

NCV4299A

Voltage Regulator - Low-Dropout

150 mA

The NCV4299A is a family of precision micropower voltage regulators with an output current capability of 150 mA. It is available in 5.0 V or 3.3 V output voltage.

The output voltage is accurate within $\pm 2\%$ with a maximum dropout voltage of 0.5 V at 100 mA. Low Quiescent current is a feature drawing only 65 μA with a 100 μA load. This part is ideal for any and all battery operated microprocessor equipment.

The device features microprocessor interfaces including an adjustable reset output and adjustable system monitor to provide shutdown early warning. An inhibit function is available. With inhibit active, the regulator turns off and the device consumes less than 1.0 μA of quiescent current.

The part can withstand load dump transients making it suitable for use in automotive environments.

Features

- 5.0 V, 3.3 V $\pm 2\%$, 150 mA
- Extremely Low Current Consumption
 - ♦ 65 μA (Typ) in the ON Mode
 - ♦ < 1.0 μA in the Off Mode
- Early Warning
- Reset Output Low Down to $V_Q = 1.0\text{ V}$
- Adjustable Reset Threshold
- Wide Temperature Range
- Fault Protection
 - ♦ 60 V Peak Transient Voltage
 - ♦ -40 V Reverse Voltage
 - ♦ Short Circuit
 - ♦ Thermal Overload
- Internally Fused Leads
- Inhibit Function with μA Current Consumption in the Off Mode
- NCV Prefix for Automotive and Other Applications Requiring Unique Site and Control Change Requirements; AEC-Q100 Qualified and PPAP Capable
- These are Pb-Free Devices

APPLICATION DESCRIPTION

NCV4299A

The NCV4299A is a family of precision micropower voltage regulators with an output current capability of 150 mA at 5.0 V and 3.3 V.

The output voltage is accurate within $\pm 2\%$ with a maximum dropout voltage of 0.5 V at 100 mA. Low quiescent current is a feature drawing only 65 μA with a 100 μA load. This part is ideal for any and all battery operated microprocessor equipment.

Microprocessor control logic includes an active reset output RO (with delay), and a SI/SO monitor which can be used to provide an early warning signal to the microprocessor of a potential impending reset signal. The use of the SI/SO monitor allows the microprocessor to finish any signal processing before the reset shuts the microprocessor down. Internal output resistors on the RO and SO pins pulling up to the output pin Q reduce external component count. An inhibit function is available on the 14-lead part. With inhibit active, the regulator turns off and the device consumes less than 1.0 μA of quiescent current.

The active reset circuit operates correctly at an output voltage as low as 1.0 V. The reset function is activated during the powerup sequence or during normal operation if the output voltage drops outside the regulation limits.

The reset threshold voltage can be decreased by the connection of an external resistor divider to the RADJ lead. The regulator is protected against reverse battery, short circuit, and thermal overload conditions. The device can withstand load dump transients making it suitable for use in automotive environments.

NCV4299A Circuit Description

The low dropout regulator in the NCV4299A uses a PNP pass transistor to give the lowest possible dropout voltage capability. The current is internally monitored to prevent oversaturation of the device and to limit current during over current conditions. Additional circuitry is provided to protect the device during overtemperature operation.

The regulator provides an output regulated to 2%.

Other features of the regulator include an undervoltage reset function and a sense circuit. The reset function has an adjustable time delay and an adjustable threshold level. The sense circuit trip level is adjustable and can be used as an early warning signal to the controller. An inhibit function that turns off the regulator and reduces the current consumption to less than 1.0 μA is a feature available in the 14 pin package.

Output Regulator

The output is controlled by a precision trimmed reference. The PNP output has saturation control for regulation while the input voltage is low, preventing oversaturation. Current limit and voltage monitors complement the regulator design to give safe operating signals to the processor and control circuits.

Stability Considerations

The input capacitor C_I is necessary for compensating input line reactance. Possible oscillations caused by input inductance and input capacitance can be damped by using a resistor of approximately 1.0 Ω in series with C_I .

