the register value by VBAT1<sub>thStep</sub> and add the fixed offset to calculate the threshold ([Equation 22](#)). The register supports settings from 300.66mV to 77.12V.

$$(EQ. 22) \quad V_{Threshold} = (RegVal) \cdot V_{BAT1_{thStep}} + Offset$$

If the measured V<sub>BAT1</sub> voltage exceeds this threshold for more than [0x09.5 Other Fault Delay on page 50](#) Scans during charge, then the fault [0x65.7 VBOVF on page 86](#) is set. The Other Fault Delay counter is bypassed if the part is not running in continuous SCAN mode.

### 5.11.2.2 0x21 V<sub>BAT1</sub> UV Threshold

The V<sub>BAT1</sub> UV Threshold register sets the threshold voltage for the digital comparator that monitors for V<sub>BAT1</sub> undervoltage. The V<sub>BAT1</sub> undervoltage threshold register format is shown in [Table 45](#).

**Table 45. 0x21 UV<sub>BAT1</sub> Threshold Register**

Bits	Bit Name	Default	VBAT1 <sub>thStep</sub>	Offset
D[7:0]	UVBAT1	0000 0000	301.25mV	300.66mV

Multiply the register value by VBAT1<sub>thStep</sub> and add the fixed offset to calculate the threshold ([Equation 22](#)). The register supports settings from 300.66mV to 77.12V.

If the measured V<sub>BAT1</sub> voltage is less than or equal to this threshold for more than [0x09.5 Other Fault Delay](#) scans during discharge, then fault [0x65.6 VBUVF](#) is set. The Other Fault Delay counter is bypassed if the part is not running in continuous SCAN mode.

### 5.11.3 0x5C - 0x5D V<sub>BAT1</sub> Voltage (R)

The V<sub>BAT1</sub> Voltage register stores the measured value of the voltage between the V<sub>BAT1</sub> and VSS pins. The pin voltage is divided internally for measurement.

**Table 46. 0x5C-5D V<sub>BAT1</sub> Voltage**

Address - Bits	Byte Order	VBAT1 <sub>Step</sub>
0x5C - D[7:0]	MSB	1.177mV
0x5D - D[7:0]	LSB	

Multiply the register value by the step size VBAT1<sub>Step</sub> and add the 1/2 LSB offset to calculate the voltage with [Equation 23](#). The register records results from 588μV to 77.12V.

**(EQ. 23)**  $V_{BAT1} = (RegVal) \cdot VBAT1_{Step} + 0.5 \cdot VBAT1_{Step}$

## 5.12 Power FET Block

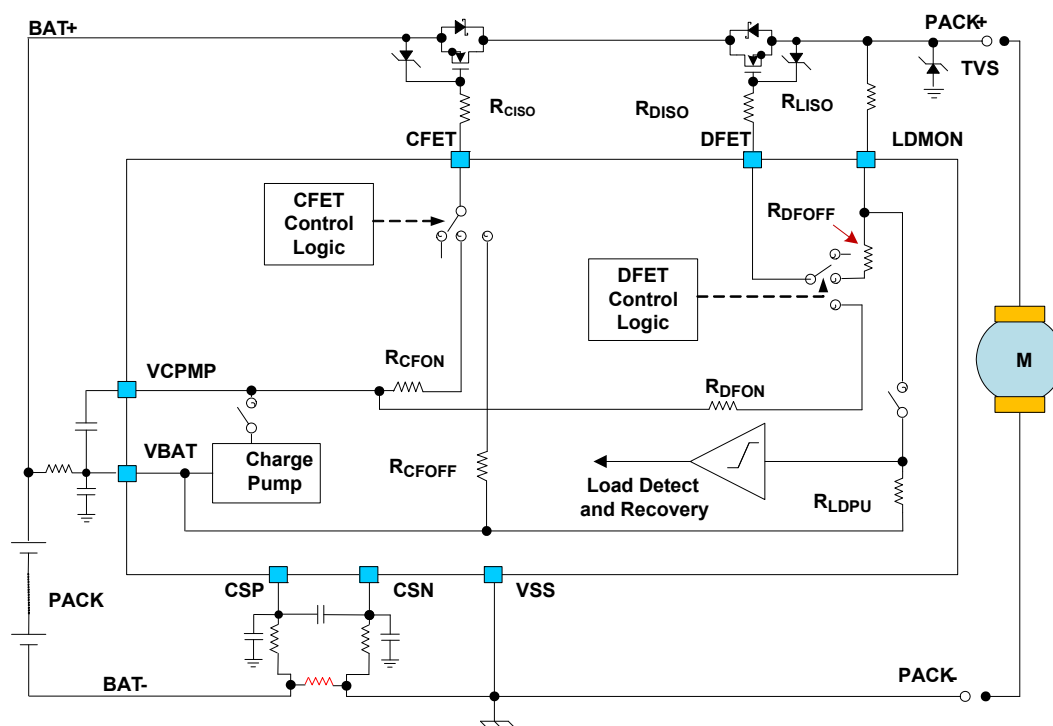

Figure 93. Block Diagram of Power FET Controls

### 5.12.1 0x24 Power FET Operation

The Power FET Operation register allows control of power FET and Open Wire functionality within the ISL94216A. This includes enable/disable of the charge pump and power FETs, and whether Cell, VBAT1 or ETAUX threshold violations can disconnect power FETs. Table 47 shows the format of this register.

See [CFET and DFET Pins \(50, 51\)](#) on page 100 and [Scan Will Not Start](#) on page 115 for details about how the Connect and Enable bits interact with fault and other control bits for FET control and System Scan.

Table 47. 0x24 Power FET Operation Register

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	CPMP EN	OW EN	OW Trigger	CELL CON	VBAT1 CON	ETA CON	DFET EN	CFET EN
Default	0	1	0	1	1	1	0	0

#### 5.12.1.1 0x24.7 CPMP EN

The Charge Pump Enable bit enables the charge pump in IDLE or SCAN Modes if set to 1. Set the bit to 0 (default) to disable the charge pump circuitry. The charge pump provides a biasing voltage to CB16. Disabling the charge pump reduces the CB16 pin maximum voltage.

When the charge pump is enabled (in IDLE or SCAN) and its output voltage rises above  $V_{pmpMin}$  (page 16), bit CPMP NRDY is automatically cleared to 0. If the voltage drops below  $V_{pmpFall}$  (page 16), bit [0x65.5 CPMP NRDY](#) on page 86 is set to 1. If CPMP EN is set to 0, then CPMP NRDY = 0.

There is a delay of about 1ms from enabling the charge pump, and also from setting CPMP NRDY to 1 by the  $V_{pmpFall}$  comparator, before the  $V_{pmpMin}$  comparator is allowed to clear CPMP NRDY.

If enabled, the charge pump circuitry is powered down when the device transitions to LOW POWER or SHIP mode, though the setting of the CPMP EN bit is not changed. When the device transitions back to IDLE or SCAN

mode, the charge pump restarts. If the CFET EN and/or DFET EN bits are 1, then CFET and/or DFET drivers are also turned back on.

#### 5.12.1.2 0x24.6 OW EN

Set the Open-Wire enable bit to 1 (default) to include an open-wire test sequence during System Scans. Set this bit to 0 to disable open-wire test during System Scans. The frequency of open-wire tests is selected by bits [0x03.6:5 OW Update on page 45](#).

During an open-wire test a current measurement is always performed, independent of the setting of the I<sub>PACK</sub> EN bit 0x03.7. The current measurement determines if the device is discharging while the open-wire test is being performed. The results of the VSS and VBAT open-wire tests are invalid during discharge so they are omitted.

#### 5.12.1.3 0x24.5 OW Trigger

The Open-Wire Trigger bit initiates an open-wire test sequence regardless of the setting of 0x24.6 OW Enable. A 0 to 1 transition instructs the device to start an open-wire test sequence. When the open-wire test has started, the Trigger bit clears, the Busy bit is set until the test complete and then it also clears. See [Open-Wire Function on page 116](#) for more information.

This Trigger bit is ignored in SHIP and LOW POWER modes and can trigger sequences in IDLE or SCAN mode only. This trigger should be used in IDLE mode because Renesas recommends to reserve SCAN mode for System Scans only.

The Open-Wire test sequence does not check the ETAUX pins; these must be checked separately. See [Aux Pins Open-Wire Test on page 96](#) for details.

#### 5.12.1.4 0x24.4 CELLCON

The V<sub>CELL</sub> Connect bit connects the outputs of the delta V<sub>CELL</sub>, UV and OV comparators from a V<sub>CELL</sub> scan to the FET control block. If any of the cell voltage OV, UV, or delta V<sub>CELL</sub> max thresholds are violated (see [0x06 - 0x07 V<sub>CELL</sub> OV/UV Threshold on page 48](#) and [0x08 V<sub>CELL</sub> Max Delta Threshold](#)), the CFET and/or DFET may be turned off per the setting of [0x0E.3 CPWR on page 55](#). A 1 (default) connects the V<sub>CELL</sub> fault outputs to the FET controller. Setting this bit to 0 moves fault handling responsibility to the MCU as these faults do not disconnect the power FET(s).

Continuous scans are halted on detection of these faults regardless of the setting of V<sub>CELL</sub> Connect. See [CFET and DFET Pins \(50, 51\) on page 100](#) and [Scan Will Not Start on page 115](#) for details on fault reaction.

#### 5.12.1.5 0x24.3 VBAT1CON

The V<sub>BAT1</sub> Connect bit connects the results from the V<sub>BAT1</sub> comparison bits to the FET control block. A 1 (default) connects the V<sub>BAT1</sub> fault outputs to the FET controller.

If the measurement result for V<sub>BAT1</sub> ([0x5C - 0x5D V<sub>BAT1</sub> Voltage \(R\)](#)) exceeds the OV threshold at 0x20 ([0x20 - 0x21 V<sub>BAT1</sub> Thresholds](#)) when bit [0x0E.3 CPWR](#) is set to 0, then both CFET and DFET are shut off and System Scan is stopped.

- If CPWR is set to 1 and [0x67.6 CHRGI on page 90](#) is 1, then a V<sub>BAT1</sub> OV shuts off CFET.
- If CPWR is set to 1 and [0x67.7 DCHRG on page 90](#) is 1, then a V<sub>BAT1</sub> UV shuts off DFET

Setting the VBAT1CON bit to 0 moves fault handling responsibility to the MCU because failing results from V<sub>BAT1</sub> threshold comparisons do not disconnect the Power FET(s), though continuous scans are halted.

### 5.12.1.6 0x24.2 ETA Connect

The External Temperature and Auxiliary Port Connect bit connects the results from the ETAUX comparison bits to the FET Control block. A 1 (default) connects the ETAUX fault outputs to the FET Controller.

If the measurement result for either the xT0 or xT1 voltage exceeds the related CUT threshold at 0x13 or 0x17 while CHRGI is 1 and CPWR is 0, the power FETs are disconnected and System Scan is stopped. If the CPWR bit is 1, in this case only, CFET is shut off.

If the measurement result for either the xT0 or xT1 voltage exceeds the related DUT threshold at 0x15 or 0x19 while DCHRGI is 1 and CPWR is 0, the power FETs are disconnected and System Scan is stopped. If the CPWR bit is 1, in this case only, DFET is shut off.

If the measurement result for either the xT0 or xT1 voltage drops below either the COT threshold at 0x14 or 0x18 while CHRGI is 1 and CPWR is 0, the power FETs are disconnected and System Scan is stopped. If the CPWR bit is 1, in this case only, CFET is shut off.

If the measurement result for either the xT0 or xT1 voltage drops below either the DOT threshold at 0x16 or 0x1A while DCHRGI is 1, and CPWR is 0, the power FETs are disconnected and System Scan is stopped. If the CPWR bit is 1, in this case only, DFET is shut off.

Setting the External Temperature and Auxiliary Port Connect bit to 0 moves fault handling responsibility to the MCU since these faults do not disconnect the power FET(s), though continuous scans are halted.

See the following sections for more information: [ETAUX Detectors](#), [0x13-1A ETAUX Thresholds](#), [0x67.6 CHRGI](#), [0x67.7 DCHRGI](#), and [0x0E.3 CPWR](#).

### 5.12.1.7 0x24.1 DFET EN

The DFET enable bit turns the DFET ON and OFF. A 1 activates the DFET unless prevented by a related fault. The default value of 0 disables the DFET. The DFET cannot be enabled when the chip is being reset, or if it is in LOW POWER or SHIP Modes. In the case of some faults, writing this bit does not turn on the DFET until the fault is cleared. This bit does not indicate the DFET pin status if a related fault is set.

The DFET is turned off and remains off under the following conditions:

[DSCF OR IOTF OR OWF OR VCCF OR CPMP NRDY OR IREG1 OR VTMPF]  
OR  
[NOT(CPWR) AND FCDC AND CHRGI AND COCF] OR [CFD AND DCHRGI AND DOCF]

The DFET is turned off and remains off under the following conditions if bit 0x24.4 CELLCON is set:

{CPWR AND [DVCF OR UVF OR (NOT{DCHRWOV} AND OVF)]}  
OR  
NOT(CPWR) AND {DVCF OR [CHRGI AND NOT(CHRWUV) OR DCHRGI] AND UVF  
OR  
[DCHRGI AND NOT(DCHRWOV) OR CHRGI] AND OVF}

V<sub>Cell</sub> OVF does not disable DFET during discharge if bit [0x02.6 DCHRWOV on page 43](#) is set.

The DFET is turned off and remains off under the following conditions if bit 0x24.3 VBAT1CON is set:

[CPWR AND DCHRGI AND VBUVF] OR [NOT(CPWR) AND CHRGI AND VBOVF]

The DFET is turned off and remains off under the following conditions if bit 0x24.2 ETAUX Connect is set:

[DCHRGI AND (DUT0 OR DUT1 OR DOT0 OR DOT1)]  
OR  
[NOT(CPWR) AND CHRGI AND (CUT0 OR CUT1 OR COT0 OR COT1)]

See [CFET and DFET Pins \(50, 51\) on page 100](#) and [Scan Will Not Start on page 115](#) for details about how the Connect and Enable bits interact with fault and other control bits for FET control and System Scan.

#### 5.12.1.8 0x24.0 CFET EN

The CFET enable bit turns the CFET ON and OFF. A 1 activates the CFET unless prevented by a related fault. The default value of 0 disables the CFET. The CFET cannot be enabled when the chip is being reset, or if it is in LOW POWER or SHIP Modes. In the case of some faults, writing this bit does not turn on the CFET until the fault is cleared. This bit does not indicate status of the CFET pin if a related fault is indicated.

The CFET is turned off and remains off under the following conditions:

[DSCF OR IOTF OR OWF OR VCCF OR CPMP NRDY OR IREG1 OR VTMPF]  
OR  
[FCDC AND CHRG1 AND COCF] OR [NOT(CPWR) AND CFD AND DCHRG1 AND DOCF]

The CFET is turned off and remains off under the following conditions if bit 0x24.4 CELLCON is set:

{CPWR AND [DVCF OR OVF OR (NOT{CHRWOV} AND UVF)]}  
OR  
NOT(CPWR) AND {DVCF OR [CHRG1 AND NOT(CHRWUV) OR DCHRG1] AND UVF  
OR  
[DCHRG1 AND NOT(DCHRWOV) OR CHRG1] AND OVF}

$V_{Cell}$  UVF does not disable the CFET during charge if bit [0x02.5 CHRWUV on page 43](#) is set.

The CFET is turned off and remains off under the following conditions if bit 0x24.3 VBAT1CON is set:

{NOT(CPWR) AND [CHRG1 AND VBOVF OR DCHRG1 AND VBUVF]}  
OR  
[CPWR AND CHRG1 AND VBOVF]

The CFET is turned off and remains off under the following conditions if bit 0x24.2 ETAUX Connect is set:

[CHRG1 AND (CUT0 OR CUT1 OR COT0 OR COT1)]  
OR  
[NOT(CPWR) AND DCHRG1 AND (DUT0 OR DUT1 OR DOT0 OR DOT1)]

See [CFET and DFET Pins \(50, 51\) on page 100](#) and [Scan Will Not Start on page 115](#) for details about how Connect and Enable bits interact with fault and other control bits for FET control and System Scan.

## 5.13 Cell Balancing Registers

### 5.13.1 0x25 CB Operation

The CB Operation register controls cell balancing features of the ISL94216A. [Table 48](#) shows the CB Operation register. Though some settings are automatically cleared on completion, Renesas recommends this register be set to default when cell balancing is not in operation.

**Table 48. 0x25 CB Operation Register**

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	CB EN	Auto CB EN	CB Config	CB TRIG	IEOC EN	CB Mask	CB EOC	CB CHRG
Default	0	0	0	0	0	0	0	1

#### 5.13.1.1 0x25.7 CB EN

Set this bit to 1 to enable cell balancing. Set this bit to 0 (default) to disable all forms of cell balancing.

#### 5.13.1.2 0x25.6 Auto CB EN

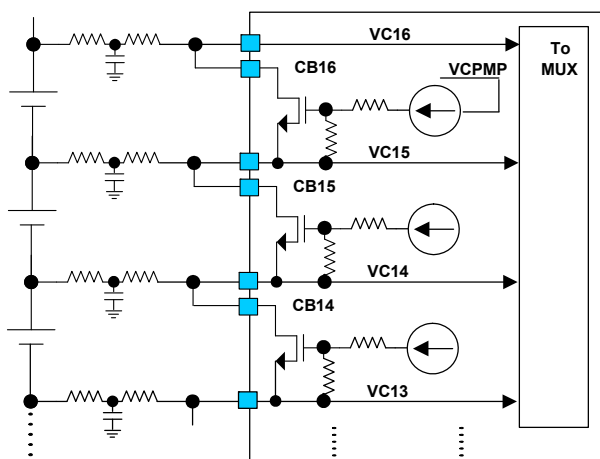

Set this bit to 1 for the ISL94216A to automatically select the cells to be balanced. If this bit is set to 0 (default) the cells to be balanced must be selected by the user in registers [0x26-27 CB Cell State on page 78](#).

When the bit [0x66.7 BAT FULL on page 88](#) is set high indicating the completion of a charging cycle, bit Auto CB EN is reset to 0. This means the microcontroller must clear the battery-full bit before enabling Auto CB EN and the next cycle of cell balancing. See [Automatic Cell Balancing on page 119](#) for more information.

#### 5.13.1.3 0x25.5 CB Configuration

The CB Configuration bit sets the ISL94216A cell balance configuration to drive internal cell balancing FETs when the bit is set to 0 (default) or to drive external cell balancing FETs if set to 1.

The internal cell balancing FETs ([Figure 94](#)) are a space saving feature ideal for low current and slow battery charging applications.

**Figure 94. Internal Cell Balancing Configuration**

Set the CB Config bit to 1 to configure the ISL94216A to drive external cell balancing FETs as shown in [Figure 95](#). External balancing FETs are used with large capacity and/or fast charging battery packs.

Figure 95. External Cell Balancing Configuration

#### 5.13.1.4 0x25.4 CB Trigger

A 0 to 1 transition of this bit in IDLE mode triggers one Cell Balancing cycle ([Figure 96 on page 81](#)). When triggered, the Busy bit transitions from 0 to 1 and the trigger bit clears. The Busy bit remains set until the action is completed, and then returns to a 0.

The trigger bit is ignored in SHIP and LOW POWER Modes and can only trigger sequences in IDLE or SCAN mode. This trigger should be used only in IDLE mode because Renesas recommends to reserve SCAN mode for System Scans.

#### 5.13.1.5 0x25.3 IEOC EN

The Current End Of Charge Enable bit selects between ending charging when a voltage is reached or when the charge current drops below a set level. If IEOC EN is 0 (default), charging ends when any cell voltage reading is above the [0x2D VEOC Threshold on page 80](#), which sets bits [0x66.4 VEOC on page 88](#) and [0x66.7 BAT FULL on page 88](#), and shuts off CFET and DFET (if CPWR = 0). When IEOC EN is set to 1, charging stops after the VEOC bit has been set (DFET shuts off if CPWR=1) and the charge current drops below the [0x10 IEOC Threshold on page 80](#), setting the bit [0x66.5 IEOC on page 88](#). This shuts off CFET and DFET (if CPWR = 0) and BAT FULL sets.

IEOC EN does not enable or disable cell balancing, but determines which cells would be balanced (if any), and how the BAT FULL bit is set. IEOC EN combined with [0x0E.3 CPWR on page 55](#) determines when or if DFET is shut off. The IEOC EN, CB EOC, and CB CHRG bits select the type of cell balancing when auto cell balancing is enabled. See [Automatic Cell Balancing on page 119](#) for more information about the behavior of cell balancing versus these bits and related bit settings.

#### 5.13.1.6 0x25.2 CB Mask

The CB Mask bit prevents adjacent cells from balancing at the same time. Balancing adjacent cells may change the amount of cell balancing current.

If the CB mask bit is 1, the ISL94216A prevents turning on cell balancing FETs of adjacent cells at the same time. Instead, it toggles between two masks that either enable even cells or odd cells to be balanced for a period of time. For a cycle of cell balancing, each mask is applied once for CBON time before turning off cell balancing for CBOFF time (see [0x28, 0x29 Cell Balancing Timers on page 81](#)). The default of 0 disables the masking feature.

while balancing. The temperature rise of the IC, because of the cell balancing FETs, is calculated using [Equation 24](#).

$$(EQ. 24) \quad \Delta T_{CB} = (\theta_{JA} \cdot n_{o_{cbOn}} \cdot I_{CB}^2 \cdot R_{cb\_On})$$

$\Delta T_{CB}$  is the temperature rise of the ISL94216A because of cell balancing. Variable  $n_{o_{cbOn}}$  is the number of cells that are balancing at once,  $R_{cb\_On}$  ([page 15](#)) is the cell balancing FET resistance,  $I_{CB}$  is the cell balancing current, and  $\theta_{JA}$  ([Thermal Information on page 12](#)) is the thermal resistivity of the ISL94216A.

#### 5.13.1.7 0x25.1 CB EOC

The Cell Balance End Of Charge bit is functional only when bit [0x66.4 VEOC on page 88](#) is set (1). The default CB EOC value of 0 disables cell balancing when any cell voltage reaches the setting of [0x2D VEOC Threshold on page 80](#). If bit CB EOC is set to 1, cell balancing is allowed after one or more cells reach the VEOC threshold, and may continue (depending on settings and conditions) until bit [0x66.7 BAT FULL on page 88](#) is set. See [Table 75 on page 119](#).

The CB EOC, IEOC EN, and CB CHRG bits select the type of auto cell balancing when cell balancing is enabled. See [Automatic Cell Balancing on page 119](#) for more information.

#### 5.13.1.8 0x25.0 CB CHRG

The CB Charge bit is functional only when bit [0x66.4 VEOC on page 88](#) is clear (0). When 0, the CB CHRG bit disables cell balancing during constant current charging while VEOC = 0. Set CB CHRG to 1 to enable cell balancing during charging while VEOC = 0. The type of cell balancing is determined by this bit and the other control bits in this register. For more details, see [Automatic Cell Balancing on page 119](#).

When bit [0x66.7 BAT FULL on page 88](#) is set to 1, both the Auto CB EN and CB CHRG bits are cleared.

### 5.13.2 0x26-27 CB Cell State

The CB Cell State registers indicate the cells selected to be balanced during the next cell balancing cycle. [Table 49](#) shows the format of these registers.

**Table 49. 0x26-27 CB Cell State Register**

Address - Bits	Bit Name	Default Value
0x26 - D[7:0]	CB Cells 16 to 9	0000 0000
0x27 - D[7:0]	CB Cells 8 to 1	0000 0000

In manual mode, when [0x25.6 Auto CB EN on page 76](#) is set to 0, these bits are written by the user. Setting these bits to 1 turns on the cell balancing current source or internal cell balancing FET corresponding to that bit when cell balancing is enabled and triggered.

The CB Cell State registers show the cells automatically determined by the chip to need cell balancing following the most recent set of cell voltage measurements during automatic cell balancing.

For the three cases of automatic cell balancing with IEOC EN = 1 **OR** CB EOC = 0, the chip finds the minimum of all the cell voltages and calculates the difference between each cell voltage and the minimum. For cells with a calculated difference higher than the [0x2A CB Min Delta Threshold on page 79](#), the CB Cell State bit is set to 1. For other cells, it is set to 0.

For automatic cell balancing cases with IEOC EN = 0 **AND** CB EOC = 1, the CB Cell State bit is set to 1 for cells that exceed the voltage set by the register [0x2D VEOC Threshold on page 80](#) minus four bits. For other cells, it is set to 0.

These registers do not indicate that any specific cell balancing pin is active. They indicate which cells are to be balanced during the next cell balancing cycle. See [Automatic Cell Balancing on page 119](#) and [Manual Cell Balancing on page 121](#) for more details.

### 5.13.3 0x2A CB Min Delta Threshold

The Cell Balancing Minimum Delta Threshold register sets the minimum cell voltage difference that determines if a cell needs balancing. [Table 50](#) shows the format of this register.

**Table 50. 0x2A CB Min Delta Threshold Register**

Bits	Byte Name	Default	CBDMIN <sub>step</sub>	Offset
D[7:0]	CBDMIN - Cell Balance Minimum Delta Threshold	0000 0000	4.707mV	4.67mV

After a cell voltage scan has completed, the ISL94216A calculates all the differences between the lowest cell voltage and the rest of the cells in the battery pack. Under certain conditions the delta value of each cell is compared to the CBDMIN threshold to determine if the cell needs balancing for automatic cell balancing cycles. If any cell needs balancing, the bit [0x66.0 Need CB](#) is set to 1. See [0x26-27 CB Cell State](#) for information about how this threshold is used to set those bits.

$$(EQ. 25) \quad V_{Threshold} = (RegVal) \cdot CBDMIN_{Step} + Offset$$

Multiply the register value by the step size CBDMIN<sub>step</sub> and add the fixed offset to calculate the threshold as shown in [Equation 25](#). The register supports settings from 4.67mV to 1204.97mV.

### 5.13.4 0x2B CBMAX Threshold

The Cell Balancing Maximum Threshold register sets the upper cell voltage threshold of the cell balancing range. [Table 51](#) shows the format of this register.

**Table 51. 0x2B CB Max Register**

Bits	Bit Name	Default	CBMAX <sub>step</sub>	Offset
D[7:0]	CBMAX - Cell Balance Overvoltage Threshold	1111 1111	18.828mV	18.791mV

The CBMAX register sets the threshold voltage for status bit [0x66.2 2HI2CB on page 89](#). After a cell voltage scan has completed, the ISL94216A compares the minimum cell voltage to the CBMAX threshold setting. If the minimum cell voltage is greater than the CBMAX value, bit 2HI2CB is set and cell balancing is blocked. Bit 2HI2CB cannot be cleared (and CB cannot restart) until the minimum measured cell voltage is below CBMAX by V<sub>CBHys</sub> ([page 16](#)), which is set to 5 x CBMAX<sub>step</sub>.

$$(EQ. 26) \quad V_{Threshold} = (RegVal) \cdot CBMAX_{Step} + Offset$$

Multiply the register value by the step size CBMAX<sub>step</sub>, and add the fixed offset to calculate the threshold ([Equation 26](#)). The register supports settings from 18.791mV to 4.82V.

### 5.13.5 0x2C CBMIN Threshold

The Cell Balancing Minimum Threshold register sets the lower cell voltage threshold of the cell balancing range. [Table 52](#) shows the format of this register.

**Table 52. 0x2C CB Minimum Register**

Bits	Bit Name	Default	CBMIN <sub>step</sub>	Offset
D[7:0]	CBMIN Cell Balance Undervoltage Threshold	0000 0000	18.828mV	36.774μV

The CBMIN register sets the threshold voltage for status bit [0x66.1 2LO2CB on page 89](#). After a cell voltage scan has completed, the ISL94216A compares the maximum cell voltage to the CBMIN threshold setting. If the maximum cell voltage is less than the CBMIN value, bit 2LO2CB is set and cell balancing is blocked. Bit 2LO2CB cannot be cleared (and CB cannot restart) until the maximum measured cell voltage is above CBMIN by  $V_{CBHys}$  ([page 16](#)), which is set to  $5 \times CBMIN_{Step}$ .

$$(EQ. 27) \quad V_{Threshold} = (RegVal) \cdot CBMIN_{Step} + Offset$$

Multiply the register value by the step size  $CBMIN_{Step}$ , and add the fixed offset to calculate the threshold ([Equation 27](#)). The register supports settings from 36.77μV to 4801.25mV.

### 5.13.6 0x2D VEOC Threshold

The Voltage End of Charge Threshold register sets the cell voltage used to set the status bit [0x66.4 VEOC on page 88](#), which in some cases ends charging by shutting off one or both power FETs. The VEOC status bit can be used by the microcontroller to signal a charger to switch from constant current to constant voltage. See [Automatic Cell Balancing on page 119](#) for the options and actions that follow VEOC. [Table 53 on page 80](#) shows the format and default value of the VEOC Threshold register.

**Table 53. 0x2D VEOC Threshold Register**

Bits	Bit Name	Default	VEOC <sub>Step</sub>	Offset
D[7:0]	VEOC - Voltage End of Charge Threshold	1111 1111	18.828mV	18.791mV

The VEOC status bit can be cleared when all measured cell voltages are below the VEOC threshold and the user writes a 0 to it, or a 1 to the [0x02.1 Clear Faults and Status on page 44](#).

$$(EQ. 28) \quad V_{Threshold} = (RegVal) \cdot VEOC_{Step} + Offset$$

Multiply the register value by the step size  $VEOC_{Step}$  and add the fixed offset to calculate the threshold [Equation 28](#). The register supports settings from 18.79mV to 4.82V.

This threshold comparison is not dependent on DCHRG1 or CHRGI. If a cell voltage remains above the VEOC Threshold at the completion of a charge cycle in some cases it may be necessary to increase this threshold to allow turn on of DFET.

### 5.13.7 0x10 IEOC Threshold

The Current End Of Charge Threshold register sets the minimum charge current by setting the threshold voltage of a digital comparator for undercurrent detection. This feature is used when bit [0x25.3 IEOC EN on page 77](#) is 1. The bit [0x66.5 IEOC on page 88](#) is set to indicate an end of charge condition when the charge current decreases to the point at which the voltage across the current sense resistor is less than this threshold setting while CFET is On. [Table 54](#) shows the format and default value of the IEOC Threshold register.

**Table 54. 0x10 IEOC Threshold Register**

Bits	Bit Name	Default	IEOC <sub>Step</sub>	Offset
D[7:0]	IEOC - End of Charge Current Threshold	0000 0000	1.345mV	5.253μV

To calculate the voltage threshold, multiply the register value by the step size  $IEOC_{Step}$  and add the fixed offset as in [Equation 29](#). Divide the voltage threshold by the sense resistor value to calculate the threshold current setting.

$$(EQ. 29) \quad V_{Threshold} = (RegVal) \cdot IEOC_{Step} + Offset$$

The register supports settings from 5.25μV to 342.95mV.

### 5.13.8 0x28, 0x29 Cell Balancing Timers

The Cell Balancing Timer registers set the time the cell balancing circuitry is on and off. The operation of these timers is shown above in [Figure 96](#), an example of Automatic Cell Balancing as part of a System Scan or started by [0x25.4 CB Trigger on page 77](#). If part of a System Scan Return refers to the next step in the sequence as shown in [Figure 106 on page 109](#), otherwise the device waits for the next trigger.

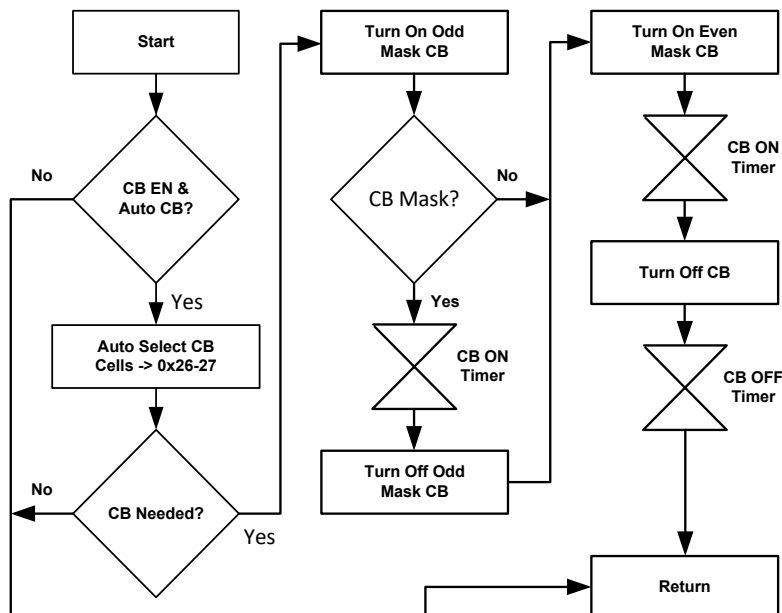

Figure 96. Simplified Auto CB Sequence

#### 5.13.8.1 0x28 CBON

The Cell Balancing On Timer bits and the Cell Balancing On Timer Unit bit of the CBON Timer register controls the amount of time the cells are balanced during each cycle. When the timer expires, the cell balancing circuitry is turned off. [Table 55](#) shows the options for the CBON bits.

Table 55. 0x28 CBON Bits

CBON Timer D[7:1]	D[0]	CB ON Unit
0000 000 (0 to 1016)	0	ms
0000 000 (0 to 1016)	1	s

The step size of the setting is 8. Multiply the unit value by the step size and the 7-bit register value to calculate the CBON time setting. The timing magnitude is set by configuring the CBON Unit bit to either seconds or ms.

#### 5.13.8.2 0x29 CBOFF

The Cell Balancing Off Timer bits and the Cell Balancing Off Timer Unit bit of the CBOFF Timer register controls the amount time that cell balancing is off before the timer controlled by [0x2E.2:0 Scan Delay on page 105](#) starts. The next continuous scan begins after the Scan Delay timer expires. If in SCAN mode following a triggered single scan the device waits for the next trigger. [Table 56](#) shows the options for the CBOFF bits.

Table 56. 0x29 CBOFF Bits

CBOFF Timer D[7:1]	D[0]	CBOFF Unit D[0]
0000 000 (0 to 1016)	0	ms
0000 000 (0 to 1016)	1	s

The step size of the setting is 8. Multiply the unit value by the step size and the 7-bit register value to calculate the CBOFF time setting. The timing magnitude is set by configuring the CBOFF Unit bit to either seconds or milliseconds.

## 5.14 System Faults and Status

### 5.14.1 0x63 Priority Fault

The Priority Fault register reports failures related to the battery pack. All bits in this register are latched high and can be cleared by writing a 0 to them, a chip  $\overline{\text{RESET}}$  or by writing a 1 to the Clear Faults and Indicators bit (0x02.1). They cannot be cleared by writing a 0 while the condition that sets them HIGH is present. The bit locations in this register are shown in Table 57. The Priority Fault Mask at address 0x83 (page 84) can be used to mask bits within this register to prevent the fault from propagating to  $\overline{\text{ALRT}}$ .

Table 57. 0x63 Priority Fault Register

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	VCCF	OWF	IOTF	COCF	DOCF	DSCF	UVF	OVF
Default	0	0	0	0	0	0	0	0

#### 5.14.1.1 0x63.7 VCCF

The  $V_{CC}$  Fault bit of the Priority Fault register reports an undervoltage event at the VCC pin. The bit is set when the measured voltage is below the setting of register 0x1C  $V_{VCC}$  Min Threshold on page 66.

In SCAN mode, setting VCCF requires three consecutive results below the minimum voltage threshold if 0x09.5 Other Fault Delay on page 50 is set to 1 and a continuous System Scan is running.

This bit shuts off both CFET and DFET and stops System Scan. If unmasked by setting bit 0x83.7 to 0, this bit also sets  $\overline{\text{ALRT}}$  low.

#### 5.14.1.2 0x63.6 OWF

The Open-Wire Fault of the Priority Fault register ORs the open-wire faults from each cell,  $V_{BAT1}$ , VSS, xT0, and xT1 pin. A 1 indicates a failure has occurred. This bit shuts off both CFET and DFET and stops System Scan. This bit also sets  $\overline{\text{ALRT}}$  low if unmasked by setting bit 0x83.6 to 0 (see 0x83 Priority Fault Mask on page 84).

#### 5.14.1.3 0x63.5 IOTF

The Internal Over-Temperature Fault reports if an over-temperature fault detection by the internal temperature sensor has occurred. The bit is set if the internal temperature is above (voltage is below) the IOTF threshold (see 0x22 - 0x23 IOTW and IOTF Thresholds on page 63).

In SCAN mode, setting IOTF requires three consecutive results below the voltage threshold (NTC Temp Sensor) if 0x09.5 Other Fault Delay on page 50 is set to 1 and a continuous System Scan is running.

This bit shuts off both CFET and DFET and stops System Scan. If unmasked by setting bit 0x83.5 to 0, this bit also sets  $\overline{\text{ALRT}}$  low.

#### 5.14.1.4 0x63.4 COCF

The Charge Overcurrent Fault bit reports the result of the charge overcurrent comparison. If the voltage reading is above the 0x0F COC Threshold on page 56, then this bit is set to 1, otherwise the bit remains at the default of 0. If unmasked by setting mask bit 0x83.4 to 0, then this bit also sets  $\overline{\text{ALRT}}$  low.

In SCAN mode, setting COCF requires a number of consecutive results, set in register 0x0D.3:0 COCD on page 53, above the overcurrent threshold while a continuous System Scan is running.

This bit shuts off CFET if the following conditions are true: the device detects charging current ( $I_{PACK} > 19$  decimal), the CPWR bit is 1 for parallel FETs (0x0E.3 CPWR on page 55), and the FCDC bit is 1 (0x0E.2 FCDC on page 55).

This bit shuts off CFET and DFET and stops System Scans if the following is true; the device detects charging current ( $I_{PACK} > 19$  decimal), CPWR bit is 0 for series FETs (0x0E.3 on page 55) and FCDC bit is 1 (0x0E.2 on page 55).

If FCDC is 0 a COCF will not shut off CFET or DFET but will stop continuous scans.

#### 5.14.1.5 0x63.3 DOCF

The Discharge Overcurrent Fault bit reports the result of the discharge overcurrent comparison. If the voltage reading is below the 0x0B DOC Threshold on page 51, then this bit is set to 1. If unmasked by setting mask bit 0x83.3 to 0, then this bit also sets  $\overline{ALRT}$  low.

In SCAN mode, setting DOCF requires a number of consecutive results, set in register 0x0D.7:4 DOCD on page 53, below the overcurrent threshold and a continuous System Scan is running.

This bit shuts off DFET if the following is true; the device detects discharge current ( $I_{PACK} < -20$  decimal), CPWR bit is 1 for parallel FETs (0x0E.3 CPWR on page 55) and CFD bit is 1 (0x0E.7 CFD on page 54).

This bit shuts off CFET and DFET and stops System Scans if the following is true; the device detects discharge current ( $I_{PACK} < -20$  decimal), CPWR bit is 0 for series FETs (0x0E.3 on page 55) and CFD bit is 1 (0x0E.7 on page 54).

If the CFD bit is 0 a DOCF does not shut off either CFET or DFET but does stop continuous scan. This setting disconnects this fault detection from FET and scan control.

#### 5.14.1.6 0x63.2 DSCF

The Discharge Short-Circuit Fault bit reports the result of the analog discharge short-circuit comparison. If the current sense voltage is more negative than 0x0A DSC Threshold for the time set by 0x0C DSC Delay, then the bit is set to 1.

When set, this bit shuts off both CFET and DFET and stops System Scan, and triggers a transition to IDLE mode. If unmasked by setting mask bit 0x83.2 to 0, it also sets  $\overline{ALRT}$  low.

If bit 0x0E.4 ELR is enabled when a DSCF occurs, and the load recovery function determines the load was removed, then the DSCF bit is automatically cleared. See Short-Circuit Detection and Recovery. This function does not re-enable CFET or DFET.

#### 5.14.1.7 0x63.1 UVF

The Undervoltage Fault bit reports a fault if one or more of the cell voltages is below the undervoltage threshold (UV) set in register 0x07 (0x06 - 0x07  $V_{CELL}$  OV/UV Threshold). A 1 indicates a UV fault.

In SCAN mode, setting UVF requires a number of consecutive results, set in register 0x09.3:0  $V_{CELL}$  Fault Delay, below the undervoltage threshold while a continuous System Scan is running.

See 0x24.1 DFET EN and 0x24.0 CFET EN for the settings that allow this fault to shut off CFET and/or DFET respectively. See Scan Will Not Start on page 115 for conditions where this bit stops and prevents start of System Scans.

If unmasked by setting mask bit 0x83.1 to 0, this bit also sets  $\overline{ALRT}$  low.

#### 5.14.1.8 0x63.0 OVF

The Overvoltage Fault bit reports a fault if one or more of the cell voltage readings is above the overvoltage threshold (OV) set in register 0x06 (0x06 - 0x07  $V_{CELL}$  OV/UV Threshold). A 1 indicates an OV fault.

In SCAN mode, setting OVF requires a number of consecutive results, set in register [0x09.3:0 V<sub>CELL</sub> Fault Delay](#), above the overvoltage threshold while a continuous System Scan is running.

See [0x24.1 DFET EN](#) and [0x24.0 CFET EN](#) for the settings that allow this fault to shut off CFET and/or DFET respectively. See [Scan Will Not Start](#) for conditions where this bit stops and prevents start of System Scans.

If unmasked by setting mask bit 0x83.0 to 0, this bit also sets  $\overline{\text{ALRT}}$  low.

### 5.14.2 0x83 Priority Fault Mask

The Priority Fault Mask register masks the fault bits of the Priority Fault register from propagating to the  $\overline{\text{ALRT}}$  pin. The default value of 1 for each bit masks the related fault. Write a 0 to the bit to allow the fault to propagate to the  $\overline{\text{ALRT}}$  pin.

[Table 58](#) displays the format and default values of the Priority Fault Mask register.

**Table 58. 0x83 Priority Fault Mask Register**

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	VCCF MASK	OWF MASK	IOTF MASK	COCF MASK	DOCF MASK	DSCF MASK	UVF MASK	OVF MASK
Default	1	1	1	1	1	1	1	1

### 5.14.3 0x64 ETAUX Fault

The ETAUX Fault register reports faults relevant to the measured voltages at the xT0 and xT1 pins. All bits in this register are latched high and can be cleared by writing a 0 to them, performing a chip  $\overline{\text{RESET}}$ , or by writing a 1 to bit [0x02.1 Clear Faults and Status](#). They cannot be cleared while the condition that sets them HIGH is present. Contents and default values of the ETAUX Fault register are displayed in [Table 59](#). The function of these bits and polarity of the comparators is based on the assumption that an NTC thermistor voltage is the monitored input.

Bit [0x24.2 ETA Connect](#) must be set for ETAUX faults to shut off CFETs and DFETs per the bit setting of [0x0E.3 CPWR](#). Continuous scan is halted for a threshold violation regardless of the setting of ETA Connect.

DFET and CFET are turned off and remain off under the following conditions if bit 0x0E.3 CPWR is 0:

```
[DCHRG1 AND (DUT0 OR DUT1 OR DOT0 OR DOT1)
OR
[CHRG1 AND (CUT0 OR CUT1 OR COT0 OR COT1) ]
```

CFET is turned off and remains off under the following conditions if bit 0x0E.3 CPWR is 1:

```
[CHRG1 AND (CUT0 OR CUT1 OR COT0 OR COT1) ]
```

DFET is turned off and remains off under the following conditions if bit 0x0E.3 CPWR is 1:

```
[DCHRG1 AND (DUT0 OR DUT1 OR DOT0 OR DOT1)
```

For a detailed description of the settings for the operation of the CFETs and DFETs see [Power FET Block](#).

In SCAN mode, setting ETAUX Faults requires three consecutive results above/below the minimum/maximum (NTC Thermistors assumed) voltage thresholds if [0x09.4 ETAUX Fault Delay](#) is set to 1 while a continuous System Scan is running. See [Scan Will Not Start](#) for conditions where ETAUX faults stop and prevent start of System Scans.

These fault bits set regardless of current direction in IDLE mode if the related threshold voltage is violated. The user selects whether the  $\overline{\text{ALRT}}$  pin is asserted LOW when one or more of these faults are triggered by programming the corresponding mask register bit [0x84 ETAUX Fault Mask](#).

Table 59. 0x64 ETAUX Fault Register

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	COT1	CUT1	DOT1	DUT1	COT0	CUT0	DOT0	DUT0
Default	0	0	0	0	0	0	0	0

#### 5.14.3.1 0x64.7 COT1

The Charge Over-Temperature Bit 1 of the ETAUX Fault register reports a fault if the xT1 voltage (0x5A-5B on [page 63](#)) is below the COT1 voltage threshold (0x18 on [page 61](#)) during charge. A 1 indicates a fault.

#### 5.14.3.2 0x64.6 CUT1

The Charge Under-Temperature Bit 1 of the ETAUX Fault register reports a fault if the xT1 voltage (0x5A-5B on [page 63](#)) is above the CUT1 voltage threshold (0x17 on [page 61](#)) during charge. A 1 indicates a fault.

#### 5.14.3.3 0x64.5 DOT1

The Discharge Over-Temperature Bit 1 of the ETAUX Fault register reports a fault if the xT1 voltage (0x5A-5B on [page 63](#)) is below the DOT1 voltage threshold (0x1A on [page 61](#)) during discharge. A 1 indicates a fault.

#### 5.14.3.4 0x64.4 DUT1

The Discharge Under-Temperature Bit 1 of the ETAUX Fault register reports a fault if the xT1 voltage (0x5A-5B on [page 63](#)) is above the DUT1 voltage threshold (0x19 on [page 61](#)) during discharge. A 1 indicates a fault.

#### 5.14.3.5 0x64.3 COT0

The Charge Over-Temperature Bit 0 of the ETAUX Fault register reports a fault if the xT0 voltage (0x58-59 on [page 63](#)) is below the COT0 voltage threshold (0x14 on [page 61](#)) during charge. A 1 indicates a fault.

#### 5.14.3.6 0x64.2 CUT0

The Charge Under-Temperature Bit 0 of the ETAUX Fault register reports a fault if the xT0 voltage (0x58-59 on [page 63](#)) is above the CUT0 voltage threshold (0x13 on [page 61](#)) during charge. A 1 indicates a fault.

#### 5.14.3.7 0x64.1 DOT0

The Discharge Over-Temperature Bit 0 of the ETAUX Fault register reports a fault if the xT0 voltage (0x58-59 on [page 63](#)) is below the DOT0 voltage threshold (0x16 on [page 61](#)) during discharge. A 1 indicates a fault.

#### 5.14.3.8 0x64.0 DUT0

The Discharge Under-Temperature Bit 0 of the ETAUX Fault register reports a fault if the xT0 voltage (0x58-59 on [page 63](#)) is above the DUT0 voltage threshold (0x15 on [page 61](#)) during discharge. A 1 indicates a fault.

### 5.14.4 0x84 ETAUX Fault Mask

The ETAUX Fault Mask register masks the fault bits of the ETAUX Fault register 0x64 from propagating to the  $\overline{\text{ALRT}}$  pin. The default value 1 of each bit masks the related fault. Write a 0 to the bit to allow the fault to propagate to the  $\overline{\text{ALRT}}$  pin. The format and default values of the ETAUX Fault Mask register are displayed in [Table 60](#).

Table 60. 0x84 ETAUX Fault Mask Register

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	COT1 MASK	CUT1 MASK	DOT1 MASK	DUT1 MASK	COT0 MASK	CUT0 MASK	DOT0 MASK	DUT0 MASK
Default	1	1	1	1	1	1	1	1

### 5.14.5 0x65 Other Fault Register

The Other Fault register reports various faults and warnings. All bits in this register are latched high and can be cleared by writing a 0 to them unless the condition that sets them HIGH is present. Unless noted otherwise in the bit descriptions below, these faults are cleared by writing 1 to Clear Faults and Indicators (0x02.1 on [page 44](#)), Soft Reset (0x01.7 on [page 41](#)), Reset To IDLE (0x01.6 on [page 41](#)) or a hardware reset with the RESET pin. The format and default values of the Other Fault register are displayed in [Table 61](#).

**Table 61. 0x65 Other Fault Register**

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	VBOVF	VBUVF	CPMP NRDY	OW XT1	OW XT0	OW VBAT1	OW VSS	CRCF
Default	0	0	1	0	0	0	0	0

#### 5.14.5.1 0x65.7 VBOVF

The V<sub>BAT1</sub> Overvoltage Fault bit reports the result of the V<sub>BAT1</sub> overvoltage comparison. If the V<sub>BAT1</sub> voltage reading (0x5C - 0x5D V<sub>BAT1</sub> Voltage (R)) is above the 0x20 V<sub>BAT1</sub> OV Threshold, then this bit is set to 1.

In SCAN mode, setting VBOVF requires a number of consecutive measured results, determined by [0x09.5 Other Fault Delay](#), above the maximum voltage threshold while a continuous System Scan is running.

See [0x24.1 DFET EN](#) and [0x24.0 CFET EN](#) for the settings that allow this fault to shut off CFET and/or DFET respectively. See [Scan Will Not Start](#) for conditions where this fault stops and prevents start of System Scans.

#### 5.14.5.2 0x65.6 VBUVF

The V<sub>BAT1</sub> Undervoltage Fault bit of the Other Fault register reports the result of the V<sub>BAT1</sub> undervoltage comparison. If the V<sub>BAT1</sub> voltage reading (0x5C - 0x5D V<sub>BAT1</sub> Voltage (R)) is below the 0x21 V<sub>BAT1</sub> UV Threshold, then this bit is set to 1.

In SCAN mode, setting VBUVF requires a number of consecutive measured results, determined by [0x09.5 Other Fault Delay](#), below the minimum voltage threshold while a continuous System Scan is running.

See [0x24.1 DFET EN](#) and [0x24.0 CFET EN](#) for the settings that allow this fault to shut off CFET and/or DFET respectively. See [Scan Will Not Start](#) for conditions where this fault stops and prevents start of System Scans.

#### 5.14.5.3 0x65.5 CPMP NRDY

If the charge pump is enabled with bit [0x24.7 CPMP EN](#) set to 1, the Charge Pump Not Ready bit indicates the status of the voltage at the VCPMP pin. A 1 indicates that the charge pump is not ready for use because the voltage is substantially below its proper operating range. The power FETs do not turn on if the bit is set. The device clears the CPMP NRDY bit automatically when the charge pump voltage is in an acceptable range.

If the charge pump is disabled with bit [0x24.7 CPMP EN](#) set to 0, the CPMP NRDY bit is cleared (0). The CPMP NRDY fault can only be set if the charge pump is enabled and its voltage fails to rise above V<sub>pmpMin</sub> ([page 16](#)) or falls below V<sub>pmpFall</sub> ([page 16](#)).

If CPMP NRDY is 1 when the charge pump is enabled (0x24.7 = 1), Cell Balancing on VC16 and continuous System Scans are inhibited and both C/DFET pins are shut off, but it does NOT clear either C/DFET\_EN register bits.

#### 5.14.5.4 0x65.4:5 OW xT1 xT0

The Open-Wire xT1 and xT0 bits indicate if an open-wire fault has occurred on pins xT1 and/or xT0. After ETAUX pins are measured, if the voltage reading is near VTEMP, the corresponding OW status bit is set to 1.

The Open-Wire test function for pins xT1 and xT0 is not part of the open-wire test sequence. See [Aux Pins Open-Wire Test on page 96](#) for details.

**5.14.5.5 0x65.2 OW V<sub>BAT1</sub>**

This bit is set to 1 when the voltage at the VC16 pin is higher than the voltage at the VBAT1 pin by  $V_{OWth2}$  (page 16). Because the VBAT1 pin supplies power to various circuits within the ISL94216A, an open wire leading to this pin renders the device nonfunctional during the open, which leads to a POR at reconnection. A Schottky diode connected from VC15 to VBAT1 can be used to power the device during this fault condition. This enables the device to operate and alert the MCU to a VBAT1 open wire.

If the V<sub>BAT1</sub> connection to the top cell is made through the pack high side load current wire and is separate from the VC15 and VC16 voltage sense connections to their respective cells, an open in the high side load current connection is detectable.

The open-wire test sequence does not test V<sub>BAT1</sub> during discharge, when bit 0x67.7 DCHRG1 is 1. See [Open-Wire Function on page 116](#) for details.

**5.14.5.6 0x65.1 OW VSS**

This bit is set to 1 when the voltage at the VSS pin is significantly higher than the voltage at the VC0 and/or the VC1 pins while the chip runs an open-wire sequence that includes the comparisons of VSS vs VC1 and VSS vs VC0. See the Electrical Specifications (VOWth3 on page 16) for the threshold voltage.

If the VSS connection to the bottom cell is made through the pack low side load current wire and is separate from the VC0 and VC1 voltage sense connections to their respective cells, an open in the pack low side load current connection is detectable. Because VSS is tied to CSN (and PACK-) the path from the VSS pin to the bottom of the pack includes the current sense resistor.

The open-wire test sequence does not test VSS during discharge. See [Open-Wire Function on page 116](#) for details.

**5.14.5.7 0x65.0 CRCF**

The CRCF bit is set and latched by the ISL94216A if the 2-byte CRC word sent by the Master does not match the value calculated internally.

If this occurs during a write command the ISL94216A ignores it and the register value remains unchanged. In the case of a read command from the Master with an incorrect CRC, the ISL94216A holds the MISO pin high during the SCL cycles when the read-back data is expected by the Master until CS returns high, signaling there was an error with an all 1's response.

As with the other bits in this register, this bit can be cleared by writing a 0 to it only if the condition that set the CRCF is cleared. Any valid Read or Write command can be used to clear the condition, and a valid Write command to this register can be used to clear the bit.

**5.14.6 0x85 Other Fault Mask**

The Other Fault Mask register masks the fault bits of the Other Fault register 0x65 from propagating to the  $\overline{\text{ALRT}}$  pin. The default value 1 of each bit masks the related fault. Write a 0 to the bit to enable the fault to propagate to the  $\overline{\text{ALRT}}$  pin.

If bit 0x85.0 is set to 0, then the Busy Bit (0x01.2 Busy) is inverted and output on the  $\overline{\text{ALRT}}$  pin. This is intended to prevent the MCU from reading measurement registers that may be in the process of being written by the ISL94216A. Table 62 displays the format and default values of the Other Fault Mask register.

**Table 62. 0x85 Other Fault Mask Register**

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	VBOVF Mask	VBUVF Mask	CPMP NRDY Mask	RSV	RSV	RSV	CRCF MASK	BUSY Mask
Default	1	1	1	1	1	1	1	1

### 5.14.7 0x66 CB Status

The CB Status register reports cell balancing and charging related status for the ISL94216A. All bits in this register are latched high unless otherwise noted and can be cleared by writing a 0 to them unless the condition that sets them HIGH is present. These bits also can be cleared by setting the Clear all Faults (0x02.1 on [page 44](#)) bit or executing one of the following actions: Soft Reset (0x01.7 on [page 41](#)), Reset To Idle (0x01.6 on [page 41](#)), or a hardware reset on the RESET pin. The format and default values of the CB Status register are displayed in [Table 63](#).

**Table 63. 0x66 CB Status Register**

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	BAT FULL	IOTW	IEOC	VEOC	DVCF	2HI2CB	2LO2CB	NEED CB
Default	0	0	0	0	0	0	0	0

#### 5.14.7.1 0x66.7 BAT FULL

The Battery Full bit indicates that charging and auto cell balancing (if enabled) has completed. The conditions that set BAT FULL with cell balancing enabled are summarized below and detailed in [Automatic Cell Balancing on page 119](#).

For constant current charging with [0x25.3 IEOC EN](#) and [0x25.1 CB EOC](#) set to 0, BAT FULL sets when the highest cell voltage reaches the [0x2D VEOC Threshold](#) and the bit [0x66.4 VEOC](#) is set.

If CB EOC is 1 and IEOC EN is 0, once VEOC is set CFET and DFET shut off. BAT FULL is set when cell balancing reduces the cell voltages below the VEOC threshold.

For charge cycles that end with constant voltage charging (CB EOC = 0 and IEOC EN = 1), BAT FULL sets after the cell voltages exceed the VEOC threshold (the VEOC bit is set and DFET shuts off) and the bit [0x66.5 IEOC](#) transitions from 0 to 1 because of the charge current dropping below the [0x10 IEOC Threshold](#).

If CB EOC is 1 and IEOC EN is 1, once VEOC is set DFET shuts off. BAT FULL is set when IEOC changes from 0 to 1 because of the charge current dropping below the IEOC Threshold.

Whenever BAT FULL is set high, [0x25.6 Auto CB EN](#) is reset to 0. The microcontroller must clear the BAT FULL bit before enabling the next cycle of automatic cell balancing (set AUTO CB EN to 1).

#### 5.14.7.2 0x66.6 IOTW

The Internal Over-Temperature Warning bit indicates that an internal temperature sensor over-temperature warning event occurred. The bit is set if the internal temperature is above (voltage is below) the IOTW threshold at 0x22 ([0x22 - 0x23 IOTW and IOTF Thresholds](#)).

In SCAN mode, setting IOTW requires three consecutive results below the voltage threshold (NTC Temp Sensor) if [0x09.5 Other Fault Delay](#) is set to 1 while a continuous System Scan is running.

#### 5.14.7.3 0x66.5 IEOC

The Current End of Charge bit is set if CFET is On, the  $I_{PACK}$  voltage ([0x52-53 on page 47](#)) has dropped below the setting of [0x10 IEOC Threshold](#), and bit [0x25.3 IEOC EN](#) is set to 1. A transition from 0 to 1 of the IEOC bit indicates the charge current has dropped below the IEOC Threshold. See [Automatic Cell Balancing](#).

The IEOC threshold voltage divided by the sense resistor value sets the IEOC current (see [CSP and CSN Pins \(24, 25\)](#)). The IEOC bit is not dependent on DCHRG1 or CHRGI.

#### 5.14.7.4 0x66.4 VEOC

The Voltage End Of Charge bit indicates the result of the comparison of the [0x2D VEOC Threshold](#) with the maximum cell voltage. A 1 indicates that one or more of the scanned cells voltage is above the threshold. Setting the VEOC bit is not dependent on DCHRG1 or CHRGI, and shuts off DFET and/or CFET in some cases, see [Automatic Cell Balancing](#).

When VEOC is clear (0), cell balancing during charging is enabled by [0x25.0 CB CHRG](#). When VEOC is set (1), cell balancing during charging is enabled by [0x25.1 CB EOC](#).

#### 5.14.7.5 0x66.3 DVCF

The Delta  $V_{CELL}$  Max Fault bit indicates the result of the digital comparison of the  $V_{CELL}$  Max Delta Threshold (0x08 on [page 49](#)) with the  $V_{CELL}$  Max Delta Voltage (0x50-51 on [page 47](#)). A 1 indicates the  $V_{CELL}$  Max Delta cell voltage has exceeded the  $V_{CELL}$  Max Delta threshold.

In SCAN mode, setting DVCF requires three consecutive results above the voltage threshold if [0x09.6 Delta  \$V\_{CELL}\$  Fault Delay](#) is set to 1 while a continuous System Scan is running.