The output or compensation capacitor helps determine three main characteristics of a linear regulator: startup delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures (-25°C to -40°C), both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet usually provides this information.

The value for the output capacitor C_O shown in Figure 33 should work for most applications, however, it is not necessarily the optimized solution. Stability is guaranteed at values $C_O \geq 22 \mu\text{F}$ and an $\text{ESR} \leq 8.0 \Omega$ within the operating temperature range. Actual limits are shown in a graph in the typical performance characteristics section.

NCV4299A

*C₁ required if regulator is located far from the power supply filter.

**C_Q required for stability. Cap must operate at minimum temperature expected.

***This RC filter is only required when transients with slew rate in excess of 10 V/μs may be present on the $\overline{\text{INH}}$ voltage source during operation. The filter is not required when $\overline{\text{INH}}$ is connected to a noise-free DC voltage.

Figure 33. Test and Application Circuit Showing all Compensation and Sense Elements

Reset Output (RO)

A reset signal, Reset Output (RO, low voltage) is generated as the IC powers up. After the output voltage V_Q increases above the reset threshold voltage V_{RT} , the delay timer D is started. When the voltage on the delay timer V_D passes V_{UD} , the reset signal RO goes high. D pin voltage in steady state is typically 2.4 V. A discharge of the delay timer (V_D) is started when V_Q drops and stays below the reset

threshold voltage V_{RT} . When the voltage of the delay timer (V_D) drops below the lower threshold voltage V_{LD} , the reset output voltage V_{RO} is brought low to reset the processor.

The reset output RO is an open collector NPN transistor, controlled by a low voltage detection circuit. The circuit is functionally independent of the rest of the IC, thereby guaranteeing that RO is valid for V_Q as low as 1.0 V.

Figure 34. Reset Timing Diagram

Reset Adjust (RADJ)

The reset threshold V_{RT} can be decreased from a typical value of 4.64 V to as low as 3.5 V by using an external voltage divider connected from the Q lead to the pin RADJ, as shown in Figure 33. The resistor divider keeps the voltage above the $V_{RADJ,TH}$ (typ. 1.36 V), for the desired input voltages and overrides the internal threshold detector. Adjust the voltage divider according to the following relationship:

$$V_{THRES} = V_{RADJ,TH} \cdot (RADJ1 + RADJ2)/RADJ2 \quad (\text{eq. 1})$$

If the reset adjust option is not needed, the RADJ-pin should be connected to GND causing the reset threshold to go to its default value (typ. 4.64 V).

Reset Delay (D)

The reset delay circuit provides a delay (programmable by capacitor C_D) on the reset output RO lead. The delay lead D provides charge current I_D (typically 7.1 μA) to the external delay capacitor C_D during the following times:

1. During Powerup (once the regulation threshold has been exceeded).
2. After a reset event has occurred and the device is back in regulation. The delay capacitor is set to discharge when the regulation (V_{RT} , reset threshold voltage) has been violated. When the delay capacitor discharges to down to V_{LD} , the reset signal RO pulls low.

Setting the Delay Time

The delay time is set by the delay capacitor C_D and the charge current I_D . The time is measured by the delay capacitor voltage charging from the low level of $V_{D,sat}$ to the higher level V_{UD} . The time delay follows the equation:

$$t_d = [C_D (V_{UD} - V_{D,sat})] / I_D \quad (\text{eq. 2})$$

Example:

Using $C_D = 100 \text{ nF}$.

Use the typical value for $V_{D,sat} = 0.1 \text{ V}$.

Use the typical value for $V_{UD} = 1.85 \text{ V}$.