#### 5.14.7.6 0x66.2 2HI2CB

The Too High To Cell Balance bit is set when the minimum of all the cell voltages is greater than [0x2B CBMAX Threshold](#). This bit inhibits cell balancing when set, and must be clear along with the condition that set it before cell balancing can start. The minimum of all cell voltages has to be below CBMAX - 5bits (~94mV hysteresis) before the ISL94216A clears this bit. Unlike the other bits in the register, 2HI2CB is not latched and clears automatically when the condition that set it clears.

#### 5.14.7.7 0x66.1 2LO2CB

The Too Low To Cell Balance bit is set when the maximum of all the cell voltages is lower than [0x2C CBMIN Threshold](#). This bit inhibits cell balancing when set, and must be clear along with the condition that set it before cell balancing can start. The maximum of all cell voltages has to be above CBMIN + 5bits (~94mV hysteresis) before the ISL94216A clears this bit. Unlike the other bits in the register, 2LO2CB is not latched and clears automatically when the condition that set it clears.

#### 5.14.7.8 0x66.0 Need CB

The Need Cell Balancing bit of the CB Status register is set when the difference between one or more of all the measured cell voltages and the minimum of all of them is greater than the [0x2A CB Min Delta Threshold](#). The comparison is valuated as soon as a set of cell voltage measurements completes. A 1 indicates cell(s) need balancing.

If AUTO CB EN = 0, the Need CB bit is just an indicator to the user. See [Auto CB Sequence](#) and [Figure 109 on page 120](#).

### 5.14.8 0x86 CB Status Mask

The Cell Balancing Status Mask register masks the status bits of the CB Status register (0x66) to prevent the status indicator from propagating to the  $\overline{ALRT}$  pin. The default value 1 of each bit masks the related status bit. Write a 0 to the bit to enable the status to propagate to the  $\overline{ALRT}$  pin. [Table 64](#) displays the format and default values of the CB Status Mask register.

Table 64. 0x86 CB Status Mask Register

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	BAT FULL MASK	IOTW MASK	IEOC MASK	VEOC MASK	DVCF MASK	2HI2CB MASK	2LO2CB MASK	NEED CB MASK
Default	1	1	1	1	1	1	1	1

### 5.14.9 0x67 Status

The Status register reports the general status of the ISL94216A with monitors for load, charge and discharge. It also has regulator, reference and other fault bits. All bits in this register are latched high unless otherwise noted and can be cleared by writing a 0 to them, performing a chip **RESET**, or by writing a 1 to the Clear Faults and Indicators bit (0x02.1). They cannot be cleared while the condition that sets them HIGH is present. [Table 65](#) displays the format and default values of the Status register.

**Table 65. 0x67 Status Register**

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	DCHRG1	CHRG1	CH PRES1	LD PRES1	OTHER FAULTS	I REG1	I REG2	VTMPF
Default	0	0	0	0	0	0	0	0

#### 5.14.9.1 0x67.7 DCHRG1

The Discharge Current Indicator bit indicates if charge is being removed from the battery pack in SCAN mode. If the current sense voltage measurement is less than approximately  $-200\mu\text{V}$  (-20 decimal register value), the DCHRG1 bit is set. This bit is not latched and indicates the current direction of the last pack current measurement. If cleared by the MCU it will remain clear until the next pack current measurement.

In continuous Scan mode, setting DCHRG1 requires three consecutive measurements below  $-200\mu\text{V}$  if [0x03.1 I<sub>DIR</sub> Delay](#) is set to 1.

When discharging with a series power FET configuration ([0x0E.3 CPWR](#) is set to 0), the discharge temperature limits are applied to the ETAUX pin measurements ([ETAUX Detectors](#)) in SCAN mode. If any ETAUX measurement exceeds the discharge limits and [0x24.2 ETA Connect](#) is enabled, both power FETs are turned OFF. For a parallel FET configuration (CPWR = 1), only DFET is shut OFF.

#### 5.14.9.2 0x67.6 CHRG1

The Charge Current Indicator bit indicates if charge is being supplied to the battery pack in SCAN mode. If the current sense voltage measurement is greater than approximately  $+200\mu\text{V}$  (+19 decimal register value), the CHRG1 bit is set. This bit is not latched and indicates the current direction of the last pack current measurement. If cleared by the MCU it will remain clear until the next pack current measurement.

In continuous Scan mode, setting CHRG1 requires three consecutive measurements above  $200\mu\text{V}$  if [0x03.1 I<sub>DIR</sub> Delay on page 45](#) is set to 1.

When charging with a series power FET configuration (CPWR = 0), the charge temperature limits are applied to the ETAUX pin measurements ([ETAUX Detectors](#)) in SCAN mode. If any AUX measurement exceeds the charge limits and [0x24.2 ETA Connect](#) is enabled, both power FETs are turned OFF. For a parallel FET configuration (CPWR = 1) only the CFET is shut OFF.

#### 5.14.9.3 0x67.5 CH PRES1

The Charger Present bit continuously follows the state of the **WAKEUP** pin (inverted) and is not latched. If **WAKEUP** is low, the CH PRES1 bit is 1. When the **WAKEUP** pin is high, the CH PRES1 bit is 0.

#### 5.14.9.4 0x67.4 LD PRES1

The Load Present bit indicates that a load is connected, if the DFET is disabled. The bit is 0 when the load connection detection function is off. See [Figure 85 on page 56](#).

If a load is attached during LOW POWER mode and the Load Connection Detection function is enabled ([0x0E.1 LDLP](#) is 1), then the device transitions to IDLE mode on the rising edge of LD PRES1. See [Figure 105 on page 106](#).

Though this bit is latched, it can be cleared by the LDLP and ELR (0x0E.4 ELR) functions if either or both are enabled.

#### 5.14.9.5 0x67.3 Other Faults

The Other Faults bit of the Status register ORs the communication time out, and oscillator frequency error bits. If a serial communication transaction has not occurred in  $t_{COM}$  (page 16) time while in IDLE mode, the flag is set and the device changes to LOW POWER mode. The  $t_{COM}$  timeout fault can be ignored by setting bit 0x1F.1 Communication Timeout EN to 0. If the frequency of any of the on-chip oscillators is too high or too low, the bit is set.

#### 5.14.9.6 0x67.2 IREG1

The Regulator overcurrent 1 indicator reports an overcurrent event has occurred while in IDLE or SCAN Modes. The  $I_{REGOC1}$  threshold at 0x1D (0x1D, 1E  $I_{REGOC1, 2}$  Threshold on page 67) is compared to the  $I_{REG}$  Voltage (0x61-62  $I_{REG}$  Voltage (R) on page 68) to determine this indicator. A 1 indicates a failure has occurred.

This fault shuts off both CFET and DFET and stops System Scan.

#### 5.14.9.7 0x67.1 IREG2

The Regulator overcurrent 2 indicator reports an overcurrent event has occurred while in LOW POWER mode. The  $I_{REGOC2}$  threshold at 0x1E (0x1D, 1E  $I_{REGOC1, 2}$  Threshold on page 67) is compared to the  $I_{REG}$  Voltage (0x61-62  $I_{REG}$  Voltage (R) on page 68) to determine this indicator. A 1 indicates a failure has occurred.

#### 5.14.9.8 0x67.0 VTMPF

The VTEMP Fault bit reports an undervoltage condition of the VTEMP pin voltage. A 1 indicates a failure has occurred. It is set when the measurement of the VTEMP voltage is lower than the  $VTEMP_{MIN}$  voltage threshold (1.1V, page 15).

This fault shuts off both CFET and DFET and stops System Scan.

#### 5.14.10 0x87 Status Mask

The Status Mask register masks the bits of Status register 0x67 from asserting the  $\overline{ALRT}$  pin low. The default value of each of the bits in this register is 1 (masked). Table 66 provides the definition of the Status Mask register. Write a 0 to the bit to allow signals to pass to the  $\overline{ALRT}$  pin.

Table 66. 0x87 Status Mask Register

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Fault Masked	DCHRG1	CHRG1	CH PRES1	LD PRES1	OTHER FAULTS	IREG1	IREG2	VTMPF
Default	1	1	1	1	1	1	1	1

#### 5.14.11 0x68-69 Open-Wire Status

Each bit in the Open-Wire Status register corresponds to one battery cell. During an open-wire test sequence (see Open-Wire Function on page 116), the ISL94216A connects a resistor, one cell at a time, between the  $VC_n$  and  $VC_{n-1}$  pins ( $n = 1:16$ ), and measures the voltage  $V(VC_n, VC_{n-1})$ . OW Cell $_n$  is set to 1 if the measured voltage is below a threshold when measuring  $V(VC_n, VC_{n-1})$ . See the Electrical Specifications (VOW $_{th1}$  on page 16) for the threshold voltage. A bit can be set if either wire to Cell $_n$  is open. An open-wire on pin  $VC_0$  is indicated with bit 0x69.0 set to 1.

To clear these fault bits, first reconnect the faulty wire(s) to the battery pack and execute an open-wire sequence. All bits in this register are latched high and can be cleared by writing a 0 to them, performing a chip  $\overline{RESET}$ , or by writing a 1 to the Clear Faults and Indicators bit (0x02.1). They cannot be cleared while the condition that sets them HIGH is present.

**Note:** The Open-Wire status of pins xT0, xT1, VSS, and V<sub>BAT1</sub> are in the [0x65 Other Fault Register on page 86](#).

Table 67. 0x68 OW Status Register

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	OW Cell16	OW Cell15	OW Cell14	OW Cell13	OW Cell12	OW Cell11	OW Cell10	OW Cell9
Default	0	0	0	0	0	0	0	0

Table 68. 0x69 OW Status Register

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Bit Name	OW Cell8	OW Cell7	OW Cell6	OW Cell5	OW Cell4	OW Cell3	OW Cell2	OW Cell1
Default	0	0	0	0	0	0	0	0

### 5.14.12 0x88-89 Open-Wire Mask

The Open-Wire Mask is used to prevent an open-wire failure on selected cell(s) from propagating to the  $\overline{\text{ALRT}}$  pin and spans two 1-byte registers. Set the bits corresponding to unused cells to 1 in this register and in registers [0x04 - 0x05 Cell Select on page 46](#).

If the Open-Wire Mask bit is 0 and an open-wire failure occurs on that cell,  $\overline{\text{ALRT}}$  goes low to indicate a fault.

Table 69. 0x88 OW Mask Register

Bits	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
Fault Masked	OWM Cell16	OWM Cell15	OWM Cell14	OWM Cell13	OWM Cell12	OWM Cell11	OWM Cell10	OWM Cell9

Default	1	1	1	1	1	1	1	1

## 6. Pin Functionality

### 6.1 VC<sub>n</sub> Pins

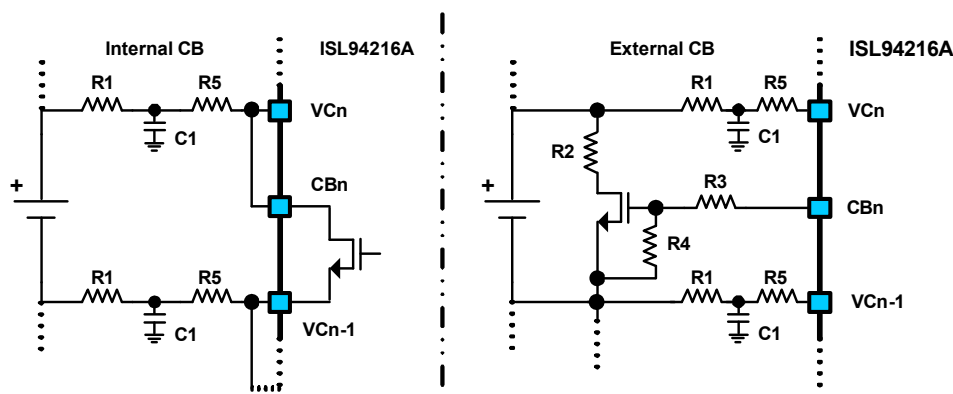

The VC0-VC16 pins are the voltage sense inputs of the ISL94216A and are used in pairs to differentially measure each cell voltage. Positive pin VC<sub>n</sub> and negative pin VC<sub>n-1</sub> are connected to the ADC through a multiplexer. Each voltage sense input uses an external filter to protect against battery voltage transients. The basic input filter structure, with capacitors to the local ground, provides protection against transients and EMI for the cell inputs. They carry the loop currents produced by EMI and should be placed as close to the battery connector as possible. The ground terminals of the capacitors must be connected directly to a solid ground plane. Any vias should be placed in line to the signal inputs so that the inductance of these forms a low pass filter with the grounded capacitors.

The filtered battery cell voltages internally connect to the cell voltage monitoring system. The monitoring system contains a multiplexer to select a specific input, and an analog to digital converter.

The components of the T network (see [Figure 97](#)) provide a current limit function during hot plug events. The typical application has a total of  $\sim 232\Omega$  series isolation resistance between the  $VC_n$  inputs and the cells, with  $R_1$  set to  $50\Omega$  and  $R_5$  at  $182\Omega$ .

The recommended value for  $C_1$  is  $0.33\mu F$ . A short in one of these capacitors dissipates the charge in the battery cell if left uncorrected for an extended period of time. Renesas recommends that capacitors connected to cells are fail safe or open mode types.

Component values for the remaining resistors in [Figure 97](#) are listed in the [CBn Pins](#) section.

**Figure 97. Voltage Sense and Cell Balance Pin Connections**

See [Reduced Cell Count on page 141](#) for instructions about connecting unused  $VC_n$  and  $CB_n$  pins in systems with fewer than 16 cells.

## 6.2 CBn Pins

The  $CB_1$  -  $CB_{16}$  pins are the Cell Balance (CB) outputs of the ISL94216A. They can be configured to use internal FETs or to drive external NMOS cell balancing FETs. The current drive for external FETs is  $\sim 25\mu A$  ( $I_{ECB}$ , [page 15](#)). The current sources are turned on and off as needed to control the external devices. The ISL94216A uses only N-channel FETs for the external balancing function.

[Figure 97](#) shows the recommended cell balancing and voltage monitoring external component configuration. In the Internal CB configuration, the cell voltage is monitored through the cell balance resistors.

The external cell balance transistor requires two extra resistors for bias and pin protection. Set the value of  $R_3$  to  $10K\Omega$  and set  $R_4$  to  $200k\Omega$  ([Figure 97](#)). With a CB pin typical output current of  $25\mu A$ , the cell balance transistor would see about 5V from gate to source.

Cell Balancing current is determined by the cell voltage divided by the resistance in the path from Cell+ through the CB FET to Cell-. The following equations assume configurations from [Figure 97](#) and component values from [VCn Pins on page 92](#).

For the external case, the CB current ( $CBI$ ) is determined by the value of  $R_2$  and the FET on resistance:

$$CBI = V_{CELL} / (R_2 + R_{DS(on)})$$

For the internal case,  $CBI$  is determined by the values of  $R_1$ ,  $R_5$ , and the FET on resistance.

$$CBI = V_{CELL} / [2 \times (R_1 + R_5) + R_{CB\_ON}]$$

The internal  $CBI$  is obtained by assuming the nominal value for the internal CB FET  $R_{CB\_ON}$  of  $70\Omega$  ([page 15](#)).

$$CBI = V_{CELL} / [2 \times (R_1 + R_5) + R_{CB\_ON}] = 4.2V / [2 \times (232\Omega) + 70\Omega] = \sim 8mA$$

Internal power dissipation of the ISL94216A increases when internal cell balancing is used (see [0x25.5 CB Configuration on page 76](#) and [Equation 24](#)). This must be accounted for in the system design to avoid triggering an Internal Over-Temperature Fault ([0x63.5 IOTF on page 82](#)).

The Cell Balance pins should not be driven by an external source.

### 6.3 CSP and CSN Pins (24, 25)

The current monitor circuit tracks charge and discharge currents. The differential input voltage is sampled within System Scans (see [0x03.7 I<sub>PACK</sub> EN on page 44](#)) or with a trigger command ([0x03.0 I<sub>PACK</sub> Trigger on page 46](#)). Current is monitored by measuring the differential voltage across a current sense or shunt resistor connected between the CSP and CSN pin filters. This is a Low Side implementation; the Current Sense Positive (CSP) pin filter is connected to the bottom of the cell-stack (negative terminal of Cell 1) and the Current Sense Negative (CSN) pin filter is connected to PACK-, the negative load/charge terminal and system/board ground ([Figure 93 on page 72](#)).

The ISL94216A compares the voltage across the sense resistor to several thresholds. The thresholds are discharge short-circuit, discharge overcurrent, and charge overcurrent (pages [page 51](#) to [page 51](#) and [page 56](#)). For short circuit detection an analog comparator is used instead of the sampled I<sub>PACK</sub> measurement. If the measured voltage exceeds the selected limit beyond the chosen duration of time, the ISL94216A acts to protect the system ([page 51](#)).

The current monitor tracks the direction of the current with digital comparators to determine if the battery is being charged or discharged (pages [page 45](#) and [page 90](#)). If either condition is detected, the ISL94216A sets an appropriate flag. Discharge currents produce a negative voltage and charge currents produce a positive voltage. If the voltage drop across R<sub>SHUNT</sub> is between approximately  $\pm 200\mu\text{V}$  ([I<sub>Zero\\_THR</sub> on page 13](#)), then neither charge or discharge condition is set.

Figure 98. Current Sense Pin Connections

Recommended component values for the current monitor external circuitry are shown in [Figure 98](#). Resistors R7 and R8 are chosen to minimize any error contributed by the pin's input current ( $\sim 10\mu\text{A}$ ) when the voltage is being measured. Capacitors C3 and C4 typically range from 1-100nF depending on the application.

The value of R<sub>SHUNT</sub> is application specific and must be determined based on peak and nominal load currents, charge current and end of charge current.

The maximum measurable voltage drop across R<sub>SHUNT</sub> is approximately -642mV for a discharge current. During charge the maximum measurable voltage is about 350mV. See [0x0A DSC Threshold](#), [0x0B DOC Threshold](#), and [0x0F COC Threshold](#) for current threshold settings.

While the overcurrent limits and operating maximum currents set the upper range of possible values for R<sub>SHUNT</sub> the minimum value is often determined by the desired End Of Charge Current Threshold ([0x10 IEOC Threshold on page 80](#)) and the zero current thresholds relative to the operational minimum current ([I<sub>Zero\\_THR</sub> on page 13](#)). Current measurements are compared to the IEOC threshold when the IEOC EN bit ([0x25.3 IEOC EN on page 77](#)) is set. The comparison determines the state of the BAT FULL bit ([0x66.7 BAT FULL on page 88](#)). For more detail about how IEOC is used in cell balancing see [Automatic Cell Balancing on page 119](#).

It is not recommended to operate at the extreme limits of the inputs. In an application care should be taken to guard-band against additional noise and transients that can cause current levels to reach or exceed the maximum limits. When the ISL94216A is consistently at or below threshold ( $I_{Zero\_THR}$  on page 13), the device may transition to LOW POWER mode. See 0x2E.5:3 Low Power Timer on page 104.

## 6.4 VSS Pin (26)

VSS is the ISL94216A analog ground pin. It must have a solid connection to the ground plane(s). The digital and analog ground planes should connect together as close to the VSS pin as possible. The Exposed Pad (EPAD) on the bottom of the ISL94216A must also be tied to analog ground. Multiple vias are recommended for good thermal conductivity.

The PACK- side of the current sense resistor must also be connected to the system and VSS ground planes (Figure 93 on page 72).

## 6.5 AUX0/xT0, VTEMP, AUX1/xT1 Pins (27, 29, 28)

### 6.5.1 External Components

AUX0/xT0 (pin 27) and AUX1/xT1 (pin 29) are auxiliary analog voltage input pins, also referred to as the ETAUX pins. Although they can be general purpose, these pins are optimized to work with external NTC thermistors to monitor the temperature of the battery pack if used in combination with the VTEMP output (Pin 28), as shown in Figure 99. When used as analog inputs, Pins 27 and 29 are called the AUX pins. When connected for temperature sense they are xT0 and xT1.

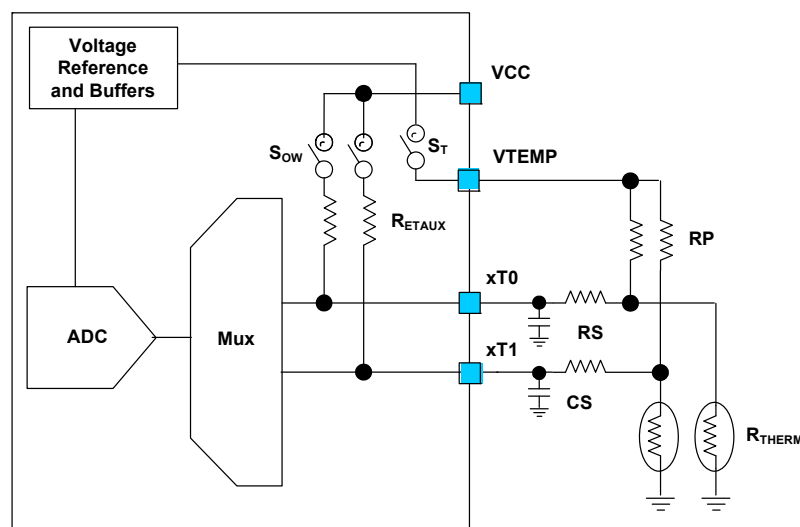

Figure 99. ETAUX Pin Configuration

The ETAUX inputs are sampled either as part of System Scans (see 0x11.7:6 ETAUX Enable on page 58) or with a trigger command (0x11.0 ETAUX Trigger on page 59). Before measurement, internal switch  $S_T$  is closed, connecting the two pull-up resistors  $R_P$  through the VTEMP pin to the reference voltage. This sets up a pair of voltage dividers consisting of  $R_P$  and  $R_{THERM}$ . The voltage between these resistors is a function of the temperature of  $R_{THERM}$ . This voltage is connected through the low pass filters consisting of  $R_S$  and  $C_S$  to the xT0 and xT1 inputs. Each of these inputs is measured in sequence relative to VSS. Switches  $S_{OW}$  are used only for Open-Wire test and must be open for accurate measurements.

Recommended values for the  $R_S$  resistors are 10k $\Omega$  and 0.01 $\mu$ F for  $C_S$  capacitors.  $R_P$  values should match the nominal value of the thermistors used, with 10k and 100k supported. Thermistors  $R_{THERM}$  are usually located within the battery pack to monitor the cell temperature(s). Because the thermistors have a known value versus

temperature the temperature can be calculated based on the voltage divider created between  $R_{THERM}$  and  $R_P$  given the known values for  $V_{TEMP}$  and  $R_P$ .

The  $V_{TEMP}$  pin is the switched output of an analog buffer which forces the reference voltage at the pin when selected. This pin operates as an analog output and should not be driven by an external source.

### 6.5.2 Aux Pins Open-Wire Test

The auxiliary pins ( $xT0$ ,  $xT1$ ) are tested for opens indirectly and are not part of the open-wire test sequence. After the pin voltages are measured, either during system-scan or a stand-alone measurement, if their resulting voltage readings are high relative to  $V_{TEMP}$ , the corresponding OW status bit is set high.

To test for or verify an OW on  $xT0$  or  $xT1$ , connect the internal  $R_{ETAUX}$  (page 14) pull-up resistors by setting bit [0x09.7 AUX/xTn Pull-Up on page 49](#) to 1. This bit closes switches  $S_{OW}$  as shown in [Figure 99](#) when set to 1. Next, trigger an auxiliary pin measurement with [0x11.0 ETAUX Trigger on page 59](#). The voltage reads full scale if the connection at the pin is open with the  $R_{ETAUX}$  resistors connected between the VCC pin and the auxiliary pins.

After the open-wire test of these pins, disconnect the internal pull-up resistors by setting the AUX Pull-up bit back to 0.

## 6.6 Regulator and Supply Pins (30-33)

The ISL94216A has an internal regulator that uses an external power transistor to provide regulated voltages for its internal circuits. The output of this regulator can also power other system circuitry, including the microcontroller. See [Figure 100](#) while reviewing sections [VCC Pin \(30\)](#) through [BASE Pin \(33\)](#) on page 97.

The EMITTER and VDD pins are connected through a multiplexer to the ADC, enabling the ISL94216A to monitor the regulator load current. The maximum voltage permitted across  $R_{SH}$  is 344mV ([0x1D,1E IREG<sub>OC1,2</sub> Threshold](#)), this limits the selection of the sense resistor  $R_{SH}$ .

These pins are to be connected per [Figure 100](#) and should not be driven from external sources.

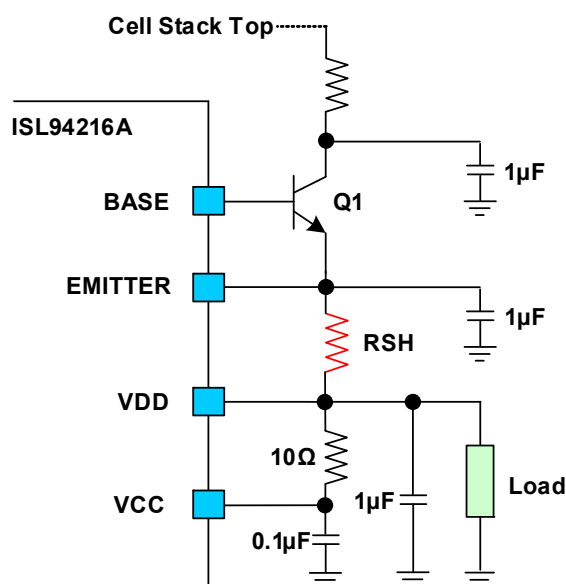

Figure 100. External Power Supply Components

### 6.6.1 VCC Pin (30)

The VCC pin is the analog 3.3V power supply input. External loads should not be tied to this pin. It connects externally to the VDD pin through a resistor and has a decoupling capacitor to VSS (analog ground). The VCC pin is also a sense input to the internal multiplexer and ADC used to determine if the regulator is functioning properly.

### 6.6.2 VDD Pin (31)

The VDD pin is the digital 3.3V power supply input. It connects externally to the VCC pin through a resistor and has a decoupling capacitor to DGND (digital ground). This pin also connects to an off-chip sense resistor (RSH) tied to the EMITTER pin in the regulator's feedback loop. The VDD and EMITTER pins are sense inputs to the internal multiplexer and ADC; together they are used to monitor the voltage across the off-chip sense resistor to determine the regulator current (see [0x61-62 I<sub>REG</sub> Voltage \(R\) on page 68](#)). The VDD pin is also the feedback point for the regulator.

This node can support external loads, the regulator is designed to source but not sink current. The source current is limited by the available base current, the power dissipation tolerance of RSH, Q1 and its collector resistor.

### 6.6.3 EMITTER Pin (32)

The EMITTER pin connects to an off-chip sense resistor and the emitter terminal of the off-chip NPN in the regulator's loop. The other end of the sense resistor connects to the VDD pin.

### 6.6.4 BASE Pin (33)

The BASE Pin drives the base terminal of the external NPN transistor in the regulator's loop. The amplifier driving the BASE pin sources a minimum of 1mA across the operating temperature range. This allows a maximum regulation current of around 100mA given a minimum NPN  $\beta$  of 100.

Use this pin only to drive the base pin of an external NPN as part of the regulator loop. It is not intended for any other purpose.

The NPN collector connection to the pack voltage should be routed separately to the battery pack from the high current load path to minimize any transient effects. A resistor should be placed between the collector and the pack along with a decoupling capacitor from collector to DGND. The value of the resistor is dependent on the expected collector current and the transistor chosen.

## 6.7 CMS0 and CMS1 Pins (34, 35)

The CMS0 and CMS1 pins select the communication protocol for the ISL94216A (see [Serial Protocol Defined on page 124](#)). They must be connected to DGND or VDD when power is applied.

## 6.8 DGND Pin (36)

DGND is the digital ground reference pin of the ISL94216A. It must have a solid connection to the digital ground plane. If separate digital and analog ground planes are used, they should be connected together at the VSS pin.

## 6.9 V2P5 Pin (37)

The V2P5 pin is the internal 2.5V digital power supply. External connections must be limited to a decoupling capacitor to DGND. This pin is for internal use only. Do not load or drive this pin from an external source.

## 6.10 $\overline{\text{RESET}}$ Pin (38)

The  $\overline{\text{RESET}}$  pin requires a pull-up resistor connected to  $V_{DD}$ , 100k $\Omega$  recommended. The pin is used to exit out of any mode and restores the factory default settings. The reset pin is referenced to the DGND pin.

When  $\overline{\text{RESET}}$  is low, all the flip-flops return to the default state, all chip functions are disabled, and all bits are reset to default values. After  $\overline{\text{RESET}}$  transitions from low to high, the fuses are read and internal calibration is performed. The chip has a communication lockout of  $t_{\text{RESET}}$  and POR lockout of  $t_{\text{StartUp}}$  ([page 17](#)). The whole power-up sequence takes the amount of time specified by  $t_{\text{StartUp}}$ . After all actions are complete, the device transitions to IDLE mode.

If  $V_{\text{BAT1}}$  voltage goes below  $V_{\text{POR}}$ , the actions by the chip are the same as if holding  $\overline{\text{RESET}}$  pin low. When  $V_{\text{BAT1}}$  rises above  $V_{\text{POR}}$ , the action is equal to  $\overline{\text{RESET}}$  transitioning from low to high.

## 6.11 $\overline{\text{WAKEUP}}$ Pin (39)

The  $\overline{\text{WAKEUP}}$  pin is a digital input pin driven by the microcontroller to inform the ISL94216A that a charger is present. CH PRES1 bit tracks the setting of this pin. The ISL94216A transitions to IDLE mode when  $\overline{\text{WAKEUP}}$  transitions from a high to low if in SHIP or LOW POWER mode. The mode remains unchanged if in SCAN mode.

A 100k $\Omega$  pull-up to VDD is recommended.

## 6.12 $\overline{\text{ALRT}}$ Pin (40)

The  $\overline{\text{ALRT}}$  pin is an active low digital output pin the ISL94216A uses to inform the microcontroller of a fault or status change. Faults, status bits, and mode transitions because of activity such as load attachment or inactivity such as no charge/discharge current can be unmasked (registers 0x83-89) to connect the bit state to the pin. A 100k $\Omega$  pull-up to VDD is recommended.

Unmasked incidences causing transitions to either SHIP or LOW POWER Modes hold the  $\overline{\text{ALRT}}$  pin low for a minimum of time specified by  $t_{\text{REGSW}}$  (page 15) before releasing it to conserve power.

The  $\overline{\text{ALRT}}$  Pulse Enable bit of the GPIO Operation register (0x12.6  $\overline{\text{ALRT}}$  Pulse EN on page 60) drives the  $\overline{\text{ALRT}}$  pin in a more power efficient manner when set to 1 (see Figure 101). When the bit is enabled, the ISL94216A turns on the  $\overline{\text{ALRT}}$  pin NMOS device for 2ms within a 10ms period if an alert is active. A 0 (Default) sets the circuit to constant drive.

The  $\overline{\text{ALRT}}$  pin is configured as a digital output pin and should not be driven by an external source.

## 6.13 $\overline{\text{ADDR/CS}}$ Pin (41)

The  $\overline{\text{ADDR/CS}}$  pin is used by both I<sup>2</sup>C and SPI communications protocols. If I<sup>2</sup>C is selected, then this pin is designated ADDR and it determines the device address. See I<sup>2</sup>C Address Values on page 125 for details. When used as an address pin, it should be permanently tied to either VDD or DGND depending on desired address. The ADDR pin should not change state while the ISL94216A is powered, if it does a device RESET may be required to recover.

If the SPI protocol is selected, then pin 41 is designated as  $\overline{\text{CS}}$  (Chip Select) and is active low. This pin is a digital input and is driven only by the master. A 100k $\Omega$  pull-up to VDD is recommended.

## 6.14 SCL Pin (42)

The SCL pin is the communications clock pin driven by the master for I<sup>2</sup>C and SPI communications protocols. A pull-up of 4.7-10k $\Omega$  to VDD is recommended.

## 6.15 MOSI Pin (43)

The Master Output Slave Input pin is a digital input for the SPI protocol. The MOSI pin is driven only by the master and is monitored by the slave when  $\overline{\text{CS}}$  is pulled low. No pull-up is required by the ISL94216A, but it may be needed depending on the master.

This pin is not used if either of the other protocols are chosen.

## 6.16 MISO/SDA/SINGLE-WIRE Pin (44)

The MISO/SDA/SINGLE-WIRE pin is used by all three communications formats as determined by the CMS0 and CMS1 pins.

For I<sup>2</sup>C communications the pin is the Serial Data (SDA) input/output pin. It is driven by the master for sending a slave address byte and for write commands. The pin is driven by the slave for data reads. In this mode the device pin is an open drain. For this protocol a 4.7-10k $\Omega$  pull-up to VDD is recommended.

In SPI mode the Master Input Slave Output (MISO) pin is a CMOS serial data output pin from the slave to the master. No pull-up is necessary on this pin for SPI mode.

Single Wire applications use this CMOS I/O pin as the only communications port. It is driven by the master or slave depending on the symbol sequence/timing. A 4.7kΩ pull-up to VDD is recommended for this protocol.

When operating as a digital output this pin should not be driven by an external source.

## 6.17 GPIO(0-3) Pin (45-48)

The General Purpose Input/Output pins are user configurable (see [0x12.5:4 GPIO CONFIG on page 60](#)) as a group as inputs or outputs. They cannot be configured individually.

If configured as inputs, the GPIO pins set the bit values of the GPIO Status bits. If configured as Outputs or Drive LED, the GPIO pins reflect the bit values of the GPIO Status bits. In Drive LED mode the active outputs are pulled low for 2ms out of every 10ms to save power, as illustrated by [Figure 88](#). These pins require pull-up resistors when configured as outputs. The pull-up resistor value for the pin should be greater than  $R_{GPIO\_PU}$  ([page 17](#)).

The FETs Out selection connects GPIO2 to the DFET logic signal and GPIO3 to the CFET logic signal. This enables the ISL94216A to control a low side FET configuration. [Table 28 on page 61](#) defines the logic state of the GPIO pins versus DFET and CFET state. GPIO1 is configured as a FETs OFF digital input pin. If the logic state is high, both DFET and CFET turn off. If the logic state is low, the DFET and CFET logic signals pass to GPIO2 and GPIO3. GPIO0 is configured as a FETs ON digital output pin. The output of the pin is high until CFET and DFET are both off.

The GPIO pins can tolerate up to 5V inputs when the ISL94216A is operated with VCC and VDD of 3.3V. If configured as digital outputs, these pins must not be driven by an external source.

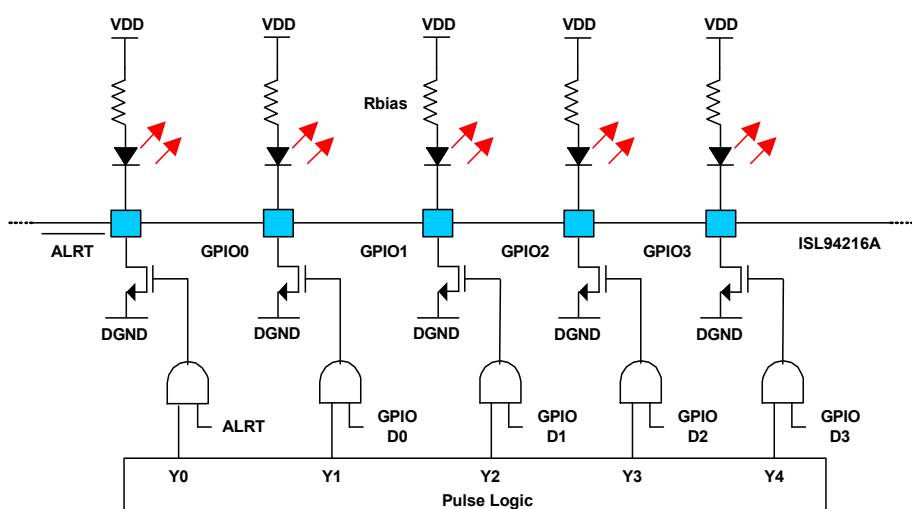

Figure 101.  $\overline{\text{ALRT}}$  Pulse EN and GPIOx Drive LEDs

## 6.18 LDMON Pin (49)

The LDMON pin of the ISL94216A is used for load connection detection ([Figure 85 on page 56](#)) and for short-circuit load release detection ([Figure 83 on page 53](#)). The ISL94216A monitors the voltage at this pin, which is connected to the load side of the DFET through an isolation resistor ([Figure 102](#)). A Schottky diode (not pictured) may be added to protect the LDMON pin from excessive transients in high current applications, the diode must be oriented to enable current flow out of the LDMON pin.

The load detect function only operates when DFET is off. It connects an on-chip pull-up resistor, determined by the [0x0E.6:5 ELD on page 54](#) setting, between the LDMON and VBAT2 pins. If PACK+ has no load, then the LDMON pin voltage is pulled above the load detect threshold  $V_{LDThr}$  (1.2V nominal, [page 14](#)). When a load is

present, the LDMON voltage is determined by the voltage division between the internal resistance selected by ELD and the load connected between PACK+ and PACK-.

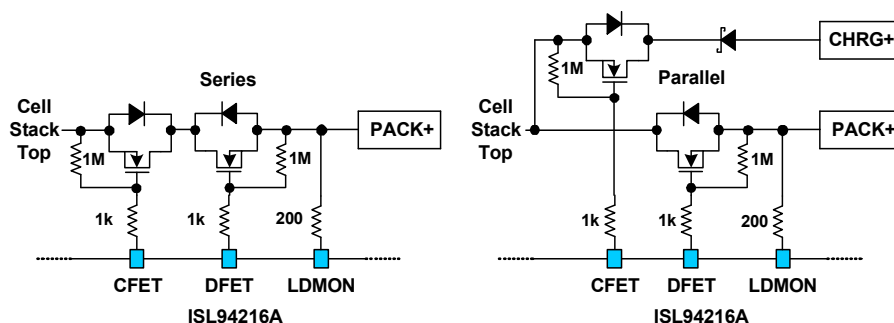

Figure 102. CFET, DFET and LDMON Connections

Setting bit [0x0E.4 ELR on page 55](#) to 1 (default) enables the Short Circuit Recovery Sequence. If a short-circuit is detected, the load recovery circuitry tests for load removal after a delay of  $t_{LDEN}$  ([page 14](#)) plus  $t_{LDDELAY}$  ([0x1B.3:2 LD Delay on page 66](#)) following the shut off of DFET. If the ELR bit is set to 0, no Short Circuit Recovery Sequence is performed. In either case the DFET remains off until the MCU resolves the issue and enables it.

See [Load Detection on page 56](#) for more details.

## 6.19 CFET and DFET Pins (50, 51)

The CFET and DFET pins are driven above pin VBAT2 by the charge pump when enabled, which turns on the power FETs. These two pins are analog outputs and should not be driven by an external source. The power FETs can be arranged in either series or parallel configuration, see [0x0E.3 CPWR on page 55](#).

Various conditions control the on and off state of these pins. The first group of conditions always applies. They turn off and keep off CFET and DFET and they stop and prevent starting System Scans:

- **Chip Reset:** POR, [RESET Pin \(38\)](#) is pulled low, set [0x01.7 Soft Reset](#), or set [0x01.6 Reset to IDLE](#).
- **System Mode:** SHIP or LOW POWER.
- **Asserted Fault(s):** [0x63.2 DSCF OR 0x63.5 IOTF OR 0x63.6 OWF OR 0x63.7 VCCF OR 0x65.5 CPMP NRDY OR 0x67.2 IREG1 OR 0x67.0 VTMPF](#).

In SCAN mode, the following group of conditions applies when [0x0E.3 CPWR on page 55](#) bit is set to 0 for series connected power FETs. They turn off and keep off CFET and DFET, and inhibit System Scans when they are set to 1:

```
If 0x67.6 CHRGI AND 0x0E.2 FCDC AND 0x63.4 COCF
If 0x67.7 DCHRG AND 0x0E.7 CFD AND 0x63.3 DOCF
If 0x24.3 VBAT1CON AND {[CHRG AND VBOVF] OR [DCHRG AND VBUVF]}
If 0x24.2 ETA Connect AND
{(DCHRG AND [DUT1 OR DUT0 OR DOT1 OR DOT0])
OR
(CHRG AND [CUT1 OR CUT0 OR COT1 OR COT0])}
If 0x24.4 CELLCON AND
{DVCF OR [{CHRG AND NOT(CHRWUV)} OR DCHRG] AND UVF
OR
[{DCHRG AND NOT(DCHRWOV)} OR CHRG] AND OV}
```

See [DFET Pin \(50\)](#) and [CFET Pin \(51\)](#) for the cases of when CPWR is set to 1 for parallel power FET applications. See [Figure 103](#) for the shutdown sequence for these pins.

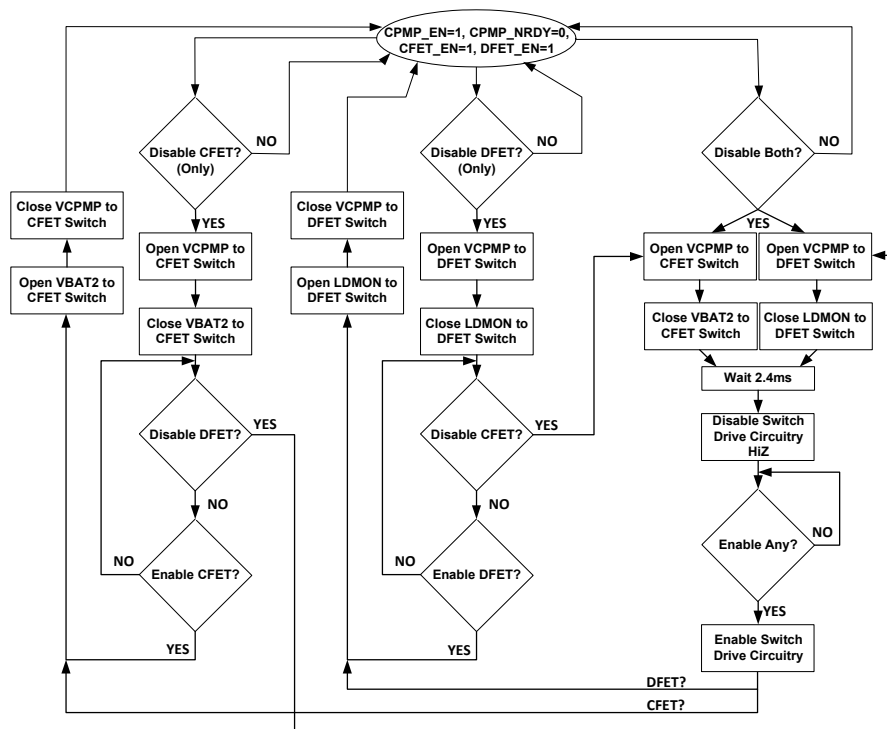

Figure 103. C/DFET Shutdown Flowchart

### 6.19.1 DFET Pin (50)

The DFET pin is the voltage driver output designed to pull the discharge FET gate to about 11V above the pack voltage to turn the device on to supply power to the load. A 1kΩ isolation resistor is recommended between this pin and the DFET gate ([Figure 102](#)). Use back-to-back gate-to-source Zener diodes (not pictured) to limit the FET gate-to-source voltage and transient induced currents at the DFET pin. Connect a large value resistor (~1MΩ) between the gate and source of the DFET. The resistor prevents the FET from turning on while in SHIP or LOW POWER mode, or when both power FETs are off.

When both power FETs are being shut off, an internal switch that connects the DFET pin to the LDMON pin is closed for 2.4ms to discharge the gate to source capacitance to shut off the discharge FET. Next, the DFET pin is set to high impedance. If only DFET is shut off, then the switch remains closed.

If the CPWR bit is set to 1 for parallel connected power FETS (separate charge and discharge paths) and any of the following conditions evaluate as True in SCAN mode, they cause only DFET to shut off and prevent turning it On.

```

If 0x25.3 IEOC EN AND 0x66.4 VEOC
If 0x0E.7 CFD AND 0x67.7 DCHRG1 AND 0x63.3 DOCF
If 0x24.3 VBAT1CON AND DCHRG1 AND 0x65.6 VBUVF
If 0x24.4 CELLCON AND {DVCF OR UVF OR [NOT(DCHRWOV) AND OV]}
If 0x24.2 ETA Connect AND (DCHRG1 AND [DUT1 OR DUT0 OR DOT1 OR DOT0])
  
```

### 6.19.2 CFET Pin (51)

The CFET pin is the voltage driver output designed to pull the charge FET gate to about 11V above the pack voltage to turn the device on to supply power to the battery pack. A 1kΩ isolation resistor is recommended between this pin and the CFET gate ([Figure 102](#)). Use back-to-back gate-to-source Zener diodes (not pictured) to limit the FET gate to source voltage and transient induced currents at the CFET pin. Connect a large value resistor

(~1MΩ) between the gate and source of the CFET. The resistor prevents the FET from turning on while in SHIP or LOW POWER mode, or when both power FETs are off.

When both power FETs are being shut off an internal switch that connects the CFET pin to the VBAT2 pin is closed for 2.4ms to discharge the gate to source capacitance to shut off the charge FET. Next, the CFET pin is set to high impedance. If only CFET is shut off, then the switch remains closed.

If CPWR bit is set to 1 for parallel connected power FETS (separate charge and discharge paths) and any of the following conditions evaluate as True in SCAN mode, they cause only CFET to shut off.

```
If 0x0E.2 FCDC AND 0x67.6 CHRG1 AND 0x63.4 COCF
If 0x24.3 VBAT1CON AND [CHRG1 AND VBOVF]
If 0x24.4 CELLCON AND {DVCF OR OVF OR [NOT(CHRWUV) AND UVF]}
If 0x24.2 ETA Connect AND (CHRG1 AND [CUT1 OR CUT0 OR COT1 OR COT0])
```

The following condition shuts off CFET in SCAN mode in association with the completion of battery charging and is not a function of the CPWR bit:

```
{ (VEOC AND NOT[IEOC EN]) OR (VEOC AND IEOC AND IEOC EN) }
```

## 6.20 VCPMP Pin (52)

The VCPMP pin is the charge pump output connection to the charge pump capacitor, which is connected between the VCPMP pin and VBAT2 pin. A charge pump capacitor value of approximately 20 times the sum of the gate capacitance of the CFET and DFET is recommended. The capacitor should be placed close to the ISL94216A pins as shown in Figure 104.

The VCPMP pin is an analog output and should not be driven by an external source.

Figure 104. VBAT1, VBAT2 and VCPMP Connections

The charge pump is enabled with bit 0x24.7 CPMP EN on page 72 and its status is indicated by bit 0x65.5 CPMP NRDY on page 86. See Charge Pump on page 122 for a detailed description of the charge pump state machine.

## 6.21 VBAT2 Pin (53)

VBAT2 is a battery power input to the ISL94216A. It provides power to the internal charge pump, gate drivers, load monitor, and cell balancing. This pin is connected internally to the CFET pin when CFET is OFF.

A filter consisting of a 200Ω resistor along with a 1.0μF capacitor to DGND is recommended between this pin and the top of the cell stack as shown in Figure 104. The low side of the charge pump capacitor also connects to this pin. These capacitors should be placed close to the ISL94216A pins.

The connection to the cell stack should be routed to the battery pack separately from the high current load path to minimize any transient effects.

## 6.22 VBAT1 Pin (54)

VBAT1 is a battery power input to the ISL94216A. It provides power to the regulators, reference, and the V<sub>CELL</sub> multiplexer. Strong or Weak regulators drive the VDD pin depending on the ISL94216A operating mode. For more information, see Regulator Measurements and Detectors on page 64.

The  $V_{PACK}$  voltage is measured at the VBAT1 pin by way of a resistor divider. The total resistance for the VBAT1 resistor divider is  $R_{VBAT1}$  on [page 15](#).

A filter consisting of a 200 $\Omega$  resistor along with a 1.0 $\mu$ F capacitor to DGND is recommended between this pin and the top of the cell stack as shown in [Figure 104](#). Place the capacitor close to the VBAT1 pin.

The connection to the cell stack should be routed to the battery pack separately from the high current load path to minimize any transient effects.

## 7. System Operation

The ISL94216A is an integral part of a Battery Management System (BMS) providing a variety of operational modes and functions useful in a wide range of applications.

[Figure 105 on page 106](#) is a flow diagram that illustrates the top level interactions between modes. Additional flow diagrams tie all the individual sections together.

## 7.1 0x2E Scan Operation

The Scan Operation register must be set before triggering a single or continuous System Scan.

**Table 71. 0x2E Scan Operation**

Bits	Bit Name	Default
D[7:6]	System Mode	00
D[5:3]	Low Power Timer	01 1
D[2:0]	Scan Delay	011

### 7.1.1 0x2E.7:6 System Mode

The System mode bits force the ISL94216A into a specific mode. If a scan or an open-wire test is executing, the mode change waits until they complete before transitioning to the new mode. Cell balancing is interrupted (stopped) by a mode change instruction without a delay.

**Table 72. SM Mode**

D[7:6]	SM Mode
00	IDLE mode
01	SCAN mode
10	LOW POWER mode
11	SHIP mode

Select SCAN mode after all relevant settings have been written. Some changes may be ignored by the ISL94216A if made during an active System Scan.

### 7.1.2 0x2E.5:3 Low Power Timer

The Low Power Timer bits control the number of consecutive System Scans with a zero current reading (between  $\pm 200\mu\text{V}$ , +19, and -20 decimal register value) that causes the ISL94216A to transition from SCAN mode to LOW POWER mode. The format and default values of the Low Power Timer bits are displayed in [Table 73](#). These bits must be set before triggering a single or continuous System Scan.

**Table 73. Low Power Timer**

Delay: D[5:3]			Number of Scans
0	0	0	OFF
0	0	1	512
0	1	0	1024
0	1	1	2048
1	0	0	4096
1	0	1	8192
1	1	0	16384
1	1	1	32768

### 7.1.3 0x2E.2:0 Scan Delay

The Scan Delay bits of the Scan Operation register control the delay time between finishing a System Scan measurement/test/cell balancing sequence in continuous scan mode and starting a new one. After a System Scan has completed all measurements, tests, and cell balancing, a delay set by the Scan Delay bits occurs before starting the next System Scan. These bits have no effect when a single System Scan is triggered. The format and default values of the Scan Delay bits are displayed in Table 74. These bits must be set before triggering a continuous System Scan.

Table 74. Scan Delay

Delay: D[2:0]			Delay (ms)
0	0	0	0
0	0	1	64
0	1	0	128
0	1	1	256
1	0	0	512
1	0	1	1024
1	1	0	2048
1	1	1	4096

## 7.2 System Modes

Reset has the highest priority and is initiated by either a  $\overline{\text{RESET}}$  assertion, a  $V_{\text{BAT1}}$  voltage lower than  $V_{\text{POR}}$  (a POR event), a Reset to Idle (0x01.6 Reset to IDLE on page 41), or a Soft Reset (0x01.7 Soft Reset on page 41). The Reset function interrupts any action the ISL94216A is performing.

The second priority is a Discharge Short-Circuit fault (0x63.2 DSCF on page 83). It interrupts any action the device is performing. DFET and CFET automatically turn off and short-circuit recovery begins if the bit 0x0E.4 ELR on page 55 is 1. The device transitions to IDLE mode if it is in a different mode.

After power-up, the default mode is IDLE. An MCU command can change the mode of the IC from the current mode to the desired mode (SM mode bits 0x2E.7:6 System Mode on page 104). If a measurement or Open-Wire test is executing, the mode change happens when those complete. Cell balancing is interrupted (stopped) by a mode change without a delay.

If a command is not received by the ISL94216A for  $t_{\text{COM}}$  (page 16) while in IDLE mode, the device transitions to LOW POWER mode unless bit 0x1F.1 Communication Timeout EN on page 69 is 0.

A  $\overline{\text{WAKEUP}}$  assertion forces the mode to change to IDLE if in LOW POWER or SHIP mode. It does not force a mode change if in SCAN mode.

If in SCAN mode without a load or charge current ( $|I_{\text{PACK}}| < I_{\text{Zero\_THR}}$  page 13) for a number of System Scans set by 0x2E.5:3 Low Power Timer on page 104, the device transitions to LOW POWER mode.

SCAN mode exits to IDLE mode for short circuit or low VCC faults.

If in LOW POWER mode and a load is detected with bit 0x0E.1 LDLP on page 55 set to 1, the mode changes to IDLE mode.

Bad Clock (Oscillator) and Power Faults (VDD/VCC, or V2P5 regulators) cause a transition to SHIP mode.

Figure 105 illustrates the mode changes initiated by the ISL94216A or by the Master.

The various system modes are described in more detail in SHIP Mode on page 106, LOW POWER Mode on page 107, IDLE Mode on page 107, and SCAN Mode on page 108.

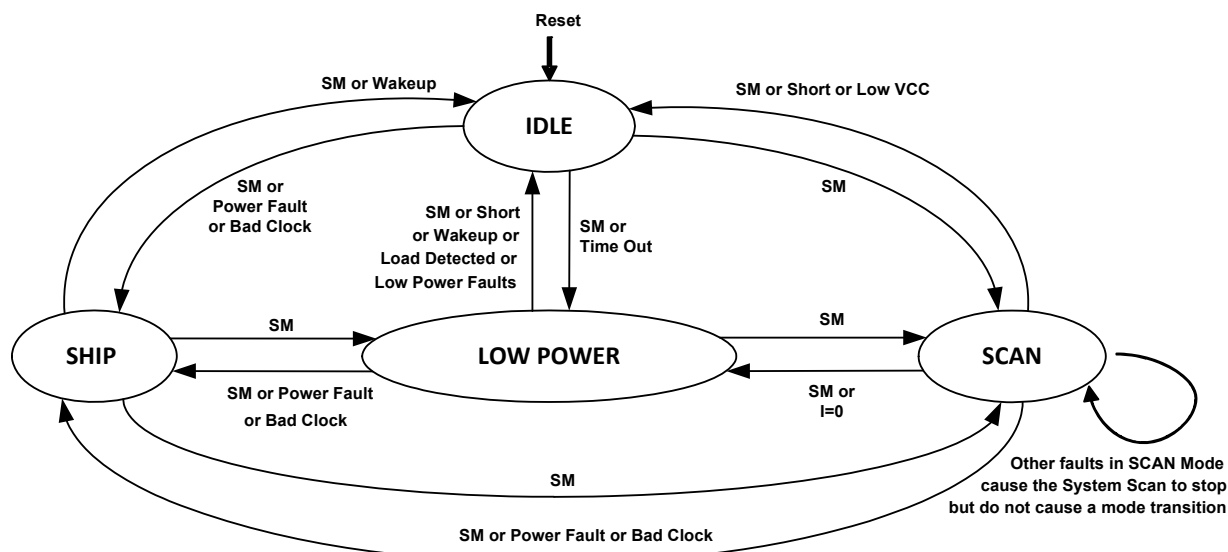

Figure 105. Top Level Flow Diagram of the ISL94216A

### 7.2.1 SHIP Mode

SHIP mode is the lowest power mode of the ISL94216A. It is entered by changing the SM mode bits (0x2E.7:6 System Mode on page 104) to SHIP mode. If a fault is detected in the internal clock, VDD/VCC, or V2P5 regulators, the device changes to SHIP mode immediately. These faults take priority and anything in progress is interrupted immediately and is not completed. If  $\overline{\text{ALRT}}$  is asserted by these faults, it is released following the transition to SHIP mode (by the  $t_{\text{REGSW}}$  timer, page 15) to save power.

The Busy bit (0x01.2 Busy on page 41) is set during the transition to SHIP mode. All functional blocks are powered down except the Strong regulator (see 0x1B.1 LP REG on page 66) and timer. First CFET and DFET, cell balancing, open-wire checks, and any measurements are shut off. Those functions remain disabled in SHIP mode. The  $t_{\text{REGSW}}$  timer is started to allow time for the MCU to transition to a low power state. When the timer expires, the oscillator is turned off along with the power-good comparators, FET drivers and the charge pump. The Strong regulator is shut off if the LP REG bit is 0. The Busy bit is cleared. The regulator function is switched to the Weak regulator unless the LP REG bit is 1, which enables the Strong regulator during LOW POWER and SHIP Modes.

The Single Wire Interface on page 136 requires a fast clock. If Single Wire communication occurs in SHIP mode or LOW POWER mode with LP REG bit set to 0, the oscillator is enabled to process the serial transaction. No oscillator fault checks (0x67.3 Other Faults on page 91) occur during serial transaction(s) while in SHIP mode. After the Single Wire transaction is complete, the oscillator is disabled again.

While in SHIP mode the IC does nothing but wait for a  $\overline{\text{WAKEUP}}$  or a  $\overline{\text{RESET}}$  assertion or a change mode command. All reads or writes that do not access the Scan Operation register (0x2E Scan Operation on page 104) return a NACK.

When  $\overline{\text{WAKEUP}}$  or  $\overline{\text{RESET}}$  are asserted or a change mode command is received, circuitry is enabled in a specific sequence:

Set Busy Bit → Oscillators → Strong Regulator → Power-Good comparators (VDD, VCC, V2P5) → Oscillator Fault Monitor → Power-Good State Machine → Wait a few milliseconds for Power-Good → Read Fuse Bits (if  $\overline{\text{RESET}}$ ) → Cal ADC Single Ended Path → Charge Pump (if enabled).

The rest of the pack settings are restored and all faults and indicators are cleared.

If the Power-Good state machine determines that the power is not good while loading register defaults during initialization after a power up or  $\overline{\text{RESET}}$  event, the device completes loading and then transitions to SHIP mode. If

the power-good state machine determines that the power is not good at any other time, then the device immediately transitions to SHIP mode.

The Busy bit is cleared when the mode transition completes. From  $\overline{\text{RESET}}$  rising edge or from VPOR (page 18), it takes about  $t_{\text{StartUp}}$  (<20ms, page 18) typically to complete the transition to IDLE.

### 7.2.2 LOW POWER Mode

LOW POWER mode includes some measurements and enables timers. This mode is entered manually by changing the System mode bits (0x2E.7:6 System Mode on page 104) or automatically by consecutive current readings below  $I_{\text{Zero\_THR}}$  (page 13) during continuous System Scans (0x2E.5:3 Low Power Timer on page 104), or no communication from the MCU for  $t_{\text{COM}}$  (page 16) while in IDLE mode unless bit 0x1F.1 Communication Timeout EN on page 69 is clear.

The Busy bit (page 41) is set during the transition to LOW POWER mode. All functional blocks are powered down except the Strong regulator and the  $t_{\text{REGSW}}$  timer which is started. After the timer expires, power switches to the Weak regulator only if bit 0x1B.1 LP REG on page 66 is 0. The oscillator remains on so the 0x54 - 0x57  $I_{\text{PACK}}$  Timer (R) on page 47 is operational. The Busy bit is cleared.

While in LOW POWER mode, every  $t_{\text{LPMEAS}}$  period (page 17) relevant circuitry (including the Strong regulator) is powered up to measure  $V_{\text{VCC}}$ ,  $I_{\text{REG}}$ ,  $V_{\text{TEMP}}$ ,  $\text{ETAUX}$ , and  $V_{\text{BAT1}}$ .  $I_{\text{REGOC2}}$  is the  $I_{\text{REG}}$  over-current limit in LOW POWER mode.