Use the typical value for Delay Charge Current $I_D = 7.1 \text{ } \mu\text{A}$.

$$t_d = [100 \text{ nF}(1.85 - 0.1 \text{ V})] / 7.1 \text{ } \mu\text{A} = 24.6 \text{ ms} \quad (\text{eq. 3})$$

When the output voltage V_Q drops below the reset threshold voltage V_{RT} , the voltage on the delay capacitor V_D starts to drop. The time it takes to drop below the lower threshold voltage of V_{LD} is the reset reaction time, t_{RR} . This time is typically $2.2 \text{ } \mu\text{s}$ for a delay capacitor of $0.1 \text{ } \mu\text{F}$. The reset reaction time can be estimated from the following relationship:

$$t_{RR} = 22 \text{ ns/nF} \times C_D \quad (\text{eq. 4})$$

Sense Input (SI)/Sense Output (SO) Voltage Monitor

An on-chip comparator is available to provide early warning to the microprocessor of a possible reset signal. The reset signal typically turns the microprocessor off instantaneously. This can cause unpredictable results with the microprocessor. The signal received from the SO pin will allow the microprocessor time to complete its present task before shutting down. This function is performed by a comparator referenced to the band gap voltage. The actual trip point can be programmed externally using a resistor divider to the input monitor (SI) (Figure 33). The typical threshold is 1.35 V on the SI Pin.

Signal Output

Figure 35 shows the SO Monitor waveforms as a result of the circuits depicted in Figure 33. As the output voltage V_Q falls, the monitor threshold $V_{SI,Low}$ is crossed. This causes the voltage on the SO output to go low sending a warning signal to the microprocessor that a reset signal may occur in a short period of time. $T_{WARNING}$ is the time the microprocessor has to complete the function it is currently working on and get ready for the reset shutdown signal. When the voltage on the SO goes low and the RO stays high the current consumption is typically $350 \text{ } \mu\text{A}$.

Figure 35. SO Warning Timing Waveform

Figure 36. Sense Timing Diagram

Calculating Power Dissipation in a Single Output Linear Regulator

The maximum power dissipation for a single output regulator is:

$$P_{D(max)} = [V_{I(max)} - V_{Q(min)}] I_{Q(max)} + V_{I(max)} I_q \quad (\text{eq. 5})$$

where:

$V_{I(max)}$ is the maximum input voltage,

$V_{Q(min)}$ is the minimum output voltage,

$I_{Q(max)}$ is the maximum output current for the application, and

I_q is the quiescent current the regulator consumes at $I_{Q(max)}$.

Once the value of $P_{D(max)}$ is known, the maximum permissible value of $R_{\theta JA}$ can be calculated:

$$R_{\theta JA} = (150^\circ\text{C} - T_A) / P_D \quad (\text{eq. 6})$$

The value of $R_{\theta JA}$ can then be compared with those in the package section of the data sheet. Those packages with $R_{\theta JA}$'s less than the calculated value in Equation 6 will keep the die temperature below 150°C. In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required. Thermal Resistance $R_{\theta JA}$ vs. Copper Area is shown in Figure 37.

Figure 37. Thermal Resistance $R_{\theta JA}$ vs. Copper Area

Heatsinks

A heatsink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\theta JA}$:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CS} + R_{\theta SA} \quad (\text{eq. 7})$$

where:

$R_{\theta JC}$ = the junction-to-case thermal resistance,
 $R_{\theta CS}$ = the case-to-heatsink thermal resistance, and
 $R_{\theta SA}$ = the heatsink-to-ambient thermal resistance.

$R_{\theta JC}$ appears in the package section of the data sheet. Like $R_{\theta JA}$, it too is a function of package type. $R_{\theta CS}$ and $R_{\theta SA}$ are functions of the package type, heatsink and the interface between them. These values appear in heatsink data sheets of heatsink manufacturers. Thermal, mounting, and heatsinking are discussed in the ON Semiconductor application note AN1040/D, available on the ON Semiconductor website.

SOLDERING FOOTPRINT*

DIMENSIONS: MILLIMETERS

*For additional information on our Pb-Free strategy and soldering details, please download the ON Semiconductor Soldering and Mounting Techniques Reference Manual, SOLDERRM/D.

GENERIC MARKING DIAGRAM*

XXXXXX = Specific Device Code
A = Assembly Location
WL = Wafer Lot
Y = Year
WW = Work Week
G = Pb-Free Package

*This information is generic. Please refer to device data sheet for actual part marking. Pb-Free indicator, "G" or microdot "▪", may or may not be present. Some products may not follow the Generic Marking.