All control registers can be written to and read from while in LOW POWER mode. The measurement registers are not updated but the measurement results are compared to limits. After measurements complete, if an unmasked fault is detected and  $\overline{\text{ALRT}}$  is asserted, the regulator remains on. Fault delay counters are not active in LOW POWER mode; single threshold violations trigger faults. A Fault causes the part to change to IDLE mode if  $\overline{\text{ALRT}}$  is asserted. Status  $\overline{\text{ALRT}}$  assertions from the unmasking of Busy and/or CPMP NRDY bits do not cause a transition to IDLE mode. When the device exits LOW POWER mode, the last measurement values are passed to the measurement registers before entering IDLE or SCAN mode.

The Single Wire Interface on page 136 requires a fast clock. If Single Wire communication occurs in SHIP or LOW POWER mode with the LP REG bit set to 0, the oscillator is enabled for the duration of the communication, but the device does not check for oscillator faults (0x67.3 Other Faults on page 91).

When  $\overline{\text{WAKEUP}}$  or  $\overline{\text{RESET}}$  are asserted, a load connection is detected, or a change mode command is received, the strong regulator is powered up and the Busy bit is set. If bit 0x24.7 CPMP EN is set, the charge pump circuitry starts. The rest of the pack settings are restored and all faults and indicators are cleared. The Busy bit is cleared when the IC completes the transition to IDLE mode.

Load Connection Detection in LOW POWER mode requires bit 0x0E.1 LDLP on page 55 to be set to 1 and 0x24.1 DFET EN to be clear (0). Load detection is described further in 0x0E.6:5 ELD on page 54, LDMON Pin (49) on page 99, and Load Detection on page 56.

**Note:** If a fault is detected, the strong regulator remains on to allow the  $\overline{\text{ALRT}}$  pin to be driven. The measurement registers are not refreshed until the mode is changed to SCAN or IDLE.

### 7.2.3 IDLE Mode

IDLE mode is entered by changing the SM mode bits (0x2E.7:6 System Mode on page 104) to IDLE mode or asserting  $\overline{\text{RESET}}$ . A load detection changes the mode to IDLE if in LOW POWER mode and bit 0x0E.1 LDLP on page 55 is enabled. If in SCAN mode and a DSCF or VCCF fault is detected, the mode changes to IDLE. Asserting the  $\overline{\text{WAKEUP}}$  pin in LOW POWER or SHIP mode also causes the mode to transition to IDLE.

Delay counters are disabled in IDLE mode. For example, a  $V_{\text{BAT1}}$  overvoltage reading would be passed to the VBOVF bit (0x65.7 VBOVF on page 86) without requiring consecutive faulty readings.

Zero current can be read indefinitely in this mode. The Low Power Timer (0x2E.5:3 Low Power Timer on page 104) is disabled in IDLE mode.

Commands from the MCU are executed while in IDLE mode.

No communication from the MCU for  $t_{COM}$  (page 16) leads to a transition to the LOW POWER mode unless bit 0x1F.1 [Communication Timeout EN](#) is 0.

Current direction indicator bits (0x67.7 [DCHRG](#) and 0x67.6 [CHRG](#)) are disabled in IDLE mode. Fault reaction is therefore limited and does not disable the power FETs. All external thermistor fault thresholds ([ETAUX Detectors](#)) are applied regardless of current direction.

## 7.2.4 SCAN Mode

SCAN mode is entered by changing the SM mode bits (0x2E.7:6 [System Mode on page 104](#)) to SCAN mode. All delay counters are cleared when entering SCAN mode.

Faults DSCF, IOTF, OWF, VCCF, CPMP NRDY, IREG1, and VTMPF will halt and prevent continuous System Scan from starting (see [Scan Will Not Start on page 115](#)).

SCAN mode executes system measurement scans as a single pass or continuously following a trigger ([System Scan Sequence on page 108](#)). The type of System Scan (single or continuous) is determined by the setting of bit 0x01.1 [Scan Select on page 42](#). Continuous System Scan can be paused without exiting SCAN mode by setting the System Scan Select bit to 1 for single Scan.

Some faults, too many current readings below  $I_{Zero\_THR}$  (see 0x2E.5:3 [Low Power Timer](#)), or a  $\overline{RESET}$  causes an exit from SCAN to IDLE mode. Fault reaction is immediate for some faults while others wait until measurement completes. See the individual fault descriptions for details. Setting the 0x01.7 [Soft Reset on page 41](#) or 0x01.6 [Reset to IDLE on page 41](#) bits causes a transition from SCAN mode to IDLE mode.

### 7.2.4.1 System Scan Sequence

A System Scan is a sequence of tests that can be executed when the ISL94216A is in SCAN mode. This mode is normally used to monitor the system during charge and discharge operation. The device includes a variety of settings that allow the user wide flexibility in choosing how often and what is monitored. [Figure 106](#) is a simplified state diagram that highlights the sequence and options which are described in the following subsections. Fault and measurement gating bits have been omitted.

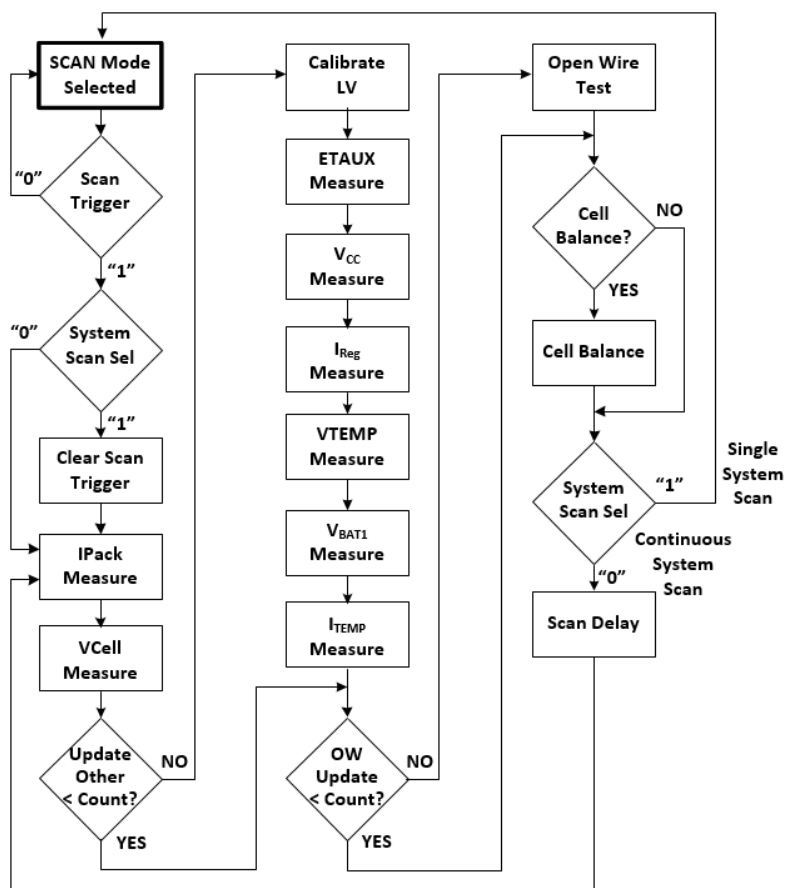

Figure 106. Simplified System Scan

#### 7.2.4.2 SCAN Mode Selected

SCAN mode is selected by setting the bits [0x2E.7:6 System Mode](#) of the System Operation register to 01. After the master selects SCAN mode the ISL94216A moves from the previous mode to this point and waits for a [0x01.0 System Trigger](#) to begin a System Scan.

All control bits and registers that determine what is measured, how frequently it is measured, and if the results affect CFET and DFET operation must be set before the assertion of a System Trigger. This includes Mask Bits that gate Fault assertions of the ALRT pin. These bits and registers are listed in the following sections as they become relevant and all must be determined before the master sends the Trigger.

All continuous System Scan loop counters are initialized (see [0x1B.5:4 Update Other](#), [0x03.6:5 OW Update](#), and [0x03.1 I<sub>DIR</sub> Delay](#)). The initial state of the counters is such that all selected tests and measurements associated with them run during the first System Scan during continuous scan.

All fault delay counts are set to 0 when a continuous System Scan is triggered. See [0x09.3:0 V<sub>CELL</sub> Fault Delay](#), [0x09.6 Delta V<sub>CELL</sub> Fault Delay](#), [0x09.4 ETAUX Fault Delay](#), and [0x09.5 Other Fault Delay](#).

#### 7.2.4.3 Scan Trigger

A Scan Trigger is required to initiate any single or continuous System Scan. Bit [0x01.0 System Trigger](#) must be set to 1 by the master to initiate a System Scan. The type of System Scan (single or continuous) is determined by the setting of bit [0x01.1 Scan Select](#).

If a System Trigger is set when any of the fault conditions listed in [Scan Will Not Start on page 115](#) is active, it is ignored.

When the System Trigger bit has been received, the **Busy** bit (0x01.2 **Busy**) transitions from a 0 to a 1. If the **Busy Mask** bit 0x85.0 was cleared before the trigger, then **ALRT** pin goes low (see 0x85 **Other Fault Mask**). Using the mask bit and **ALRT** pin in this way enables the master to determine when the ISL94216A is making measurements to avoid the possibility of reading stale results.

The **Busy** bit is reset to 0 when each System Scan ends and it is set to 1 when a new System Scan starts.

#### 7.2.4.4 System Scan Select

Following the System Trigger event the bit setting for 0x01.1 **Scan Select** determines if the triggered System Scan is a single pass or continuously looping System Scan. A setting of 0 enables continuous System Scan and a setting of 1 enables a single System Scan.

If a single System Scan is chosen, the System Trigger bit is cleared before the **I<sub>PACK</sub>** Measure step in the sequence, otherwise the trigger bit is not cleared.

The System Scan Select bit also determines when a fault response occurs. In single System Scans the fault response occurs at the end of the System Scan sequence. In continuous System Scans the fault response is immediate when the fault thresholds and delays are met. By allowing the System Scan sequence to run to completion in single System Scan the ISL94216A gives the master the option to log status and measurements following a fault detection.

#### 7.2.4.5 I<sub>PACK</sub> Measure

**I<sub>PACK</sub>** Measurement is gated by the bit 0x03.7 **I<sub>PACK</sub> EN**. Setting this bit to 0 disables the measurement and the System Scan sequence moves to the next step. If this bit is set to 1, then **I<sub>PACK</sub>** Measurement is enabled and executes.

The ISL94216A connects pins **CSP** and **CSN** to the internal ADC and measures the differential voltage based on the setting of register bits 0x03.4:2 **I<sub>PACK</sub> Averages**, which sets the number of averages for **I<sub>PACK</sub>** measurements. The measurement is stored in registers 0x52 - 0x53 **I<sub>PACK</sub> Voltage (R)** and the **I<sub>PACK</sub>** Timer value is stored in registers 0x54 - 0x57 **I<sub>PACK</sub> Timer (R)**.

A measurement result that exceeds either the 0x67.7 **DCHRG** or 0x67.6 **CHRG** thresholds (**I<sub>Zero\_THR</sub>**, page 13) sets the related bit. Also see 0x03.1 **I<sub>DIR</sub> Delay** for Continuous Scans.

If the current is between these thresholds for the number of System Scans selected by the bits 0x2E.5:3 **Low Power Timer**, the device transitions from **SCAN** to **LOW POWER** mode at the end of the sequence.

If the system is discharging, the **I<sub>PACK</sub>** voltage measurement is compared to the 0x0B **DOC Threshold**. A 0x63.3 **DOCF** is set if the **DOC** threshold is exceeded for the consecutive number of System Scans set by 0x0D **OC Delay**.

If the system is charging, then **I<sub>PACK</sub>** voltage measurement is compared to the 0x0F **COC Threshold**. A 0x63.4 **COCF** is set if the **COC** threshold is exceeded for the consecutive number of System Scans set by **COC Delay** (0x0D **OC Delay**).

If the battery is charging with 0x25.3 **IEOC EN** and 0x25.6 **Auto CB EN** both set to 1, and the **CFET** is On, the **I<sub>PACK</sub>** voltage measurement is compared to the 0x10 **IEOC Threshold** to determine if the battery is full. See **Automatic Cell Balancing on page 119** for more information.

Any faults propagate to the **ALRT** pin if the associated mask bits are clear.

Timing of a fault response to **DOCF** or **COCF** is determined by **System Scan Select on page 110**. The action taken by the ISL94216A is controlled by register 0x0E **Load/Charge Operations on page 54**. Set bit 0x0E.7 **CFD on page 54** to 1 to enable shut off of power FETs because of a **DOCF**. Set bit 0x0E.2 **FCDC on page 55** to 1 to enable shut off of power FETs because of a **COCF**. The setting of the configuration bit 0x0E.3 **CPWR on page 55** determines if both power FETs are shut off in a series configuration or an individual FET is shut off in a parallel configuration. System Scan stops when the FETs are shut off in a series configuration.

A DSCF fault is not dependent on  $I_{PACK}$  measurements and always stops System Scans shutting off CFET and DFET. See [0x63.2 DSCF on page 83](#).

#### 7.2.4.6 $V_{CELL}$ Measure

$V_{CELL}$  Measurement is gated by the bit [0x02.7  \$V\_{CELL}\$  EN](#). A 0 setting disables this measurement and the System Scan sequence moves to the next step.

The ISL94216A first connects pins VC1 and VC0 to the internal ADC and measures the differential voltage based on the setting of register bits [0x02.4:2  \$V\_{CELL}\$  Averages](#), which sets the number of averages for  $V_{CELL}$  measurements. The MUX sequentially connects each enabled cell, per registers [0x04 - 0x05 Cell Select](#), until all are measured. The results are stored in registers [0x30 - 0x4F  \$V\_{CELL}\$  Voltage \(R\)](#). The difference between the highest and lowest cell voltages is calculated and stored in register [0x50 - 0x51  \$V\_{CELL}\$  Max Delta Voltage \(R\)](#).

If any  $V_{CELL}$  voltage measurement is greater than [0x06  \$V\_{CELL}\$  Overvoltage](#) or less than [0x07  \$V\_{CELL}\$  Undervoltage](#) thresholds ([0x06 - 0x07  \$V\_{CELL}\$  OV/UV Threshold](#)), then a fault is set. A [0x63.0 OVF](#) is set if the  $V_{CELL}$  OV threshold is exceeded for the consecutive number of System Scans set by  $V_{CELL}$  Delay ([0x09.3:0  \$V\_{CELL}\$  Fault Delay](#)). If any  $V_{CELL}$  voltage drops below the  $V_{CELL}$  UV threshold for more System Scans than the  $V_{CELL}$  Delay setting, then fault [0x63.1 UVF](#) is set. These faults propagate to the  $\overline{ALRT}$  pin if the associated mask bits are clear (see [0x83 Priority Fault Mask](#)).

The  $V_{CELL}$  Max Delta Voltage is compared to [0x08  \$V\_{CELL}\$  Max Delta Threshold](#) and if the threshold is exceeded for more System Scans than the setting [0x09.6 Delta  \$V\_{CELL}\$  Fault Delay](#), fault [0x66.3 DVCF](#) is set. This fault propagates to the  $\overline{ALRT}$  pin if the associated mask bit is clear (see [0x86 CB Status Mask](#)).

Timing of the fault response to  $V_{CELL}$  OV/UV and/or DVCF is determined by [System Scan Select on page 110](#).

The action taken by the ISL94216A is controlled by register bit [0x24.4 CELLCON](#). This bit must be set to 1 to allow  $V_{CELL}$  faults to shut off the power FETs. With CELLCON set to 1 an OVF, UVF, or DVCF shuts off both power FETs and stops System Scans.

The lowest cell voltage is compared to the [0x2B CBMAX Threshold](#) and bit [0x66.2 2HI2CB](#) is set if all cell voltages are greater than this threshold.

The highest cell voltage is compared to the [0x2C CBMIN Threshold](#) and bit [0x66.1 2LO2CB](#) is set if all cell voltages are less than this threshold.

The bit [0x66.0 Need CB](#) is set when the difference between one or more of all the measured cell voltages, and the minimum of all of them is greater than the [0x2A CB Min Delta Threshold](#).

If Auto CB EN is set to 1, then [0x26-27 CB Cell State](#) shows the cells automatically determined by the chip to need cell balancing. The ISL94216A finds the minimum of all the cell voltages and calculates the difference between each cell voltage and the minimum. The CB CELL STATE bit is 1 for cells in which the calculated difference is higher than [0x2A CB Min Delta Threshold](#). The CB CELL STATE bit is 0 for other cells.

The bit [0x66.4 VEOC](#) is set if at least one cell voltage measures above the [0x2D VEOC Threshold](#).

For constant current charging with bits [0x25.1 CB EOC](#) and [0x25.3 IEOC EN](#) both set to 0, [0x66.7 BAT FULL](#) sets when the VEOC bit ([0x66.4](#)) is set.

If bit CB EOC is set to 1 and bit IEOC EN is set to 0, then BAT FULL sets when VEOC changes from 0 to 1 and then all cell voltages drop  $V_{CBHys}$  ([page 16](#)) below the VEOC threshold.

For constant voltage charging with CB EOC set to 0 and the IEOC EN bit set to 1, [0x66.7 BAT FULL](#) sets after the highest cell voltage reaches the VEOC threshold (the VEOC bit is set) and the IEOC bit ([0x66.5](#)) sets because of the charge current dropping below the [0x10 IEOC Threshold](#).

#### 7.2.4.7 Update Other

If a single scan is triggered (0x01.1 System Scan Select set to 1), or this is the first iteration of continuous System Scan, the sequence moves to the next step Calibrate LV. Otherwise the next step is determined by the Update Other setting.

Register bits [0x1B.5:4 Update Other](#) set the number of System Scans required to trigger system measurements beyond  $I_{PACK}$  and  $V_{CELL}$ . If the ISL94216A has completed a number of System Scans equal to the Update Other setting, then Scan counter is cleared and the sequence steps to Calibrate LV, otherwise the sequence steps to [Open-Wire Test](#).

#### 7.2.4.8 Calibrate LV

This step executes an internal calibration of the ADC/MUX path used for the ETAUX, VCC, VTEMP, VBAT1, and ITEMP measurements. It is followed by the ETAUX Measure step.

#### 7.2.4.9 ETAUX Measure

ETAUX Measure is gated by bits [0x11.7:6 ETAUX Enable](#). Set these bits to 0 to disable the measurement and move the sequence to the next step. If either or both bits are set to 1 the corresponding measurement is enabled and executes. The following description assumes both bits are set to 1 and the pins are connected to 10kΩ NTC thermistors as shown in [Figure 99 on page 95](#).

Bit [0x09.7 AUX/xTn Pull-Up](#) should be disabled with a setting of 0 before starting either type of System Scan. The pull-up is intended for open-wire test of the ETAUX pins. If it is enabled during the ETAUX, measurement results can be slightly higher (indicating a lower temperature). See [Aux Pins Open-Wire Test](#).

Bits [0x11.4:2 ETAUX Averages](#) set the number of averages for each AUX pin measurement. If AUX0/xT0 is enabled (0x11.6 = 1) the ADC measures its voltage relative to VSS. AUX1/xT1 is measured next if enabled (0x11.7 = 1). The results are stored in registers [ETAUX Detectors](#).

The results are next compared to thresholds for fault detection (see [0x13-1A ETAUX Thresholds](#)). When the device is charging ([0x67.6 CHRGI](#) is 1), the measurement is compared to the CUTn and COTn thresholds (n = 0 and 1). While discharging ([0x67.7 DCHRG](#) is 1), the measurement is compared to the DUTn and DOTn thresholds. If the device is neither charging or discharging, the measurement is compared to all thresholds for the measurement pin. Any threshold violation(s) set the related fault bit(s) in register [0x64 ETAUX Fault](#). These faults propagate to the ALRT pin if the associated mask bits are clear (see [0x84 ETAUX Fault Mask](#)).

Timing of the fault response to an OT or UT fault is determined by [System Scan Select on page 110](#). The action taken when a fault is detected is determined by register bit [0x24.2 ETA Connect](#). This bit must be set to 1 to allow OT or UT faults to shut off the power FETs. The setting of the configuration bit [0x0E.3 CPWR](#) determines if both power FETs are shut off in a series configuration or an individual FET is shut off in a parallel configuration.

#### 7.2.4.10 V<sub>CC</sub> Measure

V<sub>CC</sub> Measure is not gated by an enable bit. It is always executed on the first iteration of continuous System Scan or whenever a single System Scan is triggered. During continuous System Scan subsequent V<sub>CC</sub> measurements are gated by [0x1B.5:4 Update Other](#).

VCC is measured at the VCC pin relative to VSS. Bits [0x1F.4:2 Other Averages](#) of the V<sub>BAT1</sub> Operation register set the number of readings averaged per measurement before storing the results to register [0x60 V<sub>VCC</sub> Voltage \(R\)](#).

After measurement, the voltage is compared to the threshold register [0x1C V<sub>VCC</sub> Min Threshold](#) and if the comparison fails, the fault bit [0x63.7 VCCF](#) is set. Bit [0x09.5 Other Fault Delay](#) controls the required number of consecutive faults before action is taken. The fault propagates to the ALRT pin if the associated mask bit is clear (see [0x83 Priority Fault Mask](#)).

Timing of the fault response to VCCF is determined by [System Scan Select on page 110](#). The fault response is not controlled by a register Connect bit. A VCCF shuts off both power FETs. The setting of the configuration bit [0x0E.3 CPWR](#) has no effect on V<sub>CC</sub> faults.

#### 7.2.4.11 I<sub>Reg</sub> Measure

I<sub>Reg</sub> Measure is not gated by an enable bit. It is always executed on the first iteration of continuous System Scan or whenever a single System Scan is triggered. During continuous System Scan, subsequent I<sub>Reg</sub> measurements are gated by [0x1B.5:4 Update Other](#).

The I<sub>Reg</sub> voltage is a differential measurement across the external sense resistor tied between the EMITTER and VDD pins, as shown in [Figure 100 on page 96](#). Bits [0x1F.4:2 Other Averages](#) of the V<sub>BAT1</sub> Operation register set the number of readings averaged per measurement before storing the results to register [0x61-62 I<sub>REG</sub> Voltage \(R\)](#).

This measurement has two thresholds, IREG<sub>OC1</sub> and IREG<sub>OC2</sub> ([0x1D,1E IREG<sub>OC1,2</sub> Threshold](#)). When the device is in IDLE or SCAN mode the measurement is compared to IREG<sub>OC1</sub>. In LOW POWER mode the measurement is compared to IREG<sub>OC2</sub>. If the comparison fails, the respective I<sub>Reg</sub> fault bit ([0x67.2 IREG1](#) or [0x67.1 IREG2](#)) is set. This fault propagates to the  $\overline{\text{ALRT}}$  pin if the associated mask bit is clear (see [0x87 Status Mask](#)).

Timing of the fault response to I<sub>Reg</sub> Measure is determined by [System Scan Select on page 110](#). The fault response is not controlled by a register Connect bit. An I<sub>Reg</sub> fault shuts off both power FETs and stops System Scans, regardless of the setting of the configuration bit [0x0E.3 CPWR](#).

#### 7.2.4.12 VTEMP Measure

VTEMP Measure is not gated by an enable bit. It is always executed if a single System Scan is triggered or on the first iteration of continuous System Scan. During other iterations of continuous System Scan, its measurement is gated by [0x1B.5:4 Update Other](#). The VTEMP voltage is a reference voltage used to pull up the external temperature sensor circuitry (see [Figure 99 on page 95](#)). The Other Averaging bits (see [0x1F.4:2 Other Averages](#)) of the V<sub>BAT1</sub> Operation register set the number of samples averaged per measurement before storing the results to register [0x5F V<sub>VTEMP</sub> Voltage \(R\)](#).

The VTEMP voltage has a compare threshold that sets the bit [0x67.0 VTMPF](#) if violated. This fault propagates to the  $\overline{\text{ALRT}}$  pin if the associated mask bit is clear (see [0x87 Status Mask](#)). The VTEMP<sub>Min</sub> threshold limit is in the Electrical Specifications on [page 15](#) and is a fixed value. An VTMPF fault shuts off both power FETs and stops System Scans, regardless of the setting of the configuration bit [0x0E.3 CPWR](#).

#### 7.2.4.13 V<sub>BAT1</sub> Measure

V<sub>BAT1</sub> Measure is gated by bit [0x1F.7 V<sub>BAT1</sub> EN](#). Set this bit to 0 to disable the measurement and move the System Scan sequence to the next step. Set this bit to 1 to enable and execute VBAT Measurement.

The V<sub>BAT1</sub> voltage is measured by the ADC relative to VSS. The number of averages for the measurement are set by bits [0x1F.4:2 Other Averages](#). The results are stored in registers [0x5C - 0x5D V<sub>BAT1</sub> Voltage \(R\)](#).

If the V<sub>BAT1</sub> voltage measurement is greater than [0x20 V<sub>BAT1</sub> OV Threshold](#), bit [0x65.7 VBOVF](#) is set. If the measurement is less than [0x21 V<sub>BAT1</sub> UV Threshold](#), bit [0x65.6 VBUVF](#) is set. Bit [0x09.5 Other Fault Delay](#) controls the required number of consecutive faults before action is taken. VBOVF and VBUVF faults propagate to the  $\overline{\text{ALRT}}$  pin if the associated mask bits are clear (see [0x85 Other Fault Mask](#)).

Timing of the fault response to V<sub>BAT</sub> OV/UV is determined by [System Scan Select on page 110](#). The action taken when a fault is detected is determined by register bit [0x24.3 VBAT1CON](#). This bit must be set to 1 to allow VBOVF or VBUVF to shut off the power FETs. The setting of the configuration bit [0x0E.3 CPWR on page 55](#) determines if both FETs are shut off in a series configuration or an individual FET is shut off in a parallel configuration.

#### 7.2.4.14 I<sub>TEMP</sub> Measure

Internal Temperature measurement is gated by bit [0x1F.6 I<sub>TEMP</sub> EN](#). Set this bit to 1 to enable measurement of the internal temperature while in SCAN mode. Set this bit to 0 to disable the measurement and move the sequence to the next step.

The ISL94216A connects the internal temperature sensor to the ADC and measures its voltage. Bits [0x1F.4:2 Other Averages](#) set the number of averages for  $I_{TEMP}$  measurements. The results are stored in register [0x5E Internal Temperature \(R\)](#). The bit [0x09.5 Other Fault Delay](#) controls the required number of consecutive faults before action is taken.

If the  $I_{TEMP}$  voltage measurement result is less than the [0x22 IOTW Threshold](#), a warning bit [0x66.6 IOTW](#) is set. If the  $I_{TEMP}$  measurement result is less than the [0x23 IOTF Threshold](#), fault bit [0x63.5 IOTF](#) is set. The warning/fault propagates to the  $\overline{ALRT}$  pin if the associated mask bit is clear (see [0x86 CB Status Mask](#) and [0x83 Priority Fault Mask](#)). See [0x22 - 0x23 IOTW and IOTF Thresholds](#) for information about setting the thresholds.

Timing of the fault response to  $I_{TEMP}$  is determined by [System Scan Select on page 110](#), otherwise the action taken by the ISL94216A is not controlled by a register Connect bit. An IOTW does not change the status of the power FETs or stop System Scans. An IOTF shuts off both power FETs and stops System Scans regardless of the setting of bit [0x0E.3 CPWR on page 55](#).

#### 7.2.4.15 Open-Wire Test

Open-Wire Test is gated by bit [0x24.6 OW EN](#). Set this bit to 0 before starting System Scan to disable the test, and the sequence moves to the next step. When enabled, the Open-Wire Test executes if the System Scan counter set by [0x03.6:5 OW Update](#) is satisfied.

The results of the open-wire tests are found in locations [0x68-69 Open-Wire Status](#), [0x65.2 OW  \$V\_{BAT1}\$](#) , and [0x65.1 OW VSS](#). A 1 at an OW Celln bit indicates that at least one wire is not connected between the device and the corresponding cell. Bit [0x63.6 OWF](#) is the OR'd result of all the open-wire fault bits. The faults for any of the open-wire bits can propagate to the  $\overline{ALRT}$  pin if the associated mask bits are cleared. See [0x88-89 Open-Wire Mask](#) and [0x85 Other Fault Mask](#).

An OWF shuts off both power FETs and stops System Scans regardless of bit [0x0E.3 CPWR](#).

See [Open-Wire Function on page 116](#) for a detailed description of the test sequence and options.

#### 7.2.4.16 Cell Balance

Automatic Cell Balancing during a System Scan is gated by bits [0x25.7 CB EN](#) and [0x25.6 Auto CB EN](#). Set either of these bits to 0 to disable Automatic Cell Balancing and move the sequence to the next step. If both bits are set to 1 Automatic Cell Balancing is enabled and executes per the following settings:

[0x25.5 CB Configuration on page 76](#) selects internal or external Cell Balancing FETs.

[0x25.3 IEOC EN on page 77](#) selects ending charging with either a voltage or current target.

[0x25.2 CB Mask on page 77](#) selects allowing or preventing simultaneous balancing of adjacent cells.

[0x25.1 CB EOC on page 78](#) selects allowing or preventing cell balancing after reaching VEOC.

[0x25.0 CB CHRG on page 78](#) selects allowing or preventing cell balancing while charging below VEOC.

[0x2A CB Min Delta Threshold on page 79](#) sets the minimum cell voltage difference for cell balancing.

[0x2B CBMAX Threshold on page 79](#) sets the maximum cell voltage allowed for cell balancing.

[0x66.2 2HI2CB on page 89](#) is set if all cell voltages are greater than CB MAX Threshold.

[0x2C CBMIN Threshold on page 79](#) sets the minimum cell voltage allowed for cell balancing.

[0x66.1 2LO2CB on page 89](#) is set if all cell voltages are less than CB MIN Threshold.

[0x2D VEOC Threshold on page 80](#) sets the maximum cell voltage used to indicate end of (constant current) charge.

[0x10 IEOC Threshold on page 80](#) sets the minimum charge current to indicate end of constant voltage charge.

[0x28, 0x29 Cell Balancing Timers on page 81](#) sets the balance on and off times.

A thorough review of Sections [Cell Balancing Registers on page 76](#) and [Automatic Cell Balancing on page 119](#) is recommended to determine application-specific settings.

Cell balancing methods supported by the ISL94216A are detailed in [Cell Balancing Examples on page 118](#).

#### 7.2.4.17 Scan Delay

The setting of [0x2E.2:0 Scan Delay](#) controls the delay time between finishing a continuous System Scan cycle and starting the next. The Busy Bit ([0x01.2 Busy](#)) is cleared at the start of Scan Delay.

#### 7.2.4.18 System Scan Select

The continuous System Scan sequence is completed when the Scan Delay time ends. The bits [0x01.1 Scan Select](#) controls whether the System Scan is single or continuously looping. A setting of 0 enables continuous System Scan and a setting of 1 chooses a single System Scan.

If a single System Scan is selected, then the state machine returns to the SCAN mode start point [System Scan Sequence on page 108](#) and waits for the next [Scan Trigger](#).

If continuous System Scan is selected and no faults occur, then the System Scan counter is incremented and the state machine returns to step [System Scan Select on page 110](#) where the next sequence begins (see [Figure 106 on page 109](#)).

The System Scan Select bit also determines when a fault response occurs. For single System Scan, the fault response occurs at the end of the System Scan sequence. In continuous System Scan, the fault response occurs when the fault thresholds and delay counters are met.

### 7.2.5 Scan Will Not Start

System Scan can not start if the ISL94216A is being reset by POR,  $\overline{\text{RESET}}$  held low, or either [0x01.7 Soft Reset](#) or [0x01.6 Reset to IDLE](#) set to 1. System Scan only runs in SCAN mode, it can not run in IDLE, LOW POWER or SHIP Modes.

If any of the following bits are set, System Scan may not start and/or stops until the fault is clear:

- [0x63.7 VCCF on page 82](#)
- [0x63.6 OWF on page 82](#)
- [0x63.5 IOTF on page 82](#)
- [0x63.2 DSCF on page 83](#)
- [0x67.2 IREG1 on page 91](#)
- [0x67.0 VTMPF on page 91](#)
- [0x65.5 CPMP NRDY on page 86](#)

These conditions stop and prevent System Scans if the [0x0E.3 CPWR](#) bit is 0:

```
(0x0E.2 FCDC AND 0x67.6 CHRGI AND 0x63.4 COCF)
OR
(0x0E.7 CFD AND 0x67.7 DCHRG1 AND 0x63.3 DOCF)
OR
(0x24.4 CELLCON AND 0x66.3 DVCF)
OR
CELLCON AND { [(CHRG1 AND NOT[CHRWUV]) OR DCHRG1] AND UVF }
OR
CELLCON AND { [(DCHRG1 AND NOT[DCHRWUV]) OR CHRG1] AND OV }
OR
0x24.3 VBAT1CON AND [CHRG1 AND VBOVF] OR [DCHRG1 AND VBUVF]
OR
0x24.2 ETA Connect AND DCHRG1 AND (DOT0 OR DOT1 OR DUT0 OR DUT1)
OR
```

ETA CON AND CHRG1 AND (COT0 OR COT1 OR CUT0 OR CUT1)

This condition stops and prevents System Scans if the CPWR bit is 1:

CELLCON AND {DVCF OR (NOT[CHRWUV] AND UVF) OR NOT[DCHRWOV] AND OVF}

For bit descriptions see [0x63.1 UVF on page 83](#), [0x63.0 OVF on page 83](#), [0x02.5 CHRWUV on page 43](#), [0x02.6 DCHRWOV on page 43](#), [0x64.1 DOT0 on page 85](#), [0x64.5 DOT1 on page 85](#), [0x64.0 DUT0 on page 85](#), [0x64.4 DUT1 on page 85](#), [0x64.3 COT0 on page 85](#), [0x64.7 COT1 on page 85](#), [0x64.2 CUT0 on page 85](#), [0x64.6 CUT1 on page 85](#), [0x65.7 VBOVF on page 86](#), [0x65.6 VBUVF on page 86](#), [0x67.7 DCHRG1 on page 90](#) and [0x67.6 CHRG1 on page 90](#).

### 7.3 Open-Wire Function

The open-wire function tests for broken connections between the battery cells and the BMS circuit board. A block diagram of the open-wire circuit is shown in [Figure 107](#). The cell open-wire test (VC0 - VC16) checks the wires between the connector and cells (in blue) while VSS and V<sub>BAT1</sub> OW checks the connections in red.

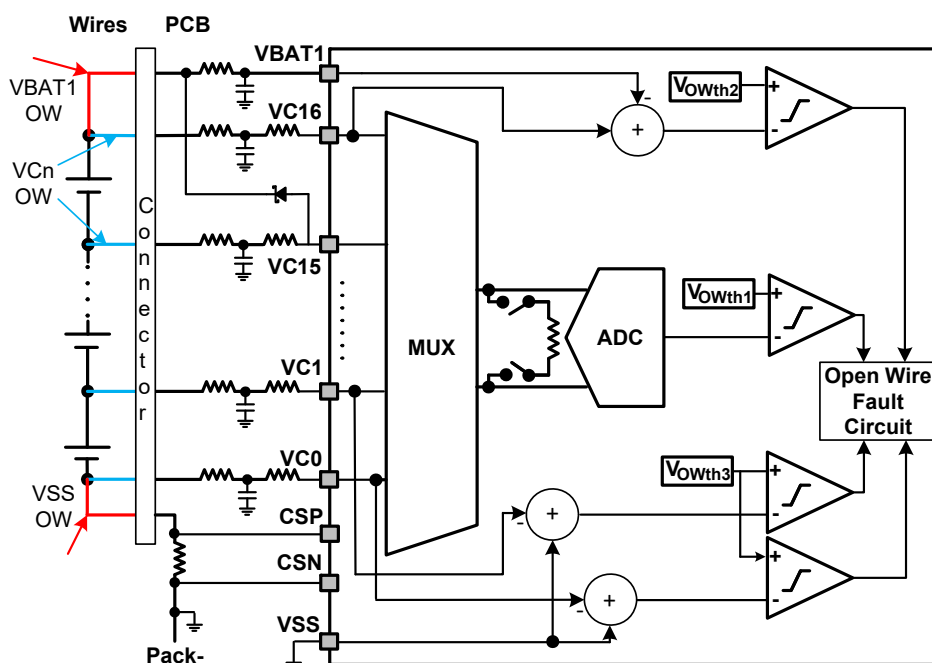

Figure 107. ISL94216A Open-Wire Circuit Block Diagram

An open-wire test can be triggered manually by setting bit [0x24.5 OW Trigger](#) to 1 while in IDLE mode. The test is executed automatically during System Scans if bit [0x24.6 OW EN](#) is set to 1. The open-wire test is run on the first and every nth System Scan per the setting of bits [0x03.6:5 OW Update](#) during continuous System Scans. If an open-wire fault occurs during a System Scan, the scan stops, DFET and CFET are turned off, and DFET EN and CFET EN are set to 0 (see [0x24 Power FET Operation](#)).

An internal resistor is connected across one cell at a time during the open-wire test. The resistor is connected for  $t_{OW}$  ([page 16](#)) across the cell. A cell measurement is performed after  $0.8 \cdot t_{OW}$ . If the voltage reading is less than  $V_{OWth1}$  ([page 16](#)), then at least one of the cell connections is considered open. Open-wire test results are a function of the capacitance connected to the device pins because the voltage across a larger capacitance takes longer to change. The open-wire circuit is designed to tolerate up to  $C_{OW}$  ([page 16](#)) of equivalent capacitance on each pin.

As an example, consider the case when the OW Test resistor is connected between device pins VC5 and VC6. If the measured cell voltage is less than  $V_{OWth1}$ , the connection between the battery and pins VC5 and/or VC6 is likely to be bad. If only one pin has a bad connection, the specific pin can be determined with two open-wire fault bits. If only Cell(n) and Cell(n-1) fail open-wire, the open pin is VC(n-1) because bits OW Cell(n) and OW Cell(n-1) (0x68-69 Open-Wire Status) are set. Open-wire mask bits are in registers 0x88-89 Open-Wire Mask. If a mask bit is set to 0 and an open is detected on that cell, then the  $\overline{ALRT}$  pin transitions low. Open-wire status of VC0 is tested with VC1 and indicated by the bit for OW Cell1.

After all of the cell voltage sense connections have been tested, the pack current is measured. If the current measurement shows that the pack is discharging, then open-wire sequence ends. If in IDLE mode when the exit from open-wire test occurs, the Busy bit is cleared. If the pack is not discharging, then VSS and VBAT1 connections are tested for open-wires before the open-wire sequence ends.

If VSS connection to the bottom cell is made through the pack low-side sense resistor and load current wire (Figure 107), separate from the VC0 and VC1 voltage sense connections to their respective cells, then an open in the pack ground return connection is detectable. The VSS pin voltage is compared to VC0 and VC1 pins. If (VSS - VC0) and/or (VSS - VC1) are greater than  $V_{OWth3}$  (page 16), the VSS ground return connection is considered open.

If a Schottky diode is connected from VC15 to  $V_{BAT1}$  and the  $V_{BAT1}$  connection to the top cell is made through the pack high-side load current wire, separate from VC15 and VC16 voltage sense connections to their respective cells, then an open in the high side load current connection is detectable. The  $V_{BAT1}$  pin voltage is compared to VC16. If (VC16 -  $V_{BAT1}$ ) is greater than  $V_{OWth2}$  (page 16), then the  $V_{BAT1}$  pin connection is considered open.

Open-wire fault indicators for VSS and VBAT1 are located in 0x65 Other Fault Register and the mask bits are in 0x85 Other Fault Mask.

Note the difference between Status bit 0x67.7 DCHRG1 and internal states charging, discharging, and not discharging. If the current voltage measurement is less than  $-200\mu V$  (-20 decimal register value), the pack is discharging. If the current voltage measurement is greater than  $+200\mu V$  (+19 decimal register value), the pack is charging. If the current voltage measurement is greater than approximately  $-200\mu V$  (-20 decimal register value), the pack is NOT discharging. These internal states are not gated by counters; in Continuous Scan mode bits DCHRG1 and 0x67.6 CHRGI are gated by 0x03.1  $I_{DIR}$  Delay.

The open-wire sequence does not include testing the ETAUX pins for open wires. See Aux Pins Open-Wire Test for a description of the test method.

Voltage measurements done as part of the open-wire test sequence are only used for open-wire detection. They are not stored in registers or used to detect overvoltage or undervoltage faults.

## 7.4 Cell Balancing Examples

Register [0x25 CB Operation on page 76](#) controls cell balancing features of the ISL94216A. The master must select either Automatic or Manual cell balancing, and the conditions under which balancing occurs.

Figure 108. A Typical Charge Characteristic Curve

The ISL94216A has features that support both Constant Current (CC) and Constant Voltage (CV) charging. A typical charging profile for a battery cell is depicted in [Figure 108](#). Cell balancing can occur only when the cell voltage is between the CBMIN and CBMAX limits, which are independent of CB EOC and CB CHRG bit settings.

The following examples are independent of the choice of internal versus external cell balancing FETs.

### 7.4.1 Automatic Cell Balancing

Bits [0x25.0 CB CHRG on page 78](#), [0x25.1 CB EOC on page 78](#) and [0x25.3 IEOC EN on page 77](#) determine the behavior of automatic cell balancing relative to [0x2D VEOC Threshold on page 80](#) and [0x10 IEOC Threshold on page 80](#). The behavior of auto cell balancing in relation to these bits and thresholds is summarized in [Table 75](#). This table assumes charging, automatic cell balancing is enabled, cell voltages are between CBMIN and CBMAX, VEOC is less than CBMAX, and at least one cell needs to be balanced.

**Table 75. Auto CB vs Bit Settings**

CB CHRG	IEOC EN	CB EOC	Sequence	Charge Type
1	0	0	Cell balancing starts when a cell needing balancing is greater than CBMIN and less than CBMAX. VEOC sets when the maximum cell voltage is >VEOC threshold, this triggers BAT FULL to set, which stops Cell Balancing, shuts off CFET (and DFET if CPWR = 0) and clears AUTO CB. DFET remains on if CPWR=1.	Constant Current
1	0	1	Cell balancing starts when cell voltages are within ~60mV of the VEOC threshold. VEOC sets when the highest cell voltage is >VEOC threshold and CFET (and DFET if CPWR = 0) shuts off. Cell balancing is applied until all cell voltages fall below VEOC - VCBHys ( <a href="#">page 16</a> ). Next, Cell Balancing stops, the BATT FULL bit is set, and AUTO CB is cleared. DFET remains on if CPWR=1.	Constant Current
1	1	0	Cell balancing starts when a cell needing balancing is greater than CBMIN and less than CBMAX. VEOC sets when the highest cell voltage is >VEOC threshold, and then cell balancing and DFET (if CPWR = 1) shut off. The charger changes from constant current to constant voltage. When the charge current drops below the IEOC limit ( <a href="#">0x10, page 80</a> ) BATT FULL is set, CFET (and DFET if CPWR = 0) is shut off, and AUTO CB is cleared.	Constant Current followed by Constant Voltage
1	1	1	Cell balancing starts when a cell needing balancing is greater than CBMIN and less than CBMAX. CB continues after VEOC is reached and the bit is set, but DFET shuts off if CPWR=1. The charger changes from constant current to constant voltage. Cell balancing continues until the charge current drops below the IEOC limit; next, BATT FULL is set, CFET (and DFET if CPWR = 0) is shut off, and AUTO CB is cleared.	Constant Current followed by Constant Voltage
0	0	1	Cells charged until the VEOC threshold is exceeded and the VEOC bit sets, which shuts off CFET (and DFET if CPWR = 0). Cell balancing starts and continues until cell voltages fall below VEOC and stops, the BATT FULL bit is set, and AUTO CB is cleared.	Constant Current
0	1	1	Constant current charging until the VEOC threshold is exceeded and the VEOC bit sets, which shuts off DFET if CPWR = 1. The charger changes from constant current to constant voltage. Cell balancing occurs while one or more cell voltages are above the VEOC limit AND the charge current is above the IEOC limit. BAT FULL is set when the charge current drops below the IEOC limit. When BATT FULL is set, CFET is shut off (and DFET if CPWR = 0), and AUTO CB is cleared.	Constant Current followed by Constant Voltage

Registers [0x26-27 CB Cell State on page 78](#) show the cells automatically determined by the chip to need cell balancing following the most recent set of cell voltage measurements during scan before automatic cell balancing.

[Figure 109 on page 120](#) is an illustration of the Automatic Cell Balancing sequence described in detail in the following subsections. All settings must be written to the ISL94216A before [0x01.0 System Trigger on page 42](#) is executed. This example assumes the ISL94216A is in SCAN mode, the system is charging the battery pack and the step [Cell Balance on page 114](#) has been reached. The same sequence is followed if AUTO CB is enabled and cell balancing is started by the bit [0x25.4 CB Trigger on page 77](#).

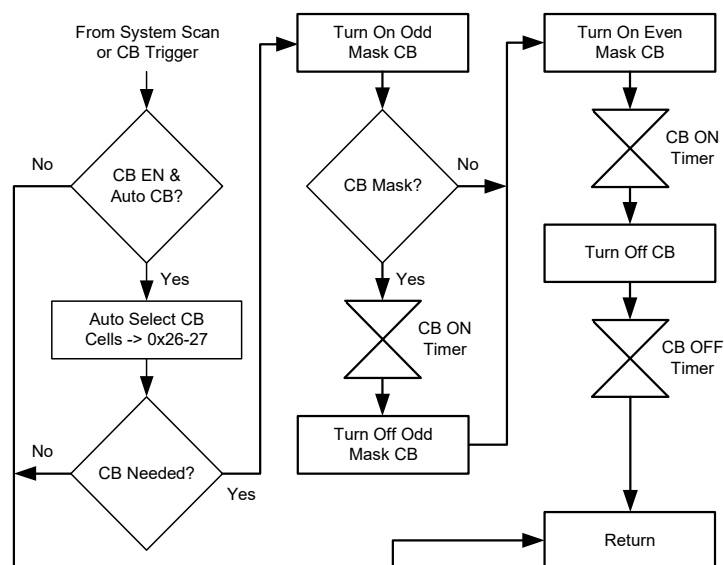

Figure 109. Auto CB Sequence

#### 7.4.1.1 Auto CB Sequence

**CB EN & Auto CB?** - If [0x25.7 CB EN](#) and [0x25.6 Auto CB EN](#) are both enabled the CB sequence moves to the next step, otherwise it exits and returns to the System Scan sequence step [Scan Delay](#).

**Auto Select CB Cells** - For the three cases of automatic cell balancing where  $\text{IEOC EN} = 1$  **OR**  $\text{CB EOC} = 0$ , the chip finds the minimum of all the cell voltages and calculates the difference between each cell voltage and the minimum. For cells with a calculated difference higher than the [0x2A CB Min Delta Threshold](#), the CB Cell State bit is set to 1. For other cells, it is set to 0.

For automatic cell balancing cases with  $\text{IEOC EN} = 0$  **AND**  $\text{CB EOC} = 1$ , the CB Cell State bit is set to 1 for cells that exceed the voltage set by the register [0x2D VEOC Threshold](#) minus four bits. For other cells, it is set to 0.

**CB Needed?** - If no cells require cell balancing or the criteria determined by the settings of bits CB CHRG, IEOC EN, and CB EOC as detailed in [Table 75](#) are not met, the cell balance sequence exits and returns to step [Scan Delay](#). Otherwise the CB sequence moves to the next step.

Note: If  $\text{AUTO CB EN} = 0$ , the bit [0x66.0 Need CB](#) is an indicator to the user.

**Turn On Odd Mask CB** - Cell balance devices for the odd numbered cells that were automatically determined to require balancing as indicated by the CB Cell State registers 0x26-27 are turned on.

**CB Mask?** - If the bit [0x25.2 CB Mask](#) is clear (0), the sequence moves to the **Turn On Even Mask CB** step, otherwise the **CBON Timer** is activated per the following step.

**CBON Timer** - The timer setting [0x28 CBON](#) determines how long the cell balance FETs are enabled for each cycle of balancing. The sequence moves to the next step after the CBON Timer times out.

**Turn Off Odd Mask CB** - Cell balance FETs for the odd cells are turned off.

**Turn On Even Mask CB** - The cell balance FETs for the even numbered cells that were automatically determined to require balancing as indicated by the CB Cell State registers 0x26-27 are turned on.

**CBON Timer** - The timer setting [0x28 CBON](#) determines how long the cell balance FETs are enabled for each cycle of balancing. The sequence moves to the next step after the CBON Timer times out.

**Turn Off CB** - Cell Balance FETs for all cells are turned off.

**CBOFF Timer** - The timer setting [0x29 CBOFF](#) determines how long the cell balance FETs are disabled following each cycle of balancing. This step is necessary when long cell balancing times relative to the setting of [0x2E.2:0](#)

**Scan Delay** are used. The CBOFF timer also manages power dissipation. The sequence moves to the next step after the CBOFF Timer times out.

**Return** - The CB state machine exits and returns to the Scan sequence at **Scan Delay** after the CBOFF Timer times out.

## 7.4.2 Manual Cell Balancing

Manual Cell Balancing follows the sequence shown in **Manual CB Sequence**, which is very similar to that of Automatic Cell Balancing with a few important differences. Bit **0x25.7 CB EN** must be set to 1 to enable manual cell balancing, and bit **0x25.6 Auto CB EN** must be set to 0 to disable automatic cell balancing.

The master must determine the cells to be balanced and write the bits in registers **0x26-27 CB Cell State**. A 1 is written to cell locations selected for charge reduction and a 0 is written to cell locations that receive the full charge current.

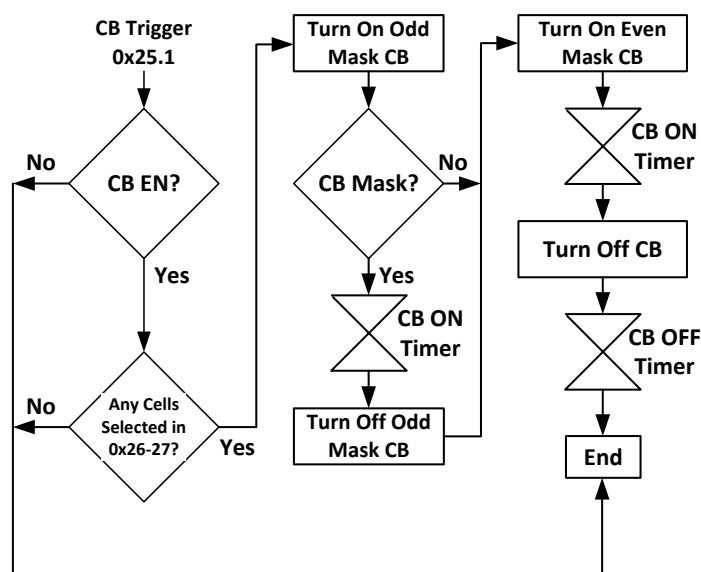

Figure 110. Manual CB Sequence

Bit **0x25.2 CB Mask** controls whether all cells that need balancing are turned on simultaneously or in separate ON cycles. Simultaneous cell balancing of too many and/or adjacent cells can be inefficient and raise the die temperature from the power dissipation of the internal cell balancing FETs if **0x25.5 CB Configuration** = 0.

The master should put the ISL94216A in SCAN mode by setting bits **0x2E.7:6 System Mode** to 01 before triggering a cycle of manual cell balancing.

All relevant settings must be written to the ISL94216A before cell balancing is triggered (**0x25.4 CB Trigger**).

### 7.4.2.1 Manual CB Sequence

**CB Trigger** - With the ISL94216A in SCAN mode (**0x01.1 Scan Select** must be set to 1 for single scan), the master must set the bits in registers **0x26-27 CB Cell State** to 1 for cells that have charged to relatively higher voltages than the rest of the pack. Bits for the other cells are set to 0 so they receive the full charge current. For manual cell balancing, the criteria used to determine which cells to get the reduced charge current is determined by the user.

When ready, the master triggers Cell Balancing by writing a 1 to **0x25.4 CB Trigger**.

**CB EN?** - If bit **0x25.7 CB EN** is not set to 1, the CB sequence exits, otherwise it moves to the next step.

**Any Cells Selected in 0x26-27?** - The master must determine the cells to be balanced, and write the bits in registers **0x26-27 CB Cell State** before the CB Trigger. If no cell is selected the cell balance sequence exits.

Note: With Auto CB EN set to 0 for Manual Cell Balancing the NEED CB bit has no function.

**Turn On Odd Mask CB** - The cell balance FETs for the odd numbered cells that were manually determined to require balancing as indicated by the CB Cell State registers 0x26-27 are turned on.

**CB Mask** - If the bit [0x25.2 CB Mask](#) is clear (0), the CB sequence moves to the **Turn On Even Mask CB** step, otherwise the **CBON Timer** is activated per the next step.

**CBON Timer** - The Timer setting [0x28 CBON](#) determines how long the cell balance FETs are enabled for each cycle of balancing. The sequence moves to the next step after the CBON Timer times out.

**Turn Off Odd Mask CB** - Cell balance FETs for the odd cells are turned off.

**Turn On Even Mask CB** - The cell balance FETs for the even numbered cells that were manually determined to require balancing as indicated by the registers [0x26-27 CB Cell State](#) are turned on.

**CBON Timer** - The timer setting [0x28 CBON](#) determines how long the cell balance FETs are enabled for each cycle of balancing. The sequence moves to the next step after the CBON Timer times out.

**Turn Off CB** - Cell balance FETs for all cells are turned off.

**CBOFF Timer** - The timer setting [0x29 CBOFF](#) determines how long the cell balance FETs are disabled for each cycle of balancing. The sequence moves to the next step after the CBOFF Timer times out.

**End** - The CB state machine exits after the CBOFF Timer times out.

## 7.5 Charge Pump

The ISL94216A has an internal Charge Pump with an external capacitor used to drive the CFET, DFET, and CB16 pins. Control bit [0x24.7 CPMP EN](#) allows the user to enable or disable the Charge Pump as needed. The default value for the control bit is 0 so the Charge Pump is disabled following a chip power up or reset. If the charge pump is enabled ( $0x24.7 = 1$ ), the status bit [0x65.5 CPMP NRDY](#) is set by the ISL94216A to 1 until the charge pump voltage is up to its operating level, then it clears to 0. If the charge pump is disabled by the Master setting  $0x24.7 = 0$ , then bit CPMP NRDY is also set to 0.

Charge Pump circuitry is automatically disabled in SHIP and LOW POWER Modes regardless of the setting of bit 0x24.7 CPMP EN. The charge Pump State Machine is detailed below in [Figure 111](#).

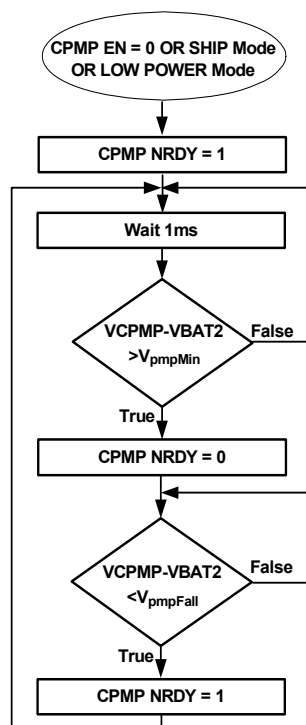

Figure 111. ISL94216A Charge Pump Ready State Machine

### 7.5.1 Charge Pump Ready State Machine

The state machine starts at the point at which the charge pump is disabled during the power up sequence (see [Figure 111](#)) or at chip reset, by being in SHIP or LOW POWER mode, or by bit 0x24.7 CPMP EN being 0. Bits [0x24.7 CPMP EN on page 72](#) and [0x65.5 CPMP NRDY on page 86](#) are set to 0 following POR or reset.

The state machine starts when the charge pump is enabled (0x24.7 = 1), in IDLE or SCAN Modes. The device begins charging the external capacitor at an operational frequency of ~4MHz. Once the charge pump voltage is above the minimum threshold  $V_{pmpMin}$  ([page 16](#)) the state machine clears bit CPMP NRDY. Next, the charge pump voltage is continuously compared to the  $V_{pmpFall}$  ([page 16](#)) threshold. If the voltage drops below that threshold, the state machine sets bit CPMP NRDY.

The charge pump enable bit is set to 0 by default at POR or Reset, or by the master. Transitions to SHIP or LOW POWER mode automatically shut off the charge pump. The mode change shuts off the charge pump regardless of whether it was executed by the master or caused by a fault detection. If the charge pump was enabled, the not ready bit is also set when the charge pump voltage drops below the internal fixed threshold.

The charge pump enable bit is not affected by a mode change, it is only changed by the master directly. After the enable of the charge pump a minimum 1ms wait occurs to allow time for the circuitry to begin charging the external capacitor.

## 7.6 Trigger Bits

Some control registers have bits called Trigger bits that execute automatic sequences when set to 1. Triggered sequences are initiated by a 0 to 1 transition of a Trigger bit. When the triggered sequence starts, the Trigger bit is reset back to 0 automatically by the chip. A 0 to 1 transition of a Trigger bit is ignored if that triggered sequence is already in progress. If a Trigger bit is ignored, the chip does not clear the Trigger bit automatically. In this case, to start a triggered sequence, the user must first write a 0 followed by a 1 to the Trigger bit.

The System Trigger bit ([0x01.0 System Trigger on page 42](#)) is ignored when the System mode bits are SHIP, LOW POWER, or IDLE. It is executed only when the bits [0x2E.7:6 System Mode on page 104](#) are set to SCAN mode. All other Trigger bits are ignored in SHIP or LOW POWER Modes, and can only trigger sequences in IDLE or SCAN mode. These Trigger bits should be used only in IDLE mode because Renesas recommends to reserve SCAN mode for System Scans only.

If the ISL94216A is running a sequence started by a previous Trigger bit transition, then the new Trigger bit transition is queued. It is scheduled for when the sequence in progress completes.

If the ISL94216A is in a condition that prevents running the desired sequence, the Trigger bit transition is ignored. It is not executed when the condition changes. For example, if the chip has a fault that prevents executing the Trigger bit, then the fault goes away, and a new 0 to 1 transition of the Trigger bit is needed to start the sequence. This applies unless the chip is in the middle of a sequence started by a previous Trigger bit transition, in which case the triggered sequence executes.

When multiple Trigger bits are in the queue, only the one with highest priority is executed. When its execution starts, all other queued Trigger bits are cleared. This means that besides the triggered sequence in progress, only one more is executed later because the queue is cleared when the second starts. When the second starts, the user can queue a third one that is executed when the second completes. The priority is fixed in design, from high to low: [0x01.0 System Trigger on page 42](#), [0x01.5 Recalibrate  \$V\_{OS}\$  Trigger on page 41](#), [0x02.0  \$V\_{CELL}\$  Trigger on page 44](#), [0x03.0  \$I\_{PACK}\$  Trigger on page 46](#), [0x11.0 ETAUX Trigger on page 59](#), [0x1B.0  \$V\_{REG}\$  Trigger on page 66](#), [0x1F.5  \$I\_{TEMP}\$  Trigger on page 69](#), [0x1F.0  \$V\_{BAT1}\$  Trigger on page 70](#), [0x24.5 OW Trigger on page 73](#), and [0x25.4 CB Trigger on page 77](#).

When the previous triggered sequence is completed, the circuit first takes the Trigger bit in queue with highest priority, and clears the entire queue. Next, it checks the conditions against the Trigger bit to be executed. If conditions do not allow it to be executed, the circuit goes back to IDLE mode, otherwise the circuit starts the new sequence. A Fault never clears the queue.

## 8. Communication Interface

The ISL94216A includes a digital interface for the user to configure operation as well as monitor input and output parameters. Serial communication interfaces are available anytime the chip is not being reset. The ISL94216A supports I<sup>2</sup>C, SPI, and Single Wire serial interfaces. The protocol is chosen by connecting the CMS0 and CMS1 pins. The CMS pins are static inputs and must not change state while the ISL94216A is powered. Never set both of these pins high simultaneously. If this occurs, set them to a valid state and RESET the ISL94216A. The hardware configuration required to support each communication protocol is listed in [Table 76](#).

The ISL94216A supports sequential read, which can start at any register address. If the master continues to send clock cycles or a presence bit is sent after reading one byte, the device indexes to the next byte and returns the byte value. This continues until the load bit or stop bit is received or CS returns high.

The ISL94216A supports sequential read back commands for all three protocols.

**Table 76. Serial Protocol Defined**

CMS1	CMS0	Protocol
DGND	DGND	I <sup>2</sup> C
DGND	VDD	SPI
VDD	DGND	Single Wire
VDD	VDD	Reserved - Invalid State!

A comparison of the approximate read times for the three protocols is shown in [Table 77](#).

**Table 77. Approximate Read Times**

Communication Sequence	Number of Bytes to Read Back	Transaction Time (ms)		
		I <sup>2</sup> C (100kHz)	SPI (2MHz)	Single Wire
Read All (0x00-0x89)	138	14.11	0.69	18.17
Read V <sub>CELL</sub> (0x30-0x51)	34	3.36	0.166	4.517
Read I <sub>PACK</sub> (0x52-0x57)	6	0.84	0.041	1.493
Read OTHER (0x58-0x62)	11	1.29	0.062	2.033
Read FAULT (0x63-0x69)	7	0.93	0.045	1.601

## 8.1 I<sup>2</sup>C Serial Interface

This device supports a bidirectional bus oriented protocol. The protocol defines any device that sends data onto the bus as a transmitter and the receiving device as the receiver. The device controlling the transfer is the master and the device being controlled is the slave. The master always initiates data transfers and provides the clock for both transmit and receive operations. Therefore, the ISL94216A operates as the slave device in all applications. All communication over the I<sup>2</sup>C interface is conducted by sending the MSB of each byte of data first.

### 8.1.1 I<sup>2</sup>C Address

The ISL94216A can be used with any I<sup>2</sup>C host device. Each device must have its own unique serial address to distinguish it from other devices on the bus. The device address is set by connecting the ADDR/ $\overline{\text{CS}}$  pin to either VDD or DGND. The available addresses are listed in [Table 78](#).

**Table 78. I<sup>2</sup>C Address Values**

Logic Selections	Address (7-bit Binary)
ADDR/ $\overline{\text{CS}}$ pin tied to VDD	0011 010
ADDR/ $\overline{\text{CS}}$ pin tied to DGND	0001 010

### 8.1.2 Protocol Conventions

Data states on the SDA line can change only during SCL LOW periods. The SDA state changes during SCL HIGH are reserved for indicating START and STOP conditions (see [Figure 112](#)). At power-up, the SDA pin is in the input mode.

All I<sup>2</sup>C interface operations must begin with a START condition, which is a HIGH to LOW transition of SDA while SCL is HIGH. The device continuously monitors the SDA and SCL lines for the START condition and does not respond to any command until this condition is met (see [Figure 112](#)). A START condition is ignored during the power-up sequence.

All I<sup>2</sup>C interface operations must be terminated by a STOP condition, which is a LOW to HIGH transition of SDA while SCL is HIGH (see [Figure 112](#)). A STOP condition at the end of a Read operation, or at the end of a Write operation returns the I<sup>2</sup>C state machine to its initial state where it waits for the next START.

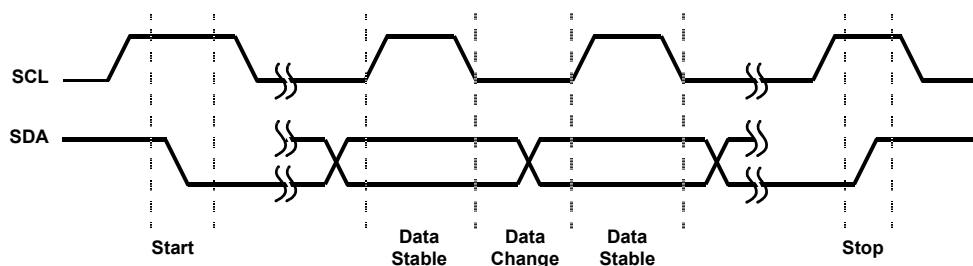

Figure 112. Valid Data Changes, Start, and Stop Conditions

Figure 113. Acknowledge Response from Receiver

An Acknowledge (ACK) is a software convention that indicates a successful data transfer. The transmitting device, either master or slave, releases the SDA bus after transmitting eight bits. During the ninth clock cycle, the receiver pulls the SDA line LOW to acknowledge the reception of the eight bits of data (see Figure 113). The device responds with an ACK after recognition of a START condition followed by a valid Slave Address byte, and once again after successful receipt of the Register Address Byte. The device also responds with an ACK after receiving each Data Byte of a Write operation. The master must respond with an ACK after receiving each Data Byte of a Read operation except the last one.

The last bit of the Slave Address byte defines a read or write operation to be performed. When this  $\overline{R/\overline{W}}$  bit is a 1, a Read operation is selected. A 0 selects a Write operation (see Figure 114).

After loading the entire Slave Address byte from the SDA bus, the device compares it with the internal Slave Address. With a correct compare, the device outputs an acknowledge on the SDA line.

### 8.1.3 Write Operation

A Write operation requires a START condition, followed by a Slave Address byte, a Register Address byte, a Data byte, and a STOP condition (see Figure 114). The slave device responds with an ACK after successfully receiving each of the three bytes. The content of the Data byte is transferred to the ISL94216A registers at the rising edge of SCL during the ACK that follows the reception of the Data byte.

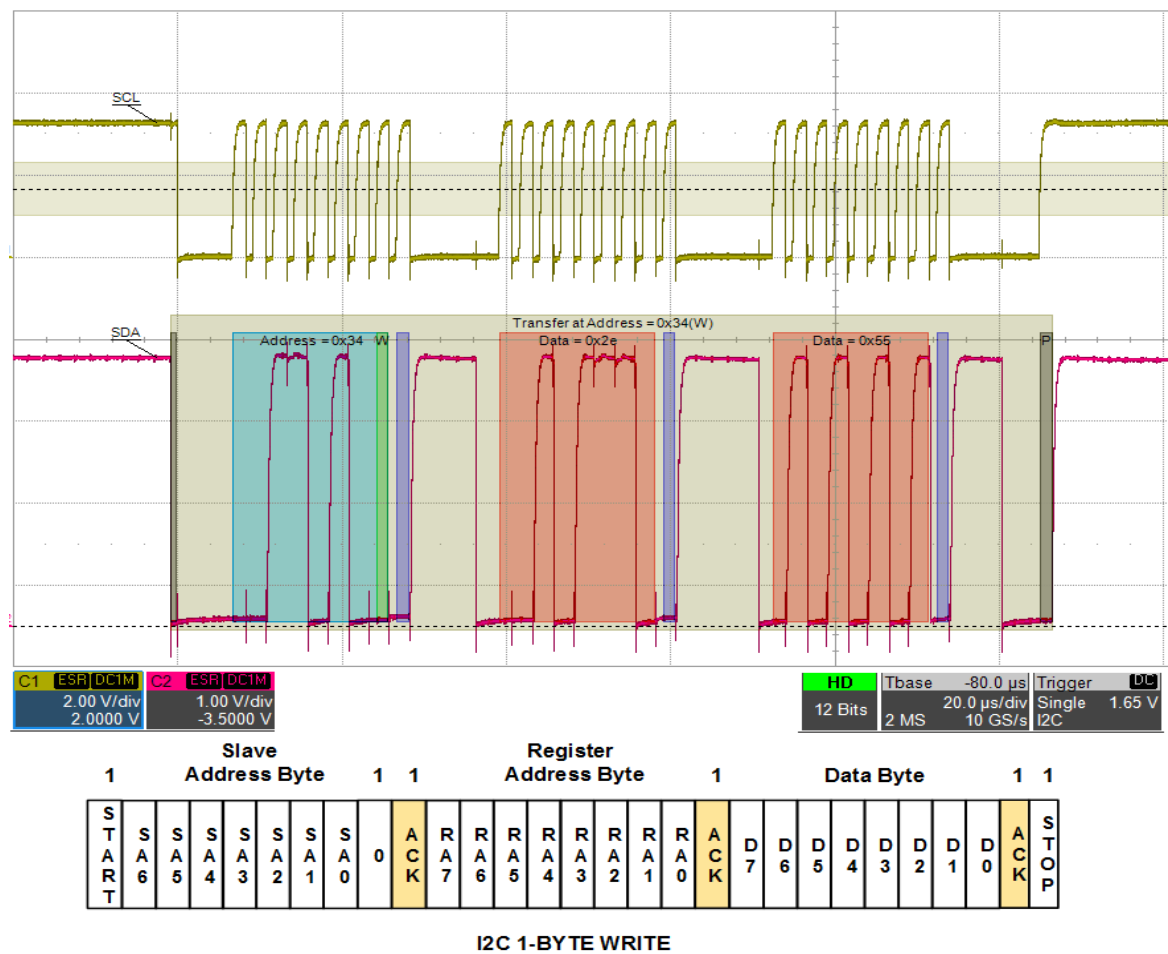

Figure 114. I2C Write Protocol

8.1.4 Read Operation

A Read operation consists of a three byte sequence, followed by one or more Data bytes (see Figure 115). The master initiates the operation issuing the following sequence: a START, the Slave Address byte with the R/W bit set to 0, a Register Address byte, a second START, and a second Slave Address byte with the same seven MSBs but with the R/W bit set to 1. After each of the three bytes, the ISL94216A responds with an ACK. The ISL94216A transmits Data bytes as long as the master responds with an ACK during the SCL cycle following the eighth bit of the first byte. The master terminates the Read operation by issuing a NACK followed by a STOP condition.

The Data bytes are from the memory location indicated by an internal pointer. This pointer's initial value is determined by the address byte in the Read operation instruction, and increments by one during transmission of each Data byte.

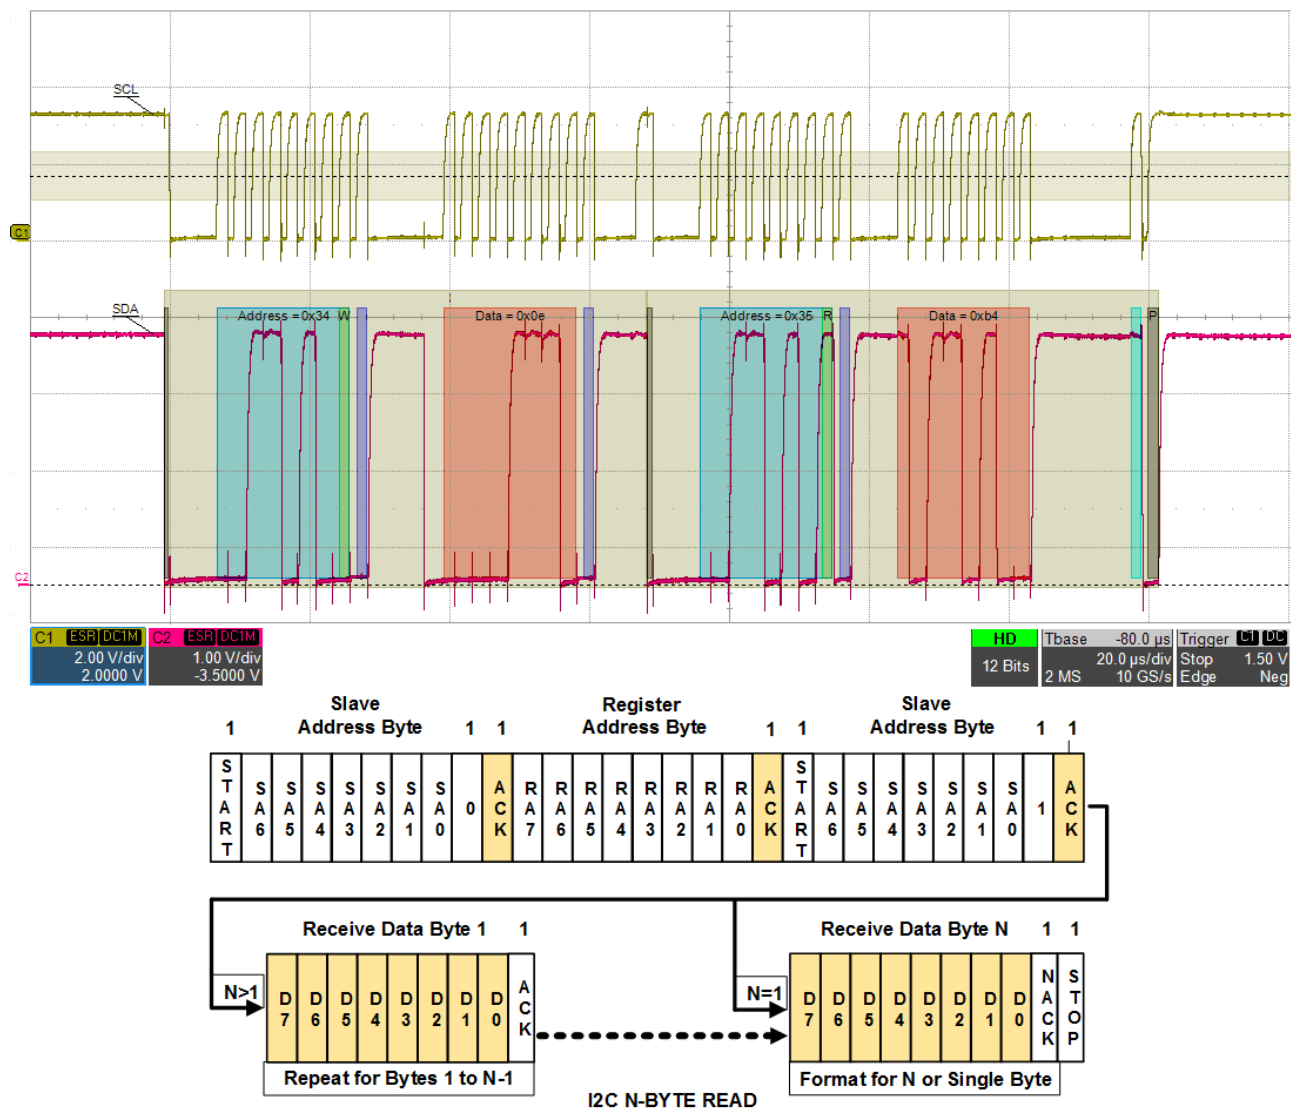

Figure 115. I2C Read Protocol

8.1.5 I2C Timing

I2C timing is illustrated in Figure 116, see specification table for specific values.

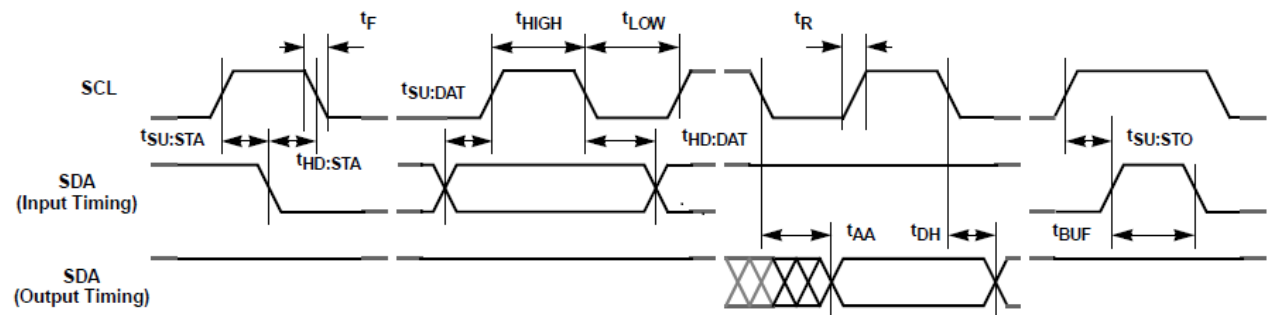

Figure 116. I2C Timing

## 8.2 SPI Serial Interface

The ISL94216A supports the SPI communication protocol. SPI has become a standard that does not have an officially released specification generated by any international committee. This gives some flexibility in implementing the SPI protocol but also requires programmable flexibility of the master microcontroller. This protocol defines any device that sends data onto the bus as a transmitter, and the receiving device as the receiver. The device controlling the transfer is called the master and the device being controlled is called the slave. The master always initiates data transfers, and provides the clock for both transmit and receive operations. The ISL94216A operates as a slave in all applications and all communication over the interface is conducted by sending the Most Significant Bit (MSB) of each byte first.

The ISL94216A is accessed through the MOSI (Master Output Slave Input) and SCL (Serial Clock) pins, and the output data is presented by the ISL94216A at the MISO (Master Input Slave Output) pin. Input data at pin MOSI is clocked in on the rising edge of SCL when  $\overline{CS}$  is LOW. Output data at pin MISO is clocked out on the falling edge of SCL.

All commands start with a falling edge at the input pin  $\overline{CS}$  and include the Identification, Register Address, and Data Bytes. Write operations end with a rising edge at the input pin  $\overline{CS}$  after the last bit of the Data bytes being written is clocked in. Read operations end with a rising edge at the input pin  $\overline{CS}$  after the last bit of the Data byte being read is clocked out.

Controlling the ISL94216A with a SPI interface is similar to I<sup>2</sup>C in that the formats are comparable with the small differences. SPI requires the use of four data lines (SCL, MOSI, MISO, and  $\overline{CS}$ ) for successful communication between master and slave. Unlike I<sup>2</sup>C, SPI does not use ACK or NACK, START is replaced by the falling edge of  $\overline{CS}$ , and STOP is replaced by the rising edge of  $\overline{CS}$ .

The ISL94216A SPI interface has a maximum clock frequency of SPI<sub>fSCL</sub> (2Mhz, [page 18](#)). A time delay of SPI<sub>tWAIT</sub> (7μs, [page 18](#)) is required between bytes.

### 8.2.1 Identification Byte

The Identification byte is the first byte sent by the Master. It is a combination of the ISL94216A SPI Slave address and the Read/Write bit. The slave address is shifted left one bit while the R/W bit is the Least Significant Bit (LSB) of the Identification Byte ([Figure 117 on page 130](#)).

#### 8.2.1.1 CRC Disabled

To operate with CRC disabled the Slave Address of the ISL94216A is 0x0A and the R/W bit is set to 1 for a Read or to 0 for a Write. When these are combined, the Identification byte is 0x15 for a Read ([Figure 119 on page 131](#)) and 0x14 for a Write ([Figure 117 on page 130](#)).

#### 8.2.1.2 CRC Enabled

To operate with CRC enabled the Slave Address of the ISL94216A is 0x4E and the R/W bit is set to 1 for a Read or to 0 for a Write. When these are combined, the Identification byte is 0x9D for a Read and 0x9C for a Write ([Figure 118 on page 130](#)) with CRC enabled.

### 8.2.2 Write Operation

Write Operation with CRC disabled is selected by setting the Read/Write bit in the Identification byte to 0 while using the slave address of 0x0A. On a write command with CRC disabled, the device transfers the Data byte to the register on the falling edge of the 24th (SCL) clock cycle. [Figure 117](#) illustrates a single byte SPI Write sequence with CRC disabled.

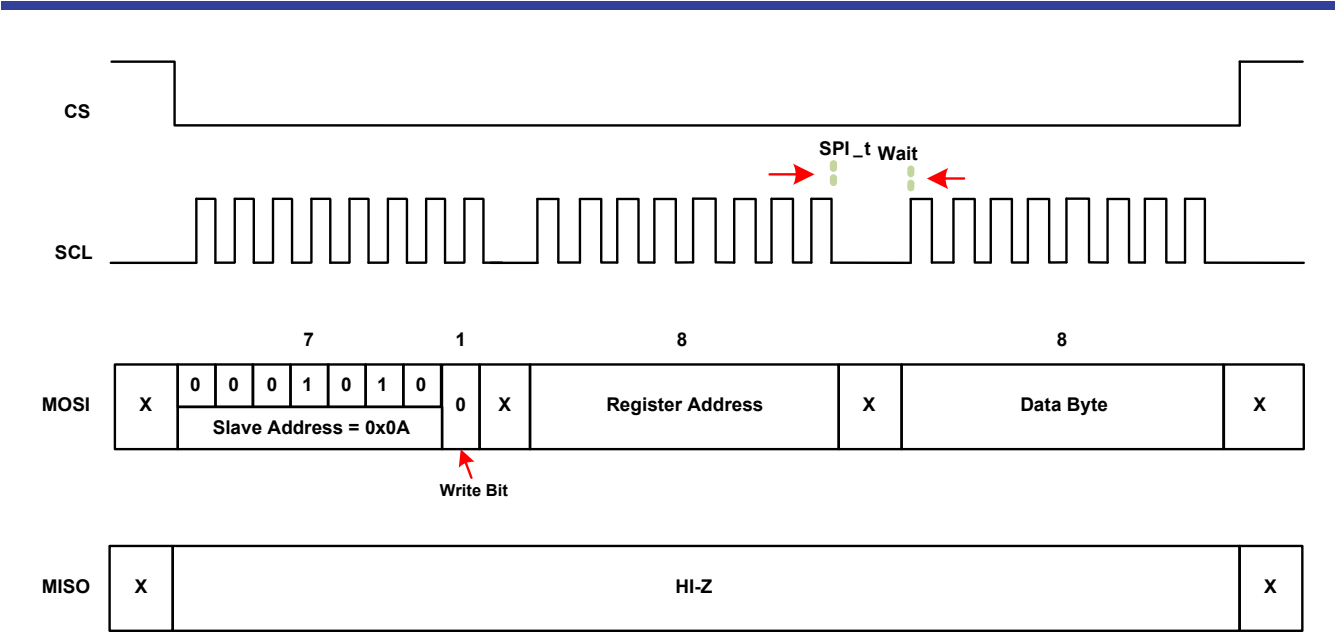

Figure 117. SPI Write

A single byte write operation with CRC enabled uses the slave address of 0x4E and requires two extra bytes for the 16-bit CRC word. Figure 118 is an example of a single byte write with CRC enabled. The CRC word is calculated by the Master from the Identification, Register Address and Data bytes. The MSB of the CRC word is transmitted first and the least significant byte follows it. See section CRC Calculation on page 132 for details of CRC calculation.

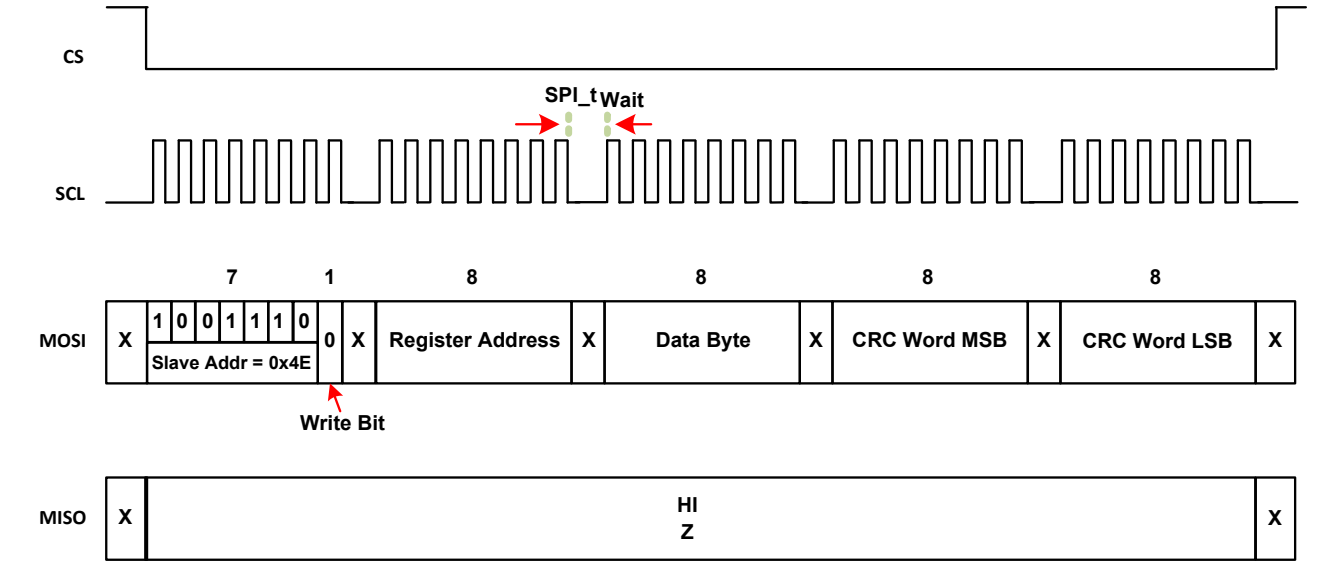

Figure 118. SPI Write w/CRC

### 8.2.3 Read Operation

Read Operation with CRC disabled is selected by setting the Read/Write bit in the Identification Byte to 1 while using the slave address of 0x0A. Figure 119 illustrates the SPI Read sequence with CRC disabled. The ISL94216A supports sequential read with CRC disabled by automatically incrementing the register address pointer to the next location.

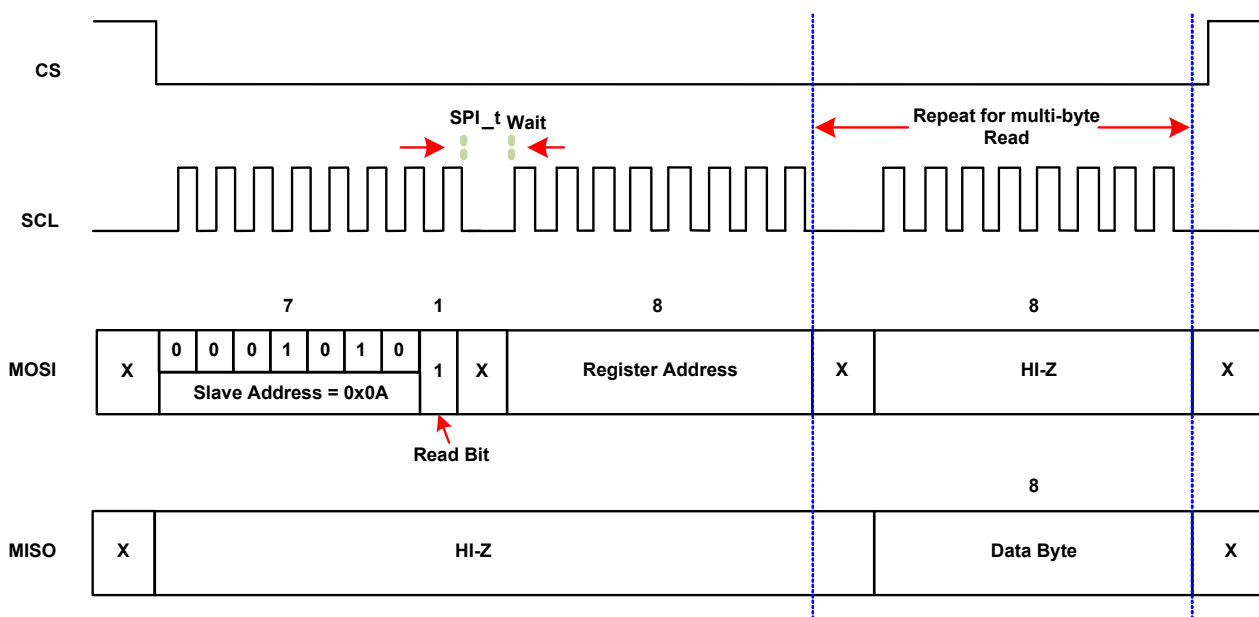

Figure 119. SPI Read

A read operation with CRC enabled uses the slave address of 0x4E and requires four bytes from the Master consisting of the Slave address with write bit ([Identification Byte on page 129](#)), an 8bit address or command code byte and 2 bytes for the 16bit CRC word. The read command CRC word is calculated by the Master from the Identification and Register Address (or command) bytes. If a register address is used, then Slave responds with one byte of register data and 2 bytes for the response 16bit CRC word (calculated by the Slave).

The sequential read of multiple bytes with CRC enabled is supported by command codes used in place of the register address in the second byte sent by the Master. The supported command codes are listed in [Table 79](#).

Table 79. CRC Read Command Codes

Read Registers	Command Code	Starting Address	Ending address	Byte Count
All Registers	0x9A	0x00	0x89	138
Measurement	0x9B	0x30	0x62	51
V <sub>CELL</sub>	0x9C	0x30	0x51	34
I <sub>PACK</sub>	0x9D	0x52	0x57	6
Other	0x9E	0x58	0x62	11
Faults	0x9F	0x63	0x69	7

[Figure 120 on page 132](#) is an example of a READ I<sub>PACK</sub> command with CRC enabled. Again, the Master calculates and transmits the first CRC word based in the Identification and Command bytes while the Slave calculates and transmits the response CRC word based on the data it sends. If the Slave determines the read command CRC is incorrect it sets fault bit [0x65.0 CRCF](#) and holds MISO high for the entire read back sequence until CS returns high signaling the end of the sequence. A CRC of all 1's is an indication of a communications fault.

See section [CRC Calculation on page 132](#), [Example CRC VBA Code on page 134](#), and [Example CRC C-Code on page 135](#) for details on CRC calculation.

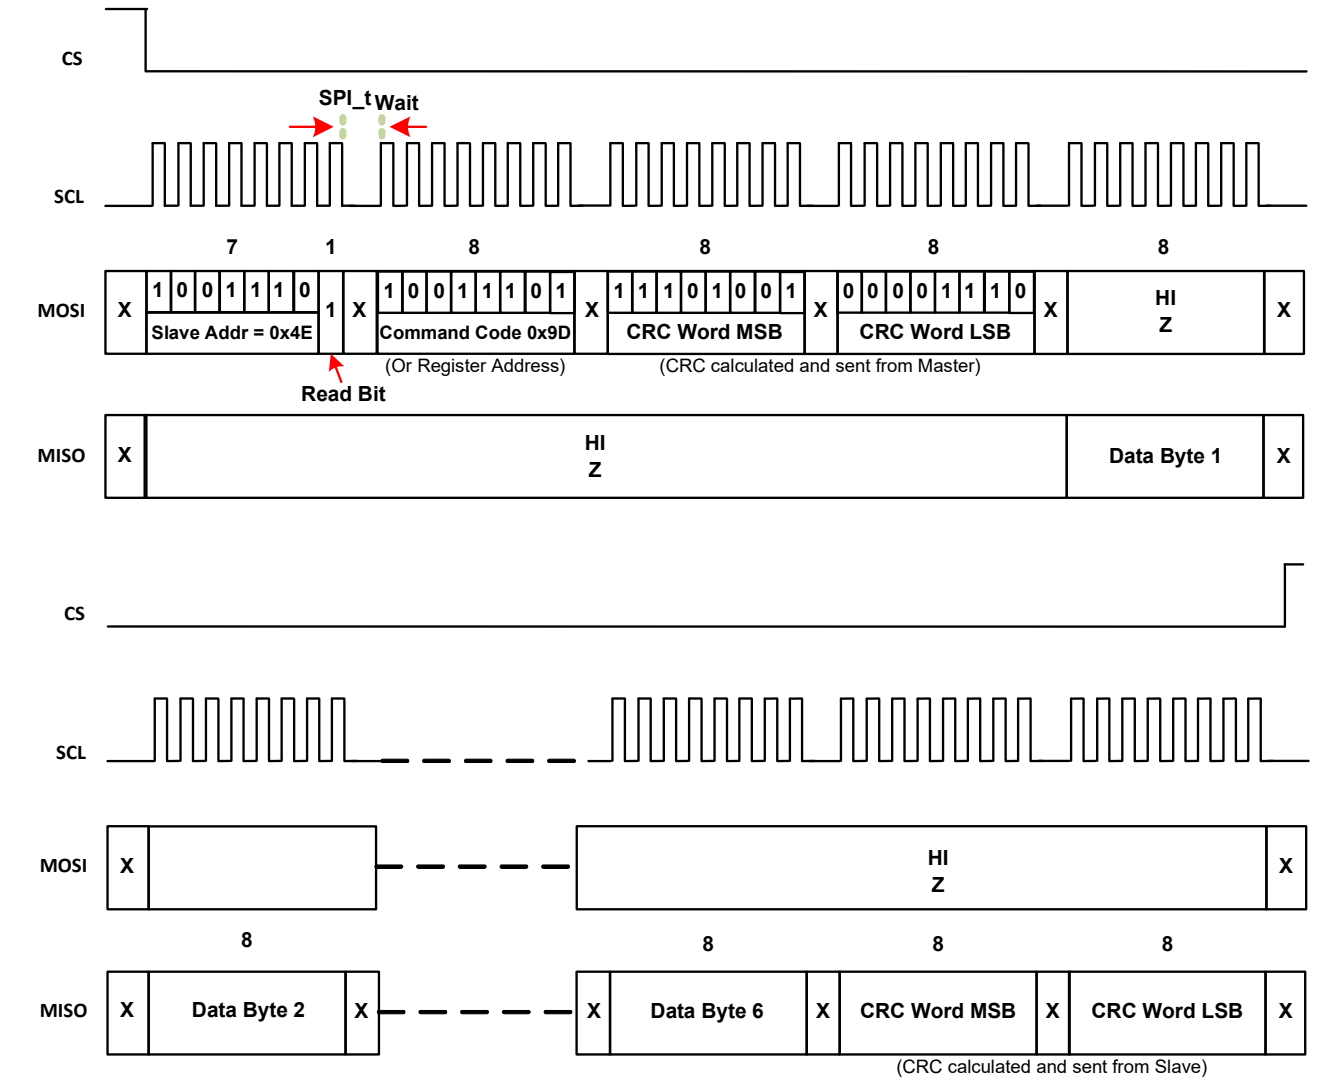

Figure 120. SPI I\_PACK Read w/CRC

### 8.2.4 CRC Calculation

The ISL94216A CRC implementation is compliant with the CRC-CITT16 X25 protocol. See [Example CRC VBA Code on page 134](#), [Example CRC C-Code on page 135](#) and [Figure 121](#) for calculation steps.

SPI Writes with CRC enabled include a 2-byte CRC word ([Figure 118 on page 130](#)) calculated by the Master from the values of the first 3-bytes of the 5-byte sequence. SPI Reads are in the format of [Figure 120 on page 132](#) where the first CRC Word is calculated by the Master from the values of the first 2-bytes of the 4-byte MOSI sequence while the CRC Word at the end read sequence is calculated by the ISL94216A Slave based on the data it sent on MISO. In all three of these cases, it is the responsibility of the receiver to calculate the CRC value of the received bytes to compare with the received CRC and then act accordingly.

If the comparison for an SPI Write fails, the ISL94216A asserts fault bit [0x65.0 CRCF on page 87](#) and ignores the Write.

If the comparison for an SPI Read fails, the ISL94216A asserts fault bit [0x65.0 CRCF](#) and ignores the read. The ISL94216A holds MISO high until the Master releases CS. A CRC value of all 1's indicates a failure. If the Master determines the CRC comparison fails following the data read, then it must determine the appropriate reaction.

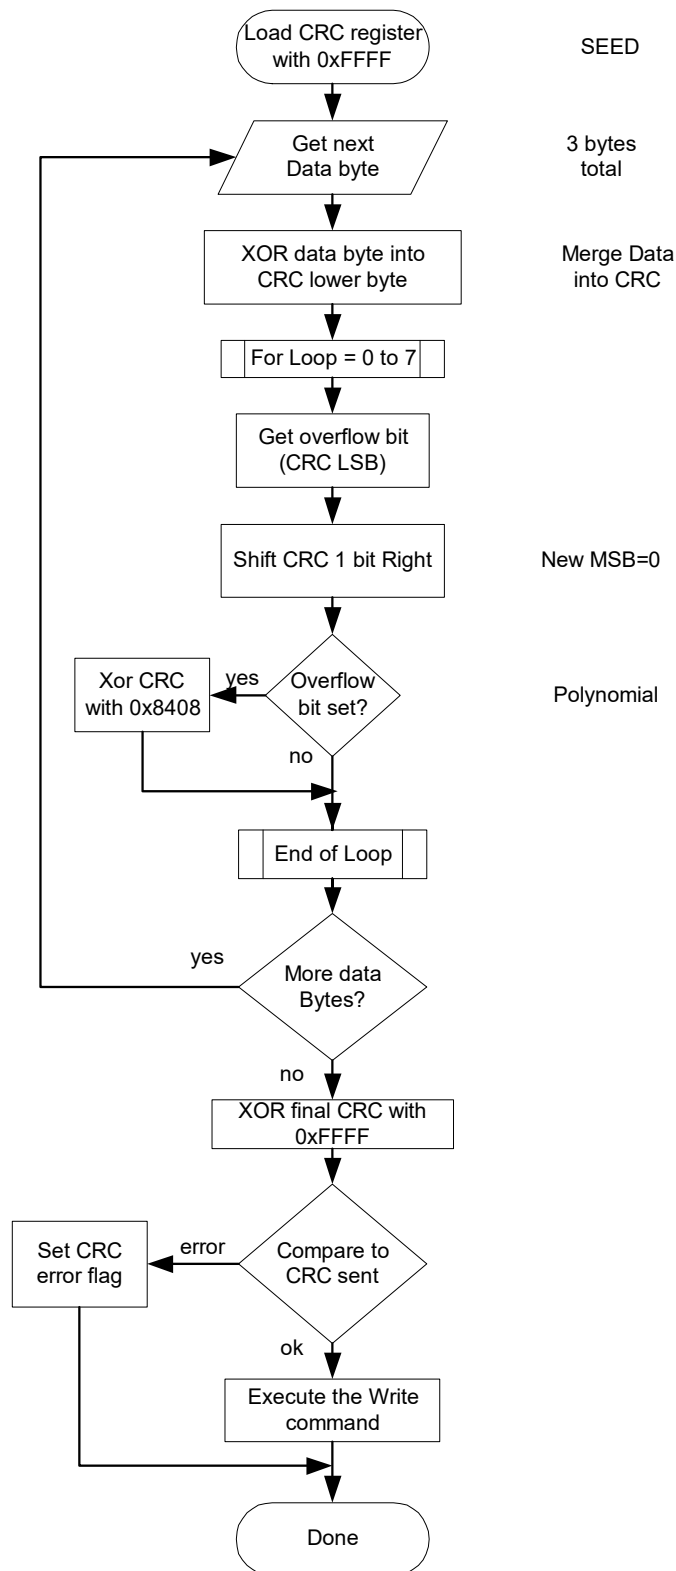

Figure 121. CRC Calculation Flowchart

### 8.2.4.1 Example CRC VBA Code

Example VBA code that calculates the CRC16-CITT-X25 checksum value (CRC word):

```
'*****
```

Option Explicit

```
Public Function crcCheckValX25(ByVal buf As String) As Long
```

```
'*****
```

```
' Equation is X16+X12+X5+1 or &H1021 (ignore X16)
```

```
' The X25 standard uses the CRC-CITT standard with the following conditions;
```

```
'     The starting CRC value is 0xFFFF.
```

```
'     The input bit stream is reflected.
```

```
'     The output CRC is reflected.
```

```
'     The final action is to XOR the value with 0xFFFF.
```

```
' Note: Reflecting the input data bits and the crc output bits is equivalent
```

```
'     to reflecting the poly (0x1021 --> 0x8408) and shifting the CRC bits right as  
opposed to left.
```

```
'*****
```

```
Dim NumBytes As Integer
```

```

    If (Len(buf) Mod 2) <> 0 Then buf = "0" & buf      ' if excel drops leading zero
```

```
    If Len(buf) < 1 Then buf = "00"                  ' if no data
```

```
    NumBytes = Len(buf) \ 2
```

```
    crc = 65535
```

```
                                'Initializes the CRC to the seed
```

```
    Debug.Print "CCITT_X25 input " & buf & " num bytes " & Str(NumBytes)
```

```
    For Bite = 0 To NumBytes - 1
```

```
                                ' for each byte
```

```
        DataStr = Mid(buf, 2 * Bite + 1, 2)
```

```
                                'read next byte
```

```
        Databyte = CInt("&H" & DataStr)
```

```
                                'convert byte string to integer
```

```
        crc = (crc Xor Databyte) And 65535
```

```
                                ' XOR the data into lower 8 bits of
```

```
    crc
```

```
        Debug.Print "    byte data " & Hex$(Databyte)
```

```
        Debug.Print "        byte crc " & Hex$(crc)
```

```
        crc = CRC16_X25(crc, &H8408)
```

```
                                ' shift the bits and XOR with polynomial
```

```
        crc = crc And 65535
```

```
                                ' this keeps the CRC value in 16bit
```

```

```
    Next bit
```

```
    CRC16_X25 = crc
```

```
End Function
```

### 8.2.4.2 Example CRC C-Code

```

Example C code that calculates the CRC16-CITT-X25 checksum value (CRC word):
/*Calculates the CRC checksum for an array of bytes for ISL94216A Rev 0 03/21/19
Renesas Corp*/
#include <stdio.h>
void main()                                     // code to run the crc and print results
{
    int i;
    unsigned long int CRCval;                   // final checksum
    unsigned char INPUT_DATA[100];             // input array (uchar=1byte)
    int NumBytes;                              // number of bytes to use
    NumBytes=3;
    INPUT_DATA[0] = 0x84;                      // fill in the input data
    INPUT_DATA[1] = 0xD0;
    INPUT_DATA[2] = 0x01;
    printf(" ---- ISL94216A CRC calculator ---- \n");
    printf("Number of Bytes   = %d   \n", NumBytes);
    printf("Input Data (hex)   = ");
    for(i=0; i<NumBytes; i++) printf("%02x ", INPUT_DATA[i]);
    printf("\n");
    CRCval = Calc_CRC_94216(NumBytes, INPUT_DATA); // find the CRC checksum
    printf("CRC16 final (hex) = %04x   \n", CRCval);
} //main
unsigned long int Calc_CRC_94216(int NumBytes, unsigned char *data)
{
    // Call with input data array & NumBytes set, returns the final crc
    // This code reflects the polynomial and shifts right instead of reflecting the data &
    CRC (easier to code)
    //
    //          standard X25          ISL94216A code
    // CRC_POLY      0x1201          0x8408
    // CRC_SEED      0xFFFF          0xFFFF
    // CRC_XOR       0xFFFF          0xFFFF
    // REFLECT_INPUT TRUE          FALSE
    // REFLECT_OUTPUT TRUE         FALSE
    // Byte XOR      MSB           LSB
    // Bit Shift     Left          Right
    //
    int i, j, XorFlag;
    unsigned long int CRCval;
    CRCval=0xFFFF;                             // starting point = SEED
    for(i=0; i<NumBytes; i++)
    {
        CRCval = CRCval ^ long(data[i]);        // XOR data with CRC
        for(j=0; j<8; j++)                      // shift for each bit & check for
        XOR
        {
            XorFlag=0;
            if(CRCval & 1)XorFlag=1;             // LSB = Xor Flag
            CRCval=CRCval>>1;                   // shift right 1 bit
            if(XorFlag>0) CRCval=CRCval ^ 0x8408; // XOR with poly
        } //for j
    } //for i
    CRCval=CRCval ^ 0xFFFF;                     // xor the final crc
    return(CRCval);
} //Calc_

```

### 8.2.5 SPI Timing

SPI timing is illustrated in Figure 122 and Figure 123, see specification table for specific values. Symbol names listed in the specification tables include leading characters SPI\_, which are omitted from the following figures for clarity.

Symbol  $t_{CS}$  is not specified because it is a function of the command sequence. Even though the device logic will recognize short  $t_{CS}$  pulse widths it cannot be expected to respond immediately with correct results if the preceding command has not completed execution. For example, a System Trigger command must be allowed to complete its task before attempting to read the results from a measurement register.

Figure 122. SPI Input Timing

Figure 123. SPI Output Timing

## 8.3 Single Wire Interface

The ISL94216A can be controlled through a Single Wire interface if the CMS0/1 pins are configured as described in Table 76 on page 124 to use this communication format. Single Wire is a single line serial communication protocol that uses a time based method for the master to communicate with the slave.

The list of symbols used by the Single Wire interface is defined to be equivalent to the list of I<sup>2</sup>C symbols, and the sequences of symbols used by the Single Wire interface are set up to match the I<sup>2</sup>C sequences. The available sequences are: Write a byte and Read one or more bytes.

The Single Wire Interface differs from I<sup>2</sup>C by the addition of time outs. The Single Wire Protocol (SWP) state machine goes to its initial state if no transition is detected at the Single Wire interface for a long time. This is equivalent to detecting a STOP symbol in an I<sup>2</sup>C communication, or the Load symbol in this SWP. Specifications for detecting a long time with no transitions are different when the wire is LOW versus when the wire is HIGH. They are called Time Out Low or  $t_{TOLSW}$  (300μs, page 21) and Time Out High or  $t_{TOHSW}$  (35ms, page 21).

The Single Wire input path in the ISL94216A has a glitch suppression filter. Any pulse narrower than the min  $t_{\text{glitch}}$  (50ns, [page 21](#)) specification is ignored by the ISL94216A. This filter is the standard 400kHz I<sup>2</sup>C filter.

Single Wire drivers are Open Drain. When the Single Wire interface is idle (no symbols are being transmitted), the logic level at the Single Wire pin is HIGH.

All symbols are active low pulses of various widths. The symbol names are listed in the Electrical Specifications on [page 20](#).

Whether doing a read or write transaction, a not present symbol sent by the slave to the master is required before a load symbol is sent. In a Read operation, the not present symbol informs the master that there are no more bytes to read. In a Write operation, the not present symbol transfers the byte contents to the register of the device.

All symbols begin with a falling edge driven by the master.

Reset, Load, Write 0, Write 1, Read 1, and Not Present symbols are fully driven by the master.

Present symbols can be fully driven by the master, or can be initiated by the master and completed by the slave, depending on the location in the communication sequence.

All Read 0 symbols and some Present symbols are initially driven by the master, and driven by both the master and the slave, and finally driven only by the slave. The slave determines the location of the rising edge that completes those symbols.

Write 0, Read 0, and Present symbols are distinguished by their location in sequences of symbols, because they have the same pulse width specifications.

Write 1, Read 1, and Not Present symbols are distinguished by their location in sequences of symbols, because they have the same pulse width specifications.

When reading a symbol from the ISL94216A, the master drives the wire with a pulse that has the pulse-width of a narrow valid pulse: a 1 or 0 symbol (see the Electrical Specifications on [page 20](#)).

If the symbol that is supposed to be read is a 1 or a Not Present, the ISL94216A does not drive the Single Wire pin. It just waits for the next falling edge, or for a time out determined with on-chip timers.

If the symbol that is supposed to be read is a 0 or a Present, soon after detecting a falling edge the ISL94216A drives the Single Wire pin to extend the total pulse-width.

### 8.3.1 Single Wire Address

The ISL94216A can be used with any Single Wire host device. More than one slave device can be used with a single Single Wire master device. Each device must have its own unique serial address to distinguish it from other devices on the bus. The device address is set by connecting the ADDR/ $\overline{\text{CS}}$  pin to either VDD or DGND. The available addresses are listed in [Table 80](#).

**Table 80. Single Wire Address Values**

Logic Selections	ISL94216A Address (7 MSBs)
ADDR/ $\overline{\text{CS}}$ pin tied to VDD	0011 010
ADDR/ $\overline{\text{CS}}$ pin tied to DGND	0001 010

8.3.2 Single Wire Read/Write Sequences

The data sequence for Single Wire read and write is the same as that for I<sup>2</sup>C read and write transactions. The Single Wire read and write sequences are shown in Figure 124 through Figure 126.

The write sequence follows these steps:

- Reset (Start) → Slave Address Byte with R/W bit = 0 → Present →
- Register Address Byte → Present → Data Byte from Master → Present → Load (Stop)

The sequence to read 1 to N Bytes is:

- Reset (Start) → Slave Address Byte with R/W bit = 0 → Present →
- Register Address Byte → Present → Reset (Start) → Slave Address Byte with R/W bit = 1 →
- Present → Data Byte from Slave {Repeat this line N times for N bytes of data}
- Load (Stop)

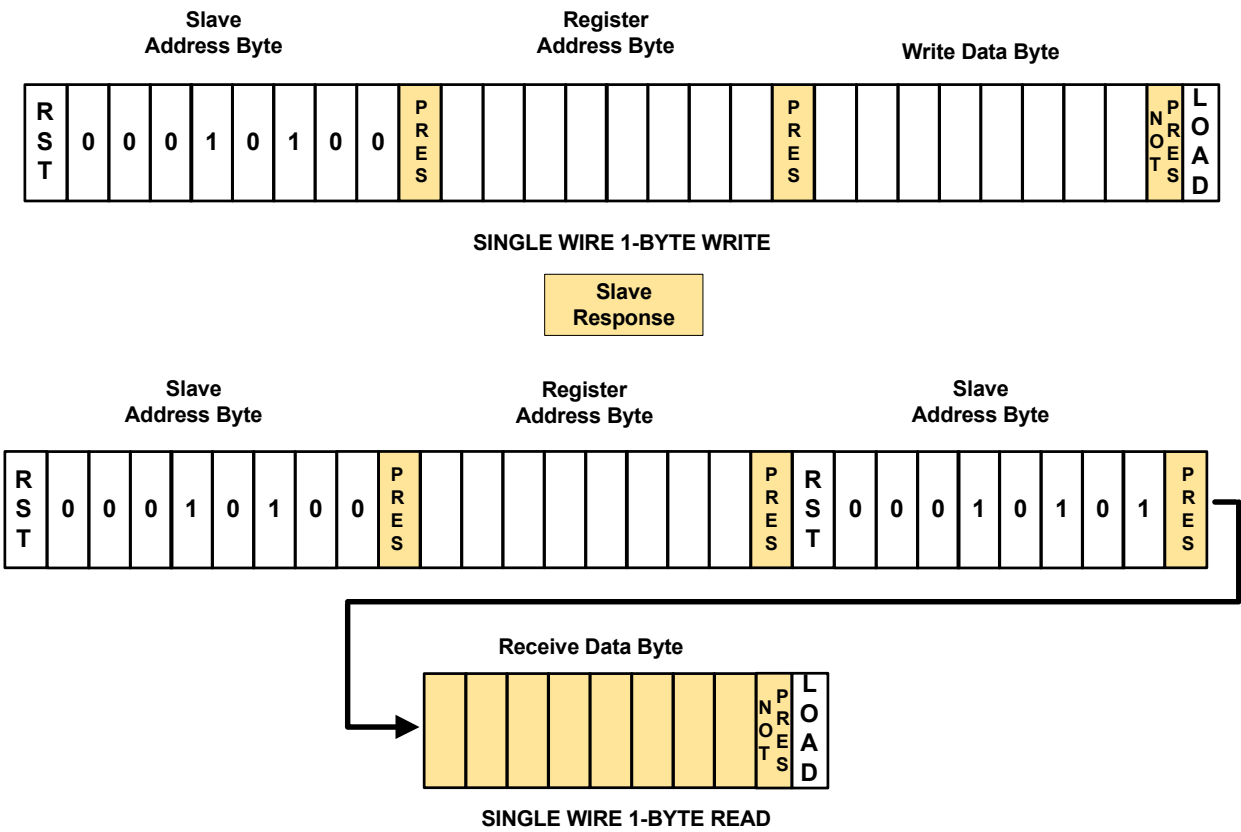

Figure 124. Single Wire Read/Write Protocol

Figure 125. Single Wire Read Example

Figure 126. Single Wire Write Example

### 8.3.3 Single Wire Timing

Figure 128 and Figure 129 illustrate the of Single Wire symbols. The relationships between the transmitter pulse widths and receiver thresholds are shown in Figure 127.

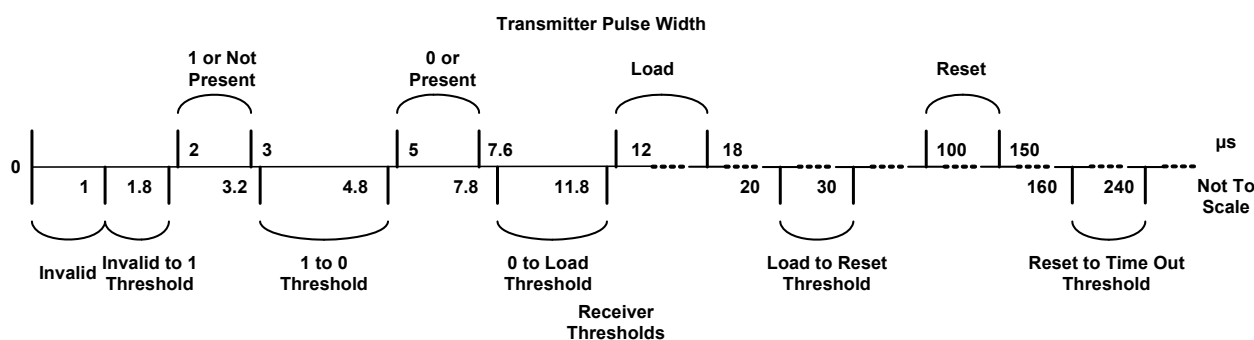

Figure 127. Single Wire Symbol Timing

The definition of pulse-width and bit periods for symbols driven by the master are detailed in Figure 128.

To identify symbols, the receiver may sample the Single Wire during the windows indicated in the graph as Receiver Thresholds, or alternatively, it may use a timer to measure falling edge to rising edge pulse-widths at the Single Wire.

The Receiver Thresholds can also be referred to as Receiver Sample Windows.

Figure 128. Timing of Symbols Driven by Master

Figure 129. Master/Slave Symbol Timing

The timing of symbols partially driven by the master and partially driven by the slave are shown in [Figure 129](#). The top waveform is the output of the master, the center waveform is the output of the slave, and the bottom waveform is the result that appears on the Single Wire line. In cases in which no slave response occurs, it remains high impedance.

The master or the slave output is high impedance when not being driven Low.

The symbol position within the communication sequence relative to a preceding R/W bit is used to differentiate between symbols that otherwise share timing specifications. That is, between a 1 and Not Present, and between a 0 and Present.

## 9. Reduced Cell Count

The ISL94216A is designed to monitor between 4 and 16 cells. When using less than 16 cells, it is important that each used cell has a normal input circuit connection to the top and bottom monitoring inputs for that cell. The simplest way to use the ISL94216A with any number of cells is to always use the full input circuit arrangement for all VCn inputs, and short together the unused inputs at the battery terminal. In this way, each cell input sees a normal source impedance regardless of whether it is monitoring a cell.

The cell balancing components associated with unconnected cell inputs are not required and can be removed. Unused cell balance outputs should be tied to the cell voltage monitoring pin below it. For example, tie CB9 to VC8 in a 15-cell application.

The input circuit component count can be reduced in cases in which fewer than 14 cells are being monitored. It is important that cell inputs that are being used are not connected to other unused cell inputs, as this affects measurement accuracy.

See [Figure 130](#) and the following table for connections with cell counts less than 16.

Figure 130. 4 to 14 Cell Count Example

## 10. Package Outline Drawing

For the most recent package outline drawing, see [L64.9x9B](#).

L64.9x9B

64 Lead Quad Flat No-Lead Plastic Package

Rev 1, 5/17

**TOP VIEW**

**BOTTOM VIEW**

### TYPICAL RECOMMENDED LAND PATTERN

**SIDE VIEW**

**DETAIL "X"**

**NOTES:**

1. Dimensions are in millimeters.  
Dimensions in ( ) for Reference Only.
2. Dimensioning and tolerancing conform to ASME Y14.5m-1994.
3. Unless otherwise specified, tolerance: Decimal  $\pm 0.05$
4. Dimension b applies to the metallized terminal and is measured between 0.20mm and 0.30mm from the terminal tip.
5. Tiebar shown (if present) is a non-functional feature.
6. The configuration of the pin #1 identifier is optional, but must be located within the zone indicated. The pin #1 identifier may be either a mold or mark feature.

## 11. Ordering Information

Part Number <sup>[1][2]</sup>	Part Marking	Package Description (RoHS Compliant)	Pkg. Dwg. #	Carrier Type <sup>[3]</sup>	Temp. Range
ISL94216AIRZ	ISL94216A IRZ	64 Ld QFN	L64.9x9B	Tray	-40 to +85°C
ISL94216AIRZ-T				Reel, 3k	
ISL94216AIRZ-T7				Reel, 1k	

- These Pb-free plastic packaged products employ special Pb-free material sets; molding compounds/die attach materials and NiPdAu-Ag plate - e4 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Pb-free products are MSL classified at Pb-free peak re-flow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J-STD-020.
- For the Moisture Sensitivity Level (MSL), see the Product Options on the [ISL94216A](#) product page (click the packaging icon). For more information about MSL, see [TB363](#).
- See [TB347](#) for details about reel specifications.

**Table 81. Key Differences Between Family of Parts**

Part Number	Cells Supported		Pack Voltage (Op)		Cell Bal.	I <sub>SENSE</sub>	Charge/Discharge FET			Supply Current (Typ)		Stand-Alone Capable	Int. ADC	Daisy Chain
	Min	Max	Min (V)	Max (V)			Ctrl.	Arrang.	Location	Normal	Sleep			
ISL94216A	4	16	12	55	Both	Low Side	Yes	Both	Both <sup>[1]</sup>	200μA	10μA	No	16b	No
RAA489204	6	14	12	65	Int./Ext.	No	No	No	No	3.3mA	19	No	14b	Yes
ISL94212	6	12	6	60	Ext.	No	No	N/A	N/A	3.31mA	12μA	No	14b	Yes
ISL94208	4	6	8	26.4	Both	Low Side	Yes	Both	Low Side	850μA	2μA	No	No	No
ISL94202	3	8	4	36	Ext.	High Side	Yes	Both	High Side	348μA	13μA	State Machine	14b	No
RAJ240100	3	10	4	50	Int.	Low Side	Yes	Both	High Side	50μA	1μA	Int MCU	15b/18b	No
RAJ240090	3	8	4	50	Int.	Low Side	Yes	Both	High Side	50μA	1μA	Int MCU	15b/18b	No
RAJ240080	2	5	4	25	Both	Low Side	Yes	Both	High Side	50μA	1μA	Int MCU	15b/18b	No

- GPIO can be configured to support low side C/DFETs.

## 12. Revision History

Rev.	Date	Description
2.02	Jun 15, 2023	Updated the typical value for the Internal Temperature Sensor Resolution spec from 0.8 to 0.85 and added the test condition. Updated cross-reference links throughout the document. Updated Tables 15, 20, 23, 26, 32, 33, 39, 40, 42, 47, 48, and 55-70.
2.01	May 18, 2023	Updated cross-reference link in the 0x63.7 VCCF section.
2.00	Jul 7, 2022	Updated Figure 1. In section 3.4, corrected typo, moved Slave Access Time max of 200ns to min of 200ns, no max. In section 5.3.1.5, Added , this command takes ~100μs to complete to the last sentence of the first paragraph. In section 5.13.4, changed maximum to minimum in the last sentence of the second paragraph. In section 5.13.5, changed minimum to maximum in the last sentence of the second paragraph. In section 7.4.2.1, replaced Scan Select text with link 0x01.1 - Scan Select in the first sentence of item 1. In section 11 table 81, added RAA489204 to the table.
1.01	Feb 3, 2022	Updated the default value in Table 53.
1.00	Aug 18, 2021	Initial release
